public ExtensionFunctionCall makeCallExpression() {
    return new ExtensionFunctionCall() {
        public SequenceIterator call(SequenceIterator[] arguments, XPathContext context)
            throws XPathException {
            long v0 = ((IntegerValue)arguments[0].next()).longValue();
            long v1 = ((IntegerValue)arguments[1].next()).longValue();
            long result = v0<<v1;
            return Value.asIterator(Int64Value.makeIntegerValue(result));
        }
    };
}
```

2. Compile the class and add it to a JAR file.
3. Add a file called `net.sf.saxon.lib.ExtensionFunctionDefinition` that contains the fully qualified name of the Java class in the `META-INF/services/` folder of the JAR file.

**Note:** To add more function definitions in the same JAR file, you need to add their fully qualified names on different lines.

To enable Oxygen XML Editor to pick up your custom function definition, the JAR file should be added to the classpath of the transformer. Here are some possibilities:

- If you develop a framework, you just need to link the JAR file in the **Classpath** tab (on page 99).
- In a validation scenario (on page 1094), you can use the **Extensions** button to open a dialog box where you can add libraries.
- In a transformation scenario, you can use the **Extensions** button in the **XSLT** tab (on page 1676) to open a dialog box where you can add libraries.
- You can also create a plugin that contributes such a JAR file in the classpath (on page 2580).

Validation Scenarios

A complex XML document is split in smaller interrelated modules. These modules do not make much sense individually and cannot be validated in isolation due to interdependencies with other modules. Oxygen XML Editor validates the main module of the document when an imported module is checked for errors.

A typical example is the chunking of a DocBook XSL stylesheet that has **chunk.xsl** as the main module and **param.xsl**, **chunk-common.xsl**, and **chunk-code.xsl** as imported modules. **param.xsl** only defines XSLT parameters. The module **chunk-common.xsl** defines an XSLT template with the name **chunk**. **Chunk-code.xsl** calls this template. The parameters defined in **param.xsl** are used in the other modules without being redefined.
Validating `chunk-code.xsl` as an individual XSLT stylesheet generates misleading errors regarding parameters and templates that are used but undefined. These errors are only caused by ignoring the context in which this module is used in real XSLT transformations and in which it is validated. To validate such a module, define a validation scenario to set the main module of the stylesheet and the validation engine used to find the errors. Usually this engine applies the transformation during the validation process to detect the errors that the transformation generates.

You can validate a stylesheet with several engines to make sure that you can use it in various environments and have the same results. For example, an XSLT stylesheet may be applied with Saxon 6.5, Xalan, and MSXML 4.0 engines in different production systems.

Other examples of documents that can benefit from a validation scenario include:

- A complex XQuery file with a main module that imports modules developed independently but validated in the context of the main module of the query. In an XQuery validation scenario, the default validator of Oxygen XML Editor (Saxon 9) or any connection to a database that supports validation (Berkeley DB XML Database, eXist XML Database, MarkLogic version 5 or newer) can be set as a validation engine.
- An XML document in which the `master file (on page 3284)` includes smaller fragment files using XML entity references.

**Note:** If a `master file` is associated with the current file, the validation scenarios defined in the `master file`, along with any Schematron schema defined in the default scenarios for that particular `framework`, are used for the validation. These take precedence over other types of validation units defined in the default scenarios for the particular `framework`. For more information on `master files`, see Master Files Support (on page 726) or Working with Modular XML Files in the Master Files Context (on page 1126).

For more information about how to use a validation scenario in Oxygen XML Editor, watch our video demonstration:

[https://www.youtube.com/embed/9RMPcckVMJA](https://www.youtube.com/embed/9RMPcckVMJA)

**Related Information:**

- Validating XML Documents Against a Schema (on page 1081)

- Presenting Validation Errors in Author Mode (on page 445)

- Presenting Validation Errors in Text Mode (on page 364)
Creating a New Validation Scenario

To create a validation scenario, follow these steps:

1. Select the Configure Validation Scenario(s) from the Validation toolbar drop-down menu, or from the Document > Validate menu (or the Validate submenu when invoking the contextual menu on a file in the Project view (on page 333)).

The Configure Validation Scenario(s) dialog box is displayed. It contains built-in and user-defined scenarios. The built-in scenarios are organized in categories depending on the type of file they apply to and you can identify them by a yellow key icon that marks them as read-only. The user-defined scenarios are organized under a single category. The default scenarios for the particular framework (on page 3282) are rendered in bold.

Note: If a master file is associated with the current file, the validation scenarios defined in the master file, along with any Schematron schema defined in the default scenarios for that particular framework, are used for the validation. These take precedence over other types of validation units defined in the default scenarios for the particular framework. For more information on master files, see Master Files Support (on page 726) or Working with Modular XML Files in the Master Files Context (on page 1126).

Figure 391. Configure Validation Scenario Dialog Box

The top section of the dialog box contains a filter that allows you to search through the scenarios list and the Settings button allows you to configure the following options:

**Show all scenarios**

Select this option to display all the available scenarios, regardless of the document they are associated with.

**Show only the scenarios available for the editor**
Select this option to only display the scenarios that Oxygen XML Editor can apply for the current document type.

**Show associated scenarios**

Select this option to only display the scenarios associated with the document you are editing.

**Import scenarios**

This option opens the **Import scenarios** dialog box that allows you to select the `scenarios` file that contains the scenarios you want to import. If one of the scenarios you import is identical to an existing scenario, Oxygen XML Editor ignores it. If a conflict appears (an imported scenario has the same name as an existing one), you can choose between two options:

- Keep or replace the existing scenario.
- Keep both scenarios.

Note: When you keep both scenarios, Oxygen XML Editor adds `imported` to the name of the imported scenario.

**Export selected scenarios**

Use this option to export selected scenarios individually. Oxygen XML Editor creates a `scenarios` file that contains the scenarios that you export. This is useful if you want to share scenarios with others or export them to another computer.

2. To add a scenario, click the **New** button.

A validation scenario configuration dialog box is displayed and it lists all the validation units for the scenario.

Figure 392. Validation Scenario Configuration Dialog Box
This scenario configuration dialog box allows you to configure the following information and options:

**Name**

The name of the validation scenario.

**Storage**

You can choose between storing the scenario in the Project Options (on page 3286) or Global Options (on page 3283).

**URL of the file to validate**

The URL of the main module that includes the current module. It is also the entry module of the validation process when the current one is validated. To edit the URL, double-click its cell and specify the URL of the main module by doing one of the following:

- Enter the URL in the text field or select it from the drop-down list.
- Use the **Browse** drop-down button to browse for a local, remote, or archived file.
- Use the **Insert Editor Variable** button to insert an editor variable (on page 276) or a custom editor variable (on page 284).

Figure 393. Insert an Editor Variable

<table>
<thead>
<tr>

<td>Value of system variable varname</td>
</tr>
</tbody>
</table>

**File type**

The type of the document that is validated in the current validation unit. Oxygen XML Editor automatically selects the file type depending on the value of the **URL of the file to validate** field.

**Validation engine**

You can select one of the engines available in Oxygen XML Editor for validation of the particular document type.
Default engine means that the default engine is used to run the validation for the current document type, as specified in the preferences page for that type of document (for example, XSLT preferences page (on page 200), XQuery preferences page (on page 208), XML Schema preferences page (on page 192)).

The DITA Validation engine performs DITA-specific checks in the context of the specifications (it is similar to the checks done with the DITA Maps Manager Validate and Check for Completeness action (on page 3036), but for a local file rather than an entire DITA map (on page 3281)).

The Table Layout Validation engine looks for table layout problems (for more information, see Report table layout problems (on page 3040)).

Automatic validation

If this option is selected, the validation operation defined by this row is also applied by the automatic validation feature (on page 1082). If the Automatic validation feature is disabled in the Document Checking preferences page (on page 180), then this option is ignored, as the preference setting has a higher priority.

Schema

This option becomes active when you set the File type to XML Document and allows you to specify the schema used for the validation unit.

Specify Schema

Opens the Specify Schema dialog box that allows you to set a schema to be used for validating XML documents.

Figure 394. Specify Schema Dialog Box

The Specify Schema dialog box contains the following options:

Use detected schema
Uses the schema detected for the particular document (on page 1113).

**Use custom schema**

Allows you to specify the schema using the following options:

- **URL** - Allows you to specify or select a URL for the schema. It also keeps a history of the last used schemas. The URL must point to the schema file that can be loaded from the local disk or from a remote server through HTTP(S), FTP(S) or a custom protocol (on page 2610). You can specify the URL by using the text field, the history drop-down, the `Insert Editor Variables` (on page 276) button, or the browsing actions in the `Browse` drop-down list.

- **Schema type** - Select a possible schema type from this combo box that is populated based on the extension of the schema file that was entered in the URL field. The possible schema types are: XML Schema, DTD, Relax NG, Relax NG Compact, Schematron, or NVDL.

- **Embedded Schematron rules** - If you have selected XML Schema or Relax NG schemas with embedded Schematron rules and you want to use those embedded rules, select this option.

- **Extensions** - Opens a dialog box that allows you to specify Java extension JARs (on page 3283) to be used during the validation.

- **Public ID** - Allows you to specify a public ID if you have selected a DTD.

- **Schematron phase** - If you select a Schematron schema, this drop-down list allows you to select a Schematron phase that you want to use for validation. The listed phases are defined in the Schematron document.

**Move Up**

Moves the selected scenario up one spot in the list.

**Move Down**

Moves the selected scenario down one spot in the list.

**Add**

Adds a new validation unit to the list.

**Remove**

Removes an existing validation unit from the list.
3. Configure any of the existing validation units according to the information above, and you can use the buttons at the bottom of the table to add, remove, or move validation units. Note that if you add a Schematron validation unit, you can also select the **validation phase**.

4. Press **OK**.
   The newly created validation scenario will now be included in the list of scenarios in the **Configure Validation Scenario(s)** dialog box. You can select the scenario in this dialog box to associate it with the current document and press the **Apply associated** button to run the validation scenario.

**Editing a Validation Scenario**

To edit an existing validation scenario, follow these steps:

1. Select the **Configure Validation Scenario(s)** from the **Validation** toolbar drop-down menu, or from the **Document > Validate** menu (or the **Validate** submenu when invoking the contextual menu on a file in the **Project view** (on page 333)).
   The **Configure Validation Scenario(s)** dialog box is displayed. It contains built-in and user-defined scenarios. The built-in scenarios are organized in categories depending on the type of file they apply to and you can identify them by a yellow key icon that marks them as **read-only**. The user-defined scenarios are organized under a single category. The default scenarios for the particular **framework** (on page 3282) are rendered in bold.

   **Note:** If a **master file** is associated with the current file, the validation scenarios defined in the **master file**, along with any Schematron schema defined in the default scenarios for that particular **framework**, are used for the validation. These take precedence over other types of validation units defined in the default scenarios for the particular **framework**. For more information on **master files**, see **Master Files Support** (on page 726) or **Working with Modular XML Files in the Master Files Context** (on page 1126).

Figure 395. Configure Validation Scenario Dialog Box
The top section of the dialog box contains a filter that allows you to search through the scenarios list and the 👇 Settings button allows you to configure the following options:

**Show all scenarios**
Select this option to display all the available scenarios, regardless of the document they are associated with.

**Show only the scenarios available for the editor**
Select this option to only display the scenarios that Oxygen XML Editor can apply for the current document type.

**Show associated scenarios**
Select this option to only display the scenarios associated with the document you are editing.

**Import scenarios**
This option opens the Import scenarios dialog box that allows you to select the scenarios file that contains the scenarios you want to import. If one of the scenarios you import is identical to an existing scenario, Oxygen XML Editor ignores it. If a conflict appears (an imported scenario has the same name as an existing one), you can choose between two options:

- Keep or replace the existing scenario.
- Keep both scenarios.

**Note:** When you keep both scenarios, Oxygen XML Editor adds imported to the name of the imported scenario.

**Export selected scenarios**
Use this option to export selected scenarios individually. Oxygen XML Editor creates a scenarios file that contains the scenarios that you export. This is useful if you want to share scenarios with others or export them to another computer.

2. Select the scenario and press the **Edit** button. If you try to edit one of the **read-only** built-in scenarios, you will receive a warning message that Oxygen XML Editor needs to creates customizable duplicate (you can also use the **Duplicate** button).

The **Edit scenario** dialog box is displayed and it lists all the validation units for the scenario.

![Edit Validation Scenario](image)

This scenario configuration dialog box allows you to configure the following information and options:

**Name**

The name of the validation scenario.

**Storage**

You can choose between storing the scenario in the **Project Options** (on page 3286) or **Global Options** (on page 3283).

**URL of the file to validate**

The URL of the main module that includes the current module. It is also the entry module of the validation process when the current one is validated. To edit the URL, double-click its cell and specify the URL of the main module by doing one of the following:

- Enter the URL in the text field or select it from the drop-down list.
- Use the ![Browse](image) drop-down button to browse for a local, remote, or archived file.
• Use the **Insert Editor Variable** button to insert an editor variable (on page 276) or a custom editor variable (on page 284).

Figure 397. Insert an Editor Variable

```
$[@desktop] - My Desktop
$[@start-dir] - Start directory of custom validator
$[@standard-params] - List of standard parameters for command line
$[@fn] - The current file name without extension
$[@current-URL] - The path of the currently edited file (URL)
$[@fd] - The path of current file directory (URL)
$[@frameworks] - Oxygen frameworks directory (URL)
$[@project] - Project directory (URL)
$[@oxygen_home] - Oxygen installation directory (URL)
$[@home] - The path to user home directory (URL)
$[@p] - Project name
$[@env[VAR_NAME]] - Value of environment variable VAR_NAME
$[@system[VAR_NAME]] - Value of system variable VAR_NAME
```

**File type**

The type of the document that is validated in the current validation unit. Oxygen XML Editor automatically selects the file type depending on the value of the **URL of the file to validate** field.

**Validation engine**

You can select one of the engines available in Oxygen XML Editor for validation of the particular document type.

**Default engine** means that the default engine is used to run the validation for the current document type, as specified in the preferences page for that type of document (for example, **XSLT preferences page** (on page 200), **XQuery preferences page** (on page 208), **XML Schema preferences page** (on page 192)).

The **DITA Validation** engine performs DITA-specific checks in the context of the specifications (it is similar to the checks done with the **DITA Maps Manager** Validate and Check for Completeness action (on page 3036), but for a local file rather than an entire DITA map (on page 3281)).

The **Table Layout Validation** engine looks for table layout problems (for more information, see **Report table layout problems** (on page 3040)).

**Automatic validation**

If this option is selected, the validation operation defined by this row is also applied by the automatic validation feature (on page 1082). If the **Automatic validation** feature is disabled in the **Document Checking preferences page** (on page 180), then this option is ignored, as the preference setting has a higher priority.
Schema

This option becomes active when you set the File type to XML Document and allows you to specify the schema used for the validation unit.

Specify Schema

Opens the Specify Schema dialog box that allows you to set a schema to be used for validating XML documents.

Figure 398. Specify Schema Dialog Box

The Specify Schema dialog box contains the following options:

Use detected schema

Uses the schema detected for the particular document (on page 1113).

Use custom schema

Allows you to specify the schema using the following options:

- **URL** - Allows you to specify or select a URL for the schema. It also keeps a history of the last used schemas. The URL must point to the schema file that can be loaded from the local disk or from a remote server through HTTP(S), FTP(S) or a custom protocol (on page 2610). You can specify the URL by using the text field, the history drop-down, the Insert Editor Variables (on page 276) button, or the browsing actions in the Browse drop-down list.

- **Schema type** - Select a possible schema type from this combo box that is populated based on the extension of the schema file that was entered in the URL field. The possible schema types are: XML Schema, DTD, Relax NG, Relax NG Compact, Schematron, or NVDL.
• **Embedded Schematron rules** - If you have selected XML Schema or Relax NG schemas with embedded Schematron rules and you want to use those embedded rules, select this option.

• **Extensions** - Opens a dialog box that allows you to specify *Java extension JARs (on page 3283)* to be used during the validation.

• **Public ID** - Allows you to specify a public ID if you have selected a DTD.

• **Schematron phase** - If you select a Schematron schema, this drop-down list allows you to select a Schematron phase that you want to use for validation. The listed phases are defined in the Schematron document.

  - **Move Up**
    
    Moves the selected scenario up one spot in the list.

  - **Move Down**
    
    Moves the selected scenario down one spot in the list.

  - **Add**
    
    Adds a new validation unit to the list.

  - **Remove**
    
    Removes an existing validation unit from the list.

3. Configure any of the existing validation units according to the information above, and you can use the buttons at the bottom of the table to add, remove, or move validation units. Note that if you add a Schematron validation unit, you can also select the **validation phase**.

4. When you are done configuring the scenario, press **OK**.

   The modified validation scenario will now be included in the list of scenarios in the **Configure Validation Scenario(s)** dialog box. If you chose to duplicate an existing one, the modified scenario will be listed with the word *copy* at the end of its name.

**Sharing Validation Scenarios**

The validation scenarios and their settings can be shared with other users by saving them at **project level (on page 3286)** or by exporting them to a specialized scenarios file (on page 276) that can then be imported. When you create a new validation scenario or edit an existing one, there is a **Storage option** to control whether the scenarios are stored in **Project Options (on page 3286)** or **Global Options (on page 3283)**.
Selecting **Project Options** *(on page 3286)* stores the scenario in the project file and can be shared with other users that have access to the project. If your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) then your team will have access to the scenarios that you define. When you create a scenario at the project level, the URLs from the scenario become relative to the project URL.

Selecting **Global Options** *(on page 3283)* stores the scenario in the global options that are stored in the user home directory.

You can also change the storage options on existing validation scenarios by using the **Change storage** action from the contextual menu of the list of scenarios.

**Related Information:**
- **Sharing Application Settings** *(on page 266)*

**Resolving References to Remote Schemas with an XML Catalog**

When a reference to a remote schema must be used in the validated XML document for interoperability purposes, but a local copy of the schema should actually be used for performance reasons, the reference can be resolved to the local copy of the schema with an **XML Catalog** *(on page 3289)*.

For example, if the XML document contains a reference to a remote schema `docbook.rng` like this:

```xml
<?xml-model href="http://www.oasis-open.org/docbook/xml/5.0/rng/docbook.rng" type="application/xml" schematypens="http://relaxng.org/ns/structure/1.0"?>
```

it can be resolved to a local copy with a catalog entry like this:

```xml
<uri name="http://www.oasis-open.org/docbook/xml/5.0/rng/docbook.rng" uri="rng/docbook.rng"/>
```

An **XML Catalog** can also be used to map an XML Schema specified with a URN in the `xsi:schemaLocation` attribute of an XML document to a local copy of the schema. For example, if the XML document specifies the schema with:

```xml
<topic xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
```

the URN can be resolved to a local schema file with a catalog entry like this:

```xml
<uri name="urn:oasis:names:tc:dita:xsd:topic.xsd:1.1"
```
Related Information:

- Working with XML Catalogs (on page 1123)

Validation Example - A DocBook Validation Error

In the following DocBook 4 document, the content of the `listitem` element does not match the rules of the DocBook 4 schema (`docbookx.dtd`).

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE article PUBLIC "-//OASIS//DTD DocBook XML V4.4//EN" "http://www.docbook.org/xml/4.4/docbookx.dtd">
<article>
  <title>Article Title</title>
  <sect1>
    <title>Section1 Title</title>
    <itemizedlist>
      <listitem>
        <link>a link here</link>
      </listitem>
    </itemizedlist>
  </sect1>
</article>
```

The Validate Document action will return the following error:

Unexpected element "link". The content of the parent element type must match

```
"(calloutlist|glosslist|bibliolist|itemizedlist|orderedlist|segmentedlist|simplelist|
variablelist|caution|important|note|tip|warning|literallayout|programlisting|
programlistingco|screen|screenco|screenshot|synopsis|cmsynthesis|functionsynopsis|
classsynopsis|fieldsynopsis|constructorsynthesis|destructorsynthesis|methodsynthesis|
formalpara|para|simparsa|address|blockquote|graphic|graphicco|mediaobject|mediaobjectco|
informalequation|informalexample|informalfigure|informaltable|equation|example|figure|
table|msgset|procedure|sidebar|gandaset|task|anchor|bridgehead|remark|highlights|
abstract|authorblurb|epigraph|indexterm|beginpage)+*.
```

This error message is a little more difficult to understand, so understanding of the syntax or processing rules for the DocBook XML DTD `listitem` element is recommended. However, the error
message does offer a clue as to the source of the problem, indicating that “The content of element type must match”.

Fortunately, most standards-based DTDs, XML Schemas, and Relax NG schemas are supplied with reference documentation. This enables you to lookup the element and read about it. In this case, you should learn about the child elements of `listitem` and their nesting rules. Once you have correctly inserted the required child element and nested it in accordance with the XML rules, the document will become valid.

Embedding Schematron Rules in XML Schema or RELAX NG

Schematron rules can be embedded into an XML Schema through annotations (using the `appinfo` element), or in any element on any level of a RELAX NG Schema (taking into account that the RELAX NG validator ignores all elements that are not in the RELAX NG namespace).

Oxygen XML Editor accepts such documents as Schematron validation schemas and it is able to extract and use the embedded rules.

**Validating XML Documents with XML Schema and Embedded Schematron**

To validate an XML document with XML Schema and its embedded Schematron, you can associate the document like this:

```xml
<?xml-model href="percent.xsd" type="application/xml"
  schematypens="http://purl.oclc.org/dsdl/schematron"?>
```

**Validating XML Documents with Relax NG and Embedded Schematron**

To validate an XML document with RELAX NG schema and its embedded Schematron rules, you need to associate the document with both schemas like this:

```xml
<?xml-model href="percent.rng" type="application/xml"
  schematypens="http://relaxng.org/ns/structure/1.0"?>
<?xml-model href="percent.rng" type="application/xml"
  schematypens="http://purl.oclc.org/dsdl/schematron"?>
```

The second association validates your document with Schematron rules extracted from the RELAX NG Schema.

**Note:** When you work with XML Schema or Relax NG documents that have embedded Schematron rules Oxygen XML Editor provides two built-in validation scenarios: **Validate XML Schema with embedded Schematron** for XML schema, and **Validate Relax NG with embedded Schematron** for Relax NG. You can use one of these scenarios to validate the embedded Schematron rules.
Example: Embedded Schematron in XML Schema

```xml
<xsd:appinfo>
  <sch:pattern>
    <sch:rule context="...">
      <sch:assert test="...">Message.</sch:assert>
    </sch:rule>
  </sch:pattern>
</xsd:appinfo>
```

Example: Embedded Schematron in Relax NG Schema

```xml
<grammar
  xmlns="http://relaxng.org/ns/structure/1.0"
  xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <sch:pattern>
    <sch:rule context="...">
      <sch:assert test="...">Message.</sch:assert>
    </sch:rule>
  </sch:pattern>
  <start>
    ..............
  </start>
</grammar>
```

Related Information:

- Embedding Schematron Quick Fixes in Relax NG or XML Schema (on page 1498)

XML Quick Fixes

The Oxygen XML Editor *Quick Fix support (on page 3287)* helps you resolve errors that appear in an XML document by offering *Quick Fixes* to problems such as missing required attributes or invalid elements. *Quick Fixes* are available in *Text* mode and *Author* mode.

To activate this feature, hover over or place the cursor in the highlighted area of text where a validation error or warning occurs. If a *Quick Fix* is available for that particular error or warning, you can access the *Quick Fix* proposals with any of the following methods:
• When hovering over the error or warning, the proposals may be presented in a tooltip pop-up window and the available quick *Quick Fixes* include a link that can be used to perform the fix.

Figure 399. Quick Fix Presented in a Tooltip in Text Mode

![Quick Fix Presented in a Tooltip in Text Mode](image)

Figure 400. Quick Fix Presented in a Tooltip in Author Mode

![Quick Fix Presented in a Tooltip in Author Mode](image)

• When hovering over the error or warning in **Author** mode, a small *Quick Fix* drop-down menu is presented. You can use the drop-down menu to display a list of available *Quick Fixes* to select from for the particular error or warning.

Figure 401. Quick Fix Drop-Down Menu in Author Mode

![Quick Fix Drop-Down Menu in Author Mode](image)

• If you place the cursor in the highlighted area where a validation error or warning occurs, a *Quick Fix* icon (.currentTarget) is displayed in the stripe on the left side of the editor. If you click this icon, Oxygen XML Editor displays the list of available fixes.

Figure 402. Quick Fix Menu Invoked by Clicking on the Icon

![Quick Fix Menu Invoked by Clicking on the Icon](image)

• With the cursor placed in the highlighted area of the error or warning, you can also invoke the *Quick Fix* menu by pressing **Alt + 1** (**Command + Alt + 1 on OS X**) on your keyboard.

Whenever you make a modification in the XML document or you apply a fix, the list of *Quick Fixes* is recomputed to ensure that you always have valid proposals.
**Note:** A *Quick Fix* that adds an element inserts it along with required and optional elements, and required and fixed attributes, depending on how the *Content Completion preferences* (on page 166) are configured.

Quick Fixes for DTD, XSD, and Relax NG Errors

Oxygen XML Editor offers *Quick Fixes* (on page 3287) for common errors that appear in XML documents that are validated against DTD, XSD, or Relax NG schemas.

**Note:** For XML documents validated against XSD schemas, the *Quick Fixes* are only available if you use the default Xerces validation engine.

*Quick Fixes* are available in *Text* mode and *Author* mode.

Oxygen XML Editor provides *Quick Fixes* for numerous types of problems, including the following:

<table>
<thead>
<tr>
<th>Problem Type</th>
<th>Available Quick Fixes</th>
</tr>
</thead>
<tbody>
<tr>
<td>A specific element is required in the current context</td>
<td>Insert the required element</td>
</tr>
<tr>
<td>An element is invalid in the current context</td>
<td>Remove the invalid element</td>
</tr>
<tr>
<td>The content of the element should be empty</td>
<td>Remove the element content</td>
</tr>
<tr>
<td>An element is not allowed to have child elements</td>
<td>Remove all child elements</td>
</tr>
<tr>
<td>Text is not allowed in the current element</td>
<td>Remove the text content</td>
</tr>
<tr>
<td>A required attribute is missing</td>
<td>Insert the required attribute</td>
</tr>
<tr>
<td>An attribute is not allowed to be set for the current element</td>
<td>Remove the attribute</td>
</tr>
<tr>
<td>The attribute value is invalid</td>
<td>Propose the correct attribute values</td>
</tr>
<tr>
<td>ID value is already defined</td>
<td>Generate a unique ID value</td>
</tr>
<tr>
<td>References to an invalid ID</td>
<td>Change the reference to an already defined ID</td>
</tr>
</tbody>
</table>

**Related Information:**

- Schematron Quick Fixes (SQF) (on page 1111)

Schematron Quick Fixes (SQF)

Oxygen XML Editor provides support for Schematron *Quick Fixes* (on page 3287) (SQF). They help you resolve issues that appear in XML documents that are validated against Schematron schemas by offering you solution proposals. The Schematron *Quick Fixes* are an extension of the Schematron
language and they allow you to define fixes for Schematron validation messages. Specifically, they are associated with *assert* or *report* messages.

A typical use case is using Schematron *Quick Fixes* to assist content authors with common editing tasks. For example, you can use Schematron rules to automatically report certain validation warnings (or errors) when performing regular editing tasks, such as inserting specific elements or changing IDs to match specific naming conventions. For more details and examples, see the following blog post: [http://blog.oxygenxml.com/2015/05/schematron-checks-to-help-technical.html](http://blog.oxygenxml.com/2015/05/schematron-checks-to-help-technical.html).

**Displaying the Schematron Quick Fix Proposals**

The defined Schematron *Quick Fixes* are displayed on validation errors in **Text mode** and **Author mode**.

Figure 403. Example of a Schematron Quick Fix

- [Editing Schematron Quick Fixes](on page 1481)
- Schematron Quick Fix Specifications
- [Presenting Schematron Validation Issues](on page 1464)

**Associating a Schema to XML Documents**

To provide as-you-type validation and to compute valid proposals for the *Content Completion Assistant* (on page 3280), Oxygen XML Editor requires a schema to be associated with the XML document. The schema specifies how the internal structure of the XML is defined.

**Supported Types of Schema**

The following schema types are supported:
- W3C XML Schema 1.0 and 1.1 (with and without embedded Schematron rules) - The association with an XML Schema is added as an attribute of the root element with one of the following:
  - xsi:schemaLocation attribute, if the root element of the document is in the namespace.
  - xsi:noNamespaceSchemaLocation attribute, if the root element is not in the namespace.
- DTD - The association with a DTD is added as a DOCTYPE declaration.
- Relax NG - XML Syntax (with and without embedded Schematron rules) - The association is added as an xml-model processing instruction.
- Relax NG - Compact Syntax - The association is added as an xml-model processing instruction.
- NVDL - The association is added as an xml-model processing instruction.
- Schematron (both ISO Schematron and Schematron 1.5) - The association is added as an xml-model processing instruction.

Detecting the Schema(s) for Validation

For validation, Oxygen XML Editor tries to detect one or more schemas by searching multiple locations, in the following order:

1. The schema or multiple schemas referenced in validation stages from the validation scenario(s) (on page 1114) associated with the current XML document.
2. If no validation scenario is selected to be used with the current XML document, then it falls back to the schema or multiple schemas defined in validation stages from the validation scenarios specified as default in the particular document type configuration (on page 1118).
3. If a schema is still not detected, then it falls back to the schema or multiple schemas associated directly in the XML document (on page 1120).

**Tip:** To quickly open the schema used for validating the current document, select the Open Associated Schema action from the toolbar (or Document > Schema menu).
4. If a schema is still not detected, then it falls back to the schema defined in the Schema tab of a framework (document type) configuration (on page 1121).

Detecting a Schema for Content Completion

For content completion, Oxygen XML Editor uses just one schema and tries to detect that schema by searching multiple locations, in the following order:

1. If no schema is detected in the document, then it falls back to the highest ranking schema defined in validation stages from the validation scenario(s) associated with the current document (on page 1114).
2. If a schema is still not detecting, then it falls back to the highest ranking schema defined in validation stages from validation scenarios specified as default in the particular document type configuration (on page 1118).
3. Oxygen XML Editor determines the most appropriate or highest ranking schema that is associated directly in the XML document (on page 1120) and uses it for content completion.
4. If a schema is still not detecting, then it falls back to the schema defined in the Schema tab of a framework (document type) configuration (on page 1121).

Related Information:

- Working with Modular XML Files in the Master Files Context (on page 1126)
- W3C: Associating Schemas with XML Documents

Associating a Schema Through a Validation Scenario

Oxygen XML Editor uses the rules defined in the detected schema to report errors and warnings during automatic and manual validations that help maintain the structural integrity of your XML documents. You can specify the schema to be used for validation directly in validation scenarios (on page 1093) and there are several methods that can be used to do so.

Configure a Validation Scenario and Specify the Schema

To associate a schema to a validation scenario to be used whenever the scenario is invoked, follow these steps:

1. Select the Configure Validation Scenario(s) from the Validation toolbar drop-down menu, or from the Document > Validate menu (or the Validate submenu when invoking the contextual menu on a file in the Project view (on page 333)).
2. Press the New button to create a new validation scenario or the Edit button to modify an existing one.
3. Add or configure validation units (on page 1102) according to your needs and click the Specify Schema button.

Step Result: The Specify Schema dialog box is displayed:

Figure 404. Specify Schema Dialog Box
The **Specify Schema** dialog box contains the following options:

**Use detected schema**

Uses the **schema detected for the particular document (on page 1113)**.

**Use custom schema**

Allows you to specify the schema using the following options:

- **URL** - Allows you to specify or select a URL for the schema. It also keeps a history of the last used schemas. The URL must point to the schema file that can be loaded from the local disk or from a remote server through HTTP(S), FTP(S) or a **custom protocol (on page 2610)**. You can specify the URL by using the text field, the history drop-down, the **Insert Editor Variables (on page 276)** button, or the browsing actions in the **Browse** drop-down list.

- **Schema type** - Select a possible schema type from this combo box that is populated based on the extension of the schema file that was entered in the **URL** field. The possible schema types are: XML Schema, DTD, Relax NG, Relax NG Compact, Schematron, or NVDL.

- **Embedded Schematron rules** - If you have selected XML Schema or Relax NG schemas with embedded Schematron rules and you want to use those embedded rules, select this option.

- **Public ID** - Allows you to specify a public ID if you have selected a DTD.

- **Extensions** - Opens a dialog box that allows you to specify **Java extension JARs (on page 3283)** to be used during the validation.

- **Schematron phase** - If you select a Schematron schema, this drop-down list allows you to select a Schematron phase that you want to use for validation. The listed phases are defined in the Schematron document.

4. Select the schema to be associated with the validation unit and configure the rest of the options according to your preferences.

5. Click **OK** on both dialog boxes.
Result: The schema is now associated with that validation scenario whenever it is invoked.

Use the Validate with Action to Specify a Schema for Validating the Current Document

To validate the current document using a specified schema, follow these steps:

1. Select the Validate with action from the Validation drop-down menu on the toolbar (or Document > Validate menu).

   Step Result: The Validate with dialog box is displayed:

   Figure 405. Validate with Dialog Box

   ![Validate with Dialog Box](image)

   This dialog box contains the following options:

   - **URL** - Allows you to specify or select a URL for the schema. It also keeps a history of the last used schemas. The URL must point to the schema file that can be loaded from the local disk or from a remote server through HTTP(S), FTP(S) or a custom protocol (on page 2610).
     
     You can specify the URL by using the text field, the history drop-down, the Insert Editor Variables (on page 276) button, or the browsing actions in the Browse drop-down list.
   
   - **Schema type** - Select a possible schema type from this combo box that is populated based on the extension of the schema file that was entered in the URL field. The possible schema types are: XML Schema, DTD, Relax NG, Relax NG Compact, Schematron, or NVDL.
   
   - **Embedded Schematron rules** - If you have selected XML Schema or Relax NG schemas with embedded Schematron rules and you want to use those embedded rules, select this option.
   
   - **Public ID** - Allows you to specify a public ID if you have selected a DTD.
   
   - **Extensions** - Opens a dialog box that allows you to specify Java extension JARs (on page 3283) to be used during the validation.
   
   - **Schematron phase** - If you select a Schematron schema, this drop-down list allows you to select a Schematron phase that you want to use for validation. The listed phases are defined in the Schematron document.

2. Select the schema to be associated with the manual validation and configure the rest of the options according to your preferences.

3. Click OK.
Result: The current document is validated using the schema you specified.

Tip: To quickly open the schema used for validating the current document, select the Open Associated Schema action from the toolbar (or Document > Schema menu).

Use the Validate with Schema Action to Specify a Schema for Validating all Selected Documents

To validate multiple documents using a specified schema, follow these steps:

1. Select all the documents you want to validate in the Project view.
2. Invoke the contextual menu (right-click) and select the Validate with Schema action from the Validate submenu.

Step Result: The Validate with dialog box is displayed:

Figure 406. Validate with Dialog Box

This dialog box contains the following options:

- **URL** - Allows you to specify or select a URL for the schema. It also keeps a history of the last used schemas. The URL must point to the schema file that can be loaded from the local disk or from a remote server through HTTP(S), FTP(S) or a custom protocol (on page 2610). You can specify the URL by using the text field, the history drop-down, the Insert Editor Variables (on page 276) button, or the browsing actions in the Browse drop-down list.

- **Schema type** - Select a possible schema type from this combo box that is populated based on the extension of the schema file that was entered in the URL field. The possible schema types are: XML Schema, DTD, Relax NG, Relax NG Compact, Schematron, or NVDL.

- **Embedded Schematron rules** - If you have selected XML Schema or Relax NG schemas with embedded Schematron rules and you want to use those embedded rules, select this option.

- **Public ID** - Allows you to specify a public ID if you have selected a DTD.

- **Extensions** - Opens a dialog box that allows you to specify Java extension JARs (on page 3283) to be used during the validation.
• **Schematron phase** - If you select a Schematron schema, this drop-down list allows you to select a Schematron phase that you want to use for validation. The listed phases are defined in the Schematron document.

3. Select the schema that you want to use to validate all selected documents and configure the rest of the options according to your preferences.

4. Click **OK**.

**Result:** The selected documents are validated using the schema you specified.

Associating a Schema in Validation Scenarios Defined in the Document Type

To report errors and warnings during automatic and manual validations that help maintain the structural integrity of particular XML document types, Oxygen XML Editor uses rules defined in the schema that is detected in the validation scenarios that are associated to each particular document type.

To associate a schema in validation scenarios defined in the framework (on page 3282) (document type) configuration, follow these steps:

1. **Open the Preferences dialog box (Options > Preferences)** (on page 79) and go to **Document Type Association**.

2. Select your particular document type and click the **Edit** or **Duplicate** button to modify an existing framework (or use the **New** button to create a new one).

   **Step Result:** This opens a **Document type configuration dialog box** (on page 95).

3. Go to the **Validation tab** (on page 121).

4. Create or edit a validation scenario:

   a. To **create a new validation scenario** (on page 1094), click the **+ New** button.

   b. To **edit the properties of an existing validation scenario** (on page 1100), select it and click the **Edit** button (you can also use the **Duplicate** button to copy an existing scenario and edit its properties).

5. **Add or configure validation units** (on page 1102) according to your needs and click the **Specify Schema** button.

   **Step Result:** The **Specify Schema** dialog box is displayed:

   Figure 407. Specify Schema Dialog Box
The **Specify Schema** dialog box contains the following options:

### Use detected schema

Uses the schema detected for the particular document *(on page 1113)*.

### Use custom schema

Allows you to specify the schema using the following options:

- **URL** - Allows you to specify or select a URL for the schema. It also keeps a history of the last used schemas. The URL must point to the schema file that can be loaded from the local disk or from a remote server through HTTP(S), FTP(S) or a custom protocol *(on page 2610)*. You can specify the URL by using the text field, the history drop-down, the ![Insert Editor Variables](on page 276) button, or the browsing actions in the ![Browse](drop-down list).

- **Schema type** - Select a possible schema type from this combo box that is populated based on the extension of the schema file that was entered in the URL field. The possible schema types are: XML Schema, DTD, Relax NG, Relax NG Compact, Schematron, or NVDL.

- **Embedded Schematron rules** - If you have selected XML Schema or Relax NG schemas with embedded Schematron rules and you want to use those embedded rules, select this option.

- **Public ID** - Allows you to specify a public ID if you have selected a DTD.

- **Extensions** - Opens a dialog box that allows you to specify *Java extension JARs (on page 3283)* to be used during the validation.

- **Schematron phase** - If you select a Schematron schema, this drop-down list allows you to select a Schematron phase that you want to use for validation. The listed phases are defined in the Schematron document.

6. Select the schema to be associated with the validation unit and configure the rest of the options according to your preferences.

7. Click **OK** on both dialog boxes.
Result: The schema is now associated with the validation scenario you just configured for that particular document type.

Associating a Schema Directly in XML Documents

The schema used by the Content Completion Assistant (on page 3280) and document validation engine can be directly associated with the current document by using the Associate Schema action. For most of the schema types, it uses the xml-model processing instruction, with the exceptions of:

- **W3C XML Schema** - The xsi:schemaLocation attribute or xsi:noNamespaceSchemaLocation attribute is used.
- **DTD** - The DOCTYPE declaration is used.

The association can specify a relative file path or a URL of the schema. The advantage of relative file path is that you can configure the schema at file level instead of framework (on page 3282) level.

To associate a schema to the current document, follow these steps:

1. Select the Associate Schema action from the toolbar (or Document > Schema menu).

   **Step Result:** The Associate Schema dialog box is displayed:

   Figure 408. Associate Schema Dialog Box

   ![Associate Schema Dialog Box]

   This dialog box contains the following options:

   - **URL** - Allows you to specify or select a URL for the schema. It also keeps a history of the last used schemas. The URL must point to the schema file that can be loaded from the local disk or from a remote server through HTTP(S), FTP(S) or a custom protocol (on page 2610).
• **Use path relative to file location** - Select this option if the XML instance document and the associated schema contain relative paths. The location of the schema file is inserted in the XML instance document as a relative file path. This practice allows you, for example, to share these documents with other users without running into problems caused by multiple project locations on physical disk.

• **Schema type** - Select a possible schema type from this combo box that is populated based on the extension of the schema file that was entered in the URL field. The possible schema types are: XML Schema, DTD, Relax NG, Relax NG Compact, Schematron, or NVDL.

• **Add additional association for embedded Schematron rules** - If you have selected XML Schema or Relax NG schemas with embedded Schematron rules and you want to use those embedded rules, select this option.

• **Public ID** - Allows you to specify a public ID if you have selected a DTD.

• **Keep existing schema associations** - Select this option to use the existing schema associations of the currently edited document.

2. Select the schema that will be associated with the XML document and configure the rest of the options according to your preferences.

3. Click **OK**.

**Result:** The schema association is created based upon the specified type.

• **XML Schema** - The association with an XML Schema is added as an attribute of the root element with one of the following:
  ◦ **xsi:schemaLocation** attribute, if the root element of the document is in the namespace.
  ◦ **xsi:noNamespaceSchemaLocation** attribute, if the root element is not in the namespace.

• **DTD** - The association with a DTD is added as a **DOCTYPE** declaration.

• **Other** - The association with a Relax NG, Schematron, or NVDL schema is added as an **xml-model processing instruction**.

**Tip:** To quickly open the schema used for validating the current document, select the **Open Associated Schema** action from the toolbar (or **Document > Schema** menu).

**Related Information:**

- Validating XML Documents ([on page 1079](#))
- Content Completion Assistant in Text Mode ([on page 844](#))
- Content Completion Assistant in Author Mode ([on page 921](#))
Associating a Schema in a Framework (Document Type) Configuration

The schema used to compute valid proposals in the Content Completion Assistant (on page 3280) and by the document validation engine to report errors and warnings can be defined in each particular framework (on page 3282) (document type). This schema will be used only if one is not detected in the current XML file (on page 1120).

To associate a schema in a particular framework (document type), follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Document Type Association.
2. Select your particular document type and click the Edit (on page 93), Extend (on page 93), or Duplicate (on page 93) button to modify an existing framework (or use the New button to create a new one).

   **Step Result:** This opens a Document type configuration dialog box (on page 95).
4. Select the schema type and its URI.
5. Click OK.

**Result:** The schema is now associated with the particular document type and will be used by the Content Completion Assistant and validation engine if a schema is not detected in the current XML document.

Learn Document Structure when Schema is not Detected

When working with documents that do not specify a schema, or for which the schema is not known or does not exist, Oxygen XML Editor is able to learn and translate the document structure to a DTD. You can choose to save the learned structure to a file to provide a DTD as an initialization source for content completion (on page 844) and document validation (on page 1079). This feature is also useful for producing DTDs for documents that contain personal or custom element types.

When you open a document that is not associated with a schema, Oxygen XML Editor automatically learns the document structure and uses it for content completion (on page 844). To disable this feature, deselect the Learn on open document option in the user preferences (on page 166).

**Related Information:**

- Detecting a Schema (on page 1112)
Create a DTD from Learn Document Structure Option

When there is no schema associated with an XML document, Oxygen XML Editor can learn the document structure by parsing the document internally. This feature is enabled by the **Learn on open document option** (on page 166) that is available in the user preferences.

To create a DTD from the learned structure, follow these steps:

1. Open the XML document for which a DTD will be created.
2. Go to **Document > XML Document > Learn Structure** (Ctrl + Shift + L (Command + Shift + L on OS X)).
   - The **Learn Structure** action reads the mark-up structure of the current document. The **Learn completed** message is displayed in the application status bar when the action is finished.
3. Go to **Document > XML Document > Save Structure** (Ctrl + Shift + S (Command + Shift + S on OS X)) and enter the DTD file path.
4. Press the **Save** button.

Working with XML Catalogs

Oxygen XML Editor uses **XML Catalogs** (on page 3289) to resolve references for validations and transformations and they are especially helpful for resolving external resources when internet access is not available or your connection is slow.

Oxygen XML Editor supports any **XML Catalog** file that conforms to one of the following:

1. **OASIS XML Catalogs Committee Specification v1.1**.
2. **OASIS Technical Resolution 9401:1997**, including the plain-text flavor described in that resolution.

The version 1.1 of the OASIS XML Catalog specification introduces the possibility to map a system ID, public ID, or a URI to a local copy using only a suffix of the ID or URI used in the actual document. This is done using the catalog elements **systemSuffix** and **uriSuffix**.

Depending on the resource type, Oxygen XML Editor uses different catalog mappings.

**Table 38. Catalog Mappings**

<table>
<thead>
<tr>
<th>Doc Type</th>
<th>Referenced Resource</th>
<th>Mappings</th>
</tr>
</thead>
<tbody>
<tr>
<td>XML</td>
<td>DTD</td>
<td>system or public</td>
</tr>
<tr>

</tr>
<tr>
<td>NVDL</td>
<td>This happens only if the <em>Resolve schema locations also through system mappings</em> option <em>(on page 190)</em> is selected (it is by default).</td>
<td></td>
</tr>
<tr>
<td>Relax NG</td>
<td>3. Resolve the root <em>namespace</em> using <em>URI</em> catalog mappings.</td>
<td></td>
</tr>
</tbody>
</table>

| XSL | XSL/ANY | *URI* |
| CSS | CSS | *URI* |
| JSON | JSON | *URI* |
| XML Schema | The following strategy is used (if one step fails to provide a resource, the next is applied): |
| Relax NG | 1. Resolve schema reference using *URI* catalog mappings. |
| Relax NG | 2. Resolve schema reference using *system* catalog mappings. |

This happens only if the *Resolve schema locations also through system mappings* option *(on page 190)* is selected (it is by default). |

3. Resolve schema *namespace* using *URI* catalog mappings. |

This happens only if the *Process namespaces through URI mappings for XML Schema* option *(on page 190)* is selected (it is not by default). |

Creating an XML Catalog with a Template

An *XML Catalog* *(on page 3289)* file can be created quickly in Oxygen XML Editor starting from the two document templates called *OASIS XML Catalog 1.0* and *OASIS XML Catalog 1.1*. They are available when creating new document templates *(on page 676)*.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE catalog
PUBLIC "-//OASIS//DTD XML Catalogs V1.1//EN"
"http://www.oasis-open.org/committees/entity/release/1.1/catalog.dtd">
<catalog xmlns="urn:oasis:names:tc:entity:xmlns:xml:catalog">
  <!-- Use "system" and "public" mappings when resolving DTDs -->
  <system
How Oxygen XML Editor Determines which Catalog to Use

Oxygen XML Editor uses **XML Catalogs** to resolve references for validations and transformations and it maps such references to the built-in local copies of the schemas associated with the various frameworks (DocBook, DITA, TEI, XHTML, SVG, etc.)

Oxygen XML Editor includes default global catalogs as well as default catalogs for each of the built-in frameworks, and you can also create your own.

Oxygen XML Editor looks for catalogs in the following order:

- Global user-defined catalogs that are set in the XML Catalog preferences page.
- User-defined catalogs that are set for each framework in the Catalog tab of the Document Type configuration dialog box.
- Default built-in catalogs.

**Example:**

An XML Catalog can be used to map an XML Schema specified with an URN in the xsi:noNamespaceSchemaLocation attribute of an XML document to a local copy of the schema.

Considering the following XML document code snippet:
Resolving Schema Locations Through XML Catalogs

Schema locations can be mapped using an XML Catalog. Oxygen XML Editor resolves the location of a schema in the following order:

• First, it attempts to resolve the schema location as a URI (uri, uriSuffix, rewriteUri, delegateUri mappings from the XML Catalog). If this succeeds, the process ends here.
• If the Resolve schema locations also through system mappings option is selected, it attempts to resolve the schema location as a system ID (system, systemSuffix, rewriteSuffix, rewriteSystem from the XML Catalog). If this succeeds, the process ends here.
• If the Process "schemaLocation" namespaces through URI mappings for XML Schema option is selected, the target namespace of the imported XML Schema is resolved through URI mappings. If the schema specified in the schemaLocation attribute is not resolved successfully, the namespace of the root element is taken into account. If this succeeds, the process ends here.
• If none of these succeeds, the actual schema location is used.

Related Information:

• Working with XML Catalogs
the support for defining the main module (or modules), allowing you to edit any file from the hierarchy in the context of the master files (on page 3284).

You can set a main XML document either using the master files support from the Project view (on page 726), or using a validation scenario.

To set a master file using a validation scenario, add validation units that point to the main modules. Oxygen XML Editor warns you if the current module is not part of the dependencies graph computed for the main XML document. In this case, it considers the current module as the main XML document.

The advantages of working with modular XML files in the context of a master file (on page 3284) include:

- Correct validation of a module in the context of a larger XML structure.
- Content Completion Assistant (on page 3280) displays all collected entities and IDs starting from the master files.
- Oxygen XML Editor uses the schema defined in the master file when you edit a module that is included in the hierarchy through the External Entity mechanism.
- The master files defined for the current module determines the scope of the search and refactoring actions (on page 1129) for ID/IDREFS values and for updating references when renaming/moving a resource. Oxygen XML Editor performs the search and refactoring actions in the context that the master files determine, improving the speed of execution.

For more information about editing modular XML files in the master files context, watch our video demonstration:

https://www.youtube.com/embed/e2oo4RWNxW8

Related Information:

- Master Files Support (on page 726)
- XML Resource Hierarchy/Dependencies View (on page 1130)

Search and Refactoring Actions for IDs and IDREFS

Oxygen XML Editor allows you to search for ID declarations and references (IDREFS) and to define the scope of the search and refactor operations (on page 1129). These operations are available for XML documents that have an associated DTD, XML Schema, or Relax NG schema. These operations are available through the search and refactoring actions in the contextual menu. In Text mode, these actions are also available in the Quick Assist (on page 872) menu.
The search and refactor actions from the contextual menu are grouped in the **Manage IDs** section:

### Rename in

Renames the ID and all its occurrences. Selecting this action opens the *Rename XML ID* dialog box. This dialog box lets you insert the new ID value and **choose the scope of the rename operation (on page 1129)**. For a preview of the changes you are about to make, click **Preview**. This opens the **Preview** dialog box, which presents a list with the files that contain changes and a preview zone of these changes.

#### Rename in File

Renames the ID you are editing and all its occurrences from the current file.

**Note:** Available in the **Text** mode only.

### Search References

Searches for the references of the ID. By default, the scope of this action is the current project. If you configure a scope using the **Select the scope for the Search and Refactor operations (on page 1129)** dialog box, this scope will be used instead.

#### Search References in

Searches for the references of the ID. Selecting this action opens the **Select the scope for the Search and Refactor operations (on page 1129)**.

### Search Declarations

Searches for the declaration of the ID reference. By default, the scope of this action is the current project. If you configure a scope using the **Select the scope for the Search and Refactor operations (on page 1129)** dialog box, this scope will be used instead.

**Note:** Available in the **Text** mode only.

#### Search Declarations in

Searches for the declaration of the ID reference. Selecting this action opens the **Select the scope for the Search and Refactor operations (on page 1129)**.

**Note:** Available in the **Text** mode only.

### Search Occurrences in file

Searches for the declaration and references of the ID in the current document.

**Tip:** A quick way to go to the declaration of an ID in **Text** mode is to move the cursor over an ID reference and use the **Ctrl + Single-Click (Command + Single-Click on OS X)** navigation.

Selecting an ID that you use for search or refactor operations differs between the **Text** and **Author** modes. In the **Text** mode, you position the cursor inside the declaration or reference of an ID. In the
Author mode, Oxygen XML Editor collects all the IDs by analyzing each element from the path to the root. If more IDs are available, you are prompted to choose one of them.

Figure 409. Selecting an ID in the Author Mode

Search and Refactor Operations Scope

The scope is a collection of documents that define the context of a search and refactor operation. To control it you can use the Change scope operation, available in the Quick Assist action set or on the Resource Hierarchy/Dependency View toolbar. You can restrict the scope to the current project or to one or multiple working sets (on page 3288). The Use only Master Files, if enabled checkbox allows you to restrict the scope of the search and refactor operations to the resources from the Master Files directory. Click read more for details about the Master Files support (on page 726).

Figure 410. Change Scope Dialog Box
The scope you define is applied to all future search and refactor operations until you modify it. Contextual menu actions allow you to add or delete files, folders, and other resources to the working set (on page 3288) structure.

**XML Resource Hierarchy/Dependencies View**

The Resource Hierarchy/Dependencies view displays the hierarchy or dependencies for an XML document. The tree structure presented in this view is built based on the XInclude and External Entity mechanisms. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

If you want to see the hierarchy or dependencies of an XML document, select the document in the Project view (on page 333) and choose Resource Hierarchy or Resource Dependencies from the contextual menu.

Figure 411. Resource Hierarchy/Dependencies View
The following actions are available on the toolbar of the Resource Hierarchy/Dependencies view:

- **Refresh**
  Refreshes the Hierarchy/Dependencies structure.

- **Stop**
  Stops the hierarchy/dependencies computing.

- **Show Hierarchy**
  Allows you to choose a resource to compute the hierarchy structure.

- **Show Dependencies**
  Allows you to choose a resource to compute the dependencies structure.

- **Configure dependencies search scope**
  Allows you to configure a scope to compute the dependencies structure. There is also an option for automatically using the defined scope for future operations.

- **History**
  Provides access to the list of previously computed dependencies. Use the **Clear history** button to remove all items from this list.

The contextual menu for a resource listed in the Resource Hierarchy/Dependencies view contains the following actions:

- **Open**
Opens the resource. You can also double-click a resource in the Hierarchy/Dependencies structure to open it.

**Go to reference**

Opens the source document where the resource is referenced.

**Copy location**

Copies the location of the resource.

**Move resource**

Moves the selected resource.

**Rename resource**

Renames the selected resource.

**Show Resource Hierarchy**

Shows the hierarchy for the selected resource.

**Show Resource Dependencies**

Shows the dependencies for the selected resource.

**Add to Master Files**

Adds the currently selected resource in the **Master Files** directory (on page 726).

**Expand All**

Expands all the children of the selected resource from the Hierarchy/Dependencies structure.

**Collapse All**

Collapses all children of the selected resource from the Hierarchy/Dependencies structure.

**Tip:** When a recursive reference is encountered in the Hierarchy view, the reference is marked with a special icon.

**Note:** The **Move resource** or **Rename resource** actions give you the option to update the references to the resource (on page 1133). Only the references made through the **XInclude** and **External Entity** mechanisms are handled.

Related Information:

- Working with Modular XML Files in the Master Files Context (on page 1126)
Moving/Renaming XML Resources

When you select the Rename action in the contextual menu of the Resource/Hierarchy Dependencies view, the Rename resource dialog box is displayed. The following fields are available:

- **New name** - Presents the current name of the edited resource and allows you to modify it.
- **Update references of the renamed resource(s)** - Select this option to update the references to the resource you are renaming. A Preview option is available that allows you to see what will be updated before selecting Rename to process the operation.

When you select the Move action from the contextual menu of the Resource/Hierarchy Dependencies view, the Move resource dialog box is displayed. The following fields are available:

- **Destination** - Presents the path to the current location of the resource you want to move and gives you the option to introduce a new location.
- **New name** - Presents the current name of the moved resource and gives you the option to change it.
- **Update references of the moved resource(s)** - Select this option to update the references to the resource you are moving, in accordance with the new location and name. A Preview option is available that allows you to see what will be updated before selecting Move to process the operation.

Combining XML Content Using DTD Entities and XInclude

When documenting large projects, it is likely that there are multiple people involved. In this case, it is usually more efficient to using a modular approach so that everyone involved in the project can work in parallel. Other advantages of modular documentation include: reusable content possibilities, smaller file units are easier to edit, and better version control.

Two possible solutions for this are to use **DTD Entities** or **XInclude** to combine XML content in a master file (on page 3284). A master document can be created with references to various document parts, users can edit those documents individually, and then apply an XSLT stylesheet over the master document to obtain the output files in various formats (for example, PDF or HTML).

Combining XML Document Content Using DTD Entities

There are two conditions for including a document fragment using DTD entities:
• The master document should declare the DTD to be used, while the external entities should declare the XML fragments to be referenced.

• The referenced documents that contain the fragments cannot also define the DTD because the main document will not be valid. If you want to validate the parts separately you have to use XInclude (on page 1135) for assembling the parts together with the master file.

The master document looks like this:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE book SYSTEM "../xml/docbookx.dtd" [ 
<!ENTITY testing SYSTEM "testing.xml" > ]>
<book>
  <chapter>
  ...
</chapter>
</book>
```

The referenced document (testing.xml) looks like this:

```xml
<section> ... here is the section content ... </section>
```

**Note:**

The indicated DTD and the element names (section, chapter) are used here only for illustrating the inclusion mechanism. You can use any DTD and element names you need.

The content from the referenced file (in the example above, it is a section in the test.xml file) can be inserted somewhere in the master document:

```xml
... &testing; ...
```

To obtain output in various formats (for example, PDF or HTML), you simply need to apply an XSLT stylesheet over the master document using a transformation scenario.

**Viewing the Expanded Content in Oxygen XML Editor**

When a transformation scenario is applied on the master file, an intermediary file combines all the referenced content and it will be expanded in the final output. If you want to see how the referenced content will be expanded before applying the transformation, you can do one of the following:

• Simply switch to **Author** mode.

• Create a minimal XSLT stylesheet that simply copies the XML content, then create a new XSLT transformation scenario that applies the stylesheet over the XML. The XSLT stylesheet would look like this:

```xml
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
```
Combining XML Documents and Fragments Using XInclude

**XInclude** is a standard for assembling XML instances into another XML document through inclusion. A *master file (on page 3284)* can be dynamically created from smaller XML documents without having to physically duplicate the content of the smaller files. The advantage of using XInclude instead of the **DTD Entities method (on page 1133)** is that each of the assembled documents is permitted to contain a Document Type Declaration (DOCTYPE). This means that each file is a valid XML instance and can be independently validated. It also means that the main document, which includes smaller instances, can be validated without having to remove or comment out the DOCTYPE (as is the case with External Entities).

**Enabling XInclude Support in Oxygen XML Editor**

The XInclude support in Oxygen XML Editor is enabled by default. It is controlled by the **Enable XInclude processing** option *(on page 192)* in the **XML > XML Parser** preferences page *(on page 191)*. When enabled, Oxygen XML Editor will be able to validate and transform documents comprised of parts added using XInclude.

**Example: Using XInclude to Combine Files**

A chapter file *(introduction.xml)* looks like this:

```xml
<?xml version="1.0"?>
<chapter>
  <title>Getting started</title>
  <section>
    <title>Section title</title>
```
The main article (master file) looks like this:

```xml
<?xml version="1.0"?>
<!DOCTYPE article PUBLIC "-//OASIS//DTD DocBook XML V4.3//EN"
"http://www.docbook.org/xml/4.3/docbookx.dtd"
[ <!ENTITY % xinclude SYSTEM "../frameworks/docbook/dtd/xinclude.mod">
%xinclude; ]>
<article>
  <title>Install guide</title>
  <para>This is the install guide.</para>
  <xi:include xmlns:xi="http://www.w3.org/2001/XInclude"
              href="introduction.xml">
    <xi:fallback>
      <para><emphasis>FIXME: MISSING XINCLUDE CONTENT</emphasis></para>
    </xi:fallback>
  </xi:include>
</article>
```

In this example, note the following:

- The DOCTYPE declaration defines an entity that references a file containing the information to add the `xi` namespace to certain elements defined by the DocBook DTD.
- The `href` attribute of the `xi:include` element specifies that the `introduction.xml` file will replace the `xi:include` element when the document is parsed.
- If the `introduction.xml` file cannot be found, the parser will use the value of the `xi:fallback` element - a `FIXME` message.

**Example: Using XInclude to Combine Fragments of Files**

If you want to include only a fragment of a file in the master file (on page 3284), the fragment must be contained in a tag having an `xml:id` attribute and you must use an XPointer expression pointing to the `xml:id` value.

**Note:** Oxygen XML Editor supports the XPointer Framework and the XPointer element() Scheme, but it does NOT support the XPointer xpointer() Scheme.
For example, if the *master file* is:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<?xml-model href="test.rng" type="application/xml"
  schematypens="http://relaxng.org/ns/structure/1.0"?>
<test>
  <xi:include href="a.xml" xpointer="a1"
    xmlns:xi="http://www.w3.org/2001/XInclude"/>
</test>
```

and the file (`a.xml`) is:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<test>
  <a xml:id="a1">test</a>
</test>
```

after resolving the XPointer reference, the document is:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<?xml-model href="test.rng" type="application/xml"
  schematypens="http://relaxng.org/ns/structure/1.0"?>
<test>
  <a xml:id="a1" xml:base="a.xml">test</a>
</test>
```

**Viewing the Expanded Content in Oxygen XML Editor**

When a transformation scenario is applied on the *master file*, an intermediary file combines all the referenced content and it will be expanded in the final output. If you want to see how the referenced content will be expanded before applying the transformation, you can do one of the following:

- Simply switch to **Author** mode.
- Create a minimal XSLT stylesheet that simply copies the XML content, then create a new XSLT transformation scenario that applies the stylesheet over the XML. The XSLT stylesheet would look like this:

```xml
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:math="http://www.w3.org/2005/xpath-functions/math"
  exclude-result-prefixes="xs math"
  version="3.0">
  <xsl:template match="node | @*"/>
</xsl:stylesheet>
```
XInclude 1.1 Features

Oxygen XML Editor offers partial support for XInclude 1.1 features. This includes support for fragment identifiers and attribute copying.

• Fragment Identifiers

You can `xi:include` a text file and specify the `@fragid` value so that you only get part of that text file in the main document. For some examples and to see how `xi:include` gets expanded when the `@fragid` specifies a line range or character range, see Textual Inclusion Examples with RFC5147 Fragment Identifiers.

• Attribute Copying

Any namespaced attribute defined on the `xi:include` element will be passed to the root element of the included content.

For example, if you have this:

```xml
<xi:include href="section2.xml" xmlns:xi="http://www.w3.org/2001/XInclude"
  xml:id="sectInner1"/>
```

and `section2.xml` looks like this:

```xml
<sect2 xmlns="http://docbook.org/ns/docbook" version="5.0"
  xmlns:xlink="http://www.w3.org/1999/xlink" xml:id="section2">
  <title>FS2</title>
  <para>P2</para>
</sect2>
```

then the final processed result will have the original `xml:id="section2"` replaced with the value specified in the `xi:included` section.

For more information, see Attribute Copying when Processing XML. Also, to see more examples, see Attribute Copying Examples.
Refactoring XML Documents

In the life cycle of XML documents there are instances when the XML structure needs to be changed to accommodate various needs. For example, when an associated schema is updated, an attribute may have been removed, or a new element added to the structure.

These types of situations cannot be resolved with a traditional *Find/Replace* tool, even if the tool accepts regular expressions. The problem becomes even more complicated if an XML document is computed or referenced from multiple modules, since multiple resources need to be changed.

To assist you with these types of refactoring tasks, Oxygen XML Editor includes a specialized **XML Refactoring** tool that helps you manage the structure of your XML documents.

**XML Refactoring Tool**

The **XML Refactoring** tool is presented in the form of an easy to use wizard that is designed to reduce the time and effort required to perform various structure management tasks. For example, you can insert, delete, or rename an attribute in all instances of a particular element that is found in all documents within your project.

To access the tool, select the ✉️ **XML Refactoring** action from one of the following locations:

- The **Tools** menu.
- The **Refactoring** submenu from the contextual menu in the **Project view** (on page 333).
- The **Refactoring** submenu from the contextual menu in the **DITA Maps Manager view** (on page 2990).

**Note:** The built-in refactoring operations are also available from the **Refactoring** submenu in the contextual menu of **Author** or **Text** mode. This is useful because by selecting the operations from the contextual menu, Oxygen XML Editor considers the editing context to skip directly to the wizard page of the appropriate operation and to help you by preconfiguring some of the parameter values. For your convenience, the last 5 operations that were finished (on page 1142) or previewed (on page 1142) also appear in the **Refactoring** submenu of the contextual menu in the **Project** view and the **DITA Maps Manager**.

**XML Refactoring Wizard**

The XML Refactoring tool includes the following wizard pages:
Refactoring operations

The first wizard page presents the available operations, grouped by category. To search for an operation, you can use the filter text box at the top of the page.

Figure 412. XML Refactoring Wizard

Configure Operation Parameters

The next wizard page allows you to specify the parameters for the refactoring operation. The parameters are specific to the type of refactoring operation that is being performed. For example, to delete an attribute you need to specify the parent element and the qualified name of the attribute to be removed.

Figure 413. XML Refactoring 2nd Wizard Page (Delete Attribute Operation)
Scope and Filters

The last wizard page allows you to select the set of files that represent the input of the operation.

Figure 414. XML Refactoring - Scope and Filters Wizard Page

Scope section

In the Scope section, you can select from predefined resource sets (such as the current file, your whole project, the current DITA map (on page 3281) hierarchy for DITA projects, etc.) or you can define your own set of resources by creating a working set (on page 3288).

Filters

The Filters section includes the following options:
• **Include files** - Allows you to filter the selected resources by using a file pattern. For example, to restrict the operation to only analyze build files you could use `build*.xml` for the file pattern.

• **Restrict only to known XML file types** - When selected, only resources with a known XML file type will be affected by the operation.

• **Look inside archives** - When selected, the resources inside archives will also be affected.

**Preview**

You can use the **Preview** button to open a comparison panel where you can review all the changes that will be made by the refactoring operation before applying the changes.

**Finish**

After clicking the **Finish** button, the operation will be processed and Oxygen XML Editor provides no automatic means for reverting the operations. Any **Undo** action will only revert changes on the current document.

**Troubleshooting:** If an operation fails, a notification will be displayed in the **Results** panel with some information about the error. For example, if the operation was invoked on a read-only resource, the error will indicate that a read-only file cannot be converted.

**Tip:** If an operation takes longer than expected you can use the ⏹ **Stop** button in the progress bar to cancel the operation.

**Restriction:** XML refactoring operations cannot preserve CDATA sections. If your document contains XML CDATA sections, the refactoring operations will convert them to plain text nodes.

**Built-in Refactoring Operations**

The XML Refactoring tool includes a variety of built-in operations that can be used for common refactoring tasks. They are grouped by category in the **Refactoring operations** wizard page. You can also access the operations from the **Refactoring** submenu in the contextual menu of **Author** or **Text** mode. The operations are also grouped by category in this submenu. When selecting the operations from the contextual menu, Oxygen XML Editor considers the editing context to get the names and namespaces of the current element or attribute, and uses this information to preconfigure some of the parameter values for the selected refactoring operation.
Tip: Each operation includes a link in the lower part of the wizard that opens the XML / XSLT-FO-XQuery / XPath preferences page where you can configure XPath options and declare namespace prefixes.

The following built-in operations are available:

Refactoring Operations for Attributes

Add/Change attribute

Use this operation to change the value of an attribute or insert a new one. This operation allows you to specify the following parameters:

Parent element section

Element

The parent element of the attribute to be changed, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

Attribute section

Local name

The local name of the affected attribute.

Namespace

The namespace of the affected attribute.

Value

The value for the affected attribute.

Options section

You can choose between one of the following options for the Operation mode:

Add the attribute in the parent elements where it is missing

Adds the attribute to all instances of the specified parent element.

Change the value in the parent elements where the attribute already exists

Replaces the value of the already existing attribute in all instance of the specified parent element.

Both
Adds the attributes to the instances where it is missing and replaces the value in instances where the attribute already exists.

**Convert attribute to element**

Use this operation to convert a specified attribute to an element. This operation allows you to specify the following parameters:

**Parent element section**

**Element**

The parent element of the attribute to be converted, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

**Attribute section**

**Local name**

The local name of the affected attribute.

**Namespace**

The namespace of the affected attribute.

**New element section**

**Local name**

The local name of the new element.

**Namespace**

The namespace of the new element.

**Delete attribute**

Use this operation to remove one or more attributes. This operation requires you to specify the following parameters:

**Element**

The parent element of the attribute to be deleted, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

**Attribute**

The name of the attribute to be deleted.

**Rename attribute**
Use this operation to rename an attribute. This operation requires you to specify the following parameters:

**Element**

The parent element of the attribute to be renamed, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

**Attribute**

The name of the attribute to be renamed.

**New local name**

The new local name of the attribute.

**Replace in attribute value**

Use this operation to search for a text fragment inside an attribute value and change the fragment to a new value. This operation allows you to specify the following parameters:

**Target attribute section**

**Element**

The parent element of the attribute to be modified, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

**Attribute**

The name of the attribute to be modified.

**Find / Replace section**

**Find**

The text fragments to find. You can use Perl-like regular expressions.

**Replace with**

The text fragment to replace the target with. This parameter can bind regular expression capturing groups (\$1, \$2, etc.) from the find pattern.

**Refactoring Operations for Comments**

**Delete comments**
Use this operation to delete comments from one or more elements. This operation requires you specify the following parameter:

**Element**

The target element (or elements) for which comments will be deleted, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

**Note:** Comments that are outside the root element will not be deleted because the serializer preserves the content before and after the root.

**Refactoring Operations for DITA**

**Change topic ID to file name**

Use this operation to change the ID of a topic to be the same as its file name.

**Convert CALS tables to simple tables**

Use this operation to convert DITA CALS tables to simple tables.

**Convert conrefs to conkeyrefs**

Use this operation to convert conref attributes to conkeyref attributes. For more information and instructions for using this operation, see [Converting Conrefs to Conkeyrefs](on page 3133).

**Convert simple tables to CALS tables**

Use this operation to convert DITA simple tables to CALS tables.

**Convert Nested Topics to New Topics (Available from the contextual menu of editable maps/nodes in the DITA Maps Manager [on page 2990])**

Use this operation on topics that contain nested `<topic>` elements to convert each nested topic to a new topic. Also, the new topics are added in the DITA Maps Manager as the first child topics of the original topic.

**Convert Sections to New Topics (Available from the contextual menu of editable maps/nodes in the DITA Maps Manager [on page 2990])**

Use this operation on topics that contain multiple sections to convert each section to a new topic. Also, the new topics are added in the DITA Maps Manager as the first child topics of the original topic.

**Convert to Concept**

Use this operation to convert a DITA topic (of any type) to a DITA Concept topic type (for example, Topic to Concept). For more information, see [Converting DITA Topics to Another Type](on page 3059).
Convert to General Task

Use this operation to convert a DITA topic (of any type) to a DITA General Task topic type (for example, Task to General Task). For more information, see Converting DITA Topics to Another Type (on page 3059).

Convert to Reference

Use this operation to convert a DITA topic (of any type) to a DITA Reference topic type (for example, Topic to Reference). For more information, see Converting DITA Topics to Another Type (on page 3059).

Convert to Task

Use this operation to convert a DITA topic (of any type) to a DITA Task topic type (for example, Topic to Task). For more information, see Converting DITA Topics to Another Type (on page 3059).

Convert to Topic

Use this operation to convert a DITA topic (of any type) to a DITA Topic (for example, Task to Topic). For more information, see Converting DITA Topics to Another Type (on page 3059).

Convert to Troubleshooting

Use this operation to convert a DITA topic (of any type) to a DITA Troubleshooting topic type (for example, Topic to Troubleshooting). For more information, see Converting DITA Topics to Another Type (on page 3059).

Rename Key

Use this operation to rename a key. It also updates all references to it. Note that it does not work on DITA 1.3 key scopes.

All of these DITA refactoring actions allow you to choose a scope for the operation and some filters:

Scope

Select from a variety of options to define the scope for which resources will be affected by the operation. For example, you can choose to affect all resources in the Project, All opened files, Current DITA map hierarchy, or just the Current file.

Filters section

Include files

Specifies files to be excluded from the operation. You can specify multiple files by separating them with commas and the patterns can include wildcards (such as * or ?).

Restrict to known XML file types only
Excludes non-XML file types from the operation.

**Look inside archives**

If this option is selected, the scope of the operation will include files inside archives.

### Refactoring Operations for *Elements*

#### Delete element

Use this operation to delete elements. This operation requires you to specify the following parameter:

**Element**

The target element to be deleted, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

#### Delete element content

Use this operation to delete the content of elements. This operation requires you to specify the following parameter:

**Element**

The target element whose content is to be deleted, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

#### Insert element

Use this operation to insert new elements. This operation allows you to specify the following parameters:

**Element section**

**Local name**

The local name of the element to be inserted.

**Namespace**

The namespace of the element to be inserted.

**Location section**

**XPath**
An XPath expression that identifies an existing element to which the new element is relative, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.

**Position**

The position where the new element will be inserted, in relation to the specified existing element. The possible selections in the drop-down menu are: After, Before, First child, or Last child.

**Rename element**

Use this operation to rename elements. This operation requires you to specify the following parameters:

**Target elements (XPath)**

The target elements to be renamed, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.

**New local name**

The new local name of the element.

**Unwrap element**

Use this operation to remove the surrounding tags of elements, while keeping the content unchanged. This operation requires you to specify the following parameter:

**Target elements (XPath)**

The target elements whose surrounding tags will be removed, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.

**Wrap element**

Use this operation to surround elements with element tags. This operation allows you to specify the following parameters:

**Target elements (XPath)**

The target elements to be surrounded with tags, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.

**Wrapper element section**
Local name
   The local name of the Wrapper element.

Namespace
   The namespace of the Wrapper element.

Wrap element content
   Use this operation to surround the content of elements with element tags. This operation allows you to specify the following parameters:

   Target elements (XPath)
      The target elements whose content will be surrounded with tags, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.

Wrapper element section
   Local name
      The local name of the Wrapper element that will surround the content of the target.

   Namespace
      The namespace of the Wrapper element that will surround the content of the target.

Refactoring Operations for Fragments

Insert XML fragment
   Use this operation to insert an XML fragment. This operation allows you to specify the following:

   XML Fragment
      The XML fragment to be inserted.

   Location section
      XPath
         An XPath expression that identifies an existing element to which the inserted fragment is relative, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.
The position where the fragment will be inserted, in relation to the specified existing element. The possible selections in the drop-down menu are: **After, Before, First child, or Last child**.

**Replace element content with XML fragment**

Use this operation to replace the content of elements with an XML fragment. This operation allows you to specify the following parameters:

**Target elements (XPath)**

The target elements whose content will be replaced, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.

**XML Fragment**

The XML fragment with which to replace the content of the target element.

**Replace element with XML fragment**

Use this operation to replace elements with an XML fragment. This operation allows you to specify the following parameters:

**Target elements (XPath)**

The target elements to be replaced, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.

**XML Fragment**

The XML fragment with which to replace the target element.

**Refactoring Operations for JATSKit**

**Add BITS DOCTYPE - NLM/NCBI Book Interchange 2.0**

Use this operation to add an NLM 'BITS' 2.0 DOCTYPE declaration.

**Add Blue DOCTYPE - NISO JATS Publishing 1.1**

Use this operation to add a JATS 'Blue' 1.1 DOCTYPE declaration.

**Normalize IDs**

Use this operation to normalize assigned IDs and assigned IDs to elements that are missing them.

All of these JATSKit refactoring actions allow you to choose a scope for the operation and some filters:
Scope

Select from a variety of options to define the scope for which resources will be affected by the operation. For example, you can choose to affect all resources in the Project, All opened files, or just the Current file.

Filters section

Include files

Specifies files to be excluded from the operation. You can specify multiple files by separating them with commas and the patterns can include wildcards (such as * or ?).

Restrict to known XML file types only

Excludes non-XML file types from the operation.

Look inside archives

If this option is selected, the scope of the operation will include files inside archives.

Refactoring Operations for Publishing Template

These operations are for those who use Oxygen Publishing Templates for WebHelp Responsive output customization.

Migrate HTML Page Layout Files to v21

Use this operation to convert custom HTML page layout files (on page 1909) that are included in a custom Publishing Template that was created in Oxygen XML Editor version 20.0 or 20.1 so that they will be compatible with Oxygen XML Editor version 21.0.

Update HTML Pages

⚠️ Attention: This operation is only used by Oxygen XML Editor and should not be used manually.

Additional Notes

⚠️ Note: There are some operations that allow <ANY> for the local name and namespace parameters. This value can be used to select an element or attribute regardless of its local name or namespace. Also, the <NO_NAMESPACE> value can be used to select nodes that do not belong to a namespace.

⚠️ Note: Some operations have parameters that accept XPath expressions to match elements or attributes. In these XPath expressions you can only use the prefixes declared in the Options >
Preferences > XML > XSLT-FO-XQUERY > XPath (on page 214) page. This preferences page can be easily opened by clicking the link in the note (Each prefix used in an XPath expression must be declared in the Default prefix-namespace mappings section) at the bottom of the Configure Operation Parameters wizard page.

Custom Refactoring Operations

While Oxygen XML Editor includes a variety of built-in XML refactoring operations to help you accomplish particular tasks, you can also create custom operations according to your specific needs. For example, you could create a custom refactoring operation to convert an attribute to an element and insert the element as the first child of the parent element.

An XML Refactoring operation is defined as a pair of resources:

- An XQuery Update script or XSLT stylesheet that Oxygen XML Editor will run to refactor the XML files.
- An XML Operation Descriptor file that contains information about the operation (such as the name, description, and parameters).

Figure 415. Diagram of an XML Refactoring Operation

All the defined custom operations are loaded by the XML Refactoring Tool and presented in the Refactoring Operations wizard page (on page 1140), along with the built-in operations.
After the user chooses an operation and specifies its parameters, Oxygen XML Editor processes an XQuery Update or XSLT transformation over the input file. This transformation is executed in a **safe mode**, which implies the following:

- **When loading the document:**
  - The **Xinclude** mechanism is disabled. This means that the resources included by using Xinclude will not be visible in the transformation.
  - The DTD entities will be processed without being expanded.
  - The associated DTD will be not loaded, so the default attributes declared in the DTD will not be visible in the transformation.

- **When saving the updated XML document:**
  - The **DOCTYPE** will be preserved.

  **Note:** This can be changed using *[Saxon extension functions in XSLT](on page 1170)*.
  - The DTD entities will be preserved as they are in the original document when the document is saved.
  - The attribute values will be kept in their original form without being normalized.
  - The spaces between attributes are preserved. Basically, the spaces are lost by a regular XML serialization since they are not considered important.

The result of this transformation overrides the initial input file.

**Note:** To achieve some of the previous goals, the XML Refactoring mechanism adds several attributes that are interpreted internally. The attributes belong to the **http://www.oxygenxml.com/ns/xmlRefactoring/additional_attributes** namespace. These attributes should not be taken into account when processing the input XML document since they are discarded when the transformed document is serialized.

**Restriction:** *Comments or processing instructions* that are in any node before or after the root element cannot be modified by an XML Refactoring operation. In other words, XML Refactoring operations can only be applied on the root element and the nodes inside it. However, as a work around to this limitation, you can use *[Saxon extension functions and the XSLT stylesheet method](on page 1170)* to implement the new custom XML refactoring operation.

**Creating a Custom Refactoring Operation**

To create a custom refactoring operation, follow these steps:

1. Create an *[XQuery Update script](on page 1160)* or *[XSLT stylesheet file](on page 1165)*.
2. Create an *[XML Refactoring Operation Descriptor]* file contains the path to the XQuery Update script (*on page 1163*) or XSLT stylesheet (*on page 1168*).
3. Store both files in one of the locations that Oxygen XML Editor (on page 1172) scans when loading the custom operations.

**Result:** Once you run the XML Refactoring tool again, the custom operation appears in the Refactoring Operations wizard page (on page 1140).

**Related Information:**
- Storing and Sharing Refactoring Operations (on page 1172)

**Custom Refactoring Script**

The first step in creating a custom refactoring operation is to create an XQuery Update script (on page 1160) or XSLT stylesheet (on page 1165) that is needed to process the refactoring operations. The easiest way to create this script file is to use the New document wizard to create a new XQuery or XSLT file and you can use the XQuery method example (on page 1160) or XSLT method example (on page 1165) to help you with the content.

There are cases when it is necessary to add parameters in the XQuery script (on page 1160) or XSLT stylesheet (on page 1165). For instance, if you want to rename an element, you may want to declare an external parameter associated with the name of the element to be renamed. To allow you to specify the value for these parameters, they need to be declared in the refactoring operation descriptor file that is associated with this operation.

**Note:** The XQuery Update processing is disabled by default in Oxygen XML Editor. Thus, if you want to create or edit an XQuery Update script you have to enable this mechanism by creating an XQuery transformation scenario (on page 1749) and choose Saxon EE as the transformation engine. Also, you need to make sure the Enable XQuery update option is selected in the Saxon processor advanced options (on page 1696).

**Note:** If you are using an XSLT file, XPath expressions that are passed as parameters will automatically be rewritten to conform with the mapping of the namespace prefixes declared in the XML /XSLT-FO-XQuery / XPath preferences page (on page 214).

The next step in creating a custom refactoring operation is to create an XML Refactoring Operation Descriptor file contains the path to the XQuery Update script (on page 1163) or XSLT stylesheet (on page 1168).

**Related Information:**
- XQuery Update Script for Creating a Custom Operation (on page 1160)
Custom Refactoring Operation Descriptor File

The second step in creating a custom refactoring operation is to create an operation descriptor file. The easiest way to do this is to use the New document wizard and choose the XML Refactoring Operation Descriptor template.

Introduction to the Descriptor File

This file contains information (such as name, description, and id) that is necessarily when loading an XML Refactoring operation. It also contains the path to the XQuery Update script (on page 1160) or XSLT stylesheet (on page 1165) that is associated with the particular operation through the script element.

You can specify a category for your custom operations to logically group certain operations. The category element is optional and if it is not included in the descriptor file, the default name of the category for the custom operations is Other operations.

The descriptor file is edited and validated against the following schema: frameworks/xml_refactoring/operation_descriptor.xsd.

Declaring Parameters in the Descriptor File

If the XQuery Update script or XSLT stylesheet includes parameters, they should be declared in the parameters section of the descriptor file. All the parameters specified in this section of the descriptor file will be displayed in the XML Refactoring tool within the Configure Operation Parameters wizard page (on page 1140) for that particular operation.

The value of the first description element in the parameters section will be displayed at the top of the Configure Operation Parameters wizard page (on page 1140).

To declare a parameter, specify the following information:

- label - This value is displayed in the user interface for the parameter.
- name - The parameter name used in the XQuery Update script or XSLT stylesheet and it should be the same as the one declared in the script.
- type - Defines the type of the parameter and how it will be rendered. There are several types available:
  - TEXT - Generic type used to specify a simple text fragment.
- **XPATH** - Type of parameter whose value is an XPATH expression. For this type of parameter, Oxygen XML Editor will use a text input with corresponding content completion and syntax highlighting.

**Note:** The value of this parameter is transferred as plain text to the XQuery Update or XSLT transformation without being evaluated. You should evaluate the XPath expression inside the XQuery Update script or XSLT stylesheet. For example, you could use the `saxon:evaluate` Saxon extension function.

**Note:** A relative XPath expression is converted to an absolute XPath expression by adding `// before it (`//XPathExp`). This conversion is done before transferring the XPath expression to the XML refactoring engine.

**Note:** When writing XPath expressions, you can only use prefixes declared in the Options > Preferences > XML > XSLT-FO-XQUERY > XPath (on page 214) options page.

- **NAMESPACE** - Used for editing namespace values.

- **REG_EXP_FIND** - Used when you want to match a certain text by using Perl-like regular expressions.

- **REG_EXP_REPLACE** - Used along with `REG_EXP_FIND` to specify the replacement string.

- **XML_FRAGMENT** - This type is used when you want to specify an XML fragment. For this type, Oxygen XML Editor will display a text area specialized for inserting XML documents.

- **NC_NAME** - The parameter for NC_NAME values. It is useful when you want to specify the local part of a QName (on page 3286) for an element or attribute.

- **BOOLEAN** - Used to edit boolean parameters.

- **TEXT_CHOICE** - It is useful for parameters whose value should be from a list of possible values. Oxygen XML Editor renders each possible value as a radio button option.

  - **description** - The description of the parameter. It is used by the application to display a tooltip when you hover over the parameter.

  - **possibleValues** - Contains the list with possible values for the parameter and you can specify the default value, as in the following example:

```xml
<possibleValues onlyPossibleValuesAllowed="true">
  <value name="before">Before</value>
  <value name="after" default="true">After</value>
  <value name="firstChild">First child</value>
  <value name="lastChild">Last child</value>
</possibleValues>
```
Specialized Parameters to Match Elements or Attributes

If you want to match elements or attributes, you can use some specialized parameters, in which case Oxygen XML Editor will propose all declared elements or attributes based on the schema associated with the currently edited file. The following specialized parameters are supported:

**elementLocation**

This parameter is used to match elements. For this type of parameter, the application displays a text field where you can enter the element name or an XPath expression. The text from the `label` attribute is displayed in the application as the label of the text field. The `name` attribute is used to specify the name of the parameter from the XQuery Update script or XSLT stylesheet. If the value of the `useCurrentContext` attribute is set to `true`, the element name from the cursor position is used as proposed values for this parameter.

Example of an `elementLocation`:

```xml
<elementLocation name="elem_loc" useCurrentContext="false">
  <element label="Element location">
    <description>Element location description.</description>
  </element>
</elementLocation>
```

**attributeLocation**

This parameter is used to match attributes. For this type of parameter, the application displays two text fields where you can enter the parent element name and the attribute name (both text fields accept XPath expressions for a finer match). The text from the `label` attributes is displayed in the application as the label of the associated text fields. The `name` attribute is used to specify the name of the parameter from the XQuery Update script or XSLT stylesheet. The value of this parameter is an XPath expression that is computed by using the values of the expression from the `element` and `attribute` text fields. For example, if `section` is entered for the element and a `title` is entered for the attribute, the XPath expression would be computed as `//section/@title`. If the value of the `useCurrentContext` attribute is set to `true`, the element and attribute name from the cursor position is used as proposed values for the operation parameters.

Example of an `attributeLocation`:

```xml
<attributeLocation name="attr_xpath" useCurrentContext="true">
  <element label="Element path">
  </element>
</attributeLocation>
```
elementParameter

This parameter is used to specify elements by local name and namespace. For this type of parameter, the application displays two combo boxes with elements and namespaces collected from the associated schema of the currently edited file. The text from the label attribute is displayed in the application as label of the associated combo. The name attribute is used to specify the name of the parameter from the XQuery Update script or XSLT stylesheet. If you specify the allowsAny attribute, the application will propose <ANY> as a possible value for the Name and Namespace combo boxes. You can also use the useCurrentContext attribute and if its value is set to true, the element name and namespace from the cursor position is used as proposed values for the operation parameters.

Example of an elementParameter:

```xml
<elementParameter id="elemID" useCurrentContext="true">
  <localName label="Name" name="element_localName" allowsAny="true">
    <description>Local name of the parent element.</description>
  </localName>

  <namespace label="Namespace" name="element_namespace" allowsAny="true">
    <description>Local name of the parent element</description>
  </namespace>
</elementParameter>
```

attributeParameter

This parameter is used to specify attributes by local name and namespace. For this type of parameter, the application displays two combo boxes with attributes and their namespaces collected from the associated schema of the currently edited file. The text from the label attribute is displayed in the application as the label of the associated combo box. You can also use the useCurrentContext attribute and if its value is set to true, the attribute name and namespace from the cursor position is used as proposed values for the operation parameters.
Note: An attributeParameter is dependant upon an elementParameter. The list of attributes and namespaces are computed based on the selection in the elementParameter combo boxes.

Example of an attributeParameter:

```xml
<attributeParameter dependsOn="elemID" useCurrentContext="true">
  <localName label="Name" name="attribute_localName">
    <description>The name of the attribute to be converted.</description>
  </localName>

  <namespace label="Namespace" name="attribute_namespace" allowsAny="true">
    <description>Namespace of the attribute to be converted.</description>
  </namespace>
</attributeParameter>
```

Note: All built-in operations are loaded from the `{OXYGEN_INSTALL_DIR}/refactoring` folder.

- Example of an Operation Descriptor File with an XQuery Update script (on page 1163)

**XQuery Update Script for Creating a Custom Operation**

To demonstrate creating a custom operation, suppose that you have a task where you need to convert an attribute into an element and insert it inside another element. A specific example would be if you have a project with a variety of `image` elements where a deprecated `alt` attribute was used for the description and you want to convert all instances of that attribute into an element with the same name and insert it as the first child of the `image` element.

Thus, the task is to convert this attribute into an element with the same name and insert it as the first child of the `image` element.

Figure 416. Example: Custom XML Refactoring Operation
An XQuery Update script can be used to implement the new custom XML refactoring operation. The second requirement is an XML Refactoring operation descriptor file (on page 1163) that contains the path to the XQuery Update script.

⚠️ **Restriction**: There is a limitation to using an XQuery script in that comments or processing instructions that are in any node before or after the root element cannot be modified by an XML Refactoring operation. In other words, XML Refactoring operations can only be performed on comments or processing instructions that are inside the root element. However, as a work around to this limitation, you can use Saxon extension functions and the XSLT stylesheet method (on page 1170) to implement the new custom XML refactoring operation.

**Example of an XQuery Update Script for Creating a Custom Operation to Convert an Attribute to an Element**

The XQuery Update script does the following:

- Iterates over all elements from the document that have the specified local name and namespace.
- Finds the attribute that will be converted to an element.
- Computes the QName (on page 3286) of the new element to be inserted and inserts it as the first child of the parent element.

```xquery
<image href="../image/insertBattery.jpg" alt="Insert the battery into the battery compartment." placement="break"/>

<image href="../image/insertBattery.jpg" placement="break">
  <alt>Insert the battery into the battery compartment.</alt>
</image>
```

```xquery
{
  XQuery document used to implement 'Convert attribute to element' operation from XML Refactoring tool.
}
```
declare namespace output = "http://www.w3.org/2010/xslt-xquery-serialization";
declare option output:method   "xml";
declare option output:indent   "no"

(: Local name of the attribute's parent element. :) 
declare variable $element_localName as xs:string external;

(: Namespace of the attribute's parent element. :) 
declare variable $element_namespace as xs:string external;

(: The local name of the attribute to be converted :) 
declare variable $attribute_localName as xs:string external;

(: The namespace of the attribute to be converted :) 
declare variable $attribute_namespace as xs:string external;

(: Local name of the new element. :) 
declare variable $new_element_localName as xs:string external;

(: Namespace of the new element. :) 
declare variable $new_element_namespace as xs:string external;

(: Convert attribute to element:) 
for $node in //*
 (: Find the attribute to convert :) 
let $attribute := 
  $node/@*[local-name() = $attribute_localName and ($attribute_namespace = '<ANY>' or $attribute_namespace = namespace-uri())]

(: Compute the prefix for the new element to insert :) 
let $prefix :=
  for $p in in-scope-prefixes($node)
    where $new_element_namespace = namespace-uri-for-prefix($p, $node)
  return $p

(: Compute the qname for the new element to insert :) 
let $new_element_qName :=
  if (empty($prefix) or $prefix[1] = '') then $new_element_localName 
  else $prefix[1] || ':' || $new_element_localName
where ('<ANY>' = $element_localName or local-name($node) = $element_localName)
   and
($element_namespace = '<ANY>' or $element_namespace = namespace-uri($node))

return
   if (exists($attribute)) then
      (insert node element {QName($new_element_namespace, $new_element_qName)}
       {string($attribute)} as first into $node,
       delete node $attribute)
   else ()

Example of an Operation Descriptor File That References the XQuery Script for Creating a Custom Operation to Convert an Attribute to an Element

After you have developed the XQuery script, you have to create an XML Refactoring operation descriptor. This descriptor is used by the application to load the operation details such as name, description, or parameters.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<refactoringOperationDescriptor
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xmlns="http://www.oxygenxml.com/ns/xmlRefactoring"
   id="convert-attribute-to-element"
   name="Convert attribute to element">
  <description>Converts the specified attribute to an element. The new element will be inserted as first child of the attribute's parent element.</description>

  <!-- For the XSLT stylesheet option uncomment the following line and comment the line referring the XQuery Update script -->
  <!-- <script type="XSLT" href="convert-attribute-to-element.xsl"/> -->
  <script type="XQUERY_UPDATE" href="convert-attribute-to-element.xq"/>

  <parameters>
    <section label="Parent element">
      <elementParameter id="elemID">
        <localName label="Name" name="element_localName" allowsAny="true">
          <description>Local name of the parent element.</description>
        </localName>
      </elementParameter>
    </section>
    <section label="Parent element">
      <namespace label="Namespace" name="element_namespace" allowsAny="true">
        <description>Local name of the parent element.</description>
      </namespace>
    </section>
  </parameters>
</refactoringOperationDescriptor>
```
<section label="Attribute">
  <attributeParameter dependsOn="elemID">
    <localName label="Name" name="attribute_localName">
      <description>Name of the attribute to be converted.</description>
    </localName>
    <namespace label="Namespace" name="attribute_namespace" allowsAny="true">
      <description>Namespace of the attribute to be converted.</description>
    </namespace>
  </attributeParameter>
</section>

<section label="New element">
  <elementParameter>
    <localName label="Name" name="new_element_localName">
      <description>The name of the new element.</description>
    </localName>
    <namespace label="Namespace" name="new_element_namespace">
      <description>The namespace of the new element.</description>
    </namespace>
  </elementParameter>
</section>

<parameters>
</refactoringOperationDescriptor>

Results

After you have created these files, copy them into a folder scanned by Oxygen XML Editor when it loads the custom operation (on page 1172). When the XML Refactoring tool is started again, you will see the created operation.

Since various parameters can be specified, this custom operation can also be used for other similar tasks. The following image shows the parameters that can be specified in the example of the custom operation to convert an attribute to an element:

Figure 417. Example: XML Refactoring Wizard for a Custom Operation
XSLT Stylesheet for Creating a Custom Operation

To demonstrate creating a custom operation, suppose that you have a task where you need to convert an attribute into an element and insert it inside another element. A specific example would be if you have a project with a variety of `image` elements where a deprecated `alt` attribute was used for the description and you want to convert all instances of that attribute into an element with the same name and insert it as the first child of the `image` element.

Thus, the task is to convert this attribute into an element with the same name and insert it as the first child of the `image` element.

Figure 418. Example: Custom XML Refactoring Operation

```xml
<image
   href="../image/insertBattery.jpg"
   alt="Insert the battery into the battery compartment."
   placement="break"/>

<alt>Insert the battery into the battery compartment.</alt>
</image>
```
An XSLT stylesheet can be used to implement the new custom XML refactoring operation. The second requirement is an XML Refactoring operation descriptor file (on page 1168) that contains the path to the XSLT stylesheet.

**Example of an XSLT Script for Creating a Custom Operation to Convert an Attribute to an Element**

The XSLT stylesheet does the following:

- Iterates over all elements from the document that have the specified local name and namespace.
- Finds the attribute that will be converted to an element.
- Adds the new element as the first child of the parent element.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    exclude-result-prefixes="xs"
    xmlns:xr="http://www.oxygenxml.com/ns/xmlRefactoring"
    version="2.0">

    <xsl:param name="element_localName" as="xs:string" required="yes"/>
    <xsl:param name="element_namespace" as="xs:string" required="yes"/>
    <xsl:param name="attribute_localName" as="xs:string" required="yes"/>
    <xsl:param name="attribute_namespace" as="xs:string" required="yes"/>
    <xsl:param name="new_element_localName" as="xs:string" required="yes"/>
    <xsl:param name="new_element_namespace" as="xs:string" required="yes"/>

    <xsl:template match="node() | @*">
        <xsl:copy>
            <xsl:apply-templates select="node() | @*"/>
        </xsl:copy>
    </xsl:template>

    <xsl:template match="/*/xr:check-local-name($element_localName, ., true())
        and
        xr:check-namespace-uri($element_namespace, .))">
        <xsl:variable name="attributeToConvert"
            select="@*[xr:check-local-name($attribute_localName, ., true())]">
        </xsl:variable>
    </xsl:template>
</xsl:stylesheet>
```
and

    xr:check-namespace-uri($attribute_namespace, .)]"/>

    <xsl:choose>
      <xsl:when test="empty($attributeToConvert)">
        <xsl:copy>
          <xsl:apply-templates select="node() | @*"/>
        </xsl:copy>
      </xsl:when>
      <xsl:otherwise>
        <xsl:copy>
          <xsl:for-each select="@*[empty(. intersect $attributeToConvert)]">
            <xsl:copy-of select="."/>
          </xsl:for-each>
        </xsl:copy>
      </xsl:otherwise>
    </xsl:choose>

    <!-- The new element namespace -->
    <xsl:variable name="nsURI" as="xs:string">
      <xsl:choose>
        <xsl:when test="$new_element_namespace eq $xr:NO-NAMESPACE">
          <xsl:value-of select="''"/>
        </xsl:when>
        <xsl:otherwise>
          <xsl:value-of select="$new_element_namespace"/>
        </xsl:otherwise>
      </xsl:choose>
    </xsl:variable>

    <xsl:element name="{$new_element_localName}" namespace="{$nsURI}">
      <xsl:value-of select="$attributeToConvert"/>
    </xsl:element>

    <xsl:apply-templates select="node()"/>
  </xsl:copy>
</xsl:otherwise>
</xsl:choose>
</xsl:template>
</xsl:stylesheet>

**Note:** The XSLT stylesheet imports a module library that contains utility functions and variables. The location of this module is resolved via an XML Catalog (on page 3289) set in the XML Refactoring framework (on page 3282).
Example of an Operation Descriptor File That References the XSLT Stylesheet for
Creating a Custom Operation to **Convert an Attribute to an Element**

After you have developed the XSLT stylesheet, you have to create an XML Refactoring operation
descriptor. This descriptor is used by the application to load the operation details such as name,
description, or parameters.

```xml
<?xml version="1.0" encoding="UTF-8"/>
<refactoringOperationDescriptor
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns="http://www.oxygenxml.com/ns/xmlRefactoring"
 id="convert-attribute-to-element"
 name="Convert attribute to element">
  <description>Converts the specified attribute to an element.
   The new element will be inserted as first child of the attribute's
   parent element.</description>
  <!-- For the XSLT stylesheet option uncomment the following line and comment
   the line referring the XQuery Update script -->
  <!-- <script type="XSLT" href="convert-attribute-to-element.xsl"/> -->
  <script type="XQUERY_UPDATE" href="convert-attribute-to-element.xq"/>
  <parameters>
    <section label="Parent element">
      <elementParameter id="elemID">
        <localName label="Name" name="element_localName" allowsAny="true">
          <description>Local name of the parent element.</description>
        </localName>
        <namespace label="Namespace" name="element_namespace" allowsAny="true">
          <description>Local name of the parent element</description>
        </namespace>
      </elementParameter>
    </section>
    <section label="Attribute">
      <attributeParameter dependsOn="elemID">
        <localName label="Name" name="attribute_localName">
          <description>Name of the attribute to be converted.</description>
        </localName>
        <namespace label="Namespace" name="attribute_namespace" allowsAny="true">
          <description>Namespace of the attribute to be converted.</description>
        </namespace>
      </attributeParameter>
    </section>
  </parameters>
</refactoringOperationDescriptor>
```
Note: If you are using an XSLT file, the line with the `<script>` element would look like this:

```xml
<script type="XSLT" href="convert-attribute-to-element.xsl"/>
```

**Results**

After you have created these files, copy them into a folder scanned by Oxygen XML Editor when it loads the custom operation (on page 1172). When the XML Refactoring tool is started again, you will see the created operation.

Since various parameters can be specified, this custom operation can also be used for other similar tasks. The following image shows the parameters that can be specified in the example of the custom operation to convert an attribute to an element:

Figure 419. Example: XML Refactoring Wizard for a Custom Operation
Using Saxon Extension Functions to Allow Custom Refactoring Operations to Read and Modify Content Outside the Root Node

One advantage to using an XSLT stylesheet is that there is limitation when using an XQuery Update script (on page 1160) in that refactoring operations can only be performed on comments or processing instructions that are inside the root element. Thus, using the XQuery method, comments or processing instructions that are in any node before or after the root element cannot be modified by an XML Refactoring operation.

The XSLT stylesheet method offers a work-around to this limitation through the use of some Saxon extension functions.

To illustrate the use of these functions, consider the following sample XML file:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!-- comment before root -->
<?pi before root ?>
<root>
  <child></child>
</root>
<!-- comment after root -->
<?pi after root ?>
```

The following Saxon extension functions can be used to read and modify content outside the root node:

• **get-content-after-root()** - Returns the content after root as `xs:string`.

For the XML above, the call of this function will return the following string value:

```xml
<!-- comment after root -->
<?pi after root ?>
```

• **set-content-after-root(xs:string)** - Updates the content that will be serialized in the refactored document after the root node.

The function call `set-content-after-root('<!-- Inserted comment -->')` will result in replacing the nodes after the root element with the comment passed as string argument. The XML document will be modified as follows:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!-- comment before root -->
<?pi before root ?>
<root>
  <child></child>
</root><!-- Inserted comment -->
```

• **get-content-before-root()** - Returns the content before root as `xs:string`.

For the XML above, the call of this function will return the following string value:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!-- comment before root -->
<?pi before root ?>
```

• **set-content-before-root(xs:string)** - Updates the content that will be serialized in the refactored document after the root node.

The function call `set-content-before-root('<!-- Inserted comment -->')` will result in replacing the nodes before the root element with the comment passed as string argument. The XML document will be modified as follows:

```xml
<!-- Inserted comment -->
<root><child></child>
</root><!-- Inserted comment -->
```

**XSLT Example:**

To process content after the root node, the XSLT would look like this:
Note: The above XSLT retrieves the nodes after the root element as string, appends a new comment, and then sets back the updated content into the XML document.

Storing and Sharing Refactoring Operations

Oxygen XML Editor scans the following locations when looking for XML Refactoring operations to provide flexibility:

- A refactoring folder, created inside a directory that is associated to a framework you are customizing. To associate the parent directory to the framework, you need to add it in the Classpath tab of the Document type configuration dialog box (on page 99).
Sharing Custom Refactoring Operations

The purpose of Oxygen XML Editor scanning multiple locations for the XML Refactoring operations is to provide more flexibility for developers who want to share the refactoring operations with the other team members. Depending on your particular use case, you can attach the custom refactoring operations to other resources, such as framework (on page 3282) or projects.

After storing custom operations, you can share them with other users by sharing the resources.

Localizing XML Refactoring Operations

Oxygen XML Editor includes localization support for the XML refactoring operations.

The translation keys for the built-in refactoring operations are located in \[OXYGEN_INSTALL_DIR]/refactoring/i18n/translation.xml.

The localization support is also available for custom refactoring operations. The following information can be translated:

- The operation name, description, and category.
- The description of the parameters element.
- The label, description, and possibleValues for each parameter.

Translated refactoring information uses the following form:

\${i18n(translation_key)}
Oxygen XML Editor scans the following locations to find the translation.xml files that are used to load the translation keys:

- A refactoring/i18n folder, created inside a directory that is associated to a customized framework.
- A i18n folder, created inside a directory that is associated to a customized framework.
- An i18n folder inside any specified folder. In this case, you need to open the Preferences dialog box (Options > Preferences) (on page 79), go to XML > XML Refactoring, and specify the folder in the Load additional refactoring operations from text box.
- An i18n folder located in directories specified through the XML Refactoring Operations Plugin Extension (on page 2601).
- The refactoring/i18n folder from the Oxygen XML Editor installation directory ([OXYGEN_INSTALL_DIR]/refactoring/i18n).

**Example: Refactoring Operation Descriptor File with i18n Support**

```xml
<?xml version="1.0" encoding="UTF-8"?>

<refactoringOperationDescriptor
    xmlns="http://www.oxygenxml.com/ns/xmlRefactoring" id="remove_text_content"
    name="$\{i18n(Remove_text_content)\}"
>
    <description>$\{i18n(Remove_text_content_description)\}$</description>

    <script type="XQUERY_UPDATE" href="remove_text_content.xq"/>

    <parameters>
        <description>$\{i18n(parameters_description)\}$</description>

        <parameter label="$\{i18n(Element_name)\}$" name="element_localName"
            type="NC_NAME">
            <description>$\{i18n(Element_name_descriptor)\}$</description>

            <possibleValues>
                <value default="true" name="value1">$\{i18n(value_1)\}$</value>

                <value name="value2">$\{i18n(value_2)\}$</value>
            </possibleValues>
        </parameter>
    </parameters>
</refactoringOperationDescriptor>
```

**XML Digital Signatures**

This chapter explains how to apply and verify digital signatures on XML documents.
Digital Signatures Overview

Digital signatures are widely used as security tokens, not just in XML. A digital signature provides a mechanism for assuring integrity of data, the authentication of its signer, and the non-repudiation of the entire signature to an external party:

- A digital signature must provide a way to verify that the data has not been modified or replaced to ensure integrity.
- The signature must provide a way to establish the identity of the data's signer for authentication.
- The signature must provide the ability for the data's integrity and authentication to be provable to a third party for non-repudiation.

A public key system is used to create the digital signature and it is also used for verification. The signature binds the signer to the document because digitally signing a document requires the originator to create a hash of the message and then encrypt that hash value with their own private key. Only the originator has that private key and that person is the only one who can encrypt the hash so that it can be unencrypted using their public key. The recipient, upon receiving both the message and the encrypted hash value, can decrypt the hash value, knowing the originator's public key. The recipient must also try to generate the hash value of the message and compare the newly generated hash value with the unencrypted hash value received from the originator. If the hash values are identical, it proves that the originator created the message, because only the actual originator could encrypt the hash value correctly.

XML Signatures can be applied to any digital content (data object), including XML (see W3C Recommendation, XML-Signature Syntax and Processing). An XML Signature may be applied to the content of one or more resources:

- Enveloped or enveloping signatures are applied over data within the same XML document as the signature
- Detached signatures are applied over data external to the signature element; the signature is "detached" from the content it signs. This definition typically applies to separate data objects, but it also includes the instance where the signature and data object reside within the same XML document but are sibling elements.

The XML Signature is a method of associating a key with referenced data. It does not normatively specify how keys are associated with persons or institutions, nor the meaning of the data being referenced and signed.

The original data is not actually signed. Instead, the signature is applied to the output of a chain of canonicalization (on page 3280) and transformation algorithms, which are applied to the data in a designated sequence. This system provides the flexibility to accommodate whatever "normalization"
or desired preprocessing of the data that might be required or desired before subjecting it to being signed.

Since the signature is dependent on the content it is signing, a signature produced from a non-canonicalized document could possibly be different from one produced from a canonicalized document. The canonical form of an XML document is physical representation of the document produced by the method described in this specification. The XML canonicalization method is the algorithm defined by this specification that generates the canonical form of a given XML document or document subset. XML canonicalization is designed to be useful for applications that require the ability to test whether or not the information content of a document or document subset has been changed. This is done by comparing the canonical form of the original document before application processing with the canonical form of the document result of the application processing.

A digital signature over the canonical form of an XML document or document subset allows the signature digest calculations to be oblivious to changes in the original document's physical representation. During signature generation, the digest is computed over the canonical form of the document. The document is then transferred to the relying party, which validates the signature by reading the document and computing a digest of the canonical form of the received document. The equivalence of the digests computed by the signing and relying parties (hence, the equivalence of the canonical forms for which they were computed) ensures that the information content of the document has not been altered since it was signed.

The following canonicalization algorithms are used in Oxygen XML Editor:

- **Canonical XML (or Inclusive XML Canonicalization) (XMLC14N)** - Used for XML where the context doesn't change.

  Inclusive Canonicalization copies all the declarations, even if they are defined outside of the scope of the signature, and all the declarations you might use will be unambiguously specified. Inclusive Canonicalization is useful when it is less likely that the signed data will be inserted in other XML document and it is the safer method from the security standpoint because it requires no knowledge of the data that are to be secured to safely sign them. A problem may occur if the signed document is moved into another XML document that has other declarations because the Inclusive Canonicalization will copy them and the signature will be invalid.

- **Exclusive XML Canonicalization (EXCC14N)** - Designed for canonicalization where the context might change.

  Exclusive Canonicalization just copies the namespaces you are actually using (the ones that are a part of the XML syntax). It does not look into attribute values or element content, so the namespace declarations required to process these are not copied. This is useful if you have a signed XML document that you want to insert into other XML documents (or you need self-signed
structures that support placement within various XML contexts), as it will ensure the signature is verified correctly each time.

The canonicalization (on page 3280) method can specify whether or not comments should be included in the canonical form output by the XML canonicalization method. If a canonical form contains comments corresponding to the comment nodes in the input node-set, the result is called canonical XML with comments. In an uncommented canonical form, comments are removed, including the delimiter for comments outside the document element.

The three operations, Canonicalize (on page 1178), Sign (on page 1179), and Verify Signature (on page 1181), are available from the Source submenu when invoking the contextual menu in Text mode or from the Tools menu.

Related Information:

• Certificates (on page 1177)

• Canonicalizing Files (on page 1178)

• Signing Files (on page 1179)

• Verifying Signature (on page 1181)

• Example of How to Digitally Sign XML Files or Content (on page 1182)

Certificates

A certificate is a digitally signed statement from the issuer (an individual, an organization, a website or a firm), saying that the public key (and some other information) of some other entity has a particular value. When data is digitally signed, the signature can be verified to check the data integrity and authenticity. Integrity means that the data has not been modified. Authenticity means the data comes indeed from the entity that claims to have created and signed it. Certificates are kept in special repositories called keystores (on page 3283).

All keystore entries (key and trusted certificate entries) are accessed via unique aliases. An alias must be assigned for every new entry of either a key or certificate as a reference for that entity. No keystore can store an entity if its alias already exists in that keystore and cannot store trusted certificates generated with keys in its keystore.
Oxygen XML Editor provides two types of keystores: Java Key Store (JKS) and Public-Key Cryptography Standards version 12 (PKCS-12). A keystore file is protected by a password. In a PKCS 12 keystore you should not store a certificate without alias together with other certificates, with or without alias, as in such a case the certificate without alias cannot be extracted from the keystore.

To configure the options for a certificate or to validate it, open the Preferences dialog box (Options > Preferences) (on page 79) and go to XML > XML Signing Certificates. This opens the certificates preferences page (on page 223).

Related Information:

- Digital Signatures Overview (on page 1174)

Canonicalizing Files

You can select the canonicalization (on page 3280) algorithm to be used for a document from the dialog box that is displayed by using the Canonicalize action that is available from the Source submenu when invoking the contextual menu in Text mode or from the Tools menu.

Figure 420. Canonicalization Settings Dialog Box

The Canonicalize dialog box allows you to set the following options:

- **Input URL** - Available if the Canonicalize action was selected from the Tools menu. It allows you to specify the location of the input file.
• **Exclusive** - If selected, the exclusive (uncommented) canonicalization (on page 3280) method is used.

  **Note:** Exclusive Canonicalization just copies the namespaces you are actually using (the ones that are a part of the XML syntax). It does not look into attribute values or element content, so the namespace declarations required to process these are not copied. This is useful if you have a signed XML document that you want to insert into other XML documents (or you need self-signed structures that support placement within various XML contexts), as it will ensure the signature is verified correctly each time.

  • **Exclusive with comments** - If selected, the exclusive with comments canonicalization (on page 3280) method is used.

  • **Inclusive** - If selected, the inclusive (uncommented) canonicalization (on page 3280) method is used.

  **Note:** Inclusive Canonicalization copies all the declarations, even if they are defined outside of the scope of the signature, and all the declarations you might use will be unambiguously specified. Inclusive Canonicalization is useful when it is less likely that the signed data will be inserted in other XML document and it is the safer method from the security standpoint because it requires no knowledge of the data that are to be secured to safely sign them. A problem may occur if the signed document is moved into another XML document that has other declarations because the Inclusive Canonicalization will copy them and the signature will be invalid.

  • **Inclusive with comments** - If selected, the inclusive with comments canonicalization (on page 3280) method is used.

  • **XPath** - The XPath expression provides the fragments of the XML document to be signed.

  • **Output** - Available if the Canonicalize action was selected from the Tools menu. It allows you to specify the output file path where the signed XML document will be saved.

  • **Open in editor** - If selected, the output file will be opened in the editor.

**Related Information:**

• Digital Signatures Overview (on page 1174)

**Signing Files**

You can select the type of signature to be used for documents from a signature settings dialog box. To open this dialog box, select the **Sign** action from the **Source** submenu when invoking the contextual menu in **Text** mode or from the **Tools** menu.

Figure 421. Signature Settings Dialog Box
The following options are available:

**Note:** If Oxygen XML Editor could not find a valid certificate, a link is provided at the top of the dialog box that opens the XML Signing Certificates preferences page (on page 223) where you can configure a valid certificate.

- **Input** - Available if the **Sign** action was selected from the **Tools** menu. Specifies the location of the input URL.
- **Transformation Options** - See the Digital Signature Overview (on page 1174) section for more information about these options.
  - **None** - If selected, no canonicalization (on page 3280) algorithm is used.
  - **Exclusive** - If selected, the exclusive (uncommented) canonicalization (on page 3280) method is used.

  **Note:** Exclusive Canonicalization just copies the namespaces you are actually using (the ones that are a part of the XML syntax). It does not look into attribute values or element content, so the namespace declarations required to process these are not copied. This is useful if you have a signed XML document that you want to insert into other XML documents.
(or you need self-signed structures that support placement within various XML contexts), as it will ensure the signature is verified correctly each time.

- **Exclusive with comments** - If selected, the exclusive with comments canonicalization (on page 3280) method is used.
- **Inclusive** - If selected, the inclusive (uncommented) canonicalization (on page 3280) method is used.

**Note:** *Inclusive Canonicalization* copies all the declarations, even if they are defined outside of the scope of the signature, and all the declarations you might use will be unambiguously specified. *Inclusive Canonicalization* is useful when it is less likely that the signed data will be inserted in other XML document and it is the safer method from the security standpoint because it requires no knowledge of the data that are to be secured to safely sign them. A problem may occur if the signed document is moved into another XML document that has other declarations because the Inclusive Canonicalization will copy them and the signature will be invalid.

- **Inclusive with comments** - If selected, the inclusive with comments canonicalization (on page 3280) method is used.

- **XPath** - The XPath expression provides the fragments of the XML document to be signed.
- **ID** - Provides ID of the XML element to be signed.
- **Envelope** - If selected, the enveloped signature is used. See the Digital Signature Overview (on page 1174) for more information.
- **Detached** - If selected, the detached signature is used. See the Digital Signature Overview (on page 1174) for more information.
- **Append KeyInfo** - If this option is selected, the ds:KeyInfo element will be added in the signed document.
- **Signature algorithm** - The algorithm used for signing the document. The following options are available: RSA with SHA1, RSA with SHA256, RSA with SHA384, and RSA with SHA512.
- **Output** - Available if the Sign action was selected from the Tools menu. Specifies the path of the output file where the signed XML document will be saved.
- **Open in editor** - If selected, the output file will be opened in Oxygen XML Editor.

**Related Information:**

- Digital Signatures Overview (on page 1174)
- Verifying Signature (on page 1181)
- Example of How to Digitally Sign XML Files or Content (on page 1182)
Verifying Signature

You can verify the signature of a file by selecting the **Verify Signature** action from the **Source** submenu when invoking the contextual menu in **Text** mode or from the **Tools** menu. The **Verify Signature** dialog box then allows you to specify the location of the file whose signature is verified.

If the signature is valid, a dialog box displays the name of the signer. Otherwise, an error shows details about the problem.

**Related Information:**

- Digital Signatures Overview (*on page 1174*)
- Signing Files (*on page 1179*)
- Example of How to Digitally Sign XML Files or Content (*on page 1182*)

Example of How to Digitally Sign XML Files or Content

Suppose you want to digitally sign an XML document, but more specifically, suppose you have multiple instances of the same element in the document and you just want to sign a specific ID. Oxygen XML Editor includes a signature tool that allows you to digitally sign XML documents or specific content.

The Oxygen XML Editor installation directory includes a **samples** folder that contains a file called **personal.xml**. For the purposes of this example, this file will be used to demonstrate how to digitally sign specific content. Notice that this file has multiple **person** elements inside the **personnel** element. Suppose you want to digitally sign the specific **person** element that contains the id=robert.taylor. To do this, follow this procedure:

1. Open the **personal.xml** file in Oxygen XML Editor in **Text** editing mode.
2. Right-click anywhere in the editor and select the **Sign** action from the **Source** submenu. The **Sign** dialog box is displayed.
   
   **Tip:** If you want to sign a file but create a new output file so that the original file remains unchanged, use the **Sign** action from the **Tools** menu. Selecting the action from this menu will allow you to choose an input file and output file in the **Sign** dialog box.
3. If Oxygen XML Editor cannot find a valid certificate, click the link at the top of the dialog box to **configure a valid certificate**. This opens the **XML Signing Certificates** preferences page (*on page 223*) that allows you to configure and validate a certificate.
4. Once a valid certificate is recognized, continue to configure the **Sign** dialog box.
   a. Select one of the **Transformation Options** (on page 1180). For the purposes of this example, select the **Inclusive with comments** option.
   b. Specify the appropriate **XPath** expression for the specific element that needs to be signed. For this example, type `/personnel/person` in the **XPath** text box.
   c. Enter the specific **ID** that needs to be signed. For this example, type `robert.taylor` in the **ID** field.
   d. Select the **Envelope** option (on page 1181) and leave the other options as their default values.

   The digital signature is added at the end of the XML document, just before the end tag. It is always added at the end of the document, even if you only sign specific content within the document.

5. You can verify the signature by choosing the **Verify Signature** action from the **Source** submenu of the contextual menu.

---

**Editing XSLT Stylesheets**

Oxygen XML Editor includes a built-in editor for XSLT stylesheets. This section presents the features of the XSLT editor and how these features can be used. The features of the XSLT editor include:

- **Create new XSLT files and templates** - You can use the built-in new file wizards to create new XSLT documents or templates (on page 676).
- **Open and Edit XSLT files** - XSLT files can be opened and edited in the source editor (Text mode (on page 828)).
- **Visual Editing** - XSLT stylesheets are rendered, and can be edited, in the visual Author editing mode (on page 893).
- **Validation** - Presents validation errors in XSLT files.
- **Content completion** - Offers proposals for properties and the values that are available for each property.
• **Syntax highlighting** - The syntax highlighting in Oxygen XML Editor makes XSLT files more readable.

**Editing XSLT Stylesheets in the Master Files Context**

Smaller interrelated modules that define a complex stylesheet cannot be correctly edited or validated individually, due to their interdependency with other modules. For example, a function defined in a main stylesheet is not visible when you edit an included or imported module. Oxygen XML Editor provides the support for defining the main module (or modules), allowing you to edit any of the imported/included files in the context of the larger stylesheet structure.

You can set a main XSLT stylesheet either using the *master files support from the Project view (on page 726)*, or using a validation scenario.

To set a *master file* using a validation scenario, add validation units that point to the main modules. Oxygen XML Editor warns you if the current module is not part of the dependencies graph computed for the main stylesheet. In this case, it considers the current module as the main stylesheet.

The advantages of editing in the context of *master file (on page 3284)* include:

- Correct validation of a module in the context of a larger stylesheet structure.
- *Content Completion Assistant (on page 3280)* displays all components valid in the current context.
- The *Outline view (on page 1197)* displays the components collected from the entire stylesheet structure.

For more information about editing XSLT stylesheets in the *master files* context, watch our video demonstration:

[https://www.youtube.com/embed/UZwg385RKNw](https://www.youtube.com/embed/UZwg385RKNw)

**Related Information:**

- [XSLT Component Dependencies View (on page 1207)](#)

**Validating XSLT Stylesheets**

Numerous XSLT code quality assurance checks are done during automatic validation to help you keep your stylesheets valid and well formed. Oxygen XML Editor performs the validation of XSLT
documents with the help of an XSLT processor that you can configure in the preferences pages (on page 200) according to the XSLT version.

For XSLT 1.0, the options are: Xalan, Saxon 6.5.5, Saxon 9.8.0.12 and a JAXP transformer specified by the main Java class. (on page 200) For XSLT 2.0, the options are: Saxon 9.8.0.12 and a JAXP transformer specified by the main Java class. (on page 200) For XSLT 3.0, the options are Saxon 9.8.0.12 and a JAXP transformer specified by the main Java class. (on page 200)

To access the XSLT preferences (on page 200) quickly, use the Validation options action from the Document > Validate menu.

Creating a Validation Scenario for XSLT Stylesheets

You can validate an XSLT document using the engine defined in the transformation scenario, or a custom validation scenario. If you choose to validate using the engine from transformation scenario, and a transformation scenario is not associated with the current document or the engine has no validation support, the default engine is used. To set the default engine, open the Preferences dialog box (Options > Preferences) (on page 79) and go to XML > XSLT/FO/XQuery > XSLT.

You can also create new validation scenarios or edit existing ones, and you can add JARS (on page 3283) and classes that contain extension functions. To create or edit a validation scenario for an XSLT stylesheet, follow these steps:

1. With the XSLT file opened in Oxygen XML Editor, select the Configure Validation Scenario(s) from the Document > Validate menu, or the Validation toolbar drop-down menu, or from the Validate submenu when invoking the contextual menu on the XSLT file in the Project view (on page 333).

   The Configure Validation Scenario(s) dialog box is displayed. It contains the existing scenarios, organized in categories depending on the type of file they apply to. You can use the options in the Settings drop-down menu to filter which scenarios are shown.

2. To edit an existing scenario, select the scenario and press the Edit button. If you try to edit one of the read-only built-in scenarios, Oxygen XML Editor creates a customizable duplicate (you can also use the Duplicate button).

3. To add a new scenario, press the New button.

   The New scenarios dialog box is displayed. It lists all validation units of the scenario.
4. Configure the following information in this dialog box:
   a. **Name** - The name of the validation scenario.
   b. **Storage** - You can choose between storing the scenario in the Project Options (on page 3286) or Global Options (on page 3283).
   c. **URL of the file to validate** - In most cases, leave this field as the default selection (the URL of the current file). If you want to specify a different URL, double-click its cell and enter the URL in the text field, select it from the drop-down list, or use the **Browse** drop-down menu or **Insert Editor Variable** (on page 276) button.
   d. **File type** - The file type should be XSLT Document.
   e. **Validation engine** - Click the cell to select a validation engine. You must select an engine to be able to add or edit extensions.
   f. **Automatic validation** - If this option is selected, the validation operation defined by this row is also used by the automatic validation feature (on page 1082).

5. To add or edit extensions, click the **Edit extensions** button. This button is only available if the **File type** is set as XSLT Document and a Validation engine is chosen.
   The Libraries dialog box is opened. It is used to specify the JARS and classes that contain extension functions called from the XSLT file of the current validation scenario. They will be searched, in the specified extensions, in the order displayed in this dialog box. To change the order of the items, select the item and press the **Move up** or **Move down** buttons.

6. Press **OK** to close the New scenario dialog box.
   The newly created validation scenario is now included in the list of scenarios in the Configure Validation Scenario(s) dialog box. You can select the scenario in this dialog box to associate it with the current XSLT document and press the Apply associated button to run the validation scenario.
Validating XSLT Stylesheets with Custom Engines

If you need to validate an XSLT stylesheet with a validation engine that is different from the built-in engine, you can configure external engines as custom XSLT validation engines in the Oxygen XML Editor preferences. After a custom validation engine is properly configured (on page 181), it can be applied on the current document by selecting it from the list of custom validation engines in the ☑ Validation toolbar drop-down menu. The document is validated against the schema declared in the document.

By default, there are two validators that are configured for XSLT stylesheets:

- **MSXML 4.0** - included in Oxygen XML Editor (Windows edition). It is associated to the XSL Editor type in Preferences page. (on page 181)
- **MSXML.NET** - included in Oxygen XML Editor (Windows edition). It is associated to the XSL Editor type in Preferences page. (on page 181)

Validating XSLT Stylesheets that Call Java Extensions

It is possible to validate XSLT that call Java extensions. This is achieved through a transformation scenario in which the Java extensions are specified, and the default validation will be processed using the parameters defined in the transformation scenario.

To validate XSLT with Java extensions, follow this procedure:

1. Create an XSLT transformation scenario (on page 1722) for your XSLT document (select ☑ Configure Transformation Scenario(s) action from the toolbar, then click New, and select XSLT transformation).
2. In the New scenario dialog box, click the Extensions button (in the XSLT tab), specify the Java extensions (JAR libraries) that are needed, and click OK.
3. Once you are finished configuring the transformation scenario, click OK, then select Save and close.
4. Use the ☑ Validate button on the toolbar (or Ctrl + Shift + V (Command + Shift + V on OS X)) and the default validation will detect and use the transformation scenario profile you just configured and saved.

Related Information:

- Debugging XSLT that Call Java Extensions (on page 2319)
XSLT Quick Fix Support

The Oxygen XML Editor Quick Fix support (on page 3287) helps you resolve various errors that appear in a stylesheet by proposing Quick Fixes to problems such as missing templates, misspelled template names, missing functions, or references to an undeclared variable or parameter.

To activate this feature, hover over or place the cursor in the highlighted area of text where a validation error or warning occurs. If a Quick Fix is available for that particular error or warning, you can access the Quick Fix proposals with any of the following methods:

• When hovering over the error or warning, the proposals are presented in a tooltip pop-up window.
• If you place the cursor in the highlighted area where a validation error or warning occurs, a Quick Fix icon (✔️) is displayed in the stripe on the left side of the editor. If you click this icon, Oxygen XML Editor displays the list of available fixes.
• With the cursor placed in the highlighted area of the error or warning, you can also invoke the Quick Fix menu by pressing Alt + 1 (Command + Alt + 1 on OS X) on your keyboard.

Note: The Quick Fixes are available only when validating an XSLT file with Saxon HE/PE/EE.

Figure 423. Example of an Undefined XSLT Functions Quick Fix

Figure 424. Example of an Undeclared XSLT Variables/Parameters Quick Fix

Oxygen XML Editor provides XSLT Quick Fixes for the following types of instances:

• **Template does not exist**, when the template name referenced in a call-template element does not exist. The following fixes are available:
  • Create template "templateName" - creates a template and generates its corresponding parameters. The template name and parameter names and types are collected from the call-template element.
• **Change reference to "newTemplateName"** - changes the name of the missing template referenced in the `call-template` element. The proposed new names are the existing templates with names similar with the missing one.

• **Variable/Parameter not declared**, when a parameter or variable reference cannot be found. The following fixes are available:
  - **Create global variable "varName"** - creates a global variable with the specified name in the current stylesheet. The new variable is added at the beginning of the stylesheet after the last global variable or parameter declaration.
  - **Create global parameter "paramName"** - creates a global parameter with the specified name in the current stylesheet. The new parameter is added at the beginning of the stylesheet after the last global parameter or variable declaration.
  - **Create local variable "varName"** - creates a local variable with the specified name before the current element.
  - **Create template parameter "paramName"** - creates a new parameter with the specified name in the current template. This fix is available if the error is located inside a template.
  - **Create function parameter "paramName"** - creates a new parameter with the specified name in the current function. This fix is available if the error is located inside a function.
  - **Change reference to "varName"** - changes the name of the referenced variable/parameter to an existing local or global variable/parameter, that has a similar name with the current one.

• **Parameter from a called template is not declared**, when a parameter referenced from a `call-template` element is not declared. The following fixes are available:
  - **Create parameter "paramName" in the template "templateName"** - creates a new parameter with the specified name in the referenced template.
  - **Change "paramName" parameter reference to "newParamName"** - changes the parameter reference from the `call-template` element to a parameter that is declared in the called template.
  - **Remove parameter "paramName" from call-template** - removes the parameter with the specified name from the `call-template` element.

• **No value supplied for required parameter**, when a required parameter from a template is not referenced in a `call-template` element. The **Add parameter "paramName" in call-template** quick-fix is available. It creates a new parameter with the specified name in call-template element.

• **Function "prefix:functionName()" has not been defined**, when a function declaration is not found. The following *Quick Fixes* are available:
  - **Create function "prefix:functionName(param1, param2)"** - creates a new function with the specified signature, after the current top level element from stylesheet.
  - **Change function to "newFunctionName(..)"** - changes the referenced function name to an already defined function. The proposed names are collected from functions with similar names and the same number of parameters.
• **Attribute-set "attrSetName" does not exist**, when the referenced attribute set does not exist. The following *Quick Fixes* are available:
  ◦ **Create attribute-set "attrSetName"** - creates a new attribute set with the specified name, after the current top level element from stylesheet.
  ◦ **Change reference to "attrSetName"** - changes the referenced attribute set to an already defined one.

• **Character-map "characterMap" has not been defined**, when the referenced character map declaration is not found. The following *Quick Fixes* are available:
  ◦ **Create character-map "characterMapName"** - creates a new character map with the specified name, after the current top level element from stylesheet.
  ◦ **Change reference to "characterMapName"** - changes the referenced character map to an already defined one.

Content Completion in XSLT Stylesheets

The list of proposals offered by the *Content Completion Assistant (on page 3280)* in XSLT are context-sensitive and includes proposals that are valid at the current cursor position. It can be manually activated with the *Ctrl + Space (Command + Space on OS X)* shortcut.

You can enhance the list of proposals by specifying an additional schema. This schema is defined in the *Content Completion / XSLT preferences (on page 169)* page and can be any of the following: XML Schema, DTD, RELAX NG schema, or NVDL schema.

Figure 425. XSLT Content Completion Assistant

The feature is activated in *Text* mode in the following situations:

• After you press the `<` character when inserting an element, it is automatically activated after a short delay. You can adjust the activation delay with the *Activation delay of the proposals window (ms) option (on page 168)* from the *Content Completion* preferences page.
After typing a partial element or attribute name, you can manually activate it by pressing Ctrl + Space (Command + Space on OS X) or Alt + ForwardSlash (Command + Alt + ForwardSlash on OS X). If there is only one valid proposal at the current location, it is inserted without displaying the list of proposals.

The Content Completion Assistant proposes numerous item types (such as templates, variables, parameters, keys, etc.) that are defined in the current stylesheet, and in the imported and included XSLT stylesheets. The Content Completion Assistant also includes code templates that can be used to quickly insert code fragments (on page 855) into stylesheets.

Note: For XSL and XSD resources, the Content Completion Assistant collects its components starting from the master files (on page 3284). The master files can be defined in the project or in the associated validation scenario. For further details about the Master Files support go to Defining Master Files at Project Level (on page 726).

The extension functions included in the Saxon 6.5.5 and 9.8.0.12 transformation engines are presented in the content completion list only if the Saxon namespace (http://saxon.sf.net for XSLT version 2.0 / 3.0 or http://icl.com/saxon for XSLT version 1.0) is declared and one of the following conditions is true:

- The edited file has a transformation scenario that uses as transformation engine Saxon 6.5.5 (for XSLT version 1.0), Saxon 9.8.0.12 PE or Saxon 9.8.0.12 EE (for XSLT version 2.0 / 3.0).
- The edited file has a validation scenario that uses as validation engine Saxon 6.5.5 (for version 1.0), Saxon 9.8.0.12 PE or Saxon 9.8.0.12 EE (for version 2.0 / 3.0).
- The validation engine specified in Options (on page 200) page is Saxon 6.5.5 (for version 1.0), Saxon 9.8.0.12 PE or Saxon 9.8.0.12 EE (for version 2.0 / 3.0).

Additionally, the Saxon-CE-specific extension functions and instructions are presented in the list of content completion assistance proposals only if the http://saxonica.com/ns/interactiveXSLT namespace is declared.

Namespace prefixes in the scope of the current context are presented at the top of the content completion assistance window to speed up the insertion into the document of prefixed elements.

Figure 426. Namespace Prefixes in the Content Completion Assistant
For the common namespaces such as XSL namespace (http://www.w3.org/1999/XSL/Transform), XML Schema namespace (http://www.w3.org/2001/XMLSchema), or Saxon namespace (http://icl.com/saxon for version 1.0, http://saxon.sf.net/ for version 2.0 / 3.0), Oxygen XML Editor provides an easy mode to declare them by proposing a prefix for these namespaces.

Content Completion in XPath Expressions

In XSLT stylesheets, the Content Completion Assistant (on page 3280) provides all the features available in the XML editor (on page 844) and also adds some enhancements. In XPath expressions used in attributes of XSLT stylesheets (elements such as match, select, and test), the Content Completion Assistant offers the names of XPath and XSLT functions, XSLT axes, and user-defined functions (the name of the function and its parameters). If a transformation scenario was defined and associated to the edited stylesheet, the Content Completion Assistant computes and presents elements and attributes based on:

- The input XML document selected in the scenario.
- The current context in the stylesheet.

The associated document is displayed in the XSLT/XQuery Input view (on page 1202).

Content completion for XPath expressions is started:

- On XPath operators detected in one of the match, select and test attributes of XSLT elements: " , /, //, (, [ , ] , : , ::, $
- For attribute value templates of non-XSLT elements, that is the { character when detected as the first character of the attribute value.
- On request, if the combination Ctrl + Space (Command + Space on OS X) is pressed inside an edited XPath expression.

The proposals presented in the Content Completion Assistant are dependent on:

- The context of the current XSLT element.
- The XML document associated with the edited stylesheet in the stylesheet transformation scenario.
- The XSLT version of the stylesheet (1.0, 2.0, or 3.0).

Note: The XSLT 3.0 content completion list of proposals includes specific elements and attributes for the 3.0 version.

For example, if the document associated with the edited stylesheet is:

```xml
<personnel>
  <person id="Big.Boss">
```

If you enter an `xsl:template` element using the Content Completion Assistant, the following actions are triggered:

- The `match` attribute is inserted automatically.
- The cursor is placed between the quotes.
- The XPath Content Completion Assistant automatically displays a pop-up window with all the XSLT axes, XPath functions and elements and attributes from the XML input document that can be inserted in the current context.

The set of XPath functions depends on the XSLT version declared in the root element `xsl:stylesheet`: 1.0, 2.0, or 3.0. Functions from other namespaces, such as `maps`, `arrays`, and `math`, are presented only if the namespaces are declared.

Figure 427. Content Completion in the `match` Attribute
If the cursor is inside the `select` attribute of an `xsl:for-each`, `xsl:apply-templates`, `xsl:value-of` or `xsl:copy-of` element the content completion proposals depend on the path obtained by concatenating the XPath expressions of the parent XSLT elements `xsl:template` and `xsl:for-each` as shown in the following figure:

**Figure 428. Content Completion in the select Attribute**

```
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="1.0">
  <xsl:template match="personnel">
    <xsl:for-each>
      <xsl:select="(name,family)"/>
    </xsl:for-each>
  </xsl:template>
</xsl:stylesheet>
```

Also XPath expressions typed in the `test` attribute of an `xsl:if` or `xsl:when` element benefit of the assistance of the content completion.

**Figure 429. Content Completion in the test Attribute**

```
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="1.0">
  <xsl:template match="personnel">
    <xsl:for-each select="name,link">
      <xsl:if test="@name">...</xsl:if>
    </xsl:for-each>
  </xsl:template>
</xsl:stylesheet>
```

XSLT variable references are easier to insert in XPath expressions with the help of the content completion pop-up triggered by the `$` character, which signals the start of such a reference in an XPath expression.

**Figure 430. Content Completion in the test Attribute**
If the `:` character is the first one in the value of the attribute, the same **Content Completion Assistant** is available also in attribute value templates of non-XSLT elements.

Figure 431. Content Completion in Attribute Value Templates

The time delay (configured in the **Content Completion** preferences page *(on page 168)*) is also applied for the content completion in XPath expressions.

**Related Information:**

- Working with XPath Expressions *(on page 2182)*

**Tooltip Helper for the XPath Functions Arguments**

When editing the arguments of an XPath/XSLT function, Oxygen XML Editor tracks the current entered argument by displaying a tooltip containing the function signature. The currently edited argument is highlighted with a bolder font.

When moving the cursor through the expression, the tooltip is updated to reflect the argument found at the cursor position.

**Examples:**

If you want to concatenate the absolute values of two variables, named `v1` and `v2`: 

```
<value-of select='abs(v1) + abs(v2)' />
```
When moving the cursor before the first `abs` function, Oxygen XML Editor identifies it as the first argument of the `concat` function. The tooltip shows in bold font the following information about the first argument:

- Its name is `$arg1`.
- Its type is `xdt:anyAtomicType`.
- It is optional (note the `?` sign after the argument type).

The function also takes other arguments that have the same type and returns a `xs:string`.

Related Information:

- The tooltip helper is also available in the XPath Builder view (on page 2185) and XPath toolbar (on page 2182).
Syntax Highlighting in XSLT

Oxygen XML Editor supports syntax highlighting in Text mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for XSLT files, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79).
2. Go to Editor > Syntax Highlight (on page 178).
3. Select and expand the XML section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.
5. Select the XSL tab in the Preview pane to see the effects of your changes.

Tip: Oxygen XML Editor also allows you to specify syntax highlighting colors for specific XML elements and attributes with specific namespace prefixes. This can be done in the Editor > Syntax Highlight > Elements/Attributes by Prefix preferences page (on page 179).

Related Information:
- Customize Syntax Highlight colors (on page 178)

XSLT Outline View

The Outline view for XSLT stylesheets displays the list of all the components (templates, attribute-sets, character-maps, variables, functions, keys, outputs) from both the edited stylesheet and its imports or includes. For XSL and XSD resources, the Outline view collects its components starting from the master files (on page 3284). The master files can be defined in the project or in the associated validation scenario. For further details about the Master Files support go to Defining Master Files at Project Level (on page 726).

By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Figure 435. XSLT Outline View
The following actions are available in the Settings menu on the Outline view toolbar:

**Filter returns exact matches**

The text filter of the Outline view returns only exact matches;

**Selection update on cursor move**

Controls the synchronization between Outline view and source document. The selection in the Outline view can be synchronized with the cursor moves or the changes in the XSLT editor. Selecting one of the components from the Outline view also selects the corresponding item in the source document.

When the Show components option is selected, the following actions are available:

**Show XML structure**

Displays the XML document structure in a tree-like structure.

**Show all components**

Displays all components that were collected starting from the master file (on page 3284). This option is set by default.

**Show only local components**

Displays the components defined in the current file only.

**Group by location/type**

The stylesheet components can be grouped by location and type.

When the Show XML structure option is selected, the following actions are available:
Show components

Switches the Outline view to the components display mode.

Flat presentation mode of the filtered results

When active, the application flattens the filtered result elements to a single level.

Show comments and processing instructions

Show/hide comments and processing instructions in the Outline view.

Show element name

Show/hide element name.

Show text

Show/hide additional text content for the displayed elements.

Show attributes

Show/hide attribute values for the displayed elements. The displayed attribute values can be changed from the Outline preferences panel (on page 259).

Configure displayed attributes

Displays the XML Structured Outline preferences page (on page 259).

The following contextual menu actions are also available when the Show components option is selected in the Settings menu:

Edit Attributes

Opens a small in-place editor that allow you to edit the attributes of the selected node.

Cut

Cuts the currently selected node.

Copy

Copies the currently selected node.

Delete

Deletes the currently selected node.

Search References Ctrl + Shift + R (Command + Shift + R on OS X)

Searches all references of the item found at current cursor position in the defined scope, if any. See Finding XSLT References and Declarations (on page 1209) for more details.

Search References in
Searches all references of the item found at current cursor position in the specified scope. See Finding XSLT References and Declarations (on page 1209) for more details.

Component Dependencies

Opens the Component Dependencies view (on page 1207) that allows you to see the dependencies for the current selected component.

Resource Hierarchy

Opens the Resource Hierarchy/Dependencies view (on page 1204) that displays the hierarchy for the currently selected resource.

Resource Dependencies

Opens the Resource Hierarchy/Dependencies view (on page 1204) that displays the dependencies of the currently selected resource.

Rename Component in

Renames the selected component. See XSLT Refactoring Actions (on page 1213) for more details.

The following contextual menu actions are available in the Outline view when the Show XML structure option is selected in the Settings menu:

Append Child

Displays a list of elements that you can insert as children of the current element.

Insert Before

Displays a list of elements that you can insert as siblings of the current element, before the current element.

Insert After

Displays a list of elements that you can insert as siblings of the current element, after the current element.

Edit Attributes

Opens a small in-place editor that allow you to edit the attributes of the selected node.

Toggle Comment

Comments/uncomments the currently selected element.

Search references

Searches for the references of the currently selected component.
Searches for the references of the currently selected component in the context of a scope that you define.

Component dependencies

Opens the Component Dependencies view (on page 1207) that displays the dependencies of the currently selected component.

Rename Component in

Renames the currently selected component in the context of a scope that you define.

Cut

Cuts the currently selected component.

Copy

Copies the currently selected component.

Delete

Deletes the currently selected component.

Expand More

Expands the structure of a component in the Outline view.

Collapse All

Collapses the structure of all the component in the Outline view.

The stylesheet components information is presented on two columns: the first column presents the name and match attributes, the second column the mode attribute. If you know the component name, match or mode, you can search it in the Outline view by typing one of these pieces of information in the filter text field from the top of the view or directly on the tree structure. When you type de component name, match or mode in the text field, you can switch to the tree structure using:

- Keyboard arrow keys
- Enter key
- Tab key
- Shift-Tab key combination

To switch from tree structure to the filter text field, you can use Tab and Shift-Tab.

Tip: The search filter is case insensitive. The following wildcards are accepted:

- * - any string
- ? - any character
- , - patterns separator
If no wildcards are specified, the string to search is used as a partial match.

The content of the Outline view and the editing area are synchronized. When you select a component in the Outline view, its definition is highlighted in the editing area.

Oxygen XML Editor allows you to sort the components of the tree in the Outline view.

Note: Sorting groups in the Outline view is not supported.

Oxygen XML Editor has a predefined order of the groups in the Outline view:

- For location, the names of the files are sorted alphabetically. The file you are editing is located at the top of the list.
- For type, the order is: parameters, variables, templates, functions, set attributes, character-map.

Note: When no grouping is available and the table is not sorted, Oxygen XML Editor sorts the components depending on their order in the document. Oxygen XML Editor also takes into account the name of the file that the components are part of.

XSLT Input View

The structure of the XML document associated to the edited XSLT stylesheet is displayed in a tree form in a view called the XSLT Input view. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu. The tree nodes represent the elements of the documents.

If you click a node in the XSLT Input view, the corresponding template from the stylesheet is highlighted. A node can be dragged from this view and dropped in the editor area for quickly inserting xsl:template, xsl:for-each, or other XSLT elements that have the match, select, or test attribute already completed. The value of the attribute is the correct XPath expression that refers to the dragged tree node. This value is based on the current editing context of the drop spot.

Example:
For the following XML document:

```xml
<personnel>
  <person id="Big.Boss">
    <name>
      <family>Boss</family>
      <given>Big</given>
    </name>
    <email>chief@oxygenxml.com</email>
    <link subordinates="one.worker"/>
  </person>
  <person id="one.worker">
    <name>
      <family>Worker</family>
      <given>One</given>
    </name>
    <email>one@oxygenxml.com</email>
    <link manager="Big.Boss"/>
  </person>
</personnel>
```

and the following XSLT stylesheet:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  version="2.0">
  <xsl:template match="personnel">
    <xsl:for-each select="*"/>
  </xsl:template>
</xsl:stylesheet>
```

if you drag the `given` element and drop it inside the `xsl:for-each` element, the following pop-up menu is displayed:
if you select **Insert xsl:copy-of** (for example), the resulting document will look like this:

```xml
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="2.0">
  <xsl:template match="personnel">
    <xsl:for-each select="v">
      <xsl:copy-of select="name/given"/>
    </xsl:for-each>
  </xsl:template>
</xsl:stylesheet>
```

### XSLT Resource Hierarchy/Dependencies View

The **Resource Hierarchy/Dependencies** view displays the hierarchy or dependencies for a stylesheet. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

If you want to see the hierarchy or dependencies of a stylesheet, select the desired stylesheet in the **Project view** and choose **Resource Hierarchy** or **Resource Dependencies** from the contextual menu.

![Resource Hierarchy/Dependencies View](image)
If you want to see the dependencies of a stylesheet, select the desired stylesheet in the **Project view (on page 333)** and choose **Resource Dependencies** from the contextual menu.

The following actions are available on the toolbar of the **Resource Hierarchy/Dependencies** view:

- **Refresh**
  
  Refreshes the Hierarchy/Dependencies structure.

- **Stop**
  
  Stops the hierarchy/dependencies computing.

- **Show Hierarchy**
  
  Allows you to choose a resource to compute the hierarchy structure.

- **Show Dependencies**
  
  Allows you to choose a resource to compute the dependencies structure.

- **Configure dependencies search scope**
  
  Allows you to configure a scope to compute the dependencies structure. There is also an option for automatically using the defined scope for future operations.

- **History**
  
  Provides access to the list of previously computed dependencies. Use the **Clear history** button to remove all items from this list.

The contextual menu for a resource listed in the **Resource Hierarchy/Dependencies** view contains the following actions:

- **Open**
  
  Opens the resource. You can also double-click a resource in the Hierarchy/Dependencies structure to open it.

- **Go to reference**
  
  Opens the source document where the resource is referenced.

- **Copy location**
  
  Copies the location of the resource.

- **Move resource**
  
  Moves the selected resource.

- **Rename resource**
  
  Renames the selected resource.

- **Show Resource Hierarchy**
Shows the hierarchy for the selected resource.

**Show Resource Dependencies**

Shows the dependencies for the selected resource.

**Add to Master Files**

Adds the currently selected resource in the **Master Files** directory (on page 726).

**Expand All**

Expands all the children of the selected resource from the Hierarchy/Dependencies structure.

**Collapse All**

Collapses all children of the selected resource from the Hierarchy/Dependencies structure.

**Tip:** When a recursive reference is encountered in the Hierarchy view, the reference is marked with a special icon 🕹️.

**Related Information:**

- Working with Modular XML Files in the Master Files Context (on page 1126)
- Search and Refactor Operations Scope (on page 1129)

**Moving/Renaming XSLT Resources**

You can move and rename a resource presented in the **Resource/Hierarchy Dependencies** view, using the **Rename resource** and **Move resource** refactoring actions from the contextual menu.

When you select the **Rename** action in the contextual menu of the **Resource/Hierarchy Dependencies** view, the **Rename resource** dialog box is displayed. The following fields are available:

- **New name** - Presents the current name of the edited resource and allows you to modify it.
- **Update references of the renamed resource(s)** - Select this option to update the references to the resource you are renaming. A **Preview** option is available that allows you to see what will be updated before selecting **Rename** to process the operation.

When you select the **Move** action from the contextual menu of the **Resource/Hierarchy Dependencies** view, the **Move resource** dialog box is displayed. The following fields are available:
• **Destination** - Presents the path to the current location of the resource you want to move and gives you the option to introduce a new location.

• **New name** - Presents the current name of the moved resource and gives you the option to change it.

• **Update references of the moved resource(s)** - Select this option to update the references to the resource you are moving, in accordance with the new location and name. A *Preview* option is available that allows you to see what will be updated before selecting *Move* to process the operation.

**XSLT Component Dependencies View**

The **Component Dependencies** view allows you to see the dependencies for a selected component. This is helpful if you want to see where components are used in the entire hierarchy. For example, if you want to find all the references where a given component is used.

If the view is not displayed, it can be opened by selecting it from the *Window > Show View* menu.

To see the dependencies of an XSLT component:

1. Right-click the desired component in the editor or *Outline* view.
2. Select the **Component Dependencies** action from the contextual menu.

The action is available for all named components (templates, variables, parameters, attribute sets, keys, functions, outputs).

If a component contains multiple references, a small table is displayed at the bottom of the view that contains all the references. When a recursive reference is encountered, it is marked with a special icon "a.

Figure 438. Component Dependencies View - Hierarchy for table.xsl
The **Component Dependencies** view includes the following toolbar actions:

- **Refresh**
  
  Refreshes the dependencies structure.

- **Stop**
  
  Stops the dependency computation.

- **Configure**
  
  Allows you to choose the search scope for computing the dependencies structure. This is helpful for making sure all imported/included resources are computed.

- **History**
  
  Allows you to select from a list of the most recently used dependency computations.

In addition, the following actions are available in the contextual menu:

- **Go to First Reference**
  
  Selects the first reference of the currently selected component in the dependencies tree.

- **Go to Component**
  
  Shows the definition of the currently selected component in the dependencies tree.

**Related Information:**
**Highlight Component Occurrences**

When a component (for example variable or named template) is found at current cursor position, Oxygen XML Editor performs a search over the entire document to find the component declaration and all its references. When found, they are highlighted both in the document and in the stripe bar, at the right side of the document.

**Note:** Oxygen XML Editor also supports occurrences highlight for template modes.

Customizable colors are used: one for the component definition and another one for component references. Occurrences are displayed until another component is selected and a new search is performed. All occurrences are removed when you start to edit the document.

This feature is enabled by default. To configure it, open the Preferences dialog box (Options > Preferences) and go to Editor > Mark Occurrences. A search can also be triggered with the Search > Search Occurrences in File (Ctrl + Shift + U (Command + Shift + U on OS X)) contextual menu action. Matches are displayed in separate tabs of the Results view.

**Finding XSLT References and Declarations**

The following search actions related with XSLT references and declarations are available from the Search submenu of the contextual menu and from the Document > References menu:

- **Search References**
  
  Searches all references of the item found at current cursor position in the defined scope, if any. If a scope is defined but the currently edited resource is not part of the range of determined resources, a warning dialog box is displayed that allows you to define another search scope.

- **Search References in**
  
  Searches all references of the item found at current cursor position in the file or files that you specify when a scope is defined.

- **Search Declarations**
  
  Searches all declarations of the item found at current cursor position in the defined scope, if any. If a scope is defined but the current edited resource is not part of the range of resources determined by this scope, a warning dialog box is displayed that allows you to define another search scope.
**Search Declarations in**

Searches all declarations of the item found at current cursor position in the file or files that you specify when a scope is defined.

**Search Occurrences in File**

Searches all occurrences of the item at the cursor position in the currently edited file.

The following action is available from the contextual menu and the Document > Schema menu:

- **Go to Definition**

  Moves the cursor to the location of the definition of the current item.

  **Note:** You can also use the Ctrl + Single-Click (Command + Single-Click on OS X) shortcut on a reference to display its definition.

**Related Information:**

- Search and Refactor Operations Scope (on page 1129)

---

**XSLT Stylesheet Component Documentation Support**

Oxygen XML Editor offers built-in support for documenting XSLT stylesheets. If the expanded QName (on page 3286) of the element has a non-null namespace URI, the `xsl:stylesheet` element may contain any element not from the XSLT namespace. Such elements are referenced as user-defined data elements. Such elements can contain the documentation for the stylesheet and its elements (top-level elements whose names are in the XSLT namespace). Oxygen XML Editor offers its own XML schema that defines such documentation elements. The schema is named `stylesheet_documentation.xsd` and can be found in `[OXYGEN_INSTALL_DIR]/frameworks/stylesheet_documentation`. The user can also specify a custom schema in XSL Content Completion options (on page 169).

**Content Completion**

When content completion is invoked inside an XSLT editor by pressing Ctrl + Space (Command + Space on OS X), it offers elements from the XSLT documentation schema (either the built-in one or one specified by user).
Adding Documentation Blocks

In **Text** mode, to add documentation blocks, press **Ctrl + Alt + D (Command + Alt + D on OS X)** or select **Add component documentation** from the contextual menu.

In **Author** mode, the following stylesheet documentation actions are available in the contextual menu, **Component Documentation** submenu:

- **Add component documentation** - Adds documentation blocks for the component at cursor position.
- **Paragraph** - Inserts a new documentation paragraph.
- **Bold** - Makes the selected documentation text bold.
- **Italic** - Makes the selected documentation text italic.
- **List** - Inserts a new list.
- **List Item** - Inserts a list item.

If the cursor is positioned inside the `xsl:stylesheet` element context, documentation blocks are generated for all XSLT elements. If the cursor is positioned inside a specific XSLT element (such as a template or function), a documentation block is generated for that element only.

**Example: Documentation Block Using Oxygen XML Editor Built-in Schema**

```xml
<xd:doc>
  <xd:desc>
    Search inside parameter `<xd:i>string</xd:i>`
    for the last occurrence of parameter
    `<xd:i>searched</xd:i>`. The substring starting from the 0 position
to the identified last occurrence will be returned.
    <xd:ref name="f:substring-after-last" type="function"
           xmlns:f="http://www.oxygenxml.com/doc/xsl/functions">See also</xd:ref>
  </xd:desc>
  <xd:param name="string">
    String to be analyzed</xd:param>
  </xd:param>
  <xd:param name="searched">
    Marker string. Its last occurrence will be identified</xd:param>
  </xd:param>
  <xd:return>
    A substring starting from the beginning of `<xd:i>string</xd:i>`
  </xd:return>
</xd:doc>
```
to the last occurrence of `<xd:i>`searched`</xd:i>`.
If no occurrence is found an empty string will be returned.

`</xd:p>`
`</xd:return>`
`</xd:doc>`

**XSLT Documentation Links**

Oxygen XML Editor includes support for links inside XSLT documentation blocks. Using a construct like `<xd:a docid="user-defined-id">TEXT</xd:a>` will cause the browser to scroll to the particular anchor (the defined ID) in the current document. Using a construct like `<xd:a href="http://www.my-web-site">TEXT</xd:a>` or `<xd:a href="local-file-path/filename">TEXT</xd:a>` will open the referenced link in a new tab.

**Example: Documentation Links**

```xml
<xd:doc xmlns:xd="http://www.oxygenxml.com/ns/doc/xsl" id="thisDoc">
  <xd:desc>
    <xd:p>
      <xd:ref name="test" type="variable">My test variable</xd:ref>
      <xd:a docid="thisDoc">Link to this documentation, see the the id="thisDoc" above</xd:a>
      <xd:a docid="otherDocID" href="included.xsl">Link to otherDocID defined in included.xsl</xd:a>
    </xd:p>
  </xd:desc>
</xd:doc>
```

**Related Information:**

- Generating Documentation for an XSLT Stylesheet *(on page 1223)*

**XSLT 3.0 Text Value Templates**

Oxygen XML Editor offers built-in support for **XSLT 3.0 Text Value Templates**, including content completion to present the variables, functions, and parameters from the current context and syntax highlighting.

A text node in the stylesheet is treated as a *text value template* if the following things are true:
• It is part of a sequence constructor or a child of an `xsl:text` instruction.
• There is an ancestor element with an `[xsl:]expand-text` attribute and on the innermost ancestor element that has such an attribute, the value of the attribute is `yes`.

**Example:**

```xml
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
xmlns:xs="http://www.w3.org/2001/XMLSchema"
expand-text="yes"
version="3.0">

  <xsl:param name="seq" as="xs:string*" select="'c', 'a', 'b', 'z'"/>
  <xsl:template name="main">
    {sort($seq)}
  </xsl:template>
</xsl:stylesheet>
```

For more information, see: [W3C XSLT Specifications: Text Value Templates](#).

---

**XSLT Refactoring Actions**

Oxygen XML Editor offers a set of actions that allow you to change the structure of an XSLT stylesheet without changing the results of running it in an XSLT transformation. Depending on the selected text, the following XSLT refactoring actions are available from the Refactoring submenu of the contextual menu (or from the **Document > Refactoring** menu):

- **Extract template (Active only when the selection contains well-formed elements)**

  Extracts the selected XSLT instructions sequence into a new template. It opens a dialog box that allows you to specify the name of the new template to be created. The possible changes to perform on the document can be previewed before altering the document. After pressing OK, the template is created and the selection is replaced with a `<xsl:call-template>` instruction referencing the newly created template.

  **Note:** The newly created template is indented and its name is highlighted in the `<xsl:call-template>` element.

- **Extract function**
Extracts the selected XSLT instructions sequence into a new function. It opens a dialog box that allows you to specify the name of the new function. It then moves the selected lines to a newly created XSLT function and inserts a function call in the place of the selected lines. You can also use parts of an XPath expression to create the new functions.

Create local variable

Creates an XSLT variable, wrapped around the selection. It opens a dialog box that allows you to specify the name of the new variable. It then wraps the selection in the variable and you can reference it at anytime in the code.

Move to another stylesheet (Active only when entire components are selected)

Allows you to move one or more XSLT global components (templates, functions, or parameters) to another stylesheet. It opens a dialog box that allows you to specify where the selected components will be moved to. Follow these steps when using the dialog box:

1. Choose whether you want to move the selected components to a new stylesheet or an existing one.
2. If you choose to move the components to an existing one, select the destination stylesheet. Press the Choose button to select the destination stylesheet file. Oxygen XML Editor will automatically check if the destination stylesheet is already contained by the hierarchy of the current stylesheet. If it is not contained, choose whether or not the destination stylesheet will be referenced (imported or included) from the current stylesheet. The following options are available:
   - Include - The current stylesheet will use an \texttt{xsl:include} instruction to reference the destination stylesheet.
   - Import - The current stylesheet will use an \texttt{xsl:import} instruction to reference the destination stylesheet.
   - None - There will be created no relation between the current and destination stylesheets.
3. Press the Move button to move the components to the destination. The moved components are highlighted in the destination stylesheet.

Convert attributes to \texttt{xsl:attribute}

Converts the attributes from the selected element and represents each of them with an \texttt{xsl:attribute} instruction. For example, the following element:

\begin{verbatim}
<person id="Big\{test\}Boss"/>
\end{verbatim}

is converted to:
Convert `xsl:attributes` to attributes

Converts `xsl:attribute` elements to inline attributes for elements outside the XSL namespace. For example, the following element: It is the reverse of the Convert attributes to `xsl:attributes` action with the following limitations:

- The `xsl:attribute` element is "text only".
- The `xsl:attribute` element has a single `xsl:text` child element.
- The `xsl:attribute` element has a single `xsl:value-of` child element. In this case, the value of the attribute will be the XPath expression from the `select` attribute surrounded by curly brackets (text value template).

```xml
<person>
  <xsl:attribute name="id">john.doe</xsl:attribute>
  <xsl:attribute name="email">john.doe@example.com</xsl:attribute>
  <xsl:attribute name="manager"><xsl:value-of select="person[@id='boss']/name"/>
  </xsl:attribute>
</person>
```

is converted to:

```xml
<person id="john.doe" email="john.doe@example.com" manager="{person[@id='boss']/name}"/>
```

Convert `xsl:if` into `xsl:choose/xsl:when`

Converts one or more `xsl:if` element blocks into one or more `xsl:when` blocks surrounded by an `xsl:choose` element. If it is invoked on a selection, the selection must contain a well-formed fragment. If there is no selection, the `xsl:if` element that surrounds the content at the current cursor position is converted.

For example, the following block:

```xml
<xsl:if test="a"/>
```
<!-- XSLT code -->
</xsl:if>

is converted to:

```xml
<xsl:choose>
  <xsl:when test="a">
    <!-- XSLT code -->
  </xsl:when>
  <xsl:when test="c1">
    <!-- XSLT statement 1 -->
  </xsl:when>
  <xsl:when test="c2">
    <!-- XSLT statement 2 -->
  </xsl:when>
  <xsl:when test="c3">
    <!-- XSLT statement 3 -->
  </xsl:when>
  <xsl:otherwise>
    <!-- XSLT "otherwise" statement-->
  </xsl:otherwise>
</xsl:choose>
```

(where the | character is the current cursor position)

**Convert xsl:choose/xsl:when into xsl:if**

Converts each `xsl:when` block into an `xsl:if` block. For the `otherwise` branch, it also adds an `and` statement to each negated form of the conditions. For example, the following block:

```xml
<xsl:choose>
  <xsl:when test="c1">
    <!-- XSLT statement 1 -->
  </xsl:when>
  <xsl:when test="c2">
    <!-- XSLT statement 2 -->
  </xsl:when>
  <xsl:when test="c3">
    <!-- XSLT statement 3 -->
  </xsl:when>
  <xsl:otherwise>
    <!-- XSLT "otherwise" statement-->
  </xsl:otherwise>
</xsl:choose>
```

is converted to:

```xml
<xsl:if test="c1">
  <!-- XSLT statement 1 -->
</xsl:if>
<xsl:if test="c2">
  <!-- XSLT statement 2 -->
</xsl:if>
```
Extract local variable (Active on a selection made inside an attribute that contains an XPath expression)

Allows you to create a new local variable by extracting the selected XPath expression. After creating the new local variable before the current element, Oxygen XML Editor allows you to edit the name of the variable.

Extract global variable (Active on a selection made inside an attribute that contains an XPath expression)

Allows you to create a new global variable by extracting the selected XPath expression. After creating the new global variable, Oxygen XML Editor allows you to edit the name of the variable.

Note: Oxygen XML Editor checks if the selected expression depends on local variables or parameters that are not available in the global context where the new variable is created.

Extract template parameter (Active on a selection made inside an attribute that contains an XPath expression)

Allows you to create a new template parameter by extracting the selected XPath expression. After creating the new parameter, Oxygen XML Editor allows you to edit the name of the parameter.

Extract global parameter (Active on a selection made inside an attribute that contains an XPath expression)

Allows you to create a new global parameter by extracting the selected XPath expression. After creating the new parameter, Oxygen XML Editor allows you to edit the name of the parameter.

Note: Oxygen XML Editor checks if the selected expression depends on local variables or parameters that are not available in the global context where the new parameter is created.

Rename Component
Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the Esc or Enter key on your keyboard.

**Rename Component in**

Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the Preview button, you can view the files to be affected by the action.

![Figure 439. Rename Identity Constraint Dialog Box](image)

**Note:** Many of these refactoring actions are also proposed by the Quick Assist support (on page 1218).

For more information about XSLT refactoring, watch our video demonstration:

https://www.youtube.com/embed/4ir5XWyp8Zo

### XSLT Quick Assist Support

The [Quick Assist support (on page 3286)](section) helps you to rapidly access search and refactoring actions. If one or more actions are available in the current context, they are accessible via a yellow bulb help...
(✔) placed at the current line in the stripe on the left side of the editor. Also, you can invoke the *Quick Assist* menu by using the **Alt + 1** (**Meta + Alt + 1** on Mac OS X) keyboard shortcuts.

Two categories of actions are available in the *Quick Assist* menu:

- Actions available on a selection made inside an attribute that contains an XPath expression:
  
  - **Extract template**
    
    Extracts the selected XSLT instructions sequence into a new template.
  
  - **Move to another stylesheet**
    
    Allows you to move one or more XSLT global components (templates, functions, or parameters) to another stylesheet.
  
  - **Extract local variable**
    
    Allows you to create a new local variable by extracting the selected XPath expression.
  
  - **Extract global variable**
    
    Allows you to create a new global variable by extracting the selected XPath expression.
  
  - **Extract template parameter**
    
    Allows you to create a new template parameter by extracting the selected XPath expression.
  
  - **Extract global parameter**
    
    Allows you to create a new global parameter by extracting the selected XPath expression.

  - **Actions available when the cursor is positioned over the name of a component:**
    
    - **Rename Component in**
      
      Renames the component and all its dependencies.
  
    - **Search Declarations**

Figure 440. XSLT Quick Assist Support - Refactoring Actions

- **Select**
  
  - **Refactor selection**
    
    - **Extract local variable**
    
    - **Extract global variable**
    
    - **Extract template parameter**
    
    - **Extract global parameter**

- **Select**
  
  - **p:name/prop/text()"/>**
  
  - **Extract the selected text to a new local variable**

- **Select**
  
  - **p:email/text()"/>**
  
  - **Extract the selected text to a new local variable**
Searches the declaration of the component in a predefined scope. It is available only when the context represents a component name reference.

- **Search References**
  Searches all references of the component in a predefined scope.

- **Component Dependencies**
  Searches the component dependencies in a predefined scope.

- **Change Scope**
  Configures the scope that will be used for future search or refactor operations.

- **Rename Component**
  Allows you to rename the current component in-place.

- **Search Occurrences**
  Searches all occurrences of the component within the current file.

XSLT Unit Test (XSpec)

XSpec is a behavior driven development (BDD) framework for XSLT, XQuery, and Schematron. XSpec consists of syntax for describing the behavior of your XSLT, XQuery, or Schematron code, and some code that enables you to test your code against those descriptions.

Creating an XSLT Unit Test

To create an XSLT Unit Test, go to File > New > XSLT Unit Test. You can also create an XSLT Unit Test from the contextual menu of an XSL file in the Project view (on page 333). Oxygen XML Editor allows you to customize the XSpec document when you create it. In the customization dialog box, you can enter the path to an XSL document or to a master XSL document.

When you create an XSpec document based on an XSL document, Oxygen XML Editor uses information from the validation and transformation scenarios associated with the XSL file. From the transformation scenario Oxygen XML Editor uses extensions and properties of Saxon 9.8.0.12, improving the Ant scenario associated with the XSpec document.

Figure 442. New XSLT Unit Test Wizard
Running an XSLT Unit Test

To run a Unit Test, open the XSpec file in an editor and click **Apply Transformation Scenario(s)** on the main toolbar. This will run the built-in **Run XSpec Test** transformation scenario that is defined in the XSpec framework (on page 3282).

Testing a Stylesheet

An XSpec file contains one or more test scenarios. You can test a stylesheet in one of the following ways:

• Test an entire stylesheet.

Testing is performed in a certain context. You can define a context as follows:

◦ Inline context, building the test based on a string.

```xml
<x:scenario label="when processing a para element">
  <x:context>
    <para>...</para>
  </x:context>
  ...
</x:scenario>
```

◦ Based on an external file, or on a part of an external file extracted with an XPath expression.

```xml
<x:scenario label="when processing a para element">
  <x:context href="source/test.xml" select="/doc/body/p[1]" />
  ...
</x:scenario>
```

• Test a function.

```xml
<x:scenario label="when capitalising a string">
  <x:call function="eg:capital-case">
    <x:param select="'an example string'" />
    <x:param select="true()" />
  </x:call>
  ...
</x:scenario>
```

• Test a template with a name.

```xml
<x:scenario label="when creating a table">
  <x:call template="createTable" />
</x:scenario>
```
You can reference test files between each other, which allows you to define a suite of tests. For further details about test scenarios, go to https://github.com/expath/xspec/wiki/Writing-Scenarios.

**Adding a Catalog to an XSpec Transformation**

If your XSLT needs a catalog, you can add one to the XSpec transformation by doing one of the following:

- If you are using a project (on page 707) in Oxygen XML Editor, create a catalog.xml file in the project directory. This catalog will then be loaded automatically.
- Edit (on page 1758) the Run XSpec Test transformation scenario, go to the Parameters tab (on page 1720), and set the value of the catalog parameter to the location of your catalog file.

**Generating Documentation for an XSLT Stylesheet**

You can use Oxygen XML Editor to generate detailed documentation in HTML format for the elements (top-level elements whose names are in the XSLT namespace) of an XSLT stylesheet. You can select what XSLT elements to include in the generated documentation and also the level of details to present for each of them. The elements are hyperlinked. To generate documentation in a custom output format (on page 1229), you can edit the XSLT stylesheet used to generate the documentation, or create your own stylesheet.

To open the XSLT Stylesheet Documentation dialog box, select XSLT Stylesheet Documentation from the Tools > Generate Documentation menu or from the Generate Documentation submenu in the contextual menu of the Project view (on page 333).

Figure 443. XSLT Stylesheet Documentation Dialog Box
The XSL URL field of the dialog box must contain the full path to the XSL Stylesheet file you want to generate documentation for. The stylesheet may be a local or a remote file. You can specify the path to the stylesheet by entering it in the text field, or by using the Insert Editor Variables button or the options in the Browse drop-down menu.

Output Tab

The following options are available in the Output tab:

- **Format** - Allows you to choose between the following formats:
  - **HTML** - The documentation is generated in HTML output format (on page 1227).
  - **Custom** - The documentation is generated in a custom output format (on page 1229), allowing you to control the output. Click the Options button to open a Custom format options dialog box (on page 1230) where you can specify a custom stylesheet for creating the output. There is also an option to Copy additional resources to the output folder and you can select the path to the additional Resources that you want to copy. You can also choose to keep the intermediate XML files created during the documentation process by deselecting the Delete intermediate XML file option.

- **Output file** - You can specify the path of the output file by entering it in the text field, or by using the Insert Editor Variables button or the options in the Browse drop-down menu.

- **Split output into multiple files** - Instructs the application to split the output into multiple files. For large XSLT stylesheets, choosing another split criterion may generate smaller output files, providing faster documentation browsing. You can choose to split them by namespace, location, or component name.
• **Open in Browser/System Application** - Opens the result in the system application associated with the output file type.

*Note:* To set the browser or system application that will be used, open the Preferences dialog box (Options > Preferences) (on page 79), go to Global, and set it in the Default Internet browser field. This will take precedence over the default system application settings.

**Settings Tab**

When you generate documentation for an XSLT stylesheet you can choose what XSLT elements to include in the output (templates, functions, global parameters, global variables, attribute sets, character maps, keys, decimal formats, output formats, XSLT elements from referenced stylesheets) and the details to include in the documentation.

![Figure 444. Settings Tab of the XSLT Stylesheet Documentation Dialog Box](image)

The **Settings** tab allows you to choose whether or not to include the following components:
- Templates, Functions, Global parameters, Global variables, Attribute sets, Character maps, Keys, Decimal formats, Output formats, Referenced stylesheets.

You can choose whether or not to include the following other details:

- **Documentation** - Shows the documentation for each XSLT element. For HTML format, the user-defined data elements that are recognized and transformed in documentation blocks of the XSLT elements they precede, are the ones from the following schemas:
  - Oxygen XML Editor built-in XSLT documentation schema.
A subset of DocBook 5 elements. The recognized elements are: section, sect1 to sect5, emphasis, title, ulink, programlisting, para, orderedlist, itemizedlist.

A subset of DITA elements. The recognized elements are: concept, topic, task, codeblock, p, b, i, ul, ol, pre, sl, sli, step, steps, li, title, xref.

Full XHTML 1.0 support.

XSLStyle documentation environment. XSLStyle uses DocBook or DITA languages inside its own user-defined data elements. The supported DocBook and DITA elements are the ones mentioned above.

DOXSL documentation framework (on page 3282). Supported elements are: codefrag, description, para, docContent, documentation, parameter, function, docSchema, link, list, listitem, module, parameter, template, attribute-set.

Other XSLT documentation blocks that are not recognized will just be serialized inside an HTML pre element. You can change this behavior by using a custom format (on page 1229) instead of the built-in HTML format (on page 1227) and providing your own XSLT stylesheets.

- **Use comments** - Controls whether or not the comments that precede an XSLT element is treated as documentation for the element they precede. Comments that precede or succeed the xsl:stylesheet element, are treated as documentation for the whole stylesheet. Note that comments that precede an import or include directive are not collected as documentation for the imported/included module. Also, comments from within the body of the XSLT elements are not collected at all.

- **Namespace** - Shows the namespace for named XSLT elements.

- **Location** - Shows the stylesheet location for each XSLT element.

- **Parameters** - Shows parameters of templates and functions.

- **References** - Shows the named XSLT elements that are referenced from within an element.

- **Used by** - Shows the list of all the XSLT elements that reference the current named element.

- **Supersedes** - Shows the list of all the XSLT elements that supersede the current element.

- **Overriding** - Shows the list of all the XSLT elements that override the current element.

- **Return type** - Shows the return type of the function.

- **Source** - Shows the text stylesheet source for each XSLT element.

- **Import precedence** - Shows the computed import precedence as declared in the XSL transformation specifications.

- **Generate index** - Creates an index with all the XSLT elements included in the documentation.

**Export settings** - Save the current settings in a settings file for further use (for example, with the exported settings file you can generate the same documentation from the command-line interface (on page 1230).)

**Import settings** - Reloads the settings from the exported file.

**Generate** - Use this button to generate the XSLT documentation.
Generate XSLT Documentation in HTML Format

When using the XSLT Stylesheet Documentation dialog box (on page 1223) to generate XSLT documentation in HTML format, it is presented in a visual diagram style with various sections, hyperlinks, and options.

Figure 445. XSLT Stylesheet Documentation Example

The generated documentation includes the following:

- Table of Contents - You can group the contents by namespace, location, or component type. The XSLT elements from each group are sorted alphabetically (named templates are presented first and the match ones second).
- Information about main, imported, and included stylesheets. This information consists of:
- XSLT modules included or imported by the current stylesheet.
- The XSLT stylesheets where the current stylesheet is imported or included.
- The stylesheet location.

Figure 446. Information About an XSLT Stylesheet

<table>
<thead>
<tr>
<th>Stylesheet table.xsl</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>This file was created automatically by html2xhtml from the HTML stylesheet.</td>
</tr>
<tr>
<td><strong>Included modules</strong></td>
</tr>
<tr>
<td>table.xsl</td>
</tr>
<tr>
<td><strong>Included from</strong></td>
</tr>
<tr>
<td>docbook.xsl</td>
</tr>
</tbody>
</table>

If you choose to split the output into multiple files, the table of contents is displayed in the left frame. The contents are grouped using the same criteria as the split.

After the documentation is generated, you can collapse or expand details for some stylesheet XSLT elements by using the **Showing** options or the **Collapse** or **Expand** buttons.

Figure 447. Showing Options

For each element included in the documentation, the section presents the element type followed by the element name (value of the name or match attribute for match templates).

Figure 448. Documentation for an XSLT Element
Generate XSLT Documentation in a Custom Format

XSLT stylesheet documentation can be also generated in a custom format. You must write your custom stylesheet based on the schema xslDocSchema.xsd from \[OXYGEN_INSTALL_DIR\]/frameworks/stylesheet_documentation. You can create a custom format starting from one of the stylesheets used in the built-in HTML, PDF, and DocBook formats. These stylesheets are available in \[OXYGEN_INSTALL_DIR\]/frameworks/stylesheet_documentation/xsl.

To generate XSLT documentation in a custom format:

1. Select Tools > Generate Documentation > XSLT Stylesheet Documentation to open the XSLT Stylesheet Documentation dialog box (on page 1223).
2. Select Custom for the Format and click the Options button.
3. In this next dialog box, specify your own stylesheet to transform the intermediary XML generated in the documentation process.
4. You can also choose to copy additional resources into the output folder or choose whether or not to keep the intermediate XML files created during the documentation process.

5. Click **OK** to close this dialog box and then click **Generate**.

Figure 449. Custom Format Options Dialog Box

Generating XSLT Documentation From the Command-Line Interface

You can export the settings of the **XSLT Stylesheet Documentation** dialog box to an XML file by pressing the **Export settings** button. With the exported settings file, you can generate the same documentation from the command line by running the script `stylesheetDocumentation.bat` (on Windows) / `stylesheetDocumentation.sh` (on OS X / Linux) located in the Oxygen XML Editor installation folder. The script can be integrated in an external batch process launched from the command-line interface.

The command-line parameter of the script is the relative path to the exported XML settings file. The files that are specified with relative paths in the exported XML settings are resolved relative to the script directory.

**Example:**

```xml
<serialized>
  <map>
    <entry>
      <String xml:space="preserve">xsd.documentation.options</String>
      <xsdDocumentationOptions>
        <field name="outputFile">
          <String xml:space="preserve">${cfn}.html</String>
        </field>
        <field name="splitMethod">
          <Integer xml:space="preserve">1</Integer>
        </field>
        <field name="openOutputInBrowser">
          <Boolean xml:space="preserve">true</Boolean>
        </field>
        <field name="format">

```
<Integer xml:space="preserve">1</Integer>
</field>
<field name="customXSL">
  <null/>
</field>
<field name="deleteXMLFiles">
  <Boolean xml:space="preserve">true</Boolean>
</field>
<field name="includeIndex">
  <Boolean xml:space="preserve">true</Boolean>
</field>
<field name="includeGlobalElements">
  <Boolean xml:space="preserve">true</Boolean>
</field>
<field name="includeGlobalAttributes">
  <Boolean xml:space="preserve">true</Boolean>
</field>
<field name="includeLocalElements">
  <Boolean xml:space="preserve">true</Boolean>
</field>
<field name="includeLocalAttributes">
  <Boolean xml:space="preserve">true</Boolean>
</field>
<field name="includeSimpleTypes">
  <Boolean xml:space="preserve">true</Boolean>
</field>
<field name="includeComplexTypes">
  <Boolean xml:space="preserve">true</Boolean>
</field>
<field name="includeGroups">
  <Boolean xml:space="preserve">true</Boolean>
</field>
<field name="includeAttributesGroups">
  <Boolean xml:space="preserve">true</Boolean>
</field>
<field name="includeRedefines">
  <Boolean xml:space="preserve">true</Boolean>
</field>
<field name="includeReferencedSchemas">
  <Boolean xml:space="preserve">true</Boolean>
</field>
Compiling an XSL Stylesheet for Saxon

As of Saxon 9.7, it is possible to export a compiled form of a stylesheet as an XML file (called a stylesheet export file or SEF). Oxygen XML Editor includes a simple tool called **Compile XSL Stylesheet for Saxon** (found in the **Tools** menu) that does this for you.

**Use-Cases for a Stylesheet Export File (SEF)**

- **Use Saxon-JS to run transformations in a browser** - A stylesheet export file (SEF) is needed if you want to use the Saxon-JS product to run transformations in a browser, as in the following example:

```javascript
<script type="text/javascript" src="SaxonJS/SaxonJS.min.js"></script>
<script>
  window.onload = function() {
    SaxonJS.transform({
      stylesheetLocation: "books.sef",
      sourceLocation: "books.xml"
    });
  }
</script>
```

- **Use SEF to run transformations in Oxygen XML Editor** - You can also use a stylesheet export file (SEF) in Oxygen XML Editor to apply an XSLT transformation over an XML file. This requires Saxon-EE or Saxon-PE versions of the Saxon product and you must select one of those two versions for the **Target when you configure the SEF file** *(on page 1234)*. When configuring the XSLT transformation, you will specify the SEF file in the **XSL URL** field *(on page 1675)*.
Compiling an SEF File

The Compile XSL Stylesheet for Saxon tool can be found in the Tools menu and it compiles a specified stylesheet as an XML file (stylesheet export file with a file extension of .sef).

Selecting this tool opens the Compile XSL Stylesheet for Saxon dialog box that allows you to configure some options for conversion.

Figure 450. Compile XSL Stylesheet for Saxon Dialog Box

This dialog box includes the following options:

**XSL URL**

Allows you to select URL of the source XSL stylesheet. You can specify the URL by using the text field, the history drop-down, or the browsing actions in the Browse drop-down list.

**Target**

Allows you to select the type of Saxon product that the export file will be used with. You can choose Saxon-JS, Saxon-EE, Saxon-PE, or Saxon-HE.

**Relocatable**

Can be used to control the Saxon -relocate parameter. You can select this option to produce a relocatable export package (SEF) that can be deployed to a different location, with a different base URI.

**Output file**

You can specify the path where the output file will be saved by entering it in the text field, using the Insert Editor Variables button, or using the browsing actions in the Browse drop-down list.

**Open in Editor**
Select this option to open the resulting stylesheet export file in the main Oxygen XML Editor editing pane.

**Use a configuration file (“-config”)**

Select this option if you want to use a Saxon 9.8.0.12 configuration file that will be executed for the XSLT transformation and validation processes. You can specify the path to the configuration file by entering it in the URL field, or by using the Insert Editor Variables button, or using the browsing actions in the Browse drop-down list.

**Compile**

Use this button to generate the stylesheet export file according the options selected in this dialog box.

---

**Editing Ant Build Files**

Oxygen XML Editor includes an Ant editor that provides a variety of specialized features to assist you with creating and editing Ant build files. The editor includes some specialized views, content completion assistance, automatic validation, syntax highlighting, Quick Assist (on page 3286) and Quick Fix (on page 3287) support, as well as numerous common editing and search features.

**Related Information:**

- Editing XML Documents in Text Mode (on page 828)

---

**Editing Ant Build Files in the Context of Master Files**

Smaller interrelated modules that define a complex Ant build file cannot be correctly edited or validated individually due to their interdependency with other modules. For example, a target defined in a main build file is not visible when you edit an included or imported module. Oxygen XML Editor provides support for defining the main module (or modules), allowing you to edit any of the imported/included files in the context of the larger Ant build structure.

You can set a main Ant build file either by using the master files support from the Project view (on page 726), or a validation scenario (on page 1236).

To set a master file using a validation scenario, add validation units that point to the main modules. Oxygen XML Editor warns you if the current module is not part of the dependencies graph computed for the main build file. In this case, it considers the current module as the main build file.

The advantages of editing in the context of master file (on page 3284) include:
• Correct validation of a module in the context of a larger build structure.
• *Content Completion Assistant (on page 3280)* displays all components valid in the current context.
• The *Outline view (on page 1239)* displays the components collected from the entire build file structure.

**Validating Ant Build Files**

Oxygen XML Editor performs the validation of Ant build files with the help of a built-in processor, which is largely based on the *Apache Ant (on page 3279)* libraries. The path to these libraries can be configured in the *Ant preferences page (on page 221)*. The validation processor accesses the parameters set in the associated Ant transformation scenario (on page 1720) and uses them as Ant properties when validating the current build script.

Oxygen XML Editor automatically validates Ant build files as you type. You can also validate the currently edited file by selecting the ☑ Validate action from the ☑ Validation toolbar drop-down menu or the Document > Validate menu.

**Tip:** To make a custom task available in the Ant validation engine, add a *JAR (on page 3283)* file that contains the task implementation to the library directory of the built-in Ant distribution that comes bundled with Oxygen XML Editor (for example, [OXYGEN_INSTALL_DIR]/tools/ant/lib folder).

**Create a Validation Scenario for Ant Build Files**

If you want to customize the validation process for Ant build files, you can create a new validation scenario (or configure an existing one). For example, if you want to validate interrelated modules that define a complex Ant build file, you can specify the main Ant file by configuring a validation scenario.

To create or configure a validation scenario, select ☑ Configure Validation Scenario(s) from the ☑ Validation toolbar drop-down menu or the Document > Validate menu.

**Passing parameters to the Ant validation engine**

Ant validation scenarios cannot be configured to accept custom Ant parameters. However, you can specify values for the parameters in your Ant document using an Ant transformation scenario:

1. Create a new *Ant transformation scenario (on page 1718)*.
2. Edit the transformation scenario and set all parameters (on page 1720) you need to pass to your Ant document.
3. Associate the new scenario with your Ant document (in the *Configure Transformation Scenarios(s) dialog box (on page 1762)*). You do not need to run the transformation scenario.
Every time a validation operation is triggered, the built-in validation engine uses the parameters set in the transformation scenario.

**Note:** This behavior is available only for the validation scenarios that use the built-in validation engine. The custom defined validation engines do not benefit from this functionality.

### Transforming Ant Build Files

Oxygen XML Editor includes a few built-in transformation scenarios that allow you to transform Ant build files. They are listed in the **Ant** section in the [Configure Transformation Scenario(s) dialog box](#) (on page 1762):

- **ANT** - This transformation scenario runs as an external process that executes the Ant build script with the built-in Ant distribution ([Apache Ant](#) version 1.9.8) that is included with Oxygen XML Editor, or optionally with a custom Ant distribution configured in the scenario.

- **ANT (with Saxon 9 EE XSLT support)** - This transformation scenario allows Ant XSLT tasks to be performed using Saxon 9 **JAR** libraries that come bundled with Oxygen XML Editor and all defined XML catalogs are also taken into account during the transformation.

**Tip:** Certain Ant tasks require additional JAR libraries (for example, Ant mail tasks). The additional libraries can be added by editing the Ant transformation scenario, and in the **Output tab, click the Libraries button** (on page 1719) in the bottom right corner. This opens a dialog box where you can add JAR libraries. For a list of library dependencies, see [https://ant.apache.org/manual/install.html#librarydependencies](https://ant.apache.org/manual/install.html#librarydependencies).

### Related Information:

- Editing a Transformation Scenario (on page 1758)
- Configure Transformation Scenario(s) Dialog Box (on page 1762)
- Applying Associated Transformation Scenarios (on page 1761)
- Ant Transformation (on page 1718)

### Ant Quick Fix Support

The Oxygen XML Editor **Quick Fix support** (on page 3287) helps you resolve missing target reference errors that may occur when developing Ant build documents.
To activate this feature, hover over or place the cursor in the highlighted area of text where a validation error or warning occurs. If a Quick Fix is available for that particular error or warning, you can access the Quick Fix proposals with any of the following methods:

- When hovering over the error or warning, the proposals are presented in a tooltip pop-up window.
- If you place the cursor in the highlighted area where a validation error or warning occurs, a Quick Fix icon ( располагается) is displayed in the stripe on the left side of the editor. If you click this icon, Oxygen XML Editor displays the list of available fixes.
- With the cursor placed in the highlighted area of the error or warning, you can also invoke the Quick Fix menu by pressing Alt + 1 (Command + Alt + 1 on OS X) on your keyboard.

Oxygen XML Editor provides the following types of Quick Fixes for Ant build files:

- **Create new target** - Creates a new target with the specified name.
- **Change reference to “targetName”** - Corrects the reference to point to an already defined target.
- **Remove target reference** - Removes the erroneous reference.

### Content Completion in Ant Build Files

The list of proposals offered by the Content Completion Assistant (on page 3280) in Ant build files are context-sensitive and includes proposals that are valid at the current cursor position. It can be manually activated with the Ctrl + Space (Command + Space on OS X) shortcut.

The Content Completion Assistant proposes various item types that are defined in the current Ant build and in the imported and included builds. The proposals include:

- Element names
- Attribute names
- Property names

**Note:** In addition to the user-defined properties, the Content Completion Assistant offers the following values:

- The system properties set in the Java Virtual Machine.
- The built-in properties that Ant provides.

- Target names
- Task and type reference IDs

**Tip:** To make a custom task available in the Content Completion Assistant, add a JAR (on page 3283) file that contains the task implementation to the library directory of the built-in Ant distribution that comes bundled with Oxygen XML Editor (for example, \{OXYGEN_INSTALL_DIR\}/tools/ant/lib folder).
**Note:** For Ant resources, the proposals are collected starting from the master files (on page 3284). The master files can be defined in the project or in the associated validation scenario. For further details about the Master Files support go to Defining Master Files at Project Level (on page 726).

**Related Information:**

## Syntax Highlighting in Ant Files

Oxygen XML Editor supports syntax highlighting in **Text** mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for Ant build files, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79).
2. Go to Editor > Syntax Highlight (on page 178).
3. Select and expand the Ant Property section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

You can see the effects of your changes in the Preview pane.

**Related Information:**
- Syntax Highlight Preferences (on page 178)

## Ant Outline View

The Outline view for Ant files displays the list of all the components (properties, targets, extension points, task/type definitions and references) from both the edited Ant build file and its imported and included modules. For Ant resources, the Outline view collects its components starting from the master files (on page 3284). The master files can be defined in the project and the main build file can be specified in a validation scenario. For more details, see Defining Master Files at Project Level (on page 726).
By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

Figure 451. Ant Outline View

The following actions are available in the **Settings** menu on the Outline view toolbar:

- **Filter returns exact matches**
  
  The text filter of the **Outline** view returns only exact matches. By default, this filter is not selected.

- **Selection update on cursor move**
  
  Controls the synchronization between **Outline** view and source document. The selection in the **Outline** view can be synchronized with the cursor moves or the changes in the Ant editor. Selecting one of the components from the outline view also selects the corresponding item in the source document.

When the **Show components** option is selected, the following actions are available:

- **Show XML structure**
  
  Displays the XML document structure in a tree-like manner.

- **Sort**
  
  Sorts the components in the **Outline** view alphabetically.

**Show all components**

Displays all components that were collected starting from the *master file (on page 3284)*. This option is set by default.

**Show only local components**

Displays the components defined in the current file only.
Group by location/type

The build file components can be grouped by location and type.

When the Show XML structure option is selected, the following actions are available:

- **Show components**
  
  Switches the Outline view to the components display mode.

- **Flat presentation mode of the filtered results**
  
  When active, the application flattens the filtered result elements to a single level.

- **Show comments and processing instructions**
  
  Show/hide comments and processing instructions in the Outline view.

- **Show element name**
  
  Show/hide element name.

- **Show text**
  
  Show/hide additional text content for the displayed elements.

- **Show attributes**
  
  Show/hide attribute values for the displayed elements. The displayed attribute values can be changed from the Outline preferences panel (on page 259).

- **Configure displayed attributes**
  
  Displays the XML Structured Outline preferences page (on page 259).

The following actions are available in the contextual menu of the Outline view (when the Show XML structure option is selected in the Settings menu):

- **Append Child**
  
  Displays a list of elements that can be inserted as children of the current element.

- **Insert Before**
  
  Displays a list of elements that can be inserted as siblings of the current element, before the current element.

- **Insert After**
  
  Displays a list of elements that can be inserted as siblings of the current element, after the current element.

- **Edit Attributes**
  
  Displays an in-place attribute editing window.
**Toggle Comment**

Comments/uncomments the currently selected element.

**Search References** Ctrl + Shift + R (Command + Shift + R on OS X)

Searches all references of the item found at current cursor position in the defined scope. See Find References and Declarations of Ant Components (on page 1246) for more details.

**Search References in**

Searches all references of the item found at current cursor position in the specified scope. See Find References and Declarations of Ant Components (on page 1246) for more details.

**Component Dependencies**

Opens the Ant Component Dependencies view (on page 1244) that allows you to see the dependencies for the current selected component.

**Rename Component in**

Renames the selected component. See Ant Refactoring Actions (on page 1247) for more details.

**Cut, Copy, Delete**

Executes the typical editing actions on the currently selected component.

**Expand More**

Expands recursively all sub-components of the selected component.

**Collapse All**

Collapses recursively all sub-components of the selected component.

You can search a component in the Outline view by typing its name in the filter text field at the top of the view or directly on the tree structure. When you type the component name in the text field, you can switch to the tree structure using the following:

- **Down** arrow key
- **Tab** key
- **Shift-Tab** key combination

To switch from tree structure to the filter text field, you can use **Tab** and **Shift-Tab**.

**Tip:** The search filter is case insensitive. The following wildcards are accepted:

- * - any string
• ? - any character
• , - patterns separator

If no wildcards are specified, the string to search is used as a partial match (such as *textToFind*).

The content of the Outline view and the editing area are synchronized. When you select a component in the Outline view, its definition is highlighted in the editing area.

Oxygen XML Editor has a predefined order for the groups in the Outline view:

• For location, the names of the files are sorted alphabetically. The file you are editing is located at the top of the list.
• For type, the order is: properties, targets, references.

Note: When no grouping is available Oxygen XML Editor sorts the components depending on their order in the document. Oxygen XML Editor also takes into account the name of the file that the components are part of.

Ant Resource Hierarchy/Dependencies View

The Resource Hierarchy/Dependencies view displays the hierarchy or dependencies for an Ant build file by analyzing imported or included build files. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

If you want to see the hierarchy or dependencies of a build file, select it in the Project view (on page 333) and choose Resource Hierarchy or Resource Dependencies from the contextual menu.

The following actions are available on the toolbar of the Resource Hierarchy/Dependencies view:

- **Refresh**
  
  Refreshes the Hierarchy/Dependencies structure.

- **Stop**
  
  Stops the hierarchy/dependencies computing.

- **Show Hierarchy**
  
  Allows you to choose a resource to compute the hierarchy structure.

- **Show Dependencies**
  
  Allows you to choose a resource to compute the dependencies structure.

- **Configure dependencies search scope**
  
  Allows you to configure a scope to compute the dependencies structure. There is also an option for automatically using the defined scope for future operations.
History

Provides access to the list of previously computed dependencies. Use the **Clear history** button to remove all items from this list.

The contextual menu for a resource listed in the **Resource Hierarchy/Dependencies** view contains the following actions:

**Open**

Opens the resource. You can also double-click a resource in the Hierarchy/ Dependencies structure to open it.

**Go to reference**

Opens the source document where the resource is referenced.

**Copy location**

Copies the location of the resource.

**Move resource**

Moves the selected resource.

**Rename resource**

Renames the selected resource.

**Show Resource Hierarchy**

Shows the hierarchy for the selected resource.

**Show Resource Dependencies**

Shows the dependencies for the selected resource.

**Add to Master Files**

Adds the currently selected resource in the **Master Files** directory (on page 726).

**Expand All**

Expands all the children of the selected resource from the Hierarchy/Dependencies structure.

**Collapse All**

Collapses all children of the selected resource from the Hierarchy/Dependencies structure.

**Tip:** When a recursive reference is encountered in the Hierarchy view, the reference is marked with a special icon `.`.
Ant Component Dependencies View

The **Component Dependencies** view allows you to see the dependencies for a selected component. This is helpful if you want to see where components are used in the entire hierarchy. For example, if you want to find all the references where a given component is used.

If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

To see the dependencies of an Ant component:

1. Right-click the desired component in the editor or **Outline** view.
2. Select the **Component Dependencies** action from the contextual menu.

The action is available for the following components: **properties**, **targets**, **extension-points**, and **references** (those that have an ID set).

If a component contains multiple references, a small table is displayed at the bottom of the view that contains all the references. When a recursive reference is encountered, it is marked with a special icon.

The **Component Dependencies** view includes the following toolbar actions:

- **Refresh**
  - Refreshes the dependencies structure.

- **Stop**
  - Stops the dependency computation.

- **Configure**
  - Allows you to choose the search scope for computing the dependencies structure. This is helpful for making sure all imported/included resources are computed.

- **History**
  - Allows you to select from a list of the most recently used dependency computations.

In addition, the following actions are available in the contextual menu:

- **Go to First Reference**
  - Selects the first reference of the currently selected component in the dependencies tree.

- **Go to Component**
  - Shows the definition of the currently selected component in the dependencies tree.

**Related Information:**
Highlight Component Occurrences

When a component (for example property or target) is found at the current cursor position, they are highlighted in both the document and in the stripe bar at the right side of the document. Oxygen XML Editor also supports occurrences highlight for type and task references.

Customizable colors are used (one for the component definition and another one for component references). Occurrences are displayed until another component is selected and a new search is performed. All highlights are removed when you start to edit the document.

This feature is enabled by default. To configure it, open the Preferences dialog box (Options > Preferences) and go to Editor > Mark Occurrences. If your particular type of file is not selected, you can perform this search by going to Search > Search Occurrences in File Ctrl + Shift + U (Command + Shift + U on OS X) in the contextual menu. Matches are displayed in separate tabs of the Results view (on page 357).

Related Information:

- Mark Occurrences Preferences (on page 179)

Find References and Declarations of Ant Components

The following search actions related to references and declarations of Ant components are available from the Search submenu of the contextual menu and from the Document > References menu:

- **Search References**
  
  Searches all references of the item found at current cursor position in the defined scope.

- **Search References in**
  
  Searches all references of the item found at current cursor position in the file or files that you specify after selecting a scope for the search operation.

- **Search Declarations**
  
  Searches all declarations of the item found at current cursor position in the defined scope.

- **Search Declarations in**
Searches all declarations of the item found at current cursor position in the file or files that you specify when defining a new scope.

**Search Occurrences in File**

Searches all occurrences of the item at the cursor position in the currently edited file.

The following action is available from the contextual menu and the **Document > Schema** menu:

- **Go to Definition**
  
  Moves the cursor to the location of the definition of the current item.

  **Note:** You can also use the **Ctrl + Single-Click (Command + Single-Click on OS X)** shortcut on a reference to display its definition.

**Related Information:**

- **Search and Refactor Operations Scope (on page 1129)**

---

### Ant Refactoring Actions

The following refactoring actions can be applied on **targets, extension-points, properties, and references** and allow you to consistently rename a component in the entire Ant build file structure. They are available from the **Refactoring** submenu in the contextual menu of the current editor or from the **Document > Refactoring** menu:

- **Rename Component**
  
  Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the **Esc** or **Enter** key on your keyboard.

- **Rename Component in**
  
  Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the **Preview** button, you can view the files to be affected by the action.

  Figure 452. Rename Identity Constraint Dialog Box
Ant Quick Assist Support

The Quick Assist support (on page 3286) helps you to rapidly access search and refactoring actions. If one or more actions are available in the current context, they are accessible via a yellow bulb icon (💡) placed at the current line in the stripe on the left side of the editor. Also, you can invoke the Quick Assist menu by using the Alt + 1 (Meta + Alt + 1 on Mac OS X) keyboard shortcuts.

The Quick Assist support offers direct access to the following actions:

- Rename Component in

  Renames the component and all its dependencies.

- Search Declarations

  Searches the declaration of the component in a predefined scope. It is available only when the context represents a component name reference.

- Search References

  Searches all references of the component in a predefined scope.

- Component Dependencies

  Searches the component dependencies in a predefined scope.

- Change Scope
Configures the scope that will be used for future search or refactor operations.

**Rename Component**

Allows you to rename the current component in-place.

**Search Occurrences**

Searches all occurrences of the component within the current file.

**Related Information:**

- Ant Component Dependencies View *(on page 1244)*
- Ant resource Hierarchy/Dependencies View *(on page 1243)*
- Ant Refactoring Actions *(on page 1247)*
- Search and Refactor Operations Scope *(on page 1129)*

---

**Editing XML Schemas**

An XML Schema describes the structure of an XML document and is used to validate XML document instances against it, to check that the XML instances conform to the specified requirements. If an XML instance conforms to the schema then it is said to be valid. Otherwise, it is invalid.

Oxygen XML Editor offers support for both XML Schema 1.0 and 1.1 and you can edit XML Schema files in the following editing modes:

- **Text editing mode *(on page 1286)*** - Allows you to edit XML Schema files in a source editing mode.
- **Grid editing mode *(on page 392)*** - Displays XML Schema files in a structured spreadsheet-like grid.
- **Design editing mode *(on page 623)*** - Visual schema designer that helps you understand the structure and develop complex schemas.
- **Author editing mode *(on page 893)*** - The visual Author mode is also available for XML Schema, allowing you to visually edit the schema annotations. It presents a polished and compact view of the XML Schema, with support for links on imported/included schemas.

For information about applying and detecting schemas, see **Associating a Schema to XML Documents *(on page 1112)***.
For more information about editing XML Schemas, see our video demonstration:

https://www.youtube.com/embed/vz1eIZELQgc

Related Information:
- Associating a Schema to XML Documents (on page 1112)

Design Editing Mode (XML Schema Diagram Editor)

XML Schemas allow document designers to specify the allowed structure and content of an XML document and to check if an XML document is valid.

Oxygen XML Editor provides a simple and expressive XML Schema diagram editor (Design mode) for editing XML Schemas. The schema diagram helps both the content authors who want to understand a schema and schema designers who develop complex schemas.

The diagram font can be increased using the usual Oxygen XML Editor shortcuts: (Ctrl (Meta on Mac OS) + "+"), (Ctrl (Meta on Mac OS)+"-"), (Ctrl (Meta on Mac OS) + 0) or (Ctrl (Meta on Mac OS) - mouse wheel). The whole diagram can also be zoomed with one of the predefined factors available in the Schema preferences panel (on page 153). The same zoom factor is applied for the print and save actions.

To switch to this mode, select Design at the bottom of the editing area.

Figure 453. XML Schema Diagram
For more information about designing XML Schemas, watch our video demonstration:

https://www.youtube.com/embed/vz1eIZELQgc

Navigation in the XML Schema Design Mode

The following editing and navigation features work for all types of schema components in the XML Schema Design mode:

- Select consecutive components on the diagram (components from the same level) using the Shift key. You can also make discontinuous selections in the schema diagram using the Ctrl (Meta on...
Mac OS) key. To deselect one of the components, use Ctrl + Single-Click (Command + Single-Click on OS X).

- Use the arrow keys to navigate the diagram vertically and horizontally.
- Use Home/End keys to jump to the first/last component from the same level. Use Ctrl + Home (Command + Home on OS X) key combination to go to the diagram root and Ctrl + End (Command + End on OS X) to go to the last child of the selected component.
- You can easily go back to a previously visited component while moving from left to right. The path will be preserved only if you use the left arrow key or right arrow key. For example, if the current selection is on the second attribute from an attribute group and you press the left arrow key to jump to the attribute group, when you press the right arrow key, then the selection will be moved to the second attribute.
- Go back and forward between components viewed or edited in the diagram by selecting them in the Outline view (on page 625):
  - Back (go to previous schema component).
  - Forward (go to next schema component).
  - Go to Last Modification (go to last modified schema component).
- Copy, reference, or move global components, attributes, and identity constraints to another position and from one schema to another using the Cut/Copy and Paste/Paste as Reference actions.
- Go to the definition of an element or attribute with the Go to Definition action.
- Search in the diagram using the Find/Replace dialog box (on page 740) or the Quick find toolbar (on page 752). You can find/replace components only in the current file scope.
- You can expand and see the contents of the imports/includes/redefines in the diagram. To edit components from other schemas, the schema for each component will be opened as a separate file in Oxygen XML Editor.

Tip: If an XML Schema referenced by the current opened schema was modified on disk, the change will be detected and you will be asked to refresh the current schema contents.

- Recursive references are marked with a recurse symbol ( recurse). Click this symbol to navigate between the element declaration and its reference.

Figure 454. Recursive Reference

Schema Editing Actions

You can edit an XML schema using drag and drop operations or contextual menu actions.
Drag and drop is the easiest way to move the existing components to other locations in an XML schema. For example, you can quickly insert an element reference in the diagram with a drag and drop from the **Outline view (on page 625)** to a compositor in the diagram. Also, the components order in an **xs:sequence** can be easily changed using drag and drop.

If this property has not been set, you can easily set the attribute/element type by dragging over it a simple type or complex type from the diagram. If the type property for a simple type or complex type is not already set, you can set it by dragging over it a simple or complex type.

Depending on the drop area, various actions are available:

- **move** - Context dependent, the selected component is moved to the destination.
- **reference** - Context dependent, the selected component is referenced from the parent.
- **copy** - If **(Ctrl (Meta on Mac OS))** key is pressed, a copy of the selected component is inserted to the destination.

Visual clues about the operation type are indicated by the mouse pointer shape:

- - When moving a component.
- - When referencing a component.
- - When copying a component.

You can edit some schema components directly in the diagram. For these components, you can edit the name and the additional properties presented in the diagram by double clicking the value you want to edit. If you want to edit the name of a selected component, you can also press **(Enter)**. The list of properties that can be displayed for each component can be customized in the **Preferences (on page 154)**.

When editing references, you can choose from a list of available components. Components from an imported schema for which the target namespace does not have an associated prefix is displayed in the list as **componentName#targetNamespace**. If the reference is from a target namespace that was not yet mapped, you are prompted to add prefix mappings for the inserted component namespace in the current edited schema.

You can also change the compositor by double-clicking it and choose the compositor you want from the proposals list.

There are some components that cannot be edited directly in the diagram: imports, includes, redefines. The editing action can be performed if you double-click or press **(Enter)** on an import/include/redefine component. An edit dialog box is displayed, allowing you to customize the directives.

-XML Schema Component Dependencies View (on page 1300)

-XML Schema Resource Hierarchy / Dependencies View (on page 1297)

-Generating Sample XML Files (on page 1306)

-Schema Design Preferences (on page 153)

Contextual Menu Actions in the Design Mode

The contextual menu of the Design mode includes the following actions:

- **Go to Definition (Ctrl + Shift + Enter)**
  
  Shows the definition for the current selected component. For references, this action is available by clicking the arrow displayed in its bottom right corner.

- **Open Schema (Ctrl + Shift + Enter)**
  
  Opens the selected schema. This action is available for xsd:import, xsd:include and xsd:redefine elements. If the file you try to open does not exist, a warning message is displayed and you have the possibility to create the file.

- **Edit Attributes ()**
  
  Allows you to edit the attributes of the selected component in a small in-place editor that presents the same attributes as in the Attributes view (on page 628) and the Facets view (on page 630). The actions that can be performed on attributes in this dialog box are the same actions presented in the two views.

- **Append child**
  
  Offers a list of valid components, depending on the context, and appends your selection as a child of the currently selected component. You can set a name for a named component after it has been added in the diagram.

- **Insert before**
Offers a list of valid components, depending on the context, and inserts your selection before the selected component, as a sibling. You can set a name for a named component after it has been added in the diagram.

**Insert after**

Offers a list of valid components, depending on the context, and inserts your selection after the selected component, as a sibling. You can set a name for a named component after it has been added in the diagram.

**New global**

Inserts a global component in the schema diagram. This action does not depend on the current context. If you choose to insert an import you have to specify the URL of the imported file, the target namespace and the import ID. The same information, excluding the target namespace, is requested for an `xsd:include` or `xsd:redefine` element.

**Note:** If the imported file has declared a target namespace, the field **Namespace** is completed automatically.

**Edit Schema Namespaces**

When performed on the schema root, it allows you to edit the schema target namespace and namespace mappings. You can also invoke the action by double-clicking the target namespace property from **Attributes view (on page 628)** for the schema or by double-clicking the schema component.

**Edit Annotations**

Allows you to edit the annotation for the selected schema component in the **Edit Annotations** dialog box. You can perform the following operations in the dialog box:

- **Edit all appinfo/documentation items for a specific annotation** - All `appinfo/documentation` items for a specific annotation are presented in a table and can be easily edited. Information about an annotation item includes: type (documentation/appinfo), content, source (optional, specify the source of the `documentation/appinfo` element) and `xml:lang`. The content of a `documentation/appinfo` item can be edited in the **Content** area below the table.

- **Insert/Insert before/Remove documentation/appinfo**. The "Add" button allows you to insert a new annotation item (`documentation/appinfo`). You can add a new item before the item selected in table by pressing the "Insert Before" button. Also, you can delete the selected item using the "Remove" button.

- **Move items up/down** - to do this use the "Move up" and "Move down" buttons.

- **Insert/Insert before/Remove annotation** - Available for components that allow multiple annotations such as schemas or redefines.
• **Specify an ID for the component annotation.** An optional identifier for the annotation.

Annotations are rendered by default under the graphical representation of the component. When you have a reference to a component with annotations, these annotations are also presented in the diagram below the referenced component. To edit the annotations, use the **Edit Annotations** action from the contextual menu. If the reference component does not have annotations, you can edit the annotations of the referenced component by double-clicking the annotations area. Otherwise, you can edit the referenced component annotations only if you go to the definition of the component.

**Note:** For imported/included components that do not belong to the currently edited schema, the **Edit Annotations** dialog box presents the annotation as read-only. To edit its annotation, open the schema where the component is defined.

**Extract Global Element**

Action that is available for local elements. A local element is made global and is replaced with a reference to the global element. The local element properties that are also valid for the global element declaration are kept.

**Figure 455. Extracting a Global Element**

If you use the **Extract Global Element** action on a `name` element, the result is:

**Figure 456. Extracting a Global Element on a name Element**

**Extract Global Attribute**
Action available for local attributes. A local attribute is made global and replaced with a reference to the global attribute. The properties of local attribute that are also valid in the global attribute declaration are kept.

Figure 457. Extracting a Global Attribute

If you use the Extract Global Attribute action on a note attribute, the result is:

Figure 458. Extracting a Global Attribute on a note Attribute

**Extract Global Group**

Action available for compositors (sequence, choice, all). This action extracts a global group and makes a reference to it. The action is available only if the parent of the compositior is not a group.
If you use the **Extract Global Group** action on the `sequence` element, the **Extract Global Component** dialog box is displayed and you can choose a name for the group. If you type `personGroup`, the result is:

![Figure 460. Extracting a Global Group on a sequence Element](image)

**Extract Global Type**

Action used to extract an anonymous simple type or an anonymous complex type as global. For anonymous complex types, the action is available on the parent element.

![Figure 461. Extracting a Global Simple Type](image)

If you use the action on the `union` component and choose `numericST` for the new global simple type name, the result is:

![Figure 462. Extracting a Global Simple Type on a union Component](image)
If you use the action on a `person` element and choose `person_type` for the new complex type name, the result is:

Figure 464. Extracting a Global Complex Type on a `person` Element

---

**Rename Component in**

Rename the selected component.

**Cut Ctrl + X (Command + X on OS X)**

Cut the selected component(s).

**Copy Ctrl + C (Command + C on OS X)**

Copy the selected component(s).
**Copy XPath**

This action copies an XPath expression that identifies the selected element or attribute in an instance XML document of the edited schema and places it in the clipboard.

**Paste Ctrl + V (Command + V on OS X)**

Paste the component(s) from the clipboard as children of the selected component.

**Paste as Reference**

Create references to the copied component(s). If not possible a warning message is displayed.

**Remove (Delete)**

Remove the selected component(s).

**Override component**

Copies the overridden component in the current XML Schema. This option is available for `xs:override` components.

**Redefine component**

The referenced component is added in the current XML Schema. This option is available for `xs:redefine` components.

**Optional**

Can be performed on element/attribute/group references, local attributes, elements, compositors, and element wildcards. The `minOccurs` property is set to 0 and the `use` property for attributes is set to `optional`.

**Unbounded**

Can be performed on element/attribute/group references, local attributes, elements, compositors, and element wildcards. The `maxOccurs` property is set to `unbounded` and the `use` property for attributes is set to `required`.

**Search**

Can be performed on local elements or attributes. This action makes a reference to a global element or attribute.

**Search References**

Searches all references of the item found at current cursor position in the defined scope if any.

**Search References in**

Searches all references of the item found at current cursor position in the specified scope.
Search Occurrences in File

Searches all occurrences of the item found at current cursor position in the current file.

Component Dependencies

Opens the Component Dependencies view (on page 1300) that allows you to see the dependencies for the current selected component.

Resource Hierarchy

Opens the Resource Hierarchy / Dependencies view (on page 1297) that allows you to see the hierarchy for the current selected resource.

Flatten Schema

Recursively adds the components of included Schema files to the main one. It also flattens every imported XML Schema from the hierarchy.

Resource Dependencies

Allows you to see the dependencies for the current selected resource.

Expand All

Recursively expands all sub-components of the selected component.

Collapse All

Recursively collapses all sub-components of the selected component.

Save as Image

Save the diagram as image, in JPEG, BMP, SVG or PNG format.

Generate Sample XML Files

Generate XML files using the current opened schema. The selected component is the XML document root. See more in the Generate Sample XML Files (on page 1306) section.

Options

Show the Schema preferences panel (on page 153).

XML Schema Components

A schema diagram contains a series of interconnected components. To quickly identify the relation between two connected components, the connection is represented as:

- A thick line to identify a connection with a required component (in the following image, family is a required element).

Figure 465. Example: Required Component
A thin line to identify a connection with an optional component (in the following image, `email` is an optional element).

Figure 466. Example: Optional Component

The following topics explain in detail all available components and their symbols as they appear in an XML schema diagram.

**xs:schema**

Figure 467. The `xs:schema` Component

![XSD Component](http://www.oxygenxml.com/supportedschemas)

Defines the root element of a schema. A schema document contains representations for a collection of schema components, such as type definitions and element declarations, that have a common target namespace. See more info at [http://www.w3.org/TR/xmlschema11-1/#element-schema](http://www.w3.org/TR/xmlschema11-1/#element-schema).

By default, it displays the `targetNamespace` property when rendered.

<table>

**xs:element**

Figure 468. The `xs:element` Component

![](image)

Defines an element. An element declaration is an association of a name with a type definition, either simple or complex, an (optional) default value and a (possibly empty) set of identity-constraint definitions. See more info at [http://www.w3.org/TR/xmlschema11-1/#element-element](http://www.w3.org/TR/xmlschema11-1/#element-element).

An element by default displays the following properties when rendered in the diagram: `default`, `fixed`, `abstract` and `type`. When referenced or declared locally, the element graphical representation also contains the value for the `minOccurs` and `maxOccurs` properties (for 0..1 and 1..1 occurs the values are implied by the connector style) and the connectors to the element are drawn using dotted lines if the element is optional.

### xs:attribute

Figure 469. The xs:attribute Component

Defines an attribute. See more info at [http://www.w3.org/TR/xmlschema11-1/#element-attribute](http://www.w3.org/TR/xmlschema11-1/#element-attribute).

An attribute by default displays the following properties when rendered in the diagram: default, fixed, use and type. Connectors to the attribute are drawn using dotted lines if the attribute use is optional. The attribute name is stroked out if prohibited.
### Table 41. xs:attribute Properties

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Description</th>
<th>Possible Value</th>
<th>Mentions</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td>Attribute name (always required)</td>
<td>Any NCName for global/local attributes, all declared attributes' QName (on page 3286) for references</td>
<td>For all local or global attributes. If missing, will be displayed as '[attribute]' in the diagram.</td>
</tr>
<tr>
<td><strong>Is Reference</strong></td>
<td>When set, the local attribute is a reference</td>
<td>true/false</td>
<td>For local attributes</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Qualified name of a simple type All global simple types and built-in simple types. In addition another 3 proposals are present: [anonymous restriction], [anonymous list], [anonymous union] for creating anonymous simple types more easily.</td>
<td>Any string</td>
<td>For all attributes. For references, the type is set to the referenced attribute.</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>Default value. When specified, an attribute is added by the schema processor (if it is missing from the instance XML document) and it is given this value. The default and fixed attributes are mutually exclusive.</td>
<td>Any string</td>
<td>For all local or global attributes. For references the value is from the referenced attribute.</td>
</tr>
<tr>
<td><strong>Fixed</strong></td>
<td>When specified, the value of the attribute is fixed and must be equal to this value. The default and fixed attributes are mutually exclusive.</td>
<td>Any string</td>
<td>For all local or global attributes. For references the value is from the referenced attribute.</td>
</tr>
<tr>
<td><strong>Use</strong></td>
<td>Possible usage of the attribute. Marking an attribute &quot;prohibited&quot; is useful to exclude attributes during derivations by restriction.</td>
<td>optional, required, prohibited</td>
<td>For local attributes</td>
</tr>
<tr>
<td><strong>Form</strong></td>
<td>Specifies whether or not the attribute is qualified (must have a namespace prefix in the instance XML document).</td>

<tr>
<td>Name</td>
<td>Attribute group name (always required)</td>
<td>Any NCName for global attribute name</td>
<td>For all global or referenced attribute groups, all declared attribute groups for reference</td>
</tr>
</tbody>
</table>

**xs:attributeGroup**

Figure 470. The xs:attributeGroup Component

Defines an attribute group to be used in complex type definitions. See more info at [http://www.w3.org/TR/xmlschema11-1/#element-attributeGroup](http://www.w3.org/TR/xmlschema11-1/#element-attributeGroup).

**Table 42. xs:attributeGroup Properties**
Figure 471. The *xs:complexType* Component

Defines a top-level complex type. Complex Type Definitions provide for: See more data at [http://www.w3.org/TR/xmlschema11-1/#element-complexType](http://www.w3.org/TR/xmlschema11-1/#element-complexType).

- Constraining element information items by providing Attribute Declarations governing the appearance and content of attributes.
- Constraining element information item children to be empty, or to conform to a specified element-only or mixed content model, or else constraining the character information item children to conform to a specified simple type definition.
- Using the mechanisms of Type Definition Hierarchy to derive a complex type from another simple or complex type.
- Specifying post-schema-validation infoset contributions for elements.
- Limiting the ability to derive additional types from a given complex type.
- Controlling the permission to substitute, in an instance, elements of a derived type for elements declared in a content model to be of a given complex type.

**Tip:** A complex type that is a base type to another type will be rendered with yellow background.

</table>

**xs:simpleType**

Figure 472. The *xs:simpleType* Component

Defines a simple type. A simple type definition is a set of constraints on strings and information about the values they encode, applicable to the normalized value of an attribute information item or of an element information item with no element children. Informally, it applies to the values of attributes and the text-only content of elements. See more info at [http://www.w3.org/TR/xmlschema11-1/#element-simpleType](http://www.w3.org/TR/xmlschema11-1/#element-simpleType).

**Tip:** A simple type that is a base type to another type will be rendered with yellow background.

### xs:group

Figure 474. The `xs:group` Component

Defines a group of elements to be used in complex type definitions. See more info at [http://www.w3.org/TR/xmlschema11-1/#element-group](http://www.w3.org/TR/xmlschema11-1/#element-group).

When referenced, the graphical representation also contains the value for the `minOccurs` and `maxOccurs` properties (for 0..1 and 1..1 occurs the values are implied by the connector style) and the connectors to the group are drawn using dotted lines if the group is optional.

</tbody>
</table>

`xs:sequence / xs:choice / xs:all`

Figure 480. `xs:sequence`

`xs:sequence` specifies that the child elements must appear in a sequence. Each child element can occur from 0 to any number of times. See more info at [http://www.w3.org/TR/xmlschema11-1/#element-sequence](http://www.w3.org/TR/xmlschema11-1/#element-sequence).

Figure 481. `xs:choice`

`xs:choice` allows only one of the elements contained in the declaration to be present within the containing element. See more info at [http://www.w3.org/TR/xmlschema11-1/#element-choice](http://www.w3.org/TR/xmlschema11-1/#element-choice).

Figure 482. `xs:all`

`xs:all` specifies that the child elements can appear in any order. See more info at [http://www.w3.org/TR/xmlschema11-1/#element-all](http://www.w3.org/TR/xmlschema11-1/#element-all).

The compositor graphical representation also contains the value for the `minOccurs` and `maxOccurs` properties (for 0..1 and 1..1 occurs the values are implied by the connector style) and the connectors to the compositor are drawn using dotted lines if the compositor is optional.
Table 52. \textit{xs:sequence, xs:choice, xs:all} Properties

<table>
<thead>

<td>Not editable property</td>
</tr>
</tbody>
</table>

**xs:keyRef**

Figure 487. The xs:keyRef Component

Specifies that an attribute or element value corresponds to that of the specified key or unique element. See more info at http://www.w3.org/TR/xmlschema11-1/#element-keyref.

A keyref by default displays the Referenced Key property when rendered.
Table 57. \textit{xs:keyRef} Properties

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Description</th>
<th>Possible Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The keyref name (always required)</td>

</tbody>
</table>
### xs:assert

Assertions provide a flexible way to control the occurrence and values of elements and attributes available in an XML Schema.

**Note:** `xs:assert` is available for XML Schema 1.1.

Figure 490. The `xs:assert` Component

```
<arb @maxPrice='@maxPrice
```

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Description</th>

<td>The component system ID</td>
<td>Not editable property</td>
</tr>
</tbody>
</table>

### xs:openContent

Figure 491. The `xs:openContent` Component

```
<arb ##targetNamespace
```

The `openContent` element enables instance documents to contain extension elements to be inserted amongst the elements declared by the schema. You can declare open content for your elements at one place (within the `complexType` definition) or at the schema level.
For further details about the `openContent` component, go to http://www.w3.org/TR/xmlschema11-1/#element-openContent.

### Table 61. `xs:openContent` Properties

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Description</th>
<th>Possible Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mode</td>
<td>Specifies where the extension elements can be inserted</td>
<td>The value can be: &quot;interleave&quot;, &quot;suffix&quot; or &quot;none&quot;. The default value is &quot;interleave&quot;.</td>
</tr>
<tr>
<td>ID</td>
<td>The component ID</td>
<td>Any ID</td>
</tr>
<tr>
<td>Component</td>
<td>The edited component name</td>
<td>Not editable property</td>
</tr>
<tr>
<td>System ID</td>
<td>The component system ID</td>
<td>Not editable property</td>
</tr>
</tbody>
</table>

**Note:** This component is available for XML Schema 1.1 only. To change the version of the XML Schema, open the Preferences dialog box (Options > Preferences) (on page 79) and go to XML > XML Parser > XML Schema.

### Constructs Used to Group Schema Components

This section explains the components that can be used for grouping other schema components.

#### Attributes

Figure 492. Attributes Construct

Groups all attributes and attribute groups belonging to a complex type.

### Table 62. `attributes` Properties

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Description</th>
<th>Possible Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component</td>
<td>The element for which the attributes are displayed</td>
<td>Not editable property</td>
</tr>
<tr>
<td>System ID</td>
<td>The component system ID</td>
<td>Not editable property</td>
</tr>
</tbody>
</table>

#### Constraints

Figure 493. Constraints Construct
Groups all constraints (xs:key (on page 1280), xs:keyRef (on page 1280), or xs:unique (on page 1279)) belonging to an element.

Table 63. constraints Properties

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Description</th>
<th>Possible Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component</td>
<td>The element for which the constraints are displayed</td>
<td>Not editable property</td>
</tr>
<tr>
<td>System ID</td>
<td>The component system ID</td>
<td>Not editable property</td>
</tr>
</tbody>
</table>

Substitutions

Groups all elements that can substitute the current element.

Table 64. substitutions Properties

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Description</th>
<th>Possible Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component</td>
<td>The element for which the substitutions are displayed</td>
<td>Not editable property</td>
</tr>
<tr>
<td>System ID</td>
<td>The component system ID</td>
<td>Not editable property</td>
</tr>
</tbody>
</table>

Schema Validation

Validation for the Design mode is seamlessly integrated in the Oxygen XML Editor. XML documents validation (on page 1079) capability.
A schema validation error is presented by highlighting the invalid component:

- In the **Attributes View (on page 628)**.
- In the diagram by surrounding the component that has the error with a red border.
- A marker on the errors stripe at the right of the diagram view.
- A status label with a red icon (⌘) below the diagram view.

Invalid facets for a component are highlighted in the **Facets View (on page 630)**.

Components with invalid properties are rendered with a red border. This is a default color, but you can customize it in the **Document checking user preferences (on page 180)**. When hovering an invalid component, the tooltip will present the validation errors associated with that component.

When editing a value that is supposed to be a qualified or unqualified XML name, the application provides automatic validation of the entered value. This proves to be very useful in avoiding setting invalid XML names for the given property.

If you validate the entire schema using the **Validate** action from the **Document > Validate** menu or from the **Validation** toolbar drop-down menu, all validation errors will be presented in the **Errors** tab. To resolve an error, just click it (or double-click for errors located in other schemas) and the corresponding schema component will be displayed as the diagram root so that you can easily correct the error.

**Important:** If the schema imports only the namespace of other schema without specifying the schema location and a **catalog is set up (on page 1123)** that maps the namespace to a certain location both the validation and the diagram will correctly identify the imported schema.
Tip: If the validation action finds that the schema contains unresolved references, the application will suggest the use of validation scenarios, but only if the current edited schema is an XML Schema module.

Edit Schema Namespaces

You can use the **XML Schema Namespaces** dialog box to easily set a target namespace and define namespace mappings for a newly created XML Schema. In the **Design** mode these namespaces can be modified anytime by choosing **Edit Schema Namespaces** from the contextual menu. You can also do this by double-clicking the schema root in the diagram.

The **XML Schema Namespaces** dialog box allows you to edit the following information:

- **Target namespace** - The target namespace of the schema.
- **Prefixes** - The dialog box displays a table with namespaces and the mapped prefixes. You can add a new prefix mapping or remove an already existing one.

Editing XML Schema in Text Editing Mode

The Oxygen XML Editor **Text** editing mode can be used for editing XML Schema in a source editing mode. It offers powerful content completion support, a synchronized Outline view, and multiple refactoring actions (on page 1302). The Outline view has two display modes: the standard outline (on page 347) mode and the components (on page 625) mode.

A diagram of the XML Schema can be presented side by side with the text. To activate the diagram presentation, select the **Show Full Model XML Schema diagram** option (on page 129) in the **Diagram preferences page** (on page 129).

Editing XML Schema in the Master Files Context

Smaller interrelated modules that define a complex XML Schema cannot be correctly edited or validated individually, due to their interdependency with other modules. For example, an element defined in a main schema document is not visible when you edit an included module. Oxygen XML Editor provides the support for defining the main module (or modules), thus allowing you to edit any of the imported/included schema files in the context of the larger schema structure.

You can set a main XML document either using the **master files support from the Project view** (on page 726), or using a validation scenario.

To set a **master file** using a validation scenario, add validation units that point to the main schemas. Oxygen XML Editor warns you if the current module is not part of the dependencies graph computed for the main schema. In this case, it considers the current module as the main schema.
The advantages of editing in the context of a master file (on page 3284) include:

- Correct validation of a module in the context of a larger schema structure.
- Content Completion Assistant (on page 3280) displays all the referable components valid in the current context. This include components defined in modules other than the currently edited one.
- The Outline view (on page 625) displays the components collected from the entire schema structure.

Validating XML Schema Documents

By default, XML Schema files are validated as you type. To change this, open the Preferences dialog box (Options > Preferences) (on page 79), go to Editor > Document Checking, and deselect the Enable automatic validation option (on page 181).

To validate an XML Schema document manually, select the Validate action from the Validation toolbar drop-down menu or the Document > Validate menu. When Oxygen XML Editor validates an XML Schema file, it expands all the included modules so the entire schema hierarchy is validated. The validation problems are highlighted directly in the editor, making it easy to locate and fix any issues.

Validation of an XML Schema containing a type definition with a minOccurs or maxOccurs attribute having a value larger than 256 limits the value to 256 and issues a warning about this restriction in the Message panel at the bottom of the Oxygen XML Editor window. Otherwise, for large values of the minOccurs and maxOccurs attributes, the validator fails with an OutOfMemory error that might make Oxygen XML Editor unusable without restarting the entire application.

⚠️ Important: If the schema imports only a namespace without specifying the schema location and a catalog is set up (on page 1123) to map the namespace to a certain location, both validation and the schema components will correctly identify the imported schema.

Related Information:

- Embedding Schematron Rules in XML Schema or RELAX NG (on page 1469)
- Validation Scenario (on page 1093)
- Associating a Schema to XML Documents (on page 1112)
- Presenting Validation Errors in Author Mode (on page 445)
Quick Fixes for DTD, XSD, and Relax NG Errors

Oxygen XML Editor offers Quick Fixes (on page 3287) for common errors that appear in XML documents that are validated against DTD, XSD, or Relax NG schemas.

**Note:** For XML documents validated against XSD schemas, the Quick Fixes are only available if you use the default Xerces validation engine.

Quick Fixes are available in Text mode and Author mode.

Oxygen XML Editor provides Quick Fixes for numerous types of problems, including the following:

<table>
<thead>
<tr>
<th>Problem Type</th>
<th>Available Quick Fixes</th>
</tr>
</thead>
<tbody>
<tr>
<td>A specific element is required in the current context</td>
<td>Insert the required element</td>
</tr>
<tr>
<td>An element is invalid in the current context</td>
<td>Remove the invalid element</td>
</tr>
<tr>
<td>The content of the element should be empty</td>
<td>Remove the element content</td>
</tr>
<tr>
<td>An element is not allowed to have child elements</td>
<td>Remove all child elements</td>
</tr>
<tr>
<td>Text is not allowed in the current element</td>
<td>Remove the text content</td>
</tr>
<tr>
<td>A required attribute is missing</td>
<td>Insert the required attribute</td>
</tr>
<tr>
<td>An attribute is not allowed to be set for the current element</td>
<td>Remove the attribute</td>
</tr>
<tr>
<td>The attribute value is invalid</td>
<td>Propose the correct attribute values</td>
</tr>
<tr>
<td>ID value is already defined</td>
<td>Generate a unique ID value</td>
</tr>
<tr>
<td>References to an invalid ID</td>
<td>Change the reference to an already defined ID</td>
</tr>
</tbody>
</table>

Related Information:

- Schematron Quick Fixes (SQF) (on page 1111)

Content Completion in XML Schema

The intelligent Content Completion Assistant (on page 3280) allows you to quickly identify and insert elements, attributes, and attribute values that are valid in the current editing context. All available proposals are listed in a pop-up menu displayed at the current cursor position.
The Content Completion Assistant is enabled by default. To disable it, open the Preferences dialog box (Options > Preferences) (on page 79), go to Editor > Content Completion, and deselect the Enable content completion option (on page 167).

When active, the Content Completion Assistant displays a list of context-sensitive proposals valid at the current cursor position. It can be manually activated with the Ctrl + Space (Command + Space on OS X) shortcut. You can navigate through the list of proposals by using the Up and Down keys on your keyboard. For each selected item in the list, the Content Completion Assistant displays a documentation window. You can customize the size of the documentation window by dragging its top, right, and bottom borders.

To insert the selected proposal in Text mode, do one of the following:

- Press Enter or Tab to insert both the start and end tags and position the cursor inside the start tag in a position suitable for inserting attributes.
- Press Ctrl + Enter (Command + Enter on OS X) to insert both the start and end tags and positions the cursor between the tags in a position where you can start typing content.

Depending on the selected schema version (on page 1335), Oxygen XML Editor populates the proposals list with information taken either from XML Schema 1.0 or 1.1.

Oxygen XML Editor helps you to easily reference a component by providing the list of proposals (complex types, simple types, elements, attributes, groups, attribute groups, or notations) valid in the current context. The components are collected from the current file or from the imported/included schemas.

When editing xs:annotation/xs:appinfo elements of an XML Schema, the Content Completion Assistant proposes elements and attributes from a custom schema (by default ISO Schematron). This feature can be configured from the XSD Content Completion (on page 170) preferences page.

Syntax Highlighting in XML Schema

Oxygen XML Editor supports syntax highlighting in Text mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for XML Schema files, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79).
2. Go to Editor > Syntax Highlight (on page 178).
3. Select and expand the XML section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.
5. Select the **XSD** tab in the **Preview** pane to see the effects of your changes.

**Tip:** Oxygen XML Editor also allows you to specify syntax highlighting colors for specific XML elements and attributes with specific namespace prefixes. This can be done in the **Editor > Syntax Highlight > Elements/Attributes by Prefix** preferences page (on page 179).

### Related Information:

- Customize Syntax Highlight colors (on page 178)

### XML Schema Outline View

The **Outline** view for XML Schemas presents all the global components grouped by their location, namespace, or type. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

![Outline View for XML Schema](image)

The **Outline** view provides the following options in the **Settings** menu on the **Outline** view toolbar:

- **Filter returns exact matches**
The text filter of the Outline view returns only exact matches;

**Selection update on cursor move**

Allows a synchronization between Outline view and schema diagram. The selected view from the diagram is also selected in the Outline view.

**Sort**

Allows you to sort alphabetically the schema components.

**Show all components**

Displays all components that were collected starting from the master files (on page 3284). Components that are not referable from the current file are marked with an orange underline. To reference them, add an import directive with the componentNS namespace.

**Show referable components**

Displays all components (collected starting from the master files (on page 3284)) that can be referenced from the current file. This option is set by default.

**Show only local components**

Displays the components defined in the current file only.

**Group by location/namespace/type**

These three operations allow you to group the components by location, namespace, or type. When grouping by namespace, the main schema target namespace is the first presented in the Outline view.

The following contextual menu actions are available in the Outline view:

**Remove (Delete)**

Removes the selected item from the diagram.

**Search References (Ctrl (Meta on Mac OS)+Shift+R)**

Searches all references of the item found at current cursor position in the defined scope, if any.

**Search References in**

Searches all references of the item found at current cursor position in the specified scope.

**Component Dependencies (Ctrl (Meta on Mac OS)+Shift+F4)**

Opens the Component Dependencies view (on page 1300) that allows you to see the dependencies for the current selected component.

**Resource Hierarchy (F4)**
Opens the **Resource Hierarchy / Dependencies view (on page 1130)** that allows you to see the hierarchy for the current selected resource.

**Resource Dependencies (Shift + F4)**

Opens the **Resource Hierarchy / Dependencies view (on page 1130)** that allows you to see the dependencies for the current selected resource.

**Renew Component in**

Renames the selected component.

**Generate Sample XML Files**

Generate XML files using the current opened schema. The selected component is the XML document root.

The upper part of the **Outline** view contains a filter box that allows you to focus on the relevant components. Type a text fragment in the filter box and only the components that match it are presented. For advanced usage you can use wildcard characters (such as `*`, `?`) and separate multiple patterns with commas.

**Tip:** The search filter is case insensitive. The following wildcards are accepted:

- `*` - any string
- `?` - any character
- `,` - patterns separator

If no wildcards are specified, the string to search will be searched as a partial match.

The content of the **Outline** view and the editing area are synchronized. When you select a component in the **Outline** view, its definition is highlighted in the editing area.

- [Editing Relax NG Schema in the Master Files Context (on page 1389)]
XML Schema Attributes View

The Attributes view for XML Schemas presents the properties for the selected component in the schema diagram. By default, it is displayed on the right side of the editor. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Properties for components that do not belong to the current edited schema are read-only but if you double-click them you can choose to open the corresponding schema and edit them.

You can edit a property by double-clicking by pressing Enter. For most properties you can choose valid values from a list or you can specify another value. If a property has an invalid value or a warning, it will be highlighted in the table with the corresponding foreground color. By default, properties with errors are highlighted with red and the properties with warnings are highlighted with yellow. You can customize these colors from the Document checking user preferences (on page 180).

For imports, includes and redefines, the properties are not edited directly in the Attributes view. A dialog box will open that allows you to specify properties for them.

The schema namespace mappings are not presented in Attributes view. You can view/edit these by choosing Edit Schema Namespaces from the contextual menu on the schema root. See more in the Edit Schema Namespaces (on page 1286) section.

The Attributes view has five actions available on the toolbar and also on the contextual menu:
+ Add

Allows you to add a new member type to an union's member types category.

× Remove

Allows you to remove the value of a property.

▲ Move Up

Allows you to move up the current member to an union's member types category.

▼ Move Down

Allows you to move down the current member to an union's member types category.

COPY

Copy the attribute value.

Go to Definition

Shows the definition for the selected type.

Show Facets

Allows you to edit the facets for a simple type.

XML Schema Palette View

The Palette view is designed to offer quick access to XML Schema components and to improve the usability of the XML Schema diagram builder. You can use the Palette to drag and drop components in the Design mode. The components offered in the Palette view depend on the XML schema version set in the XML Schema preferences page (on page 192). If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Figure 498. Palette View

Components are organized functionally into 4 collapsible categories:
• Basic components: elements, group, attribute, attribute group, complex type, simple type, type alternative.
• Compositors and Wildcards: sequence, choice, all, any, any attribute, open content.
• Directives: import, include, redefine, override.
• Identity constraints: key, keyref, unique, selector, field, assert.

Note: The type alternative, open content, override, and assert components are available for XML Schema 1.1.

To add a component to the edited schema:

• Click and hold a graphic symbol from the Palette view, then drag the component into the Design view.
• A line dynamically connects the component with the XML schema structure.
• Release the component into a valid position.

Note: You cannot drop a component into an invalid position. When you hover the component into an invalid position, the mouse cursor changes its shape into . Also, the connector line changes its color from the usual dark gray to the color defined in the Validation error highlight color option (on page 180) (default color is red).

For more information about the Schema palette, watch our video demonstration:

https://www.youtube.com/embed/KalHUXmpuAA

XML Schema Facets View

The Facets view for XML Schemas presents the facets for the selected component, if available. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Figure 499. Facets View
The default value of a facet is rendered in the **Facets** view with a blue color. The facets that cannot be edited are rendered with a gray color. The grouping categories (for example: **Enumerations** and **Patterns**) are not editable. If these categories contain at least one child they are rendered with bold. Bold facets are facets with values set explicitly to them.

⚠️ **Important:** Usually inherited facets are presented as default in the **Facets** view but if patterns are inherited from a base type and also specified in the current simple type only the current specified patterns will be presented. You can see the effective pattern value obtained by combining the inherited and the specified patterns as a tooltip on the **Patterns** category.

Facets for components that do not belong to the current edited schema are read-only but if you double-click them you can choose to open the corresponding schema and edit them.

You can edit a facet by double-clicking it or by pressing Enter, when that facet is selected. For some facets you can choose valid values from a list or you can specify another value. If a facet has an invalid value or a warning, it will be highlighted in the table with the corresponding foreground color. By default, facets with errors are presented with red and the facets with warnings with yellow. You can customize the error colors from the **Document Checking user preferences** *(on page 180)*.

The **Facets** view provides the following actions in its toolbar and contextual menu:

- **Add**
  - Allows you to add a new enumeration or a new pattern.

- **Remove**
  - Allows you to remove the value of a facet.

- **Edit Annotations**
  - Allows you to edit an annotation for the selected facet.

- **Move Up**
  - Allows you to move up the current enumeration/pattern in **Enumerations/Patterns** category.

- **Move Down**
  - Allows you to move down the current enumeration/pattern in **Enumerations/Patterns** category.

- **Copy**
  - Copy the attribute value.

**Open in Regular Expressions Builder**
Rather than editing regular expressions manually, this action allows you to open the pattern in the XML Schema Regular Expressions Builder (on page 1332) that guides you through the process of testing and constructing the pattern.

Facets can be fixed to prevent a derivation from modifying its value. To fix a facet value just press the Pin button.

XML Schema Resource Hierarchy / Dependencies View

The Resource Hierarchy / Dependencies view displays the hierarchy or dependencies for an XML Schema. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

The Resource Hierarchy / Dependencies is useful when you want to start from an XML Schema (XSD) file and build and review the hierarchy of all the other XSD files that are imported, included or redefined in the given XSD file. The view is also able to build the tree structure, that is the structure of all other XSD files that import, include or redefine the given XSD file. The scope of the search is configurable (the current project, a set of local folders, etc.)

If you want to see the hierarchy or dependencies of an XML schema, select the desired schema in the Project view (on page 333) and choose Resource Hierarchy or Resource Dependencies from the contextual menu.

Figure 500. Resource Hierarchy/Dependencies View

The following actions are available on the toolbar of the Resource Hierarchy/Dependencies view:

- **Refresh**
  Refreshes the Hierarchy/Dependencies structure.
Stop

Stops the hierarchy/dependencies computing.

Show Hierarchy

Allows you to choose a resource to compute the hierarchy structure.

Show Dependencies

Allows you to choose a resource to compute the dependencies structure.

Configure dependencies search scope

Allows you to configure a scope to compute the dependencies structure. There is also an option for automatically using the defined scope for future operations.

History

Provides access to the list of previously computed dependencies. Use the 🗑️ Clear history button to remove all items from this list.

The contextual menu for a resource listed in the Resource Hierarchy/Dependencies view contains the following actions:

Open

Opens the resource. You can also double-click a resource in the Hierarchy/Dependencies structure to open it.

Go to reference

Opens the source document where the resource is referenced.

Copy location

Copies the location of the resource.

Move resource

Moves the selected resource.

Rename resource

Renames the selected resource.

Show Resource Hierarchy

Shows the hierarchy for the selected resource.

Show Resource Dependencies

Shows the dependencies for the selected resource.

Add to Master Files

Adds the currently selected resource in the Master Files directory (on page 726).
Expand All

Expands all the children of the selected resource from the Hierarchy/Dependencies structure.

Collapse All

Collapses all children of the selected resource from the Hierarchy/Dependencies structure.

Tip: When a recursive reference is encountered in the Hierarchy view, the reference is marked with a special icon.

Note: The Move resource or Rename resource actions give you the option to update the references to the resource (on page 1299).

Related Information:

- Working with Modular XML Files in the Master Files Context (on page 1126)
- Search and Refactor Operations Scope (on page 1129)

Moving/Renaming XML Schema Resources

You can move and rename a resource presented in the Resource/Hierarchy Dependencies view, using the Rename resource and Move resource refactoring actions from the contextual menu.

When you select the Rename action in the contextual menu of the Resource/Hierarchy Dependencies view, the Rename resource dialog box is displayed. The following fields are available:

- New name - Presents the current name of the edited resource and allows you to modify it.
- Update references of the renamed resource(s) - Select this option to update the references to the resource you are renaming. A Preview option is available that allows you to see what will be updated before selecting Rename to process the operation.

When you select the Move action from the contextual menu of the Resource/Hierarchy Dependencies view, the Move resource dialog box is displayed. The following fields are available:

- Destination - Presents the path to the current location of the resource you want to move and gives you the option to introduce a new location.
- New name - Presents the current name of the moved resource and gives you the option to change it.
• **Update references of the moved resource(s)** - Select this option to update the references to the resource you are moving, in accordance with the new location and name. A **Preview** option is available that allows you to see what will be updated before selecting **Move** to process the operation.

**XML Schema Component Dependencies View**

The **Component Dependencies** view allows you to see the dependencies for a selected component. This is helpful if you want to see where components are used in the entire hierarchy. For example, if you want to find all the references where a given component is used.

If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

To see the dependencies of an XML Schema component:

1. Right-click the desired component in the editor or **Outline** view.
2. Select the **Component Dependencies** action from the contextual menu.

The action is available for all named components (for example, elements or attributes).

If a component contains multiple references, a small table is displayed at the bottom of the view that contains all the references. When a recursive reference is encountered, it is marked with a special icon.

Figure 501. Component Dependencies View - Hierarchy for **xhtml11.xsd**
The **Component Dependencies** view includes the following toolbar actions:

- **Refresh**
  
  Refreshes the dependencies structure.

- **Stop**
  
  Stops the dependency computation.

- **Configure**
  
  Allows you to choose the search scope for computing the dependencies structure. This is helpful for making sure all imported/included resources are computed.

- **History**
  
  Allows you to select from a list of the most recently used dependency computations.

In addition, the following actions are available in the contextual menu:

- **Go to First Reference**
  
  Selects the first reference of the currently selected component in the dependencies tree.

- **Go to Component**
  
  Shows the definition of the currently selected component in the dependencies tree.
For more information, see the Maintain Complex XML Schemas section of our Developing XML Schemas video demonstration:

https://www.youtube.com/embed/vz1eIZELQgc

Related Information:

- Search and Refactor Operations Scope (on page 1129)

Highlight Component Occurrences

When a component (for example types, elements, attributes) is found at current cursor position, Oxygen XML Editor performs a search over the entire document to find the component declaration and all its references. When found, they are highlighted both in the document and in the stripe bar, at the right side of the document. Customizable colors are used: one for the component definition and another one for component references. Occurrences are displayed until another component is selected and a new search is performed. All occurrences are removed when you start to edit the document.

This feature is on by default. To configured it, open the Preferences dialog box (Options > Preferences) (on page 79) and go to Editor > Mark Occurrences. A search can also be triggered with the Search > Search Occurrences in File () contextual menu action. All matches are displayed in a separate tab of the Results view (on page 357).

Searching and Refactoring Actions in XML Schemas

Search Actions

The following search actions can be applied on attribute, attributeGroup, element, group, key, unique, keyref, notation, simple, or complex types and are available from the Search submenu in the contextual menu of the current editor or from the Document > References menu:

- Search References
  
  Searches all references of the item found at current cursor position in the defined scope, if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box is displayed and you have the possibility to define another search scope.

- Search References in
Searches all references of the item found at current cursor position in the file or files that you specify when define a scope in the Search References dialog box.

**Search Declarations**

Searches all declarations of the item found at current cursor position in the defined scope if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box will be displayed and you have the possibility to define another search scope.

**Search Declarations in**

Searches all declarations of the item found at current cursor position in the file or files that you specify when you define a scope for the search operation.

**Search Occurrences in File**

Searches all occurrences of the item at the cursor position in the currently edited file.

The following action is available from the contextual menu and the Document > Schema menu:

**Go to Definition**

Moves the cursor to the definition of the referenced XML Schema item.

**Note:** You can also use the **Ctrl + Single-Click (Command + Single-Click on OS X)** shortcut on a reference to display its definition.

**Refactoring Actions**

The following refactoring actions can be applied on attribute, attributeGroup, element, group, key, unique, keyref, notation, simple, or complex types and are available from the Refactoring submenu in the contextual menu of the current editor or from the Document > Refactoring menu:

**Rename Component**

Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the Esc or Enter key on your keyboard.

**Rename Component in**

Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the Preview button, you can view the files to be affected by the action.

Figure 502. Rename Identity Constraint Dialog Box

- Search and Refactor Operations Scope (on page 1129)

XML Schema Quick Assist Support

The **Quick Assist support** (on page 3286) improves the development workflow, offering fast access to the most commonly used actions when you edit schema documents.

The **Quick Assist feature** (on page 3286) is activated automatically when the cursor is positioned over the name of a component. It is accessible via a yellow bulb icon (💡) placed at the current line in the stripe on the left side of the editor. Also, you can invoke the quick assist menu by using the **Alt + 1** (Meta + Alt + 1 on Mac OS X) keyboard shortcuts.

Figure 503. Quick Assist Support
The *Quick Assist* support offers direct access to the following actions:

- **Rename Component in**
  Renames the component and all its dependencies.

- **Search Declarations**
  Searches the declaration of the component in a predefined scope. It is available only when the context represents a component name reference.

- **Search References**
  Searches all references of the component in a predefined scope.

- **Component Dependencies**
  Searches the component dependencies in a predefined scope.

- **Change Scope**
  Configures the scope that will be used for future search or refactor operations.

- **Rename Component**
  Allows you to rename the current component in-place.

- **Search Occurrences**
  Searches all occurrences of the component within the current file.

For more information about improving schema development using the *Quick Assist* action set, watch our video demonstration:

https://www.youtube.com/embed/X-2-gkrFSGU

- Component Dependencies View (*on page 1300*)
Generating Sample XML Files

Oxygen XML Editor offers support to generate sample XML files both from XML schema 1.0 and XML schema 1.1, depending on the XML schema version set in XML Schema preferences page (on page 193).

To generate sample XML files from an XML Schema, use the Generate Sample XML Files action from the Tools menu. This action is also available in the contextual menu of the schema Design mode (on page 1252). The action opens the Generate Sample XML Files dialog box that allows you to configure a variety of options for generating the files.

The Generate Sample XML Files dialog box contains three tabs with various configurable options. Default values for these options can be set in the Sample XML Files Generator preferences page (on page 196). You can also run the tool from the command line using exported options.

Schema Tab (Generate Sample XML Files Tool)

The Generate Sample XML Files tool includes a dialog box that allows you to configure a variety of options for generating the XML files. The first set of options are found in the Schema tab.

This tab includes the following options:
URL

Specifies the URL of the Schema location. You can specify the path by using the text field, the history drop-down menu, or the browsing actions in the Browse drop-down list.

Namespace

Displays the namespace of the selected schema.

Root Element

After the schema is selected, this drop-down menu is populated with all root candidates gathered from the schema. Choose the root of the output XML documents.

Output folder

Path to the folder where the generated XML instances will be saved.

Filename prefix and Extension

You can specify the prefix and extension for the file name that will be generated. Generated file names have the following format: prefix\textit{N}\.extension, where \textit{N} represents an incremental number from 0 up to the specified Number of instances (on page 1307).

Number of instances

The number of XML files to be generated.

Open first instance in editor

When selected, the first generated XML file is opened in the editor.

Namespaces section

You can specify the Default Namespace, as well as the prefixes for the namespaces.

Export settings

Use this button to save the current settings for future use.

Import settings

Use this button to load previously exported settings.

You can click OK at any point to generate the sample XML files.

Options Tab (Generate Sample XML Files Tool)

The Generate Sample XML Files tool includes a dialog box that allows you to configure a variety of options for generating the XML files. The Options tab allows you to set specific options for namespaces and elements.

Figure 505. Generate Sample XML Files Dialog Box (Options Tab)
This tab includes the following options:

**Namespace / Element table**

Allows you to set a namespace for each element name that appears in an XML document instance. The following prefix-to-namespace associations are available:

- All elements from all namespaces (<ANY> - <ANY>). This is the default setting.
- All elements from a specific namespace.
- A specific element from a specific namespace.

**Settings subtab**

**Namespace**

Displays the namespace specified in the table at the top of the dialog box.

**Element**

Displays the element specified in the table at the top of the dialog box.

**Generate optional elements**

When selected, all elements are generated, including the optional ones (having the \texttt{minOccurs} attribute set to 0 in the schema).
Generate optional attributes

When selected, all attributes are generated, including the optional ones (having the `use` attribute set to `optional` in the schema).

Values of elements and attributes

Controls the content of generated attribute and element values. The following choices are available:

- **None** - No content is inserted.
- **Default** - Inserts a default value depending on the data type descriptor of the particular element or attribute. The default value can be either the data type name or an incremental name of the attribute or element (according to the global option from the Sample XML Files Generator preferences page). Note that type restrictions are ignored when this option is selected. For example, if an element is of a type that restricts an `xs:string` with the `xs:maxLength` facet to allow strings with a maximum length of 3, the XML instance generator tool may generate string element values longer than 3 characters.
- **Random** - Inserts a random value depending on the data type descriptor of the particular element or attribute.

⚠️ **Important:** If all of the following are true, the Generate Sample XML Files tool outputs invalid values:
- At least one of the restrictions is a `regexp`.
- The value generated after applying the `regexp` does not match the restrictions imposed by one of the facets.

Preferred number of repetitions

Allows you to set the preferred number of repeating elements related to `minOccurs` and `maxOccurs` facets defined in the XML Schema.

- If the value set here is between `minOccurs` and `maxOccurs`, then that value is used.
- If the value set here is less than `minOccurs`, then the `minOccurs` value is used.
- If the value set here is greater than `maxOccurs`, then `maxOccurs` is used.

Maximum recursion level

If a recursion is found, this option controls the maximum allowed depth of the same element.
**Type alternative strategy**

Used for the `xs:alternative` element from XML Schema 1.1. The possible strategies are:

- **First** - The first valid alternative type is always used.
- **Random** - A random alternative type is used.

**Choice strategy**

Used for `xs:choice` or `substitutionGroup` elements. The possible strategies are:

- **First** - The first branch of `xs:choice` or the head element of `substitutionGroup` is always used.
- **Random** - A random branch of `xs:choice` or a substitute element or the head element of a `substitutionGroup` is used.

**Generate the other options as comments**

If selected, generates the other possible choices or substitutions (for `xs:choice` and `substitutionGroup`). These alternatives are generated inside comments groups so you can uncomment and use them later. Use this option with care (for example, on a restricted namespace and element) as it may generate large result files.

**Element values subtab**

Allows you to add values that are used to generate the content of elements. If there are multiple values, then the values are used in a random order.

**Attribute values subtab**

Allows you to add values that are used to generate the content of attributes. If there are multiple values, then the values are used in a random order.

**Export settings**

Use this button to save the current settings for future use.

**Import settings**

Use this button to load previously exported settings.

You can click **OK** at any point to generate the sample XML files.
Advanced Tab (Generate Sample XML Files Tool)

The Generate Sample XML Files tool includes a dialog box that allows you to configure a variety of options for generating the XML files. The Advanced tab allows you to set some options regarding output values and performance.

Figure 506. Generate Sample XML Files Dialog Box (Advanced Tab)

This tab includes the following options:

**Use incremental attribute / element names as default**

If selected, the value of an element or attribute starts with the name of that element or attribute. For example, for an `a` element the generated values are: `a1`, `a2`, `a3`, and so on. If not selected, the value is the name of the type of that element / attribute (for example: `string`, `decimal`, etc.)

**Maximum length**

The maximum length of string values generated for elements and attributes.

**Discard optional elements after nested level**

The optional elements that exceed the specified nested level are discarded. This option is useful for limiting deeply nested element definitions that can quickly result in very large XML documents.

**Export settings**

Use this button to save the current settings for future use.

**Import settings**

Use this button to load previously exported settings.

Running the Generate Sample XML Files Tool from the Command Line

The Generate Sample XML Files tool can be also used from command line by running the script called `xmlGenerator.bat` (on Windows) / `xmlGenerator.sh` (on Mac OS X / Unix / Linux) located in the Oxygen XML Editor installation folder. The parameters can be set in the dialog box, exported to an XML file on disk with the Export settings button, and then reused from command line. With the
exported settings file, you can generate the same XML instances from the command line as from the dialog box. For example:

```
xmlGenerator.bat path_of_CFG_file
```

The script can be integrated in an external batch process launched from the command line. The command-line parameter of the script is the relative path to the exported XML settings file. The files specified with relative paths in the exported XML settings will be made absolute relative to the folder where the script is run.

The following example shows such an XML configuration file:

```xml
<settings>
  <schemaSystemId>http://www.w3.org/2001/XMLSchema.xsd</schemaSystemId>
  <documentRoot>schema</documentRoot>
  <outputFolder>D:\projects\output</outputFolder>
  <filenamePrefix>instance</filenamePrefix>
  <filenameExtension>xml</filenameExtension>
  <noOfInstances>1</noOfInstances>
  <openFirstInstance>true</openFirstInstance>
  <defaultNamespace>&lt;NO_NAMESPACE&gt;</defaultNamespace>
  <element namespace="&lt;ANY&gt;" name="&lt;ANY&gt;">
    <generateOptionalElements>false</generateOptionalElements>
    <generateOptionalAttributes>false</generateOptionalAttributes>
    <valuesForContentType>DEFAULT</valuesForContentType>
    <preferredNumberOfRepetitions>2</preferredNumberOfRepetitions>
    <maximumRecursivityLevel>1</maximumRecursivityLevel>
    <choicesAndSubstitutions strategy="RANDOM">
      <generateOthersAsComments>false</generateOthersAsComments>
      <attribute namespace="&lt;ANY&gt;" name="&lt;ANY&gt;">
        <attributeValue>attrValue1</attributeValue>
        <attributeValue>attrValue2</attributeValue>
      </attribute>
    </choicesAndSubstitutions>
  </element>
  <element namespace="&lt;NO_NAMESPACE&gt;">
    <generateOptionalElements>true</generateOptionalElements>
    <generateOptionalAttributes>true</generateOptionalAttributes>
    <valuesForContentType>DEFAULT</valuesForContentType>
    <preferredNumberOfRepetitions>2</preferredNumberOfRepetitions>
    <maximumRecursivityLevel>1</maximumRecursivityLevel>
  </element>
</settings>
```
Generating Documentation for an XML Schema

Oxygen XML Editor can generate detailed documentation for the components of an XML Schema in HTML, PDF, DocBook, or other custom formats. You can select the components and the level of detail. The components are hyperlinked in both HTML and DocBook documents.

Note: You can generate documentation for both XML Schema version 1.0 and 1.1.

To generate documentation for an XML Schema document, select XML Schema Documentation from the Tools > Generate Documentation menu or from the Generate Documentation submenu in the contextual menu of the Project view (on page 333).

Figure 507. XML Schema Documentation Dialog Box
The **Schema URL** field of the dialog box must contain the full path to the XML Schema (XSD) file for which you want to generate documentation. The schema may be a local or a remote file. You can specify the path to the schema by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.

### Output Tab

The following options are available in the **Output** tab:

- **Format** - Allows you to choose between the following formats:
  - **HTML** - The documentation is generated in [HTML output format](on page 1318).
  - **PDF** - The documentation is generated in [PDF output format](on page 1321).
  - **DocBook** - The documentation is generated in [DocBook output format](on page 1321).
  - **DITA** - The documentation is generated in [DITA output format](on page 1321).
  - **Custom** - The documentation is generated in a [custom output format](on page 1321), allowing you to control the output. Click the **Options** button to open a **Custom format options** dialog box where you can specify a custom stylesheet for creating the output. There is also an option to **Copy additional resources to the output folder** and you can select the path to the additional **Resources** that you want to copy. You can also choose to keep the
intermediate XML files created during the documentation process by deselecting the **Delete intermediate XML file** option.

- **Output file** - You can specify the path of the output file by entering it in the text field, or by using the `Insert Editor Variables` button or the options in the `Browse` drop-down menu.

- **Split output into multiple files** - Instructs the application to split the output into multiple files. You can choose to split them by namespace, location, or component name.

- **Open in Browser/System Application** - Opens the result in the system application associated with the output file type. For DITA and DocBook documents, this option appears as **Open in Editor** and the result will be opened in Oxygen XML Editor (in the current editor).

**Note:** To set the browser or system application that will be used, open the **Preferences** dialog box (Options > Preferences) (on page 79), go to **Global**, and set it in the **Default Internet browser** field. This will take precedence over the default system application settings.

- **Keep only the annotations with xml:lang set to** - The generated output will contain only the annotations with the `xml:lang` attribute set to the selected language. If you choose a primary language code (for example, `en` for English), this includes all its possible variations (`en-us`, `en-uk`, etc.).

**Settings Tab**

When you generate documentation for an XML schema you can choose what components to include in the output and the details to be included in the documentation.

Figure 508. Settings Tab of the XML Schema Documentation Dialog Box
The **Settings** tab allows you to choose whether or not to include the following components: **Global elements**, **Global attributes**, **Local elements**, **Local attributes**, **Simple Types**, **Complex Types**, **Groups**, **Attribute Groups**, **Redefines**, **Referenced schemas**, **Include notations**.

You can choose whether or not to include the following other details:

- **Diagram** - Displays the diagram for each component. You can choose the image format (JPEG, PNG, GIF, SVG) to use for the diagram section. The generated diagrams are dependent on the options from the **Schema Design Properties** (on page 154) page.
- **Diagram annotations** - This option controls whether or not the annotations of the components presented in the diagram sections are included.
- **Namespace** - Displays the namespace for each component.
- **Location** - Displays the schema location for each component.
- **Type** - Displays the component type if it is not an anonymous one.
- **Type hierarchy** - Displays the types hierarchy.
- **Model** - Displays the model (sequence, choice, all) presented in BNF form. The separator characters that are used depend upon the information item used:
  - **xs:all** - Its children will be separated by space characters.
  - **xs:sequence** - Its children will be separated by comma characters.
  - **xs:choice** - Its children will be separated by / characters.
• **Children** - Displays the list of component’s children.

• **Instance** - Displays an XML instance generated based on each schema element.

• **Used by** - Displays the list of all the components that reference the current one. The list is sorted by component type and name.

• **Properties** - Displays some of the component’s properties.

• **Facets** - Displays the facets for each simple type

• **Identity constraints** - Displays the identity constraints for each element. For each constraint there are presented the name, type (unique, key, keyref), reference attribute, selector and field(s).

• **Attributes** - Displays the attributes for the component. For each attribute there are presented the name, type, fixed or default value, usage and annotation.

• **Asserts** - Displays the `assert` elements defined in a complex type. The test, XPath default namespace, and annotation are presented for each assert.

• **Annotations** - Displays the annotations for the component. If you choose **Escape XML Content**, the XML tags are present in the annotations.

• **Source** - Displays the text schema source for each component.

• **Generate index** - Displays an index with the components included in the documentation.
  - **Include local elements and attributes** - If selected, local elements and attributes are included in the documentation index.
  - **Include resource hierarchy** - Specifies whether or not the resource hierarchy for an XML Schema documentation is generated. It is deselected by default.

**Export settings** - Save the current settings in a settings file for further use (for example, with the exported settings file you can generate the same documentation from the command line interface (on page 1323).)

**Import settings** - Reloads the settings from the exported file.

**Generate** - Use this button to generate the XML Schema documentation.

**Related Information:**

- Customizing PDF or DocBook Output of Generated XML Schema Documentation (on page 1322)

**Output Formats for Generating XML Schema Documentation**

XML Schema documentation can be generated in HTML, PDF, DocBook, or a custom format. You can choose the format from the **Schema Documentation** (on page 1313) dialog box. For the PDF and DocBook formats, the option to split the output in multiple files is not available.
**HTML Output Format**

The XML Schema documentation generated in HTML format contains images corresponding to the same schema definitions as the ones displayed by the schema diagram editor. (on page 623) These images are divided in clickable areas that are linked to the definitions of the names of types or elements. The documentation of a definition includes a **Used By** section with links to the other definitions that reference it. If the **Escape XML Content** option is unchecked, the HTML or XHTML tags used inside the `xs:documentation` elements of the input XML Schema for formatting the documentation text (for example, `<b>`, `<i>`, `<u>`, `<ul>`, `<li>`, etc.) are rendered in the generated HTML documentation.

The generated images format is **PNG**. The image of an XML Schema component contains the graphical representation of that component as it is rendered in the schema diagram panel of the Oxygen XML Editor XSD editor panel. (on page 623)

Figure 509. XML Schema Documentation Example

The generated documentation includes a table of contents. You can group the contents by namespace, location, or component type. After the table of contents there is some information about the main, imported, included, and redefined schemas. This information contains the schema target
namespace, schema properties (attribute form default, element form default, version), and schema location.

Figure 510. Information About a Schema

<table>
<thead>
<tr>
<th>Namespace Properties</th>
<th>Schema Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>No namespace</td>
<td>file:D/personalized.xsd</td>
</tr>
<tr>
<td>attribute form default: unqualified</td>
<td></td>
</tr>
<tr>
<td>element form default: unqualified</td>
<td></td>
</tr>
</tbody>
</table>

If you choose to split the output into multiple files, the table of contents is displayed in the left frame. The contents are grouped in the same mode. If you split the output by location, each file contains a schema description and the components that you have chosen to include. If you split the output by namespace, each file contains information about schemas from that namespace and the list with all included components. If you choose to split the output by component, each file contains information about a schema component.

After the documentation is generated, you can collapse or expand details for some schema components by using the Showing options or the Collapse or Expand buttons.

Figure 511. Showing Options

For each component included in the documentation, the section presents the component type follow by the component name. For local elements and attributes, the name of the component is specified as parent name/component name. You can easily go to the parent documentation by clicking the parent name.

Figure 512. Documentation for a Schema Component
If the schema contains imported or included modules, their dependencies tree is generated in the documentation.

Figure 513. Example: Generated Documentation
PDF Output Format

For the PDF output format, the documentation is generated in DocBook format and a transformation using the FOP processor is applied to obtain the PDF file. To configure the FOP processor, see the FO Processors (on page 216) preferences page.

For information about customizing the PDF output, see Customizing PDF or DocBook Output of Generated XML Schema Documentation (on page 1322).

DocBook Output Format

If you generate the documentation in DocBook output format, the documentation is generated as a DocBook XML file. You can then apply a built-in DocBook transformation scenario (on page 1667) (such as, DocBook PDF or DocBook HTML) on the output file, or configure your own transformation scenario (on page 1674) to convert it into whatever format you desire.

For information about customizing the DocBook output, see Customizing PDF or DocBook Output of Generated XML Schema Documentation (on page 1322).

DITA Output Format

If you generate the documentation in DITA output format, each element of the schema is converted to a DITA Topic and all the generated topics are referenced in a DITA map (on page 3281) file. You can then apply a built-in DITA transformation scenario (on page 1642) (such as, DITA Map PDF or DITA Map XHTML), or configure your own DITA OT transformation scenario (on page 1702) to convert it into whatever format you desire.

For information about customizing the DITA output, see Customizing DITA Output of Generated XML Schema (on page 1323).

Custom Output Format

For the custom format, you can specify a stylesheet to transform the intermediary XML file generated in the documentation process. You have to edit your stylesheet based on the schema xsdDocSchema.xsd from [OXYGEN_INSTALL_DIR]/frameworks/schema_documentation.

You can create a custom format starting from one of the stylesheets used in the built-in HTML, PDF, DocBook, and DITA formats. These stylesheets are available in [OXYGEN_INSTALL_DIR]/frameworks/schema_documentation/xsl.

When using a custom format you can also copy additional resources into the output folder and choose to keep the intermediate XML files created during the documentation process.
Important: If you create a custom format for DITA, you must select the Split output into multiple files option in the Output tab (on page 1315) and choose Split by component.

Customizing PDF or DocBook Output of Generated XML Schema Documentation

To customize the PDF or DocBook output of the generated XML Schema documentation, use the following procedure:

1. Customize the [OXYGEN_INSTALL_DIR]/frameworks/schema_documentation/xsl/xsdDocDocbook.xsl stylesheet to include the content that you want to add in the PDF or DocBook output. Add the content in the XSLT template with the match="schemaDoc" attribute between the info and xsl:apply-templates elements, as commented in the following example:

   ```xml
   <info>
     <pubdate><xsl:value-of select="format-date(current-date(),'[Mn] [D], [Y]', 'en', (), ())"/></pubdate>
   </info>
   <!-- Add the XSLT template content with match="schemaDoc" attribute here -->
   <xsl:apply-templates select="schemaHierarchy"/>
   ```

2. Create an intermediary file that holds the content of your XML Schema documentation by following these steps:
   a. Go to Tools > Generate Documentation > XML Schema Documentation.
   b. Select Custom for the output format and click the Options button.
   c. In the Custom format options dialog box, do the following:
      i. Enter the customized stylesheet in the Custom XSL field ([OXYGEN_INSTALL_DIR]/frameworks/schema_documentation/xsl/xsdDocDocbook.xsl).
      ii. Select the Copy additional resources to the output folder option and leave the default selection in the Resources field.
      iii. Click OK.
   d. When you return to the XML Schema Documentation dialog box, just press the Generate button to generate a DocBook XML file with an intermediary form of the Schema documentation.

3. If you want the DocBook file to be transformed into a PDF document, follow these steps:
   a. Use the Configure Transformation Scenario(s) action from the toolbar or the Document > Transformation menu, click New, and select XML transformation with XSLT.
   b. In the New Scenario dialog box, go to the XSL URL field and choose the [OXYGEN_INSTALL_DIR]/frameworks/docbook/oxygen/xsdDocDocbookCustomizationFO.xsl file.
c. Go to the **FO Processor** tab and select the **Perform FO Processing** and **XSLT result as input** options.

d. Go to the **Output** tab and select the directory where you want to store the XML Schema documentation output and click **OK**.

e. Click **Apply Associated**.

**Tip:** If you want your modifications to be permanent so that you can simply select the PDF output format in the **XML Schema Documentation** dialog box, rather than configuring a custom format each time you generate this documentation, follow this procedure:

1. Create a JAR (on page 3283) or ZIP file that includes the modified stylesheet (customized in step 1 above), placed in the following directory structure: `builtin/documentation/schema_documentation/xsdDocDocbook.xsl`.
2. Create a new directory named **endorsed** inside the `[OXYGEN_INSTALL_DIR]/lib` directory and place the created JAR or ZIP file inside it.
3. Restart Oxygen XML Editor and the PDF output format will now use your customized stylesheet.

**Customizing DITA Output of Generated XML Schema**

To customize the DITA output of the generated XML Schema documentation, use the following procedure:

1. Customize the `[OXYGEN_INSTALL_DIR]/frameworks/schema_documentation/xsl/xsdDocDita.xsl` stylesheet to incorporate your desired changes.
2. Create an intermediary file that holds the content of your XML Schema documentation by following these steps:
   a. Go to **Tools > Generate Documentation > XML Schema Documentation**.
   b. Select **Custom** for the output format and click the **Options** button.
   c. In the **Custom format options** dialog box, do the following:
      i. Enter the customized stylesheet in the **Custom XSL** field (`[OXYGEN_INSTALL_DIR]/frameworks/schema_documentation/xsl/xsdDocDita.xsl`).
      ii. Select the **Copy additional resources to the output folder** option and leave the default selection in the **Resources** field.
      iii. Click **OK**.
   d. Make sure the **Split output into multiple files option (on page 1315)** is selected and choose **Split by component**.
   e. When you return to the **XML Schema Documentation** dialog box, just press the **Generate** button to generate a DITA map file that contains the XML Schema documentation.
Generating XML Schema Documentation From the Command-Line Interface

You can export the settings of the XML Schema Documentation dialog box (on page 1313) to an XML file by pressing the Export settings button. With the exported configuration file, you can generate the same documentation from the command-line interface by running the following script:

- `schemaDocumentation.bat` on Windows.
- `schemaDocumentation.sh` on OS X / Linux.

The script is located in the Oxygen XML Editor installation folder. The script can be integrated in an external batch process launched from the command-line interface. The script accepts a variety of command-line arguments that allow you to configure the documentation.

The accepted syntax and arguments are as follows:

```
```

- `schemaFile`
  The XML Schema file.

- `cfg:configfile`
  The exported configuration file. It contains the output file, output format options, split method, and some advanced options regarding the included components and components details. If an external configuration file is specified, all other supplied arguments except for the XML Schema file will be ignored.

- `out:outputFile`
  The file where the generated documentation will be saved. By default, it is the name of the schema file with an html extension.

- `format:<value>`
  The output format type used when generating the documentation. Possible values are as follows:

  - `html` - To generate documentation in HTML format.
  - `pdf` - To generate documentation in PDF format.
  - `docbook` - To generate documentation in DocBook format.
  - `custom` - To generate documentation in a custom format.

- `xsl:<xslFile>`
  The XSL file to be applied on the intermediate XML format. If there is no XSL file provided, the result will be in the HTML format.
The split method used when generating the documentation. Splitting is recommended for large schemas. Possible values are as follows:

- none (default value) - To generate one single output file.
- namespace - To generate an output file for every namespace in the schema.
- component - To generate an output file for every component in the schema.
- location - To generate an output file for every schema location.

Opens the result of the transformation in a browser or system application. Possible values are true or false (default value).

Displays the available options.

Example:

Example of the script in a Windows command line:

```
schemaDocumentation example.xsd -out:schemaDocumentation.html
-format:custom -xsl:example.xsl -split:namespace
```

Converting Schema to Another Schema Language

The Generate/Convert Schema tool allows you to convert a DTD or Relax NG (full or compact syntax) schema or a set of XML files to an equivalent XML Schema, DTD or Relax NG (full or compact syntax) schema. Where perfect equivalence is not possible due to limitations of the target language, Oxygen XML Editor generates an approximation of the source schema. Oxygen XML Editor uses Trang multiple format converter to perform the actual schema conversions.

To use this tool, select the Generate/Convert Schema (Alt + Shift + C (Command + Alt + C on OS X)) action from the Tools menu or from the Open with submenu when invoking the contextual menu in the Project view (on page 333). This action opens the Generate/Convert Schema dialog box that allows you to configure various options for conversion.

Figure 514. Generate/Convert Schema Dialog Box
The **Generate/Convert Schema** dialog box includes the following options:

**Input section**

Allows you to select the language of the source schema. If the conversion is based on a set of XML files, rather than just a single XML file, select the **XML Documents** option and use the file selector to add the XML files involved in the conversion.

**Output section**

Allows you to select the language of the target schema.

**Options**

You can choose the **Encoding**, the maximum **Line width**, and the **Indent size** (in number of spaces) for one level of indentation.

**Output file**

Specifies the path for the output file that will be generated.

**Close dialog when finished**

If you deselect this option, the dialog box will remain opened after the conversion so that you can easily continue to convert more files.

**Advanced options**

If you select **XML 1.0 DTD** for the input, you can click this button to access more advance options to further fine-tune the conversion. The following advanced options are available:
XML 1.0 DTD Input section

These options apply to the source DTD:

- **xmlns** - Specifies the default namespace, that is the namespace used for unqualified element names.
- **attlist-define** - Specifies how to construct the name of the definition representing an attribute list declaration from the name of the element. The specified value must contain exactly one percent character. This percent character is replaced by the name of element (after colon replacement) and the result is used as the name of the definition.
- **colon-replacement** - Replaces colons in element names with the specified chars when constructing the names of definitions used to represent the element declarations and attribute list declarations in the DTD.
- **any-name** - Specifies the name of the definition generated for the content of elements declared in the DTD as having a content model of ANY.
- **element-define** - Specifies how to construct the name of the definition representing an element declaration from the name of the element. The specified value must contain exactly one percent character. This percent character is replaced by the name of element (after colon replacement) and the result is used as the name of the definition.
- **annotation-prefix** - Default values are represented using an annotation attribute prefix:defaultValue where prefix is the specified value and is bound to http://relaxng.org/ns/compatibility/annotations/1.0 as defined by the RELAX NG DTD Compatibility Committee Specification. By default, the conversion engine will use a for prefix unless that conflicts with a prefix used in the DTD.
- **inline-attlist** - Instructs the application not to generate definitions for attribute list declarations, but instead move attributes declared in attribute list declarations into the definitions generated for element declarations. This is the default behavior when the output language is XSD.
- **strict-any** - Preserves the exact semantics of ANY content models by using an explicit choice of references to all declared elements. By default, the conversion engine uses a wildcard that allows any element
- **generate-start** - Specifies whether or not the conversion engine should generate a start element. DTD’s do not indicate what elements
are allowed as document elements. The conversion engine assumes that all elements that are defined but never referenced are allowed as document elements.

• **xmlns mappings** table - Each row specifies the prefix used for a namespace in the input schema.

**W3C XML Schema Output section**

This section is available if you select **W3C XML Schema** for the output.

• **disable-abstract-elements** - Disables the use of abstract elements and substitution groups in the generated XML Schema. This can also be controlled using an annotation attribute.

• **any-process-contents** - One of the values: strict, lax, skip. Specifies the value for the `processContents` attribute of any elements. The default is skip (corresponding to RELAX NG semantics) unless the input format is DTD, in which case the default is strict (corresponding to DTD semantics).

• **any-attribute-process-contents** - Specifies the value for the `processContents` attribute of `anyAttribute` elements. The default is skip (corresponding to RELAX NG semantics).

**Converting Database to XML Schema**

Oxygen XML Editor includes a tool that allows you to create an XML Schema from the structure of a database.

To convert a database structure to an XML Schema, use the following procedure:

1. Select the **Convert DB Structure to XML Schema** action from the **Tools** menu.

   **Result:** The **Convert DB Structure to XML Schema** dialog box is opened and your current database connections are displayed in the **Connections** section.

2. If the database source is not listed, click the **Configure Database Sources** button to open the **Data Sources preferences page** (on page 229) where you can configure data sources and connections.

3. In the **Format for generated schema** section, select one of the following formats:

   • **Flat schema** - A flat structure that resembles a tree-like view of the database without references to elements.

   • **Hierarchical schema** - Display the table dependencies visually, in a type of tree view where dependent tables are shown as indented child elements in the content model. Select this option if you want to configure the database columns of the tables to be converted.

4. Click **Connect**.
5. Select the database tables that you want to be included in the XML Schema.

6. If you selected Hierarchical schema for the format, you can configure the database columns.
   a. Select the database column you want to configure.
   b. In the Criterion section you can choose to convert the selected database column as an Element, Attribute, or to be Skipped in the resulting XML Schema.
   c. You can also change the name of the selected database column by changing it in the Name text field.

7. Click Generate XML Schema.

   Result: The database structure is converted to an XML Schema and it is opened for viewing and editing.

Flatten an XML Schema

You can organize an XML schema linked by `xs:include` and `xs:import` statements on several levels. In some cases, working on such a schema as if it were a single file is more convenient than working on multiple files separately. The Flatten Schema operation allows you to flatten an entire hierarchy of XML schemas. Starting with the main XML schema, Oxygen XML Editor calculates its hierarchy by processing the `xs:include` and `xs:import` statements.

The Flatten Schema action is available from the Tools menu or the contextual menu in Text mode. The action opens the Flatten Schema dialog box that allows you to configure the operation.

Figure 515. Flatten Schema Dialog Box
For the main schema file and for each imported schema, a new flattened schema is generated in the specified output folder. These schemas have the same name as the original ones.

**Note:** If necessary, the operation renames the resulted schemas to avoid duplicated file names.

A flattened XML schema is obtained by recursively adding the components of the included schemas into the main one. This means Oxygen XML Editor replaces the `xs:include`, `xs:redefine`, and `xs:override` elements with the ones coming from the included files.

### Options in the Flatten Schema Dialog Box

The following options are available in the **Flatten Schema** dialog box:

**File name**

The name of the output file.

**Output directory**

The path of the output directory where the flattened schema file will be saved.

**Open the flattened XML Schema file in editor**

Opens the main flattened schema in the editing area after the operation completes.

**Use the XML Catalogs when collecting the referenced XML Schemas**
Enables the imported and included schemas to be resolved through the available XML Catalogs (on page 3289).

**Note:** Changing this option triggers the recalculation of the dependencies graph for the main schema.

**Process the imported XML Schemas resolved through the XML Catalogs**

Specifies whether or not the imported schemas that were resolved through an XML Catalog (on page 3289) are also processed.

**Flatten the imported XML Schema(s)**

Specifies whether or not the imported schemas are flattened.

**Note:** For the schemas skipped by the flatten operation, no files are created in the output folder and the corresponding import statements remain unchanged.

**Flatten Schema from the Command Line**

The Flatten Schema tool can be also ran from command line by using the following command:

- `flattenSchema.bat` on Windows
- `sh flattenSchema.sh` on OS X and Linux

The command line accepts the following parameters:

- `-in:inputSchemaURL` - The input schema URL.
- `-outDir:outputDirectory` - The directory where the flattened schemas should be saved.
- `-flattenImports:<boolean_value>` - Controls whether or not the imported XML Schemas should be flattened. The default value `true`.
- `-useCatalogs:<boolean_value>` - Controls if the references to other XML Schemas should be resolved through the available XML Catalogs (on page 3289). The default value `false`.
- `-flattenCatalogResolvedImports:<boolean_value>` - Controls whether or not the imported schemas that were resolved through the XML Catalogs (on page 3289) should be flattened. The default value is `true`.

**Note:** This option is used only when `-useCatalogs` is set to `true`.

- `-verbose` - Provides information about the current flatten XML Schema operation.
- `--help | -help | --h | -h` - Prints the available parameters for the operation.

**Example: Command-Line Example for Windows**

```bash
flattenSchema.bat -in:http://www.w3.org/MarkUp/SCHEMA/xhtml11.xsd
-outDir:mySchemas/flattened/xhtml -flattenImports:true -useCatalogs:true
```
Example: Command-Line Example for OS X

```
sh flattenSchema.sh -in:http://www.w3.org/MarkUp/SCHEMA/xhtml11.xsd
-outDir:mySchemas/flattened/xhtml -flattenImports:true -useCatalogs:true
-flattenCatalogResolvedImports:true -verbose
```

Example: Command-Line Example for Unix/Linux

```
sh flattenSchema.sh -in:http://www.w3.org/MarkUp/SCHEMA/xhtml11.xsd
-outDir:mySchemas/flattened/xhtml -flattenImports:true -useCatalogs:true
-flattenCatalogResolvedImports:true -verbose
```

XML Schema Regular Expressions Builder

The XML Schema regular expressions builder allows you to test regular expressions on a fragment of text as they are applied to an XML instance document. Start the tool by selecting XML Schema Regular Expressions Builder from the Tools menu.

Figure 516. XML Schema Regular Expressions Builder Dialog Box

The dialog box contains the following:
Regular expressions editor

Allows you to edit the regular expression to be tested and used. Content completion is available and presents a list with all the predefined expressions. It is triggered by pressing \texttt{Ctrl + Space (Command + Space on OS X)}.

Error display area

If the edited regular expression is incorrect, an error message will be displayed here. The message contains the description and the exact location of the error. Also, clicking the quick navigation button (↩) highlights the error inside the regular expression.

Category

You can choose from several categories of predefined expressions. The selected category influences the displayed expressions in the Available expressions table.

Available expressions

This table includes the available regular expressions and a short description for each of them. The set of expressions depends on the category selected in the previous Category combo box. You can add an expression in the Regular expressions editor by double-clicking the expression row in the table. You will notice that in the case of Character categories and Block names, the expressions are also listed in complementary format.

Evaluate expression on

You can choose between two options:

- Evaluate expression on each line - The edited expression will be applied on each line in the Test area.
- Evaluate expression on all text - The edited expression will be applied on the whole text.

Test

A text editor that allows you to enter a text sample for which the regular expression will be applied. All matches of the edited regular expression will be highlighted.

After editing and testing your regular expression you can insert it in the current editor. The Insert button will become active when an editor is opened in the background and there is an expression in the Regular expressions editor.

The regular expression builder cannot be used to insert regular expressions in the Grid mode (on page 392) or schema Design mode (on page 623). Accordingly, the Insert button will be not available if the current document is edited in these modes.
Note: Some regular expressions may indefinitely block the Java Regular Expressions engine. If the execution of the regular expression does not end in about five seconds, the application displays a dialog box that allows you to interrupt the operation.

XML Schema 1.1

Oxygen XML Editor offers full support for XML Schema 1.1, including:

- XML Documents Validation (on page 1079) and Content Completion (on page 844) based on XML Schema 1.1.
- XML Schema 1.1 Validation (on page 1287) and Content Completion (on page 1288).
- Editing XML Schema 1.1 files in the Schema Design mode (on page 623).
- The Flatten Schema (on page 1329) action.
- Resource Hierarchy/Dependencies (on page 1297) and Refactoring Actions (on page 1302).
- Master files (on page 3284).
- Support for generating XML instances based on XML Schema.
- Support for validating XML documents with an NVDL schema that contains an XML Schema 1.1 validation step.

Note: To enable XML Schema 1.1 validation in NVDL, you need to pass the following option to the validation engine to specify the schema version: http://www.thaiopensource.com/validate/xsd-version (the possible values are 1.0 or 1.1).

Tip: To enable the full XPath expression in assertions and type alternatives, you need to set the http://www.thaiopensource.com/validate/full-xpath option.

XML Schema 1.1 is a superset of XML Schema 1.0, that offers lots of new powerful capabilities.

Figure 517. XML Schema 1.1

The significant new features in XSD 1.1 are:
- **Assertions** - Support to define assertions against the document content using XPath 2.0 expressions (an idea borrowed from Schematron).

- **Conditional type assignment** - The ability to select the type of schema an element is validated against, based on the values of the attribute of the element.

- **Open content** - Content models can use the `openContent` element to specify content models with `open content`. These content models allow elements not explicitly mentioned in the content model to appear in the document instance. It is as if wildcards were automatically inserted at appropriate points within the content model. A default may be set that causes all content models to be open unless specified otherwise.

To see the complete list with changes since version 1.0, go to [http://www.w3.org/TR/xmlschema11-1/#ch_specs](http://www.w3.org/TR/xmlschema11-1/#ch_specs).

XML Schema 1.1 is intended to be mostly compatible with XML Schema 1.0 and to have approximately the same scope. It also addresses bug fixes and brings improvements that are consistent with the constraints on scope and compatibility.

**Note:** An XML document conforming to a 1.0 schema can be validated using a 1.1 validator, but an XML document conforming to a 1.1 schema may not validate using a 1.0 validator.

If you are constrained to use XML Schema 1.0 (for example, if you develop schemas for a server that uses an XML Schema 1.0 validator that cannot be updated), change the default XML Schema version to 1.0. If you keep the default XML Schema version set to 1.1, the Content Completion Assistant ([on page 3280](#)) presents XML Schema 1.1 elements that you can insert accidentally in an 1.0 XML Schema. So even if you make a document invalid conforming with XML Schema 1.0, the validation process does not signal any issues.

To change the default XML Schema version, open the Preferences dialog box (Options > Preferences) ([on page 79](#)) and go to XML > XML Parser > XML Schema.

For more information about the XML Schema 1.1 support, watch our video demonstration:

[https://www.youtube.com/embed/DAkrubQNm0w](https://www.youtube.com/embed/DAkrubQNm0w)

**Related Information:**

- Setting the XML Schema Version ([on page 1335](#))

Setting the XML Schema Version

Oxygen XML Editor lets you set the version of the XML Schema you are editing either in the XML Schema preferences page, or through the versioning attributes. If you want to use the versioning
attributes, set the \textit{minVersion} and \textit{maxVersion} attributes, from the http://www.w3.org/2007/XMLSchema-versioning namespace, on the \textit{schema} root element.

\textbf{Note:} The versioning attributes take priority over the XML Schema version defined in the preferences page.

| Table 65. Using the \textit{minVersion} and \textit{maxVersion} Attributes to Set the XML Schema Version |
|-----------------|-----------------|
| Versioning Attributes | XML Schema Version |
| \textit{minVersion} = "1.0" \textit{maxVersion} = "1.1" | 1.0 |
| \textit{minVersion} = "1.1" | 1.1 |
| \textit{minVersion} = "1.0" \textit{maxVersion} = greater than "1.1" | The XML Schema version defined in the XML Schema preferences page (on page 192) |
| Not set in the XML Schema document | The XML Schema version defined in the XML Schema preferences page (on page 192) |

To change the XML Schema version of the current document, use the \textbf{Change XML Schema version} action from the contextual menu. This is available both in the \textbf{Text} mode, and in the \textbf{Design} mode and opens the \textbf{Change XML Schema version} dialog box. The following options are available:

- **XML Schema 1.0** - Inserts the \textit{minVersion} and \textit{maxVersion} attributes on the \textit{schema} element and gives them the values "1.0" and "1.1" respectively. Also, the namespace declaration (xmlns:vc=http://www.w3.org/2007/XMLSchema-versioning) is inserted automatically if it does not exist.

- **XML Schema 1.1** - Inserts the \textit{minVersion} attribute on the \textit{schema} element and gives it the value "1.1". Also, removes the \textit{maxVersion} attribute if it exists and adds the versioning namespace (xmlns:vc=http://www.w3.org/2007/XMLSchema-versioning) if it is not declared.

- **Default XML Schema version** - Removes the \textit{minVersion} and \textit{maxVersion} attributes from the \textit{schema} element. The default schema version, defined in the XML Schema preferences page, is used.

\textbf{Note:} The \textbf{Change XML Schema version} action is also available in the informative panel presented at the top of the edited XML Schema. If you close this panel, it will no longer appear until you restore Oxygen XML Editor to its default options.

Oxygen XML Editor automatically uses the version set through the versioning attributes, or the default version if the versioning attributes are not declared, when proposing content completion elements and validating an XML Schema. Also, the XML instance validation against an XML Schema is aware of the versioning attributes defined in the XML Schema.

When you generate sample XML files from an XML Schema, Oxygen XML Editor takes into account the \textit{minVersion} and \textit{maxVersion} attributes defined in the XML Schema.

\textbf{Related Information:}
Editing XQuery Documents

XQuery is the query language for XML and is officially defined by a W3C Recommendation document. Oxygen XML Editor provides support for XQuery 3.1, which is also backwards compatible with XQuery 3.0 and 1.0.

The many benefits of XQuery include:

- XQuery allows you to work in one common model no matter what type of data you are working with: relational, XML, or object data.
- XQuery is ideal for queries that must represent results as XML, to query XML stored inside or outside the database, and to span relational and XML sources.
- XQuery allows you to create many different types of XML representations of the same data.
- XQuery allows you to query both relational sources and XML sources, and create one XML result.

Related Information:

- XQuery and Databases (on page 2260)

XQuery Validation

With Oxygen XML Editor, you can validate your documents before using them in your transformation scenarios. The validation uses the Saxon 9.8.0.12 PE, EE, or HE processor, or you can use some database engines (such as MarkLogic or eXist) if you installed them. Any other XQuery processor that offers an XQJ API implementation (on page 2253) can also be used. This is in conformance with the XQuery Working Draft. The processor is used in two cases: validation of the expression and execution. Although the execution implies a validation, it is faster to check the expression syntactically, without executing it. The errors that occurred in the document are presented in the messages view at the bottom of editor window, with a full description message. As with all error messages, if you click an entry, the line where the error appeared is highlighted.

Figure 518. XQuery Validation
Note: If you choose a processor that does not support XQuery validation, Oxygen XML Editor displays a warning when trying to validate.

The Validation options button, available in the Document > Validate menu, allows quick access to the XQuery options (on page 208) in the Oxygen XML Editor preferences.

When you open an XQuery document from a connection that supports validation (for example, MarkLogic, or eXist), by default Oxygen XML Editor uses this connection for validation. If you open an XQuery file using a MarkLogic connection, the validation resolves imports better.

Content Completion in XQuery

Oxygen XML Editor provides content completion for keywords and all known XQuery functions and operators. The Content Completion Assistant (on page 3280) can be manually activated with the (Ctrl (Meta on Mac OS)+Space) shortcut. The functions and operators are presented together with a description of the parameters and functionality, depending on the validation or transformation engine.

For some supported database engines such as MarkLogic, eXist, and Berkeley DB, the content completion list offers the specific XQuery functions implemented by that engine. This feature is available when the XQuery file has an associated transformation scenario that uses one of these database engines or the XQuery validation engine is set to one of them via a validation scenario or in the XQuery Preferences (on page 208) page. For more information about the support for working with XQuery with regard to databases, see XQuery and Databases (on page 2260).

The extension functions included in the Saxon engine are available on content completion if one of the following conditions are true:

- The edited file has a transformation scenario associated that uses as transformation engine Saxon 9.8.0.12 PE or Saxon 9.8.0.12 EE.
• The edited file has a validation scenario associated that use as validation engine Saxon 9.8.0.12 PE or Saxon 9.8.0.12 EE.
• The validation engine specified in Preferences (on page 208) is Saxon 9.8.0.12 PE or Saxon 9.8.0.12 EE.

If the Saxon namespace (http://saxon.sf.net) is mapped to a prefix, the functions are presented using this prefix. Otherwise, the default prefix for the Saxon namespace (saxon) is used.

If you want to use a function from a namespace mapped to a prefix, just type that prefix and the content completion displays all the XQuery functions from that namespace. When the default namespace is mapped to a prefix, the XQuery functions from this namespace offered by content completion are also prefixed. Otherwise, only the function name being used.

The content completion pop-up window presents all the variables and functions from both the edited XQuery file and its imports.

Figure 519. XQuery Content Completion

Syntax Highlighting in XQuery

Oxygen XML Editor supports syntax highlighting in Text mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for XQuery files, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79).
2. Go to Editor > Syntax Highlight (on page 178).
3. Select and expand the XQuery/XPath section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

You can see the effects of your changes in the Preview pane.

Related Information:
Editing XQuery documents may lead to large chunks of content that are not easily readable by human audience. Also, each developer may have a particular way of writing XQuery code. Oxygen XML Editor assists you in maintaining a consistent code writing style with the Format and Indent action that is available in the Document > Source menu and also on the toolbar.

The Format and Indent action achieves this by performing the following steps:

- Manages whitespaces, by collapsing or inserting space characters where needed.
- Formats complex expressions on multiple, more readable lines by properly indenting each of them. The amount of whitespaces that form an indent unit is controlled through one of the Indent with tabs and Indent size options from the Format Preferences page (on page 157).

**Note:** These operations can be performed only if your XQuery document conforms with XQuery 1.0, 3.0, 3.1, or XQuery Update Facility 1.0 specifications. If the Format and Indent operation fails, the document is left unaltered and an error message is presented in the Results view (on page 357).

Folding in XQuery Documents

In a large XQuery document, the instructions enclosed in the '{' and '}' characters can be collapsed so that only the needed instructions remain in focus. The same folding features available for XML documents (on page 840) are also available in XQuery documents.

Figure 520. Folding in XQuery Documents
There is available the action **Go to Matching Bracket Ctrl + Shift + G** on contextual menu of XQuery editor for going to matching character when cursor is located at '{' character or '}' character. It helps for finding quickly matching character of current folding element (on page 3282).

**XQuery Outline View**

The XQuery document structure is presented in the **Outline** view. The outline tree presents the list of all the components (namespaces, imports, variables, and functions) from both the edited XQuery file and its imports and it allows quick access to components. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

Figure 521. XQuery Outline View
The following actions are available in the Settings menu on the Outline view toolbar:

**Selection update on cursor move**

Controls the synchronization between Outline view and source document. The selection in the Outline view can be synchronized with the cursor moves or the changes performed in the XQuery editor. Selecting one of the components from the Outline view also selects the corresponding item in the source document.

**Sort**

Allows you to alphabetically sort the XQuery components.

**Show all components**

Displays all collected components starting from the current file. This option is set by default.

**Show only local components**

Displays the components defined in the current file only.

**Group by location/namespace/type**

Allows you to group the components by location, namespace, and type. When grouping by namespace, the main XQuery module namespace is presented first in the Outline view.

If you know the component name, you can search it in the Outline view by typing its name in the filter text field from the top of the view or directly on the tree structure. When you type the component
name in the filter text field you can switch to the tree structure using the arrow keys of the keyboard, (Enter), (Tab), (Shift-Tab). To switch from tree structure to the filter text field, you can use (Tab), (Shift-Tab).

**Tip:** The search filter is case insensitive. The following wildcards are accepted:

- `*` - any string
- `?` - any character
- `,` - patterns separator

If no wildcards are specified, the string to search is used as a partial match.

The upper part of the **Outline** view contains a filter box that allows you to focus on the relevant components. Type a text fragment in the filter box and only the components that match it are presented. For advanced usage you can use wildcard characters (such as `*`, `?`) and separate multiple patterns with commas.

**XQuery Builder View**

The **XPath/XQuery Builder** view allows you to compose complex XQuery expressions and execute them over the currently edited XML document. You can use the `doc()` function to specify the source file for which the expressions are executed. When you connect to a database, the expressions are executed over that database. If you are using the **XPath/XQuery Builder** view and the current file is an XSLT document, Oxygen XML Editor executes the expressions over the XML document in the associated scenario.

If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

The upper part of the view contains the following actions:

**XPath version chooser drop-down menu**

A drop-down menu that allows you to select the type of the expression you want to execute. You can choose between:

- XPath 1.0 (Xerces-driven)
- XPath 2.0, XPath 2.0 SA, XPath 3.1, XPath 3.1 SA, Saxon-HE XQuery, Saxon-PE XQuery, or Saxon-EE XQuery (all of them are Saxon-driven)
- Custom connection to XML databases that can execute XQuery expressions

**Note:** The results returned by XPath 2.0 SA and XPath 3.1 SA have a location limited to the line number of the start element (there are no column information and no end specified).
Note: Oxygen XML Editor uses Saxon to execute XPath 3.1 expressions. Since Saxon implements a part of the 3.1 functions, when using a function that is not implemented, Oxygen XML Editor returns a compilation error.

Execute XPath button

Use this button to start the execution of the XPath or XQuery expression you are editing. The result of the execution is displayed in the Results view (on page 357).

Favorites button

Allows you to save certain expressions that you can later reuse. To add an expression as a favorite, press the star button and enter a name for it. The star turns yellow to confirm that the expression was saved. Expand the drop-down menu next to the star button to see all your favorites. Oxygen XML Editor automatically groups favorites in folders named after the method of execution.

History drop-down menu

Keeps a list of the last 15 executed XPath or XQuery expressions. Use the ★ Clear history action from the bottom of the list to remove them.

Settings drop-down menu

Contains the following three options:

- Update on cursor move

  When selected and you navigate through a document, the XPath expression corresponding to the XML node at the current cursor position is displayed. For JSON documents, it displays the XPath expression for the current property.

- Evaluate as you type

  When you select this option, the XPath expression you are composing is evaluated in real time.

  Note: This option and the automatic validation are disabled when you edit huge documents (on page 781) or when the scope is other than Current file.

- Options

  Opens the Preferences page of the currently selected processing engine.

XPath scope menu
Oxygen XML Editor allows you to define a scope for which the XPath operation will be executed. You can choose where the XPath expression will be executed:

- **Current file** - Current selected file only.
- **Project** - All the files in the project.
- **Selected project resources** - The files selected in the project.
- **All opened files** - All files opened in the application.
- **Current DITA Map hierarchy** - All resources referenced in the currently selected DITA map, opened in the DITA Maps Manager view (on page 2990).
- **Opened archive** - Files open in the Archive Browser view (on page 2191).
- **Working sets** - The selected working sets (on page 3288).

At the bottom of the scope menu the following scope configuration actions are available:

- **Configure XPath working sets** - Allows you to configure and manage collections of files and folders, encapsulated in logical containers called working sets (on page 3288).
- **XPath file filter** - You can filter the files from the selected scope for which the XPath expression will be executed. By default, the XPath expression will be executed only on XML or JSON files, but you can also define a set of patterns that will filter out files from the current scope. If you select the **Include archive** option, the XPath expression will be also executed on the files in any archive (including EPUB and DocX) found at the current scope.

Figure 522. XPath/XQuery Builder View
While you edit an XPath or XQuery expression, Oxygen XML Editor assists you with the following features:

- **Content Completion Assistant (on page 3280)** - It offers context-dependent proposals and takes into account the cursor position in the document you are editing. The set of functions proposed by the **Content Completion Assistant** also depends on the engine version. Select the engine version from the drop-down menu available in the toolbar.

- Syntax Highlighting - Allows you to identify the components of an expression. To customize the colors of the components of the expression, open the Preferences dialog box (Options > Preferences) (on page 79) and go to **Editor > Syntax Highlight** (on page 178).

- Automatic validation of the expression as you type.

  **Note:** When you type invalid syntax, a red serrated line underlines the invalid fragments.

- Function signature and documentation balloon, when the cursor is located inside a function.

The usual edit actions (Cut, Copy, Paste, Select All, Undo, Redo) are available in the contextual menu of the top editable part of the view.
XQuery Input View

The structure of the source documents of an edited XQuery is displayed in a tree form in a view called the **XQuery Input** view. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu. The tree nodes represent the elements of the documents.

You can use the **XQuery Input** view to drag and drop a node into the editing area to quickly insert XQuery expressions.

**Figure 523. XQuery Input View**

![XQuery Input View]

**Example:**

For the following XML documents:

```xml
<movies>
  <movie id="1">
    <title>The Green Mile</title>
    <year>1999</year>
  </movie>
  <movie id="2">
    <title>Taxi Driver</title>
    <year>1976</year>
  </movie>
</movies>

<reviews>
  <review id="100" movie-id="1">
    <rating>5</rating>
    <comment>It is made after a great Stephen King book.</comment>
  </review>
</reviews>
```
and the following XQuery:

```xml
let $review := doc("reviews.xml")
for $movie in doc("movies.xml")/movies/movie
let $movie-id := $movie/@id
return
<movie id="{$movie/@id}">
  {$movie/title}
  {$movie/year}
  <maxRating>
    {}
  </maxRating>
</movie>
```

If you drag the `review` element and drop it between the braces, the following pop-up menu is displayed:

Select **FLWOR review**, the resulting document will look like this:
Generating HTML Documentation for an XQuery Document

To generate HTML documentation for an XQuery document, use the XQuery Documentation dialog box. It is opened with the XQuery Documentation action that is available from the Tools > Generate Documentation menu or from the Generate Documentation submenu in the contextual menu of the Project view (on page 333).

The dialog box allows you to configure a set of parameters for the process of generating the HTML documentation.

Figure 524. XQuery Documentation Dialog Box

The following options are available:

- **Input** - The full path to the XQuery file must be specified in one of the two fields in this section:
  - **URL** - The URL of the file in which you want to generate the documentation.
  - **Folder** - The directory that contains the files for which you want to generate the documentation. You can also specify the XQuery file extensions to be searched for in the specified directory.

- **Default function namespace** - Optional URI for the default namespace for the submitted XQuery.

```xml
for $review in doc("reviews.xml")/reviews/review
return
  where (1=1
      and ($review/xmivis-id = $xmivis/id)
  )
return $review/author
```
• **Predefined function namespaces** - Optional, engine-dependent, predefined namespaces that the submitted XQuery refers to. They allow the conversion to generate annotation information to support the presentation component hypertext linking (only if the predefined modules have been loaded into the local xqDoc XML repository).

• **Open in Browser/System Application** - Select this option if you want the result to be opened in the system application associated with that file type.

[Note: To set the browser or system application that will be used, open the Preferences dialog box ([Options > Preferences](on page 79)), go to **Global**, and set it in the **Default Internet browser** field. This will take precedence over the default system application settings.]

• **Output** - Allows you to specify where the generated documentation is saved on disk.

### Transforming XML Documents Using XQuery

XQuery is similar to XSL stylesheets, both being capable of transforming an XML input into another format. You specify the input URL when you define the transformation scenario ([on page 1674]). The result can be saved and opened in the associated application. You can even run a FO processor ([on page 1738]) on the output of an XQuery. The transformation scenarios may be shared between many XQuery files, are exported ([on page 276]) together with the XSLT scenarios and can be managed in the **Configure Transformation Scenario** dialog box ([on page 1762]), or in the **Scenarios** view ([on page 1768]). The transformation can be performed on the XML document specified in the **XML URL** field, or, if this field is empty, the documents referenced from the query expression. The parameters of XQuery transforms must be set in the **Parameters** dialog box ([on page 1674]). Parameters that are in a namespace must be specified using the qualified name (for example, a `param` parameter in the `http://www.oxygenxml.com/ns` namespace must be set with the name `{http://www.oxygenxml.com/ns}param`).

The transformation uses one of the Saxon 9.8.0.12 HE, Saxon 9.8.0.12 PE, Saxon 9.8.0.12 EE processors, a database connection ([details can be found in the **Working with Databases** ([on page 2198]) chapter - in the **XQuery transformation** ([on page 2261]) section]) or any XQuery processor that provides an XQJ API implementation.

The Saxon 9.8.0.12 EE processor also supports XQuery 3.1 transformations.

**Related Information:**

• **XQuery and Databases** ([on page 2260])
Display XQuery Result in Sequence View

The result of an XQuery executed on a database can be very large and sometimes only a part of the full result is needed. To avoid the long time necessary for fetching the full result, select the Present as a sequence option (on page 1697) in the Output tab of the Edit scenario dialog box. This option fetches only the first chunk of the result. Clicking the More results available label that is displayed at the bottom of the Sequence view fetches the next chunk of results.

The size of a chunk can be set with the Size limit of Sequence view option (on page 209). The XQuery options button from the More results available label provides a quick access to this option by opening the XQuery preferences page (on page 208) where the option can be modified.

Figure 525. XQuery transformation result displayed in Sequence view

A chunk of the XQuery transformation result is displayed in the Sequence view.

Figure 526. XQuery transformation result displayed in Sequence view
Tip: You can right-click the results in the Sequence view and if the item is an XML element, the Go to definition action will open the XML file from where the queried node was obtained.

Advanced Saxon HE/PE/EE XQuery Transformation Options

The XQuery transformation scenario allows you to configure advanced options that are specific for the Saxon HE (Home Edition), PE (Professional Edition), and EE (Enterprise Edition) engines. They are the same options as those in the Saxon HE/PE/EE preferences page (on page 209) but they are configured as a specific set of transformation options for each transformation scenario, while the values set in the preferences page apply as global options. The advanced options configured in a transformation scenario override the global options (on page 3283) defined in the preferences page.

Saxon-HE/PE/EE Options

The advanced options for Saxon 9.8.0.12 Home Edition (HE), Professional Edition (PE), and Enterprise Edition (EE) are as follows:

Use a configuration file ("-config")

Sets a Saxon 9.8.0.12 configuration file that is used for XQuery transformation and validation scenarios.

Enable Optimizations ("-opt")

This option is selected by default, which means that optimization is enabled. If not selected, the optimization is suppressed, which is helpful when reducing the compiling time is important, optimization conflicts with debugging, or optimization causes extension functions with side-effects to behave unpredictably.

Use linked tree model ("-tree:linked")

This option activates the linked tree model.

Recoverable errors ("-warnings")

Specifies how dynamic errors are handled. The following options can be selected:

- Recover silently ("silent") - Continues processing without reporting the error.
- Recover with warnings ("recover") - Issues a warning but continues processing.
- Signal the error and do not attempt recovery ("fatal") - Issues an error and stops processing.

Strip whitespaces ("-strip")

Specifies how the strip whitespaces operation is handled. You can choose one of the following values:
• **All** (*"all"*) - Strips all whitespace text nodes from source documents before any further processing, regardless of any `xml:space` attributes in the source document.

• **Ignore** (*"ignorable"*) - Strips all ignorable whitespace text nodes from source documents before any further processing, regardless of any `xml:space` attributes in the source document. Whitespace text nodes are ignorable if they appear in elements defined in the DTD or schema as having element-only content.

• **None** (*"none"*) - Strips no whitespace before further processing.

### Saxon-PE/EE Options

The following advanced options are specific for Saxon 9.8.0.12 Professional Edition (PE) and Enterprise Edition (EE) only:

**Allow calls on extension functions** (*"-ext"*)

If selected, calls on external functions are allowed. Selecting this option is recommended in an environment where untrusted stylesheets may be executed. It also disables user-defined extension elements and the writing of multiple output files, both of which carry similar security risks.

### Saxon-EE Options

The advanced options that are specific for Saxon 9.8.0.12 Enterprise Edition (EE) are as follows:

**Validation of the source file** (*"-val"*)

Requests schema-based validation of the source file and of any files read using `document()` or similar functions. It can have the following values:

• **Schema validation** (*"strict"*) - This mode requires an XML Schema and allows for parsing the source documents with strict schema-validation enabled.

• **Lax schema validation** (*"lax"*) - If an XML Schema is provided, this mode allows for parsing the source documents with schema-validation enabled but the validation will not fail if, for example, element declarations are not found.

• **Disable schema validation** - This specifies that the source documents should be parsed with schema-validation disabled.

**Validation errors in the result tree treated as warnings** (*"-outval"*)

Normally, if validation of result documents is requested, a validation error is fatal. Selecting this option causes such validation failures to be treated as warnings.

**Write comments for non-fatal validation errors of the result document**
The validation messages for non-fatal errors are written (wherever possible) as a comment in the result document itself.

**Enable XQuery update (**"-update:(on|off)"**)**

This option controls whether or not XQuery update syntax is accepted. The default value is off.

**Backup files updated by XQuery (**"-backup:(on|off)"**)**

If selected, backup versions for any XML files updated with an XQuery Update are generated. This option is available when the **Enable XQuery update** option is selected.

**Other Options**

**Initializer class**

Equivalent to the **-init** Saxon command-line argument. The value is the name of a user-supplied class that implements the **net.sf.saxon.lib.Initializer** interface. This initializer is called during the initialization process, and may be used to set any options required on the configuration programmatically. It is particularly useful for tasks such as registering extension functions, collations, or external object models, especially in Saxon-HE where the option cannot be set via a configuration file. Saxon only calls the initializer when running from the command line, but the same code may be invoked to perform initialization when running user application code.

**Updating XML Documents using XQuery Update 1.0**

Using the bundled Saxon 9.8.0.12 EE XQuery processor Oxygen XML Editor offers support for XQuery Update 1.0. The XQuery Update Facility provides expressions that can be used to make persistent changes to instances of the XQuery 1.0 and XPath 2.0 Data Model. Thus, besides querying XML documents, you can modify them using the various insert/delete/modify/create methods available in the **XQuery Update 1.0** standard.

Choose Saxon 9.8.0.12 EE as a transformer in the scenario associated with the XQuery files containing update statements and Oxygen XML Editor will notify you if the update was successful.

**Example: Using XQuery Update to modify a tag name in an XML file**

```
rename node doc("books.xml")//publisher[1]/book[1] as "firstBook"
```
Editing WSDL Documents

WSDL is an XML format for describing network services as a set of endpoints operating on messages containing either document-oriented or procedure-oriented information. The operations and messages are described abstractly, and then bound to a concrete network protocol and message format to define an endpoint. Related concrete endpoints are combined into abstract endpoints (services).

Oxygen XML Editor provides a special type of editor dedicated to WSDL documents. The WSDL editor offers support for validation, a specialized Content Completion Assistant (on page 3280), a component oriented Outline view (on page 1358), searching and refactoring operations, and support to generate documentation.

Both WSDL version 1.1 and 2.0 are supported and SOAP versions 1.1 and 1.2. That means that in the location where a SOAP extension can be inserted the Content Completion Assistant offers elements from both SOAP 1.1 and SOAP 1.2. Validation of SOAP requests is executed first against a SOAP 1.1 schema and then against a SOAP 1.2 schema. In addition to validation against the XSD schemas, Oxygen XML Editor also checks if the WSDL file conforms with the WSDL specification (available only for WSDL 1.1 and SOAP 1.1).

In the following example you can see how the errors are reported.

Figure 527. Validating a WSDL file

For more information about the WSDL editing support in Oxygen XML Editor, watch our video demonstration:

https://www.youtube.com/embed/OS5Ucm9b8sY

Related Information:

- Editing XML Documents in Text Mode (on page 828)
Editing WSDL Documents in the Master Files Context

Smaller interrelated modules that define a complex WSDL structure cannot be correctly edited or validated individually, due to their interdependency with other modules. Oxygen XML Editor provides the support for defining the main module (or modules), allowing you to edit any of the imported/included files in the context of the larger WSDL structure.

You can set a main WSDL document either using the master files support from the Project view (on page 726), or using a validation scenario.

To set a master file using a validation scenario, add validation units that point to the main modules. Oxygen XML Editor warns you if the current module is not part of the dependencies graph computed for the main WSDL document. In this case, it considers the current module as the main WSDL document.

The advantages of editing in the context of a master file (on page 3284) include:

- Correct validation of a module in the context of a larger WSDL structure.
- Content Completion Assistant (on page 3280) displays all components valid in the current context.
- The Outline view (on page 1358) displays the components collected from the entire WSDL structure.

Note: When you edit an XML schema document that has a WSDL document set as master, the validation operation is performed over the master WSDL document.

For more information about editing WSDL documents in the master files context, watch our video demonstration:

https://www.youtube.com/embed/gn_YPD5xDCo

Validating WSDL Documents

By default, WSDL files are validated as you type. To change this, open the Preferences dialog box (Options > Preferences) (on page 79), go to Editor > Document Checking, and deselect the Enable automatic validation option (on page 181).

To validate a WSDL document manually, select the Validate action from the Validation toolbar drop-down menu or the Document > Validate menu. The validation problems are highlighted directly in the editor, making it easy to locate and fix any issues.
Content Completion Assistance in WSDL Documents

The Content Completion Assistant (on page 3280) is a powerful feature that enhances the editing of WSDL documents. It helps you define WSDL components by proposing context-sensitive element names. It can be manually activated with the Ctrl + Space (Command + Space on OS X) shortcut.

Another important capability of the Content Completion Assistant is to propose references to the defined components when you edit attribute values. For example, when you edit the type attribute of a binding element, the Content Completion Assistant proposes all the defined port types. Each proposal that the Content Completion Assistant offers is accompanied by a documentation hint.

❗ Note: XML schema specific elements and attributes are offered when the current editing context is the internal XML schema of a WSDL document.

Figure 528. WSDL Content Completion Assistant

❗ Note: If you are using the concept of master files (on page 3284) to import/include modules, the Content Completion Assistant collects its components starting from the master files. The master files can be defined in the project or in the associated validation scenario. For more information about the Master Files support in Oxygen XML Editor, see Defining Master Files at Project Level (on page 726).

Namespace prefixes in the scope of the current context are presented at the top of the content completion assistance window to speed up the insertion into the document of prefixed elements.

Figure 529. Namespace Prefixes in the Content Completion Assistant
For the common namespaces, such as XML Schema namespace (http://www.w3.org/2001/XMLSchema) or SOAP namespace (http://schemas.xmlsoap.org/wsdl/soap/), Oxygen XML Editor provides an easy mode to declare them by proposing a prefix for these namespaces.

WSDL Syntax Highlighting

Oxygen XML Editor supports syntax highlighting in Text mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for WSDL files, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79).
2. Go to Editor > Syntax Highlight (on page 178).
3. Select and expand the XML section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.
5. Select the XML tab in the Preview pane to see the effects of your changes.

Tip: Oxygen XML Editor also allows you to specify syntax highlighting colors for specific XML elements and attributes with specific namespace prefixes. This can be done in the Editor > Syntax Highlight > Elements/Attributes by Prefix preferences page (on page 179).

Related Information:

• Customize Syntax Highlight colors (on page 178)

WSDL Outline View

The Outline view for WSDL documents displays the list of all the components (services, bindings, port types and so on) of the currently open WSDL document along with the components of its imports.

If you use the Master Files support (on page 726), the Outline view collects the components of a WSDL document starting from the master files of the current document.

By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Figure 530. WSDL Outline View
The **Outline** view can display both the components of the current document and its XML structure, organized in a tree-like fashion. You can switch between the display modes by using the **Show XML structure** and **Show components** actions in the **Settings** menu on the **Outline** view toolbar. The following actions are available:

**Filter returns exact matches**

The text filter of the **Outline** view returns only exact matches.

**Selection update on cursor move**

Controls the synchronization between the **Outline** view and the current document. The selection in the **Outline** view can be synchronized with the cursor moves or the changes in the WSDL editor. Selecting one of the components from the **Outline** view also selects the corresponding item in the current document.

When the **Show components** option is selected, the following actions are available:

- **Show XML structure**
  Displays the XML structure of the current document in a tree-like manner.

- **Sort**
  Sorts the components in the **Outline** view alphabetically.

**Show all components**

Displays all the components that were collected starting from current document or from the main document, if it is defined.
**Show referable components**
Displays all the components that you can reference from the current document.

**Show only local components**
Displays the components defined in the current file only.

**Group by location**
Groups the WSDL components by their location.

**Group by type**
Groups the WSDL components by their type.

**Group by namespace**
Groups the WSDL components by their namespace.

**Note:** By default, all the three grouping criteria are active.

When the **Show XML structure** option is selected, the following actions are available:

**Show components**
Switches the Outline view to the components display mode.

**Flat presentation mode of the filtered results**
When active, the application flattens the filtered result elements to a single level.

**Show comments and processing instructions**
Show/hide comments and processing instructions in the Outline view.

**Show element name**
Show/hide element name.

**Show text**
Show/hide additional text content for the displayed elements.

**Show attributes**
Show/hide attribute values for the displayed elements. The displayed attribute values can be changed from the Outline preferences panel (on page 259).

**Configure displayed attributes**
Displays the XML Structured Outline preferences page (on page 259).

The following contextual menu actions are available in the Outline view when the **Show components** option is selected in the **Settings** menu:

**Edit Attributes**
Opens a dialog box that allows you to edit the attributes of the currently selected component.

Cut
Cuts the currently selected component.

Copy
Copies the currently selected component.

Delete
Deletes the currently selected component.

Search references
Searches for the references of the currently selected component.

Search references in
Searches for the references of the currently selected component in the context of a scope that you define.

Component dependencies
Opens the Component Dependencies view (on page 1365) that displays the dependencies of the currently selected component.

Resource Hierarchy
Opens the Resource Hierarchy/Dependencies view (on page 1363) that displays the hierarchy for the currently selected resource.

Resource Dependencies
Opens the Resource Hierarchy/Dependencies view (on page 1363) that displays the dependencies of the currently selected resource.

Rename Component in
Renames the currently selected component in the context of a scope that you define.

The following contextual menu actions are available in the Outline view when the Show XML structure option is selected in the Settings menu:

Append Child
Displays a list of elements that you can insert as children of the current element.

Insert Before
Displays a list of elements that you can insert as siblings of the current element, before the current element.

Insert After
Displays a list of elements that you can insert as siblings of the current element, after the current element.

**Edit Attributes**

Opens a dialog box that allows you to edit the attributes of the currently selected component.

**Toggle Comment**

Comments/uncomments the currently selected element.

**Search references**

Searches for the references of the currently selected component.

**Search references in**

Searches for the references of the currently selected component in the context of a scope that you define.

**Component dependencies**

Opens the Component Dependencies view (on page 1365) that displays the dependencies of the currently selected component.

**Rename Component in**

Renames the currently selected component in the context of a scope that you define.

**Cut**

Cuts the currently selected component.

**Copy**

Copies the currently selected component.

**Delete**

Deletes the currently selected component.

**Expand More**

Expands the structure of a component in the Outline view.

**Collapse All**

Collapses the structure of all the component in the Outline view.

To switch from the tree structure to the text filter, use Tab and Shift-Tab.

**Tip:** The search filter is case insensitive. The following wildcards are accepted:

- `*` - any string
- `?` - any character
• , - patterns separator

If no wildcards are specified, the string to search is used as a partial match.

The content of the Outline view and the editing area are synchronized. When you select a component in the Outline view, its definition is highlighted in the editing area.

**WSDL Resource Hierarchy/Dependencies View in WSDL Documents**

The Resource Hierarchy/Dependencies view displays the hierarchy or dependencies for a WSDL resource. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

**Note:** The hierarchy of a WSDL resource includes the hierarchy of imported XML Schema resources. The dependencies of an XML Schema resource present the WSDL documents that import the schema.

To view the hierarchy or dependencies of a WSDL document, select the document in the Project view (on page 333) and choose Resource Hierarchy or Resource Dependencies from the contextual menu.

![Figure 531. Resource Hierarchy/Dependencies View](image)

The following actions are available on the toolbar of the Resource Hierarchy/Dependencies view:

- **Refresh**
  Refreshes the Hierarchy/Dependencies structure.

- **Stop**
  Stops the hierarchy/dependencies computing.
Show Hierarchy

Allows you to choose a resource to compute the hierarchy structure.

Show Dependencies

Allows you to choose a resource to compute the dependencies structure.

Configure dependencies search scope

Allows you to configure a scope to compute the dependencies structure. There is also an option for automatically using the defined scope for future operations.

History

Provides access to the list of previously computed dependencies. Use the Clear history button to remove all items from this list.

The contextual menu for a resource listed in the Resource Hierarchy/Dependencies view contains the following actions:

Open

Opens the resource. You can also double-click a resource in the Hierarchy/Dependencies structure to open it.

Go to reference

Opens the source document where the resource is referenced.

Copy location

Copies the location of the resource.

Move resource

Moves the selected resource.

Rename resource

 Renames the selected resource.

Show Resource Hierarchy

 Shows the hierarchy for the selected resource.

Show Resource Dependencies

 Shows the dependencies for the selected resource.

Add to Master Files

 Adds the currently selected resource in the Master Files directory (on page 726).

Expand All

Expands all the children of the selected resource from the Hierarchy/Dependencies structure.
Collapse All

Collapses all children of the selected resource from the Hierarchy/Dependencies structure.

Tip: When a recursive reference is encountered in the Hierarchy view, the reference is marked with a special icon.

Note: The Move resource or Rename resource actions give you the option to update the references to the resource (on page 1365).

Related Information:

- Working with Modular XML Files in the Master Files Context (on page 1126)
- Search and Refactor Operations Scope (on page 1129)

Moving/Renaming WSDL Resources

You can move and rename a resource presented in the Resource/Hierarchy Dependencies view, using the Rename resource and Move resource refactoring actions from the contextual menu.

When you select the Rename action in the contextual menu of the Resource/Hierarchy Dependencies view, the Rename resource dialog box is displayed. The following fields are available:

- New name - Presents the current name of the edited resource and allows you to modify it.
- Update references of the renamed resource(s) - Select this option to update the references to the resource you are renaming. A Preview option is available that allows you to see what will be updated before selecting Rename to process the operation.

When you select the Move action from the contextual menu of the Resource/Hierarchy Dependencies view, the Move resource dialog box is displayed. The following fields are available:

- Destination - Presents the path to the current location of the resource you want to move and gives you the option to introduce a new location.
- New name - Presents the current name of the moved resource and gives you the option to change it.
- Update references of the moved resource(s) - Select this option to update the references to the resource you are moving, in accordance with the new location and name. A Preview option is available that allows you to see what will be updated before selecting Move to process the operation.
WSDL Component Dependencies View

The Component Dependencies view allows you to see the dependencies for a selected component. This is helpful if you want to see where components are used in the entire hierarchy. For example, if you want to find all the references where a given component is used.

If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

To see the dependencies of a WSDL component:

1. Right-click the desired component in the editor or Outline view.
2. Select the Component Dependencies action from the contextual menu.

This action is available for all WSDL components (messages, port types, operations, bindings, and so on).

If a component contains multiple references, a small table is displayed at the bottom of the view that contains all the references. When a recursive reference is encountered, it is marked with a special icon.

Figure 532. Component Dependencies View

The Component Dependencies view includes the following toolbar actions:

- **Refresh**
  
  Refreshes the dependencies structure.

- **Stop**
  
  Stops the dependency computation.

- **Configure**
  
  Allows you to choose the search scope for computing the dependencies structure. This is helpful for making sure all imported/included resources are computed.

- **History**
Allows you to select from a list of the most recently used dependency computations.

In addition, the following actions are available in the contextual menu:

**Go to First Reference**

Selects the first reference of the currently selected component in the dependencies tree.

**Go to Component**

Shows the definition of the currently selected component in the dependencies tree.

Related Information:

- Searching and Refactoring Operations Scope in WSDL Documents *(on page 1369)*

---

### Highlight Component Occurrences in WSDL Documents

When you position your mouse cursor over a component in a WSDL document, Oxygen XML Editor searches for the component declaration and all its references and highlights them automatically.

Customizable colors are used: one for the component definition and another one for component references. Occurrences are displayed until another component is selected.

To change the default behavior of Highlight Component Occurrences, open the Preferences dialog box *(Options > Preferences)* *(on page 79)* and go to Editor > Mark Occurrences. You can also trigger a search using the Search > Search Occurrences in File () action from contextual menu. Matches are displayed in separate tabs of the Results view *(on page 357)*.

### Searching and Refactoring Operations in WSDL Documents

#### Search Actions

The following search actions are available from the Search submenu in the contextual menu of the current editor or from the Document > References menu:

- **Search References**

  Searches all references of the item found at current cursor position in the defined scope, if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box is displayed and you have the possibility to define another search scope.
Searches all references of the item found at current cursor position in the file or files that you specify when define a scope in the **Search References** dialog box.

**Search Declarations**

Searches all declarations of the item found at current cursor position in the defined scope if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box will be displayed and you have the possibility to define another search scope.

**Search Declarations in**

Searches all declarations of the item found at current cursor position in the file or files that you specify when you define a scope for the search operation.

**Search Occurrences in File**

Searches all occurrences of the item at the cursor position in the currently edited file.

The following action is available from the **Document > Schema** menu:

**Go to Definition**

Takes you to the location of the definition of the current item.

**Note:** You can also use the **Ctrl + Single-Click** (**Command + Single-Click on OS X**) shortcut on a reference to display its definition.

**Refactoring Actions**

The following refactoring actions are available from the **Refactoring** submenu from the **Document > Refactoring** menu or in the contextual menu of the current editor:

**Rename Component**

Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the **Esc** or **Enter** key on your keyboard.

**Rename Component in**

Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the **Preview** button, you can view the files to be affected by the action.

Figure 533. Rename Identity Constraint Dialog Box
Searching and Refactoring Operations Scope in WSDL Documents

The scope is a collection of documents that define the context of a search and refactor operation. To control it you can use the Change scope operation, available in the Quick Assist action set or on the Resource Hierarchy/Dependency View toolbar. You can restrict the scope to the current project or to one or multiple working sets (on page 3288). The Use only Master Files, if enabled checkbox allows you to restrict the scope of the search and refactor operations to the resources from the Master Files directory. Click read more for details about the Master Files support (on page 726).

Figure 534. Change Scope Dialog Box
The scope you define is applied to all future search and refactor operations until you modify it. Contextual menu actions allow you to add or delete files, folders, and other resources to the working set (on page 3288) structure.

Quick Assist Support in WSDL Documents

The Quick Assist feature (on page 3286) is activated automatically when the cursor is positioned over the name of a component. It is accessible via a yellow bulb icon (💡) placed at the current line in the stripe on the left side of the editor. Also, you can invoke the quick assist menu by using the Alt + 1 (Meta + Alt + 1 on Mac OS X) keyboard shortcuts.

Figure 535. WSDL Quick Assist Support

The Quick Assist support offers direct access to the following actions:

- Rename Component in
Renames the component and all its dependencies.

**Search Declarations**
Searches the declaration of the component in a predefined scope. It is available only when the context represents a component name reference.

**Search References**
Searches all references of the component in a predefined scope.

**Component Dependencies**
Searches the component dependencies in a predefined scope.

**Change Scope**
Configures the scope that will be used for future search or refactor operations.

**Rename Component**
Allows you to rename the current component in-place.

**Search Occurrences**
Searches all occurrences of the component within the current file.

---

### Generating Documentation for WSDL Documents

You can use Oxygen XML Editor to generate detailed documentation for the components of a WSDL document in HTML format. You can select the WSDL components to include in your output and the level of details to present for each of them. Also, the components are hyperlinked. You can also generate the documentation in a custom output format (on page 1375) by using a custom stylesheet.

**Note:** The WSDL documentation includes the XML Schema components that belong to the internal or imported XML schemas.

To generate documentation for a WSDL document, select **WSDL Documentation** from the **Tools > Generate Documentation** menu or from the **Generate Documentation** submenu in the contextual menu of the **Project view** (on page 333).

Figure 536. WSDL Documentation Dialog Box
The **Input URL** field of the dialog box must contain the full path to the WSDL document that you want to generate documentation for. The WSDL document may be a local or a remote file. You can specify the path to the WSDL file by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.

### Output Tab

The following options are available in the **Output** tab:

- **Format** - Allows you to choose between the following formats:
  - **HTML** - The documentation is generated in [HTML output format](on page 1374).
  - **Custom** - The documentation is generated in a custom output format (on page 1375), allowing you to control the output. Click the **Options** button to open a **Custom format options** dialog box where you can specify a custom stylesheet for creating the output. There is also an option to **Copy additional resources to the output folder** and you can select the path to the additional **Resources** that you want to copy. You can also choose to keep the intermediate XML files created during the documentation process by deselecting the **Delete intermediate XML file** option.

- **Output file** - You can specify the path of the output file by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.

- **Split output into multiple files** - Instructs the application to split the output into multiple files. For large WSDL documents, choosing a different split criterion may generate smaller output files providing a faster documentation browsing. You can choose to split them by namespace, location, or component name.
• **Open in Browser/System Application** - Opens the result in the system application associated with the output file type.

**Note:** To set the browser or system application that will be used, open the **Preferences** dialog box (Options > Preferences) (on page 79), go to **Global**, and set it in the **Default Internet browser** field. This will take precedence over the default system application settings.

• **Keep only the annotations with xml:lang set to** - The generated output will contain only the annotations with the `xml:lang` attribute set to the selected language. If you choose a primary language code (for example, `en` for English), this includes all its possible variations (en-us, en-uk, etc.).

**Setting Tab**

When you generate documentation for a WSDL document, you can choose what components to include in the output and the details to be included in the documentation.

**Figure 537. Settings Tab of the WSDL Documentation Dialog Box**

The **Settings** tab allows you to choose whether or not to include the following:

• **Components**
  - **Services** - Specifies whether or not the generated documentation includes the WSDL services.
  - **Bindings** - Specifies whether or not the generated documentation includes the WSDL bindings.
- **Port Types** - Specifies whether or not the generated documentation includes the WSDL port types.
- **Messages** - Specifies whether or not the generated documentation includes the WSDL messages.
- **XML Schema Components** - Specifies whether or not the generated documentation includes the XML Schema components.
- **Only global elements and types** - Specifies whether or not the generated documentation includes only global elements and types.

**Component Details**
- **Namespace** - Presents the namespace information for WSDL or XML Schema components.
- **Location** - Presents the location information for each WSDL or XML Schema component.
- **Used by** - Presents the list of components that reference the current one.
- **Documentation** - Presents the component documentation. If you choose *Escape XML Content*, the XML tags are presented in the documentation.
- **Source** - Presents the XML fragment that defines the current component.
- **Instance** - Generates a sample XML instance for the current component.

**Note:** This option applies to the XML Schema components only.
- **XML Schema Diagram** - Displays the diagram for each XML Schema component. You can choose the image format (JPEG, PNG, GIF, SVG) to use for the diagram section.
- **Diagram annotations** - Specifies whether or not the annotations of the components presented in the diagram sections are included.

**Generate index** - Displays an index with the components included in the documentation.
- **Include local elements and attributes** - If selected, local elements and attributes are included in the documentation index.
- **Include resource hierarchy** - Specifies whether or not the resource hierarchy for an XML Schema documentation is generated. It is deselected by default.

**Export settings** - Save the current settings in a settings file for further use (for example, with the exported settings file you can generate the same documentation from the command-line interface). (on page 1376)

**Import settings** - Reloads the settings from the exported file.

**Generate** - Use this button to generate the WSDL documentation.

Generating WSDL Documentation in HTML Format

The WSDL documentation generated in HTML format is presented in a visual diagram style with various sections, hyperlinks, and options.

Figure 538. WSDL Documentation in HTML Format
The documentation of each component is presented in a separate section. The title of the section is composed of the component type and the component name. The component information (namespace, documentation, etc.) is presented in a tabular form.

If you choose to split the output into multiple files, the table of contents is displayed in the left frame and is divided in two tabs: **Components** and **Resource Hierarchy**.

The **Components** tab allows you to group the contents by namespace, location, or component type. The WSDL components from each group are sorted alphabetically. The **Resource Hierarchy** tab displays the dependencies between WSDL and XML Schema modules in a tree-like fashion. The root of the tree is the WSDL document that you generate documentation for.

After the documentation is generated, you can collapse or expand details for some WSDL components by using the **Showing** options or the **Collapse** or **Expand** buttons.

Figure 539. Showing Options
Generating WSDL Documentation in a Custom Format

To obtain the default HTML documentation output from a WSDL document, Oxygen XML Editor uses an intermediary XML document to which it applies an XSLT stylesheet. To create a custom output from your WSDL document, edit the wsdlDocHtml.xsl XSLT stylesheet or create your own.

**Note:** The wsdlDocHtml.xsl stylesheet that is used to obtain the HTML documentation is located in the `[OXYGEN_INSTALL_DIR]/frameworks/wsdl_documentation/xsl` folder.

**Note:** The intermediary XML document complies with the wsdlDocSchema.xsd XML Schema. This schema is located in the `[OXYGEN_INSTALL_DIR]/frameworks/wsdl_documentation` folder.

Figure 540. Custom Format Options Dialog Box

When using a custom format, you can also copy additional resources into the output folder or choose to keep the intermediate XML files created during the documentation process.

Generating WSDL Documentation from the Command-Line Interface

To generate documentation for a WSDL document from the command line, open the **WSDL Documentation** dialog box and click **Export settings**. Using the exported settings file you can generate the same documentation from the command line by running the following scripts:

- `wsdlDocumentation.bat` on Windows.
- `wsdlDocumentation.sh` on Mac OS X and Linux.

The scripts are located in the installation folder of Oxygen XML Editor. You can integrate the scripts in an external batch process launched from the command-line interface.

WSDL SOAP Analyzer

**WSDL SOAP Analyzer** is a tool that helps you test if the messages defined in a Web Service Descriptor (WSDL) are accepted by a Web Services server.
After you edit and validate your Web service descriptor against a mix of the XML Schemas for WSDL and SOAP, it is easy to check if the defined SOAP messages are accepted by the remote Web Services server by using the integrated WSDL SOAP Analyzer tool (available from the toolbar or Tools menu).

Oxygen XML Editor provides two ways of testing, one for the currently edited WSDL document and another for the remote WSDL documents that are published on a web server. To open the WSDL SOAP Analyzer tool for the currently edited WSDL document do one of the following:

- Click the 🔄 WSDL SOAP Analyzer toolbar button.
- Use the 🔄 WSDL SOAP Analyzer action from the Tools menu.
- Go to Open with > 🔄 WSDL SOAP Analyzer in the contextual menu of the Project (on page 333) view.

Figure 541. WSDL SOAP Analyzer Dialog Box
This tool contains a SOAP analyzer and sender for Web Services Description Language file types. The analyzer fields are as follows:

- **Services** - The list of services defined by the WSDL file.
- **Ports** - The ports for the selected service.
- **Operations** - The list of available operations for the selected service.
- **Action URL** - The script that serves the operation.
- **SOAP Action** - Identifies the action performed by the script.
- **Version** - Choose between 1.1 and 1.2. The SOAP version is selected automatically depending on the selected port.
- **Request Editor** - It allows you to compose the web service request. When an action is selected, Oxygen XML Editor tries to generate as much content as possible for the SOAP request. The envelope of the SOAP request has the correct namespace for the selected SOAP version, that is http://schemas.xmlsoap.org/soap/envelope/ for SOAP 1.1 or http://www.w3.org/2003/05/soap-envelope for SOAP 1.2. Usually you just have to change a few values for the request to be valid. The **Content Completion Assistant (on page 3280)** is available for this editor and is driven by the schema that defines the type of the current message. While selecting various operations, Oxygen XML Editor remembers the modified request for each one. You can press the **Regenerate** button to overwrite your modifications for the current request with the initial generated content.
- **Attachments List** - You can define a list of file URLs to be attached to the request.
- **Response Area** - Initially it displays an auto generated server sample response so you can have an idea about how the response looks like. After pressing the **Send** button, it presents the message received from the server in response to the Web Service request. It may show also error messages. If the response message contains attachments, Oxygen XML Editor prompts you to save them, then tries to open them with the associated system application.
- **Errors List** - There may be situations where the WSDL file is respecting the WSDL XML Schema, but it fails to be valid (for example, in the case of a message that is defined by means of an element that is not found in the types section of the WSDL). In such a case, the errors are listed here. This list is presented only when there are errors.
- **Send Button** - Executes the request. A status dialog box is displayed when Oxygen XML Editor is connecting to the server.

The testing of a WSDL file is straight-forward: click the WSDL analysis button, then select the service, the port, and the operation. The editor generates the skeleton for the SOAP request. You can edit the request, eventually attach files to it and send it to the server. Watch the server response in the response area. You can find more details in the **Testing Remote WSDL Files (on page 1379)** section.

**Note:** SOAP requests and responses are automatically validated in the **WSDL SOAP Analyzer** using the XML Schemas specified in the WSDL file.
Once defined, a request derived from a Web Service descriptor can be saved with the Save button to a Web Service SOAP Call (WSSC) file for later reuse. In this way, you save time in configuring the URLs and parameters.

You can open the result of a Web Service call in an editor panel using the Open button.

Testing Remote WSDL Files

To open and test a remote WSDL file the steps are the following:

1. Go to Tools > WSDL SOAP Analyzer.

2. On the WSDL File tab enter the URL of the remote WSDL file.
   You enter the URL:
   • by typing
   • by browsing the local file system
   • by browsing a remote file system
   • by browsing a UDDI Registry (on page 1379)

3. Press the OK button.
   This will open the WSDL SOAP Analyzer tool (on page 1376). In the Saved SOAP Request tab you can open directly a previously saved Web Service SOAP Call (WSSC) file, thus skipping the analysis phase.

UDDI Registry Browser

Pressing the button in the WSDL File Opener dialog box (menu Tools > WSDL SOAP Analyzer) opens the UDDI Registry Browser dialog box.

Figure 542. UDDI Registry Browser Dialog Box
The fields of the dialog box are as follows:

- **URL** - Type the URL of an UDDI registry or choose one from the default list.
- **Keywords** - Enter the string you want to be used when searching the selected UDDI registry for available Web services.
- **Rows to fetch** - The maximum number of rows to be displayed in the result list.
- **Search by** - You can choose to search either by company or by provided service.
- **Case sensitive** - When selected, the search takes into account the keyword case.
- **Search** - The WSDL files that matched the search criteria are added in the result list.

When you select a WSDL from the list and click the **OK** button, the **UDDI Registry Browser** dialog box is closed and you are returned to the **WSDL File Opener** dialog box.

**Editing CSS Stylesheets**

Oxygen XML Editor includes a built-in editor for CSS stylesheets. This section presents the features of the CSS editor and how these features should be used. The features of the CSS editor include:

- **Create new CSS files and templates** - You can use the built-in new file wizards to create new CSS documents or templates *(on page 676).*
- **Open and Edit CSS files** - CSS files can be opened and edited in a source editing mode.
• **Validation** - Presents validation errors in CSS files.

• **Content completion** - Offers proposals for properties and the values that are available for each property.

• **Syntax highlighting** - The syntax highlighting in Oxygen XML Editor makes CSS files more readable.

• **Shortcut to open resources** - You can use Ctrl + Single-Click (Command + Single-Click on OS X) to open imported stylesheets or other resources (such as images) in the default system application for the particular type of resource.

---

**Related Information:**

- Customizing Author Mode Through CSS *(on page 2477)*

- Supported CSS Selectors *(on page 2483)*

- Supported CSS Properties *(on page 2491)*

- Oxygen CSS Extensions *(on page 2501)*

---

**Validating CSS Stylesheets**

Oxygen XML Editor includes a built-in CSS Validator, integrated with general validation support. This makes the usual validation features *(on page 1081)* for presenting errors also available for CSS stylesheets.

When you edit a CSS document, you can access the CSS validator options *(on page 188)* by selecting **Validation options** from the **Document > Validate** menu.

The CSS properties accepted by the validator are those included in the current CSS profile that is selected in the CSS validation preferences *(on page 188)*. The CSS 3 with Oxygen extensions profile includes all the CSS 3 standard properties plus the CSS extensions specific for Oxygen *(on page 2501)* that can be used in Author mode *(on page 402)*. That means all Oxygen-specific extensions are accepted in a CSS stylesheet by the built-in CSS validator *(on page 1381)* when this profile is selected.

---

**Specify Custom CSS Properties**

To specify custom CSS properties, follow these steps:
1. Create a file named CustomProperties.xml that has the following structure:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<css_keywords
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://www.oxygenxml.com/ns/css
    http://www.oxygenxml.com/ns/css/CssProperties.xsd"
    xmlns="http://www.oxygenxml.com/ns/css">
    <property name="custom">
        <summary>Description for custom property.</summary>
        <value name="customValue"/>
        <value name="anotherCustomValue"/>
    </property>
</css_keywords>
```

2. Go to your desktop and create the builtin/css-validator/ folder structure.

3. Press and hold Shift and right-click anywhere on your desktop. From the contextual menu, select Open Command Window Here.

4. In the command line, run the `jar cvf custom_props.jar builtin/` command.
   The custom_props.jar file is created.

5. Go to `[OXYGEN_INSTALL_DIR]/lib` and create the endorsed folder. Copy the custom_props.jar file to `[OXYGEN_INSTALL_DIR]/lib/endorsed`.

### Content Completion in CSS Stylesheets

A Content Completion Assistant (on page 3280), similar to the one available for XML documents (on page 844) offers the CSS properties and the values available for each property. It can be manually activated with the Ctrl + Space (Command + Space on OS X) shortcut and is context-sensitive when invoked for the value of a property. The Content Completion Assistant also includes code templates that can be used to quickly insert code fragments (on page 855) into CSS stylesheets. The code templates that are proposed include form controls, actions, and Author mode operations.

Figure 543. Content Completion in CSS Stylesheets
The properties and values available are dependent on the CSS Profile selected in the CSS preferences (on page 188). The CSS 2.1 set of properties and property values is used for most of the profiles. However, with CSS 1 and CSS 3 specific proposal sets are used.

The profile CSS 3 with Oxygen extensions includes all the CSS 3 standard properties plus the CSS extensions specific for Oxygen XML Editor (on page 2501) that can be used in Author mode (on page 402).

**Proposals for CSS Selectors** - After inserting a CSS selector, the content completion assistance will propose a list of pseudo-elements and pseudo-classes that are available for the selected CSS profile.

**Proposals for @media and @import Rules** - After inserting @media or @import <url> rules, the content completion assistance will propose a list of supported media types.

---

### Related Information:

- Specify Custom CSS Properties (on page 1381)

---

### Syntax Highlighting in CSS Files

Oxygen XML Editor supports syntax highlighting in **Text** mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for CSS files, follow these steps:

1. Open the **Preferences** dialog box (Options > Preferences) (on page 79).
2. Go to **Editor > Syntax Highlight** (on page 178).
3. Select and expand the **CSS** section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

You can see the effects of your changes in the **Preview** pane.

---

### Related Information:

- Syntax Highlight Preferences (on page 178)
CSS Outline View

The Outline view for CSS stylesheets presents the import declarations for other CSS stylesheet files and all the selectors defined in the current CSS document. The selector entries can be presented as follows:

- In the order they appear in the document.
- Sorted by the element name used in the selector.
- Sorted by the entire selector string representation.

You can synchronize the selection in the Outline view with the cursor moves or changes you make in the stylesheet document. When you select an entry from the Outline view, Oxygen XML Editor highlights the corresponding import or selector in the CSS editor.

By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Figure 544. CSS Outline View

The selectors presented in this view can be found quickly using the key search field. When you press a sequence of character keys while the focus is in the view, the first selector that starts with that sequence is selected automatically.

Folding in CSS Stylesheets

In a large CSS stylesheet document, some styles can be collapsed so that only the styles that are needed remain in focus. The same folding features available for XML documents (on page 840) are also available in CSS stylesheets.
**Editor's Note:** To enhance your editing experience, you can select entire blocks (parts of text delimited by brackets) by double-clicking somewhere inside the brackets.

### Formatting and Indenting CSS Stylesheets (Pretty Print)

If the edited CSS stylesheet becomes unreadable because of the bad alignment of the text lines, the format and indent operation available for XML documents ([on page 863](#)) is also available for CSS stylesheets. It works in the same way as for XML documents and is available as the same menu and toolbar action.

### Minifying CSS Stylesheets

*Minification* (or compression) of a CSS document is the practice of removing unnecessary code without affecting the functionality of the stylesheet.

To minify a CSS, invoke the contextual menu anywhere in the edited document and choose the `Minify CSS` action. Oxygen XML Editor opens a dialog box that allows you to:

- Set the location of the resulting CSS.
- Place each style rule on a new line.

After pressing **OK**, Oxygen XML Editor performs the following actions:

- All spaces are normalized (all leading and trailing spaces are removed, while sequences of white spaces are replaced with single space characters).
- All comments are removed.

**Editor’s Note:** The CSS minifier relies heavily upon the W3C CSS specification. If the content of the CSS file you are trying to minify does not conform with the specifications, an error dialog box will be displayed, listing all errors encountered during the processing.

The resulting CSS stylesheet gains a lot in terms of execution performance, but loses in terms of readability. The source CSS document is left unaffected.

**Editor’s Note:** To restore the readability of a minified CSS, invoke the `Format and Indent` action from the `Document > Source` menu, the `Source` submenu from the contextual menu, or `Source` toolbar. However, this action will not recover any of the deleted comments.
Editing LESS Stylesheets

Oxygen XML Editor provides support for stylesheets coded with the LESS dynamic stylesheet language. LESS extends the CSS language by adding features that allow mechanisms such as variables, nesting, mixins, operators, and functions. Oxygen XML Editor offers additional LESS-editing features that include:

- **Create new LESS files and templates** - You can use the built-in new file wizards to create new LESS documents or templates (on page 676).
- **Open and Edit LESS files** - LESS files can be opened and edited in a source editing mode.
- **Validation** - Presents validation errors in LESS files.
- **Content completion** - Offers proposals for properties and the values that are available for each property.
- **Compile to CSS** - Options are available to compile LESS files to CSS.
- **Syntax highlighting** - Oxygen XML Editor supports syntax highlighting in LESS files, although there may be some limitations in supporting all the LESS constructs.
- **Shortcut to open resources** - While editing LESS files, you can use Ctrl + Single-Click (Command + Single-Click on OS X) to open imported stylesheets or other resources (such as images) in the default system application for the particular type of resource.

For more information about LESS go to: [http://lesscss.org/](http://lesscss.org/).

Related Information:

- Customizing Author Mode Through CSS (on page 2477)
- Supported CSS Selectors (on page 2483)
- Supported CSS Properties (on page 2491)
- Oxygen CSS Extensions (on page 2501)

Validating LESS Stylesheets

Oxygen XML Editor includes a built-in LESS CSS Validator, integrated with general validation support. The usual validation features (on page 1081) for presenting errors also available for LESS stylesheets.

Oxygen XML Editor provides three validation methods:
• Automatic validation as you type - marks validation errors in the document as you are editing.
• Validation upon request, by pressing the Validate button from the Validation toolbar drop-down menu. An error list is presented in the message panel at the bottom of the editor.
• Validation scenarios, by selecting Configure Validation Scenario(s) from the Validation toolbar drop-down menu. Errors are presented in the message panel at the bottom of the editor. This is useful when you need to validate the current file as part of a larger LESS import hierarchy (for instance, you may change the URL of the file to validate to the root of the hierarchy).

Content Completion in LESS Stylesheets

A Content Completion Assistant offers the LESS properties and the values available for each property. It can be manually activated with the Ctrl + Space (Command + Space on OS X) shortcut and is context-sensitive when invoked for the value of a property in a LESS file. The Content Completion Assistant also includes code templates that can be used to quickly insert code fragments into LESS stylesheets. The code templates that are proposed include form controls, actions, and Author mode operations.

Figure 545. Content Completion in LESS Stylesheets

The properties and values available are dependent on the CSS Profile selected in the CSS preferences.

Syntax Highlighting in LESS Files

Oxygen XML Editor supports syntax highlighting in Text mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for LESS files, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79).
2. Go to Editor > Syntax Highlight (on page 178).
3. Select and expand the LESS section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

You can see the effects of your changes in the **Preview** pane.

Related Information:

- Syntax Highlight Preferences *(on page 178)*

---

**Compiling LESS Stylesheets to CSS**

When editing LESS files, you can compile the files into CSS. Oxygen XML Editor provides both manual and automatic options to compile LESS stylesheets into CSS.

⚠️ **Important:** The LESS processor works well only with files having the *UTF-8* encoding. Thus, it is highly recommended that you always use the *utf-8* encoding when working with LESS files or the files they import (other LESS or CSS files). You can use the following directive at the beginning of your files:

```
@charset "utf-8";
```

You have two options for compiling LESS files to CSS:

1. Use the contextual menu in a LESS file and select **Compile to CSS** *(Ctrl + Shift + C (Command + Shift + C on OS X))*.
2. Select the **Automatically compile LESS to CSS when saving** option *(on page 157)* (in the **Save** preferences page). If selected, when you save a LESS file it will automatically be compiled to CSS (this option is deselected by default).

⚠️ **Important:** If this option is selected, when you save a LESS file, the CSS file that has the same name as the LESS file is overwritten without warning. Make sure all your changes are made in the LESS file. Do not edit the CSS file directly, as your changes might be lost.

---

**Editing Relax NG Schemas**

An XML Schema describes the structure of an XML document and is used to validate XML document instances against it, to check that the XML instances conform to the specified requirements. If an XML instance conforms to the schema then it is said to be valid. Otherwise, it is invalid.

Oxygen XML Editor offers support for editing Relax NG schema files in the following editing modes:
- **Text editing mode (on page 1286)** - Allows you to edit Relax NG schema files in a source editing mode, along with a schema design pane with two tabs that offer a [Full Model View (on page 1390)](on_page) and [Logical Model View (on page 1391)](on_page).

- **Grid editing mode (on page 392)** - Displays Relax NG schema files in a structured spreadsheet-like grid.

- **Author editing mode (on page 893)** - The visual Author mode is also available for Relax NG schema files, presenting the schema similar to the Relax NG compact syntax. It links to imported schemas and external references. Embedded Schematron is also supported in Relax NG schemas with XML syntax.

For information about applying and detecting schemas, see [Associating a Schema to XML Documents (on page 1112)](on_page).

- [Associating a Schema to XML Documents (on page 1112)](on_page)

---

### Editing Relax NG Schema in the Master Files Context

Smaller interrelated modules that define a complex Relax NG Schema cannot be correctly edited or validated individually, due to their interdependency with other modules. For example, an element defined in a main schema document is not visible when you edit an included module. Oxygen XML Editor provides the support for defining the main module (or modules), thus allowing you to edit any of the imported/included schema files in the context of the larger schema structure.

You can set a main Relax NG document either using the [master files support from the Project view (on page 726)](on_page), or using a validation scenario.

To set a master file using a validation scenario, add validation units that point to the main schemas. Oxygen XML Editor warns you if the current module is not part of the dependencies graph computed for the main schema. In this case, it considers the current module as the main schema.

The main advantage of editing in the context of a [master file (on page 3284)](on_page) is that it provides correct validation of a module in the context of a larger schema structure.

---

Related Information:

- [Creating a New Validation Scenario (on page 1094)](on_page)
Relax NG Schema Diagram Editor

This section explains how to use the graphical diagram editor for Relax NG schemas.

Introduction to Relax NG Schema Diagram Editor

Oxygen XML Editor provides a simple, expressive, and easy-to-read schema diagram editor for Relax NG schemas.

With this new feature you can easily develop complex schemas, print them on multiple pages or save them as JPEG, PNG, or BMP images. It helps both schema authors in developing the schema and content authors who are using the schema to understand it.

Oxygen XML Editor is the only XML editor to provide a side by side source and diagram presentation and have them real-time synchronized:

- The changes you make in the Editor are immediately visible in the Diagram (no background parsing).
- Changing the selected element in the diagram selects the underlying code in the source editor.

Full Model View

When you create a new schema document or open an existing one, the editor panel is divided in two sections: one containing the schema diagram and the second the source code. The schema diagram editor has two tabs that offer a Full Model View and Logical Model View (on page 1391).

Figure 546. Relax NG Schema Editor - Full Model View
The following references can be expanded in place: patterns, includes, and external references. This expansion mechanism, coupled with the synchronization support, makes the schema navigation easy.

All the element and attribute names are editable by double-clicking the names.

Logical Model View

The **Logical Model View** presents the compiled schema in the form of a single pattern. The patterns that form the element content are defined as top level patterns with generated names. These names are generated depending of the elements name class.

Figure 547. Logical Model View for a Relax NG Schema
Symbols Used in the Schema Diagram

The views in the schema diagram editor renders all the Relax NG schema patterns with the following intuitive symbols:

- **• - define pattern with the name attribute set to the value shown inside the rectangle (in this example name ).**
- **• - define pattern with the combine attribute set to interleave and the name attribute set to the value shown inside the rectangle (in this example attlist.person ).**
- **• - define pattern with the combine attribute set to choice and the name attribute set to the value shown inside the rectangle (in this example attlist.person ).**
- **• - element pattern with the name attribute set to the value shown inside the rectangle (in this example name ).**
- **• - attribute pattern with the name attribute set to the value shown inside de rectangle (in this case note ).**
- ref pattern with the name attribute set to the value shown inside the rectangle (in this case family).

- oneOrMore pattern.

- zeroOrMore pattern.

- optional pattern.

- choice pattern.

- value pattern (for example, used inside a choice pattern).

- group pattern.

- A pattern from the Relax NG Annotations namespace (http://relaxng.org/ns/compatibility/annotations/1.0) that is treated as a documentation element in a Relax NG schema.

- text pattern.

- empty pattern.

Actions Available in the Schema Diagram Editor

When editing Relax NG schemas in Full Model View (on page 1390), the contextual menu offers the following actions:

Go to definition (Available for imported components)

This action is available for imported components from other RNG files, and it shows where that component is defined.

Append child

Appends a child to the selected component.

Insert Before

Inserts a component before the selected component.

Insert After

Inserts a component after the selected component.

Edit attributes

Edits the attributes of the selected component.
Remove

Removes the selected component.

Show only the selected component

Depending on its state (selected/not selected), either the selected component or all the diagram components are shown.

Show Annotations

Depending on its state (selected/not selected), the documentation nodes are shown or hidden.

Auto expand to references

This option controls how the schema diagram is automatically expanded. If you select it and then edit a top-level element or you make a refresh, the diagram is expanded until it reaches referenced components. If this option is left unchecked, only the first level of the diagram is expanded, showing the top-level elements. For large schemas, the editor disables this option automatically.

Collapse Children

Collapses the children of the selected view.

Expand Children

Expands the children of the selected view.

Print Selection

Prints the selected view.

Save as Image

Saves the current selection as JPEG, BMP, SVG or PNG image.

Refresh

Refreshes the schema diagram according to the changes in your code. They represent changes in your imported documents or changes that are not reflected automatically in the compiled schema).

If the schema is not valid, you see only an error message in the Logical Model View (on page 1391) instead of the diagram.

Validating Relax NG Schema Documents

By default, Relax NG schema files are validated as you type. To change this, open the Preferences dialog box (Options > Preferences) (on page 79), go to Editor > Document Checking, and deselect the Enable automatic validation option (on page 181).
To validate a Relax NG schema document manually, select the **Validate** action from the **Validation** toolbar drop-down menu or the **Document > Validate** menu. When Oxygen XML Editor validates a Relax NG schema file, it expands all the included modules so the entire schema hierarchy is validated. The validation problems are highlighted directly in the editor, making it easy to locate and fix any issues.

## Content Completion in Relax NG Schemas

The intelligent **Content Completion Assistant** *(on page 3280)* allows you to quickly identify and insert elements, attributes, and attribute values that are valid in the current editing context. All available proposals are listed in a pop-up menu displayed at the current cursor position.

The **Content Completion Assistant** is enabled by default. To disable it, open the **Preferences** dialog box *(Options > Preferences)* *(on page 79)*, go to **Editor > Content Completion**, and deselect the Enable content completion option *(on page 167)*.

When active, the **Content Completion Assistant** displays a list of context-sensitive proposals valid at the current cursor position. It can be manually activated with the **Ctrl + Space** *(Command + Space on OS X)* shortcut. You can navigate through the list of proposals by using the **Up** and **Down** keys on your keyboard. For each selected item in the list, the **Content Completion Assistant** displays a documentation window. You can customize the size of the documentation window by dragging its top, right, and bottom borders.

To insert the selected proposal in **Text** mode, do one of the following:
- Press **Enter** or **Tab** to insert both the start and end tags and position the cursor inside the start tag in a position suitable for inserting attributes.

- Press **Ctrl + Enter (Command + Enter on OS X)** to insert both the start and end tags and positions the cursor between the tags in a position where you can start typing content.

If you are using the concept of *master files (on page 3284)* to import/include modules, the **Content Completion Assistant** collects its components starting from the *master files*. The *master files* can be defined in the project or in the associated validation scenario. For more information about the *Master Files* support in Oxygen XML Editor, see **Defining Master Files at Project Level (on page 726)**.

The **Content Completion Assistant** also offers additional information for the element and attribute proposals in the form of schema annotations that is displayed in a tooltip.

Figure 548. Relax NG Content Completion Assistant

Syntax Highlighting in Relax NG Schemas

Oxygen XML Editor supports syntax highlighting in **Text** mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for Relax NG schemas, follow these steps:

1. Open the **Preferences** dialog box (**Options > Preferences**) (on page 79).
2. Go to **Editor > Syntax Highlight** (on page 178).
3. Select and expand the **XML** section in the top pane (for RELAX NG Compact Syntax schemas, select and expand the **RNC** section).
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.
5. Select the **XML** tab in the **Preview** pane to see the effects of your changes (for RELAX NG Compact Syntax schemas, the tab is **RNC**).
Tip: Oxygen XML Editor also allows you to specify syntax highlighting colors for specific XML elements and attributes with specific namespace prefixes. This can be done in the Editor > Syntax Highlight > Elements/Attributes by Prefix preferences page (on page 179).

Related Information:

• Syntax Highlight Preferences (on page 178)

Quick Fixes for DTD, XSD, and Relax NG Errors

Oxygen XML Editor offers Quick Fixes (on page 3287) for common errors that appear in XML documents that are validated against DTD, XSD, or Relax NG schemas.

Note: For XML documents validated against XSD schemas, the Quick Fixes are only available if you use the default Xerces validation engine.

Quick Fixes are available in Text mode and Author mode.

Oxygen XML Editor provides Quick Fixes for numerous types of problems, including the following:

<table>
<thead>
<tr>
<th>Problem Type</th>
<th>Available Quick Fixes</th>
</tr>
</thead>
<tbody>
<tr>
<td>A specific element is required in the current context</td>
<td>Insert the required element</td>
</tr>
<tr>
<td>An element is invalid in the current context</td>
<td>Remove the invalid element</td>
</tr>
<tr>
<td>The content of the element should be empty</td>
<td>Remove the element content</td>
</tr>
<tr>
<td>An element is not allowed to have child elements</td>
<td>Remove all child elements</td>
</tr>
<tr>
<td>Text is not allowed in the current element</td>
<td>Remove the text content</td>
</tr>
<tr>
<td>A required attribute is missing</td>
<td>Insert the required attribute</td>
</tr>
<tr>
<td>An attribute is not allowed to be set for the current element</td>
<td>Remove the attribute</td>
</tr>
<tr>
<td>The attribute value is invalid</td>
<td>Propose the correct attribute values</td>
</tr>
<tr>
<td>ID value is already defined</td>
<td>Generate a unique ID value</td>
</tr>
<tr>
<td>References to an invalid ID</td>
<td>Change the reference to an already defined ID</td>
</tr>
</tbody>
</table>

Related Information:

• Schematron Quick Fixes (SQF) (on page 1111)
Relax NG Outline View

The Outline view for Relax NG schemas presents a list with the patterns that appear in the diagram in both the Full Model View (on page 1390) and Logical Model View (on page 1391) cases and it allows for quick access to a component by name. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Figure 549. Relax NG Outline View

This view has two modes, with the tree showing either the XML structure or the defined pattern (components) collected from the current document. By default, the Outline view presents the components.

When the Show components option is selected in the Settings menu on the Outline view toolbar, the following option is available:

Show XML structure

Shows the XML structure of the current document in a tree-like manner.

The following actions are available in the Settings menu on the Outline view toolbar when the Show XML structure option is selected:

Filter returns exact matches
The text filter of the Outline view returns only exact matches.

Selection update on cursor move
Allows a synchronization between Outline view and schema diagram. The selected view from the diagram will be also selected in the Outline view.

Show components
Shows the defined pattern collected from the current document.

Flat presentation mode of the filtered results
When active, the application flattens the filtered result elements to a single level.

Show comments and processing instructions
Show/hide comments and processing instructions in the Outline view.

Show element name
Show/hide element name.

Show text
Show/hide additional text content for the displayed elements.

Show attributes
Show/hide attribute values for the displayed elements. The displayed attribute values can be changed from the Outline preferences panel (on page 259).

Configure displayed attributes
Displays the XML Structured Outline preferences page (on page 259).

The following contextual menu actions are also available in the Outline view when the Show XML structure option is selected in the Settings menu:

Append Child
Displays a list of elements that you can insert as children of the current element.

Insert Before
Displays a list of elements that you can insert as siblings of the current element, before the current element.

Insert After
Displays a list of elements that you can insert as siblings of the current element, after the current element.

Edit Attributes
Opens a dialog box that allows you to edit the attributes of the currently selected component.

**Toggle Comment**

Comments/uncomments the currently selected element.

**Search references**

Searches for the references of the currently selected component.

**Search references in**

Searches for the references of the currently selected component in the context of a scope that you define.

**Component dependencies**

Opens the Component Dependencies view (on page 1403) that displays the dependencies of the currently selected component.

**Rename Component in**

Renames the currently selected component in the context of a scope that you define.

**Cut**

Cuts the currently selected component.

**Copy**

Copies the currently selected component.

**Delete**

Deletes the currently selected component.

**Expand More**

Expands the structure of a component in the Outline view.

**Collapse All**

Collapses the structure of all the component in the Outline view.

The upper part of the Outline view contains a filter box that allows you to focus on the relevant components. Type a text fragment in the filter box and only the components that match it are presented. For advanced usage you can use wildcard characters (such as *, ?) and separate multiple patterns with commas.
RNG Resource Hierarchy/Dependencies View

The Resource Hierarchy/Dependencies view displays the hierarchy or dependencies for an RNG schema. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

If you want to see the hierarchy or dependencies of an RNG schema, select the desired schema in the Project view (on page 333) and choose Resource Hierarchy or Resource Dependencies from the contextual menu.

Figure 550. Resource Hierarchy/Dependencies View

The following actions are available on the toolbar of the Resource Hierarchy/Dependencies view:

- **Refresh**
  Refreshes the Hierarchy/Dependencies structure.

- **Stop**
  Stops the hierarchy/dependencies computing.

- **Show Hierarchy**
  Allows you to choose a resource to compute the hierarchy structure.

- **Show Dependencies**
  Allows you to choose a resource to compute the dependencies structure.

- **Configure dependencies search scope**
  Allows you to configure a scope to compute the dependencies structure. There is also an option for automatically using the defined scope for future operations.

- **History**
Provides access to the list of previously computed dependencies. Use the Clear history button to remove all items from this list.

The contextual menu for a resource listed in the Resource Hierarchy/Dependencies view contains the following actions:

**Open**

Opens the resource. You can also double-click a resource in the Hierarchy/Dependencies structure to open it.

**Go to reference**

Opens the source document where the resource is referenced.

**Copy location**

Copies the location of the resource.

**Move resource**

Moves the selected resource.

**Rename resource**

Renames the selected resource.

**Show Resource Hierarchy**

Shows the hierarchy for the selected resource.

**Show Resource Dependencies**

Shows the dependencies for the selected resource.

**Add to Master Files**

Adds the currently selected resource in the Master Files directory (on page 726).

**Expand All**

Expands all the children of the selected resource from the Hierarchy/Dependencies structure.

**Collapse All**

Collapses all children of the selected resource from the Hierarchy/Dependencies structure.

**Tip:** When a recursive reference is encountered in the Hierarchy view, the reference is marked with a special icon.

**Note:** The Move resource or Rename resource actions give you the option to update the references to the resource (on page 1365).
Moving/Renaming RNG Resources

You can move and rename a resource presented in the Resource/Hierarchy Dependencies view, using the Rename resource and Move resource refactoring actions from the contextual menu.

When you select the Rename action in the contextual menu of the Resource/Hierarchy Dependencies view, the Rename resource dialog box is displayed. The following fields are available:

- **New name** - Presents the current name of the edited resource and allows you to modify it.
- **Update references of the renamed resource(s)** - Select this option to update the references to the resource you are renaming. A Preview option is available that allows you to see what will be updated before selecting Rename to process the operation.

When you select the Move action from the contextual menu of the Resource/Hierarchy Dependencies view, the Move resource dialog box is displayed. The following fields are available:

- **Destination** - Presents the path to the current location of the resource you want to move and gives you the option to introduce a new location.
- **New name** - Presents the current name of the moved resource and gives you the option to change it.
- **Update references of the moved resource(s)** - Select this option to update the references to the resource you are moving, in accordance with the new location and name. A Preview option is available that allows you to see what will be updated before selecting Move to process the operation.

**Note:** Updating the references of a resource that is resolved through a catalog is not supported. Also, the update references operation is not supported if the path to the renamed or moved resource contains entities.

Relax NG Schema Component Dependencies View

The Component Dependencies view allows you to see the dependencies for a selected component. This is helpful if you want to see where components are used in the entire hierarchy. For example, if you want to find all the references where a given component is used.
If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

To see the dependencies of a RelaxNG component:

1. Right-click the desired component in the editor or **Outline** view.
2. Select the **Component Dependencies** action from the contextual menu.

The action is available for all named defines.

If a component contains multiple references, a small table is displayed at the bottom of the view that contains all the references. When a recursive reference is encountered, it is marked with a special icon.

**Figure 551. Component Dependencies View - Hierarchy for base.rng**

The **Component Dependencies** view includes the following toolbar actions:

- **Refresh**
  
  Refreshes the dependencies structure.

- **Stop**
  
  Stops the dependency computation.

- **Configure**
  
  Allows you to choose the search scope for computing the dependencies structure. This is helpful for making sure all imported/included resources are computed.

- **History**
  
  Allows you to select from a list of the most recently used dependency computations.

In addition, the following actions are available in the contextual menu:

- **Go to First Reference**
  
  Selects the first reference of the currently selected component in the dependencies tree.

- **Go to Component**
Shows the definition of the currently selected component in the dependencies tree.

Related Information:

- Search and Refactor Operations Scope (on page 1129)

Searching and Refactoring Actions in RNG Schemas

Search Actions

The following search actions can be applied on named defines and are available from the Search submenu in the contextual menu of the current editor or from the Document > References menu:

- **Search References**
  
  Searches all references of the item found at current cursor position in the defined scope, if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box is displayed and you have the possibility to define another search scope.

- **Search References in**
  
  Searches all references of the item found at current cursor position in the file or files that you specify when define a scope in the Search References dialog box.

- **Search Declarations**
  
  Searches all declarations of the item found at current cursor position in the defined scope if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box will be displayed and you have the possibility to define another search scope.

- **Search Declarations in**
  
  Searches all declarations of the item found at current cursor position in the file or files that you specify when you define a scope for the search operation.

- **Search Occurrences in File**
  
  Searches all occurrences of the item at the cursor position in the currently edited file.

The following action is available from the contextual menu and the Document > Schema menu:

- **Go to Definition**
Moves the cursor to the definition of the current element in the Relax NG (full syntax) schema.

Note: You can also use the **Ctrl + Single-Click (Command + Single-Click on OS X)** shortcut on a reference to display its definition.

**Refactoring Actions**

The following refactoring actions can be applied on named *defines* and are available from the **Refactoring** submenu in the contextual menu of the current editor or from the **Document > Refactoring** menu:

**Rename Component**

Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the **Esc** or **Enter** key on your keyboard.

**Rename Component in**

Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the **Preview** button, you can view the files to be affected by the action.

Figure 552. Rename Identity Constraint Dialog Box
RNG Quick Assist Support

The Quick Assist support (on page 3286) improves the development workflow, offering fast access to the most commonly used actions when you edit schema documents.

The Quick Assist feature (on page 3286) is activated automatically when the cursor is positioned over the name of a component. It is accessible via a yellow bulb icon (💡) placed at the current line in the stripe on the left side of the editor. Also, you can invoke the quick assist menu by using the Alt + 1 (Meta + Alt + 1 on Mac OS X) keyboard shortcuts.

Figure 553. RNG Quick Assist Support

The Quick Assist support offers direct access to the following actions:

- Rename Component in
  Renames the component and all its dependencies.

- Search Declarations
  Searches the declaration of the component in a predefined scope. It is available only when the context represents a component name reference.

- Search References
  Searches all references of the component in a predefined scope.

- Component Dependencies
  Searches the component dependencies in a predefined scope.

- Change Scope
  Configures the scope that will be used for future search or refactor operations.

- Rename Component
  Allows you to rename the current component in-place.

- Search Occurrences
Searches all occurrences of the component within the current file.

Related Information:

- Component Dependencies View (on page 1403)
- Resource Hierarchy/Dependencies View (on page 1400)
- Searching and Refactoring Actions (on page 1405)
- Search and Refactor Operations Scope (on page 1129)

Configuring a Custom Datatype Library for a RELAX NG Schema

A RELAX NG schema can declare a custom datatype library for the values of elements found in XML document instances. The datatype library must be developed in Java and it must implement the interface specified on the www.thaiopensource.com website.

The JAR (on page 3283) file containing the custom library and any other dependent JAR file must be added to the classpath of the application, that is the JAR files must be added to the folder [OXYGEN_INSTALL_DIR]/lib.

To load the custom library, restart Oxygen XML Editor.

Editing NVDL Schemas

Some complex XML documents are composed by combining elements and attributes from namespaces. Furthermore, the schemas that define these namespaces are not even developed in the same schema language. In such cases, it is difficult to specify in the document all the schemas that must be taken into account for validation of the XML document or for content completion. An NVDL (Namespace Validation Definition Language) schema can be used. This schema allows the application to combine and interleave multiple schemas of different types (W3C XML Schema, RELAX NG schema, Schematron schema) in the same XML document.

Oxygen XML Editor offers support for editing NVDL schema files in the following editing modes:

- **Text editing mode (on page 1286)** - Allows you to edit NVDL schema files in a source editing mode, along with a schema design pane with two tabs that offer a Full Model View (on page 1409) and Logical Model View (on page 1410).
• **Grid editing mode** *(on page 392)* - Displays NVDL schema files in a structured spreadsheet-like grid.

• **Author editing mode** - The visual **Author** mode is also available for Relax NG schema files, presenting them in a compact and easy to understand representation.

For information about applying and detecting schemas, see **Associating a Schema to XML Documents** *(on page 1112)*.

**Related Information:**

• **Associating a Schema to XML Documents** *(on page 1112)*

---

**NVDL Schema Diagram**

This section explains how to use the graphical diagram of a NVDL schema.

**Introduction to NVDL Schema Diagram Editor**

Oxygen XML Editor provides a simple, expressive, and easy-to-read schema diagram editor for NVDL schemas.

With this new feature you can easily develop complex schemas, print them on multiple pages or save them as JPEG, PNG, and BMP images. It helps both schema authors in developing the schema and content authors that are using the schema to understand it.

Oxygen XML Editor is the only XML Editor to provide a side by side source and diagram presentation and have them real-time synchronized:

• The changes you make in the Editor are immediately visible in the Diagram (no background parsing).
• Changing the selected element in the diagram, selects the underlying code in the source editor.

**Full Model View**

When you create a schema document or open an existing one, the editor panel is divided in two sections: one containing the schema diagram and the second the source code. The diagram view has two tabbed panes offering a **Full Model View** and a **Logical Model View** *(on page 1410)*.

Figure 554. NVDL Schema Editor - Full Model View
The **Full Model View** renders all the NVDL elements with intuitive icons. This representation coupled with the synchronization support makes the schema navigation easy.

Double-click any diagram component to edit its properties.

**Logical Model View**

The **Logical Model View** presents the compiled schema in the form of a single pattern. The patterns that form the element content are defined as top level patterns with generated names. These names are generated depending of the elements name class.

Figure 555. Logical Model View for an NVDL Schema
Actions Available in the Diagram Editor

The contextual menu offers the following actions:

**Show only the selected component**

Depending on its state (selected/not selected), either the selected component or all the diagram components are shown.

**Show Annotations**

Depending on its state (selected/not selected), the documentation nodes are shown or hidden.

**Auto expand to references**

This option controls how the schema diagram is automatically expanded. For instance, if you select it and then edit a top-level element or you trigger a diagram refresh, the diagram will be expanded until it reaches the referenced components. If this option is left unchecked, only the first level of the diagram is expanded, showing the top-level elements. For large schemas, the editor disables this option automatically.

**Collapse Children**

Collapses the children of the selected view.

**Expand Children**

Expands the children of the selected view.

**Print Selection**

Prints the selected view.

**Save as Image**

Saves the current selection as image, in JPEG, BMP, SVG or PNG format.

**Refresh**
Refreshes the schema diagram according to the changes in your code (changes in your imported documents or those that are not reflected automatically in the compiled schema).

If the schema is not valid, you see only an error message in the Logical Model View (on page 1410) instead of the diagram.

Validating NVDL Schema Documents

By default, NVDL schema files are validated as you type. To change this, open the Preferences dialog box (Options > Preferences) (on page 79), go to Editor > Document Checking, and deselect the Enable automatic validation option (on page 181).

To validate an NVDL schema document manually, select the Validate action from the Validation toolbar drop-down menu or the Document > Validate menu. When Oxygen XML Editor validates an NVDL schema file, it expands all the included modules so the entire schema hierarchy is validated. The validation problems are highlighted directly in the editor, making it easy to locate and fix any issues.

Related Information:

- Validating XML Documents Against a Schema (on page 1081)

Content Completion in NVDL Schemas

The intelligent Content Completion Assistant (on page 3280) allows you to quickly identify and insert elements, attributes, and attribute values that are valid in the current editing context. All available proposals are listed in a pop-up menu displayed at the current cursor position.

The Content Completion Assistant is enabled by default. To disable it, open the Preferences dialog box (Options > Preferences) (on page 79), go to Editor > Content Completion, and deselect the Enable content completion option (on page 167).

When active, the Content Completion Assistant displays a list of context-sensitive proposals valid at the current cursor position. It can be manually activated with the Ctrl + Space (Command + Space on OS X) shortcut. You can navigate through the list of proposals by using the Up and Down keys on your keyboard. For each selected item in the list, the Content Completion Assistant displays a documentation window. You can customize the size of the documentation window by dragging its top, right, and bottom borders.

To insert the selected proposal in Text mode, do one of the following:
• Press **Enter** or **Tab** to insert both the start and end tags and position the cursor inside the start tag in a position suitable for inserting attributes.

• Press **Ctrl + Enter (Command + Enter on OS X)** to insert both the start and end tags and positions the cursor between the tags in a position where you can start typing content.

If you are using the concept of master files (on page 3284) to import/include modules, the Content Completion Assistant collects its components starting from the master files. The master files can be defined in the project or in the associated validation scenario. For more information about the Master Files support in Oxygen XML Editor, see Defining Master Files at Project Level (on page 726).

The Content Completion Assistant also offers additional information for the element and attribute proposals in the form of schema annotations that is displayed in a tooltip.

Figure 556. NVDL Content Completion Assistant

Syntax Highlighting in NVDL Schemas

Oxygen XML Editor supports syntax highlighting in Text mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for NVDL schemas, follow these steps:

1. Open the **Preferences** dialog box (Options > Preferences) (on page 79).
2. Go to **Editor > Syntax Highlight** (on page 178).
3. Select and expand the **XML** section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.
5. Select the **XML** tab in the Preview pane to see the effects of your changes.

**Tip:** Oxygen XML Editor also allows you to specify syntax highlighting colors for specific XML elements and attributes with specific namespace prefixes. This can be done in the Editor > Syntax Highlight > Elements/Attributes by Prefix preferences page (on page 179).

**Related Information:**
NVDL Outline View

The Outline view for NVDL schemas presents a list with the named or anonymous rules that appear in the diagram and it allows for quick access to a rule by name. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

NVDL Schema Component Dependencies View

The Component Dependencies view allows you to see the dependencies for a selected component. This is helpful if you want to see where components are used in the entire hierarchy. For example, if you want to find all the references where a given component is used.

If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

To see the dependencies of an NVDL component:

1. Right-click the desired component in the editor or Outline view.
2. Select the Component Dependencies action from the contextual menu.

The action is available for all named modes.

If a component contains multiple references, a small table is displayed at the bottom of the view that contains all the references. When a recursive reference is encountered, it is marked with a special icon.

Figure 557. Component Dependencies View - Hierarchy for test.nvdl

The Component Dependencies view includes the following toolbar actions:

- Refresh
  Refreshes the dependencies structure.
Stop

Stops the dependency computation.

Configure

Allows you to choose the search scope for computing the dependencies structure. This is helpful for making sure all imported/included resources are computed.

History

Allows you to select from a list of the most recently used dependency computations.

In addition, the following actions are available in the contextual menu:

Go to First Reference
Selects the first reference of the currently selected component in the dependencies tree.

Go to Component
Shows the definition of the currently selected component in the dependencies tree.

Searching and Refactoring Actions in NVDL Schemas

Search Actions

The following search actions can be applied on name, useMode, and startMode attributes and are available from the Search submenu in the contextual menu of the current editor or from the Document > References menu:

Search References

Searches all references of the item found at current cursor position in the defined scope, if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box is displayed and you have the possibility to define another search scope.

Search References in

Searches all references of the item found at current cursor position in the file or files that you specify when define a scope in the Search References dialog box.

Search Declarations

Searches all declarations of the item found at current cursor position in the defined scope if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box will be displayed and you have the possibility to define another search scope.

Search Declarations in
Searches all declarations of the item found at current cursor position in the file or files that you specify when you define a scope for the search operation.

**Search Occurrences in File**

Searches all occurrences of the item at the cursor position in the currently edited file.

The following action is available from the contextual menu and the Document > Schema menu:

**Go to Definition**

Moves the cursor to its definition in the schema used by the NVDL to validate it.

**Note:** You can also use the **Ctrl + Single-Click (Command + Single-Click on OS X)** shortcut on a reference to display its definition.

**Refactoring Actions**

The following refactoring actions can be applied on `name`, `useMode`, and `startMode` attributes and are available from the Refactoring submenu in the contextual menu of the current editor or from the Document > Refactoring menu:

**Rename Component**

Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the **Esc** or **Enter** key on your keyboard.

**Rename Component in**

Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the **Preview** button, you can view the files to be affected by the action.

Figure 558. Rename Identity Constraint Dialog Box
Editing JSON Documents

Oxygen XML Editor includes a document template to help you get started with JSON documents. The template is called JSON and it can be found in the New Document folder in the New document wizard (on page 676).

This section explains the features of the Oxygen XML Editor JSON Editor and how to use them.

For more information about JSON editing support, watch our video demonstration:

https://www.youtube.com/embed/wglkagwSDrU

Editing JSON Documents in Text Mode

When editing JSON documents in the Text editing mode, the usual text editing actions (on page 832) are available, along with other editor-specific actions, including:

- Find/Replace (on page 740)
- Drag and Drop (on page 841)
- Validation (on page 1420)
- Format and Indent (Pretty Print) (on page 863)
Note: You can run XPath expressions on opened JSON documents, but in Text mode the XPath results cannot be mapped in the document. However, they can be mapped in the Grid editing mode. You can use the Grid button at the bottom of the editor panel to switch to that editing mode.

Navigating References in JSON Documents

When editing JSON documents (or JSON Schema), you can easily navigate JSON Pointer references and hyperlinks by using the Ctrl + Click shortcut. Holding the Ctrl key while hovering over a JSON Pointer references or hyperlink will change the reference to a clickable link.

Related Information:

- Text Preferences (on page 127)
- Editing JSON Documents in Grid Mode (on page 1418)

Editing JSON Documents in Grid Mode

Oxygen XML Editor allows you to view and edit the JSON documents in the Grid mode (on page 392). The JSON is represented in Grid mode as a compound layout of nested tables in which the JSON data and structure can be easily manipulated with table-specific operations or drag and drop operations on the grid components.

Figure 559. JSON Editor Grid Mode
You can also use the following JSON-specific contextual actions:

**Array**

Useful when you want to convert a JSON value to array.

**Insert value before**

Inserts a value before the currently selected one.

**Insert value after**

Inserts a value after the currently selected one.

**Append value as child**

Appends a value as a child of the currently selected value.

You can **customize the JSON grid appearance (on page 130)** according to your needs. For instance, you can change the font, the cell background, foreground, or even the colors from the table header gradients. The default width of the columns can also be changed.

**Related Information:**

- Grid Editing Mode (on page 392)
Validating JSON Documents

Oxygen XML Editor includes a built-in JSON validator that is used to validate JSON documents against JSON Schemas, as well as a built-in JSON Well-Formedness validator (based on the free JAVA source code available on www.json.org).

For more information, see the following video demonstration:

https://www.youtube.com/embed/3JEL6nFUozQ

Checking Well-Formedness in JSON Documents

A Well-formed JSON document is a sequence of Unicode code points that strictly conforms to the JSON grammar defined by the JSON Data Interchange Syntax specification. By default, Oxygen XML Editor automatically checks the document for Well-formedness as you type.

Check for Well-Formedness Manually

To manually check documents for Well-formedness:

- Select the Check Well-Formedness (Ctrl + Shift + W (Command + Shift + W on OS X)) action from the Validation drop-down menu on the toolbar or from the Document > Validate menu.
- A selection of files can be checked for well-formedness by selecting the Check Well-Formedness action from the Validate submenu when invoking the contextual menu in the Project view (on page 333).

Result: If any errors are found, the result is displayed in the message panel at the bottom of the editor. Each error is displayed as one record in the result list and is accompanied by an error message. Clicking the record will open the document containing the error and highlight its approximate location.

Example: A non Well-formed JSON Document

```
{"person": { "name": "John Doe" }
```

This would result in the following error:

```
Expected a '},' or ')'
```
To resolve the error, click the record in the result list and it will locate and highlight the approximate position of the error. In this case, you would need to identify where the missing end bracket needs to be placed.

Validating JSON Documents Against JSON Schema

A Valid JSON document is a Well-Formed document that also conforms to the rules of a JSON Schema that defines the legal syntax of a JSON document. The purpose of the JSON schema is to define the legal properties and values of a JSON document.

This section contains topics that explain the automatic and manual validation possibilities in Oxygen XML Editor, how validation errors are presented, and information about built-in validation scenarios.

For information about how to associate a JSON schema for the purposes of validation, see Associating a JSON Schema Through a Validation Scenario (on page 1428).

Automatic Validation

By default, Oxygen XML Editor is configured to automatically mark validation errors in the JSON document as you are editing. The Enable automatic validation option (on page 181) in the Document Checking preferences page (on page 180) controls whether or not all validation errors and warnings will automatically be highlighted in the editor panel.

The automatic validation starts parsing the document and marking the errors after a configurable delay (on page 181) from the last key typed. Errors are highlighted with underline markers in the main editor panel and small rectangles on the right side ruler of the editor panel. Hovering over a validation error presents a tooltip message with more details about the error.

If the error message is long and it is not displayed completely in the error line at the bottom of the editing area, double-clicking the error icon at the left of the error line or on the error line displays an information dialog box with the full error message. You can use the arrow buttons in this dialog box to navigate through the errors issued by the Automatic Validation feature.

Related Information:

- Manual Validation Actions (on page 1421)
- Presenting Validation Errors in JSON Documents (on page 1423)
Manual Validation Actions

You can choose to validate JSON documents at any time by using the manual validation actions that are available in Oxygen XML Editor.

Manual Validation Actions

To manually validate the currently edited document, use one of the following actions:

☑ Validate (Ctrl + Shift + V (Command + Shift + V on OS X))

Available from the ☑ Validation drop-down menu on the toolbar, the Document > Validate menu, or from the Validate submenu when invoking the contextual menu in the Project view (on page 333).

Validate with

Available from the ☑ Validation drop-down menu on the toolbar or the Document > Validate menu.

This action opens a dialog box that allows you to specify a schema for validating the current document (on page 1429).

Note: The Validate with action does not work for files loaded through an Oxygen XML Editor custom protocol plugin (on page 2595) developed independently and added to Oxygen XML Editor after installation.

Validate with Schema

Available from the Validate submenu when invoking the contextual menu in the Project view (on page 333).

This action opens a dialog box that allows you to specify a schema for validating the current document (on page 1429).

Other Validation Options

Tip: If a large number of validation errors are detected and the validation process takes too long, you can limit the maximum number of reported errors in the Document Checking preferences page (on page 180).

Related Information:

• Automatic Validation (on page 1421)
Presenting Validation Errors in JSON Documents

Validation errors and warnings in JSON documents are presented in various locations within the interface.

Validation Marker Locations

Validation issues are marked in the following locations:

- In the main editing pane, with the issue underlined in a color according to the type of issue.
- In the right-side vertical stripe, with a marker that is colored according to the type of issue.
- In the Outline view, with an icon that is colored according to the type of issue.

Validation Marker Colors

The colors for each type of issue are as follows:

- **Validation Errors** [Red] - By default, the underline in the editing pane, the marker in the right vertical stripe, and the foreground color of the attribute in the Attributes view are colored in red.
- **Validation Warnings** [Yellow] - By default, the underline in the editing pane, the marker in the right vertical stripe, and the foreground color of the attribute in the Attributes view are colored in yellow.
- **Validation Info** [Blue] - By default, the underline in the editing pane, the marker in the right vertical stripe, and the foreground color of the attribute in the Attributes view are colored in blue.

You can configure the color for each type in the Document Checking preferences page (on page 180).

Validation Markers in the Right-Side Stripe

Also, the stripe on the right side of the editor panel is designed to display the issues found during the validation process and to help you locate them in the document. The stripe contains the following:

**Upper Part of the Stripe**

A success indicator square will turn green if the validation is successful or only info messages are found, red if validation errors are found, or yellow if only validation warnings are found. More details about the issues are displayed in a tool tip when you hover over indicator square. If there are numerous problems, only the first three are presented in the tool tip.
Middle Part of the Stripe

Errors are presented with red markers, warnings with yellow markers, and info message with blue markers. If you want to limit the number of markers that are displayed, open the Preferences dialog box (Options > Preferences) (on page 79), go to Editor > Document checking, and specify the desired limit in the Maximum number of validation highlights option (on page 180).

Clicking a marker will highlight the corresponding text area in the editor. The validation message is also displayed both in a tool tip (when hovering over the marker) and in the message area on the bottom of the editor panel (clicking the Document checking options button opens the Document Checking preferences page (on page 180).

Bottom Part of the Stripe

Two navigation arrows (⇒) allow you to jump to the next or previous issue. The same actions can be triggered from Document > Automatic validation > Next error (Ctrl + Period (Command + Period on OS X)) and Document > Automatic validation > Previous error (Ctrl + Comma (Command + Comma on OS X)). Also, the Remove All button can be used to clear all the validation markers.

Hovering Over Validation Issues

Hovering over a validation issue presents a tooltip message with more details about the problem. Also, when hovering over an issue, pressing F2 will change the focus to the tooltip.

Details About Validation Issues

- Information about the issue is also displayed in the message area on the bottom of the editor panel (clicking the Document checking options button opens the Document Checking preferences page (on page 180) where you can configure some validation options (such as the colors used to present the validation issues).
- Status messages from every validation action are also logged in the Information view (on page 822).
- If you want to see all the validation messages grouped in the Results panel (on page 357), you should use the Validate action from the toolbar or Document > Validate menu..

Creating a JSON Validation Scenario

Validation scenarios can be used to associate one or more JSON Schemas with a JSON document (on page 1428).
Creating a JSON Validation Scenario

To create a validation scenario, follow these steps:

1. Select the Configure Validation Scenario(s) action in one of the following ways:
   - From the Validation toolbar drop-down menu.
   - From the Document > Validate menu.
   - From the Validate submenu, when invoking the contextual menu on a file in the Project view (on page 333).

   **Step Result:** The Configure Validation Scenario(s) dialog box is displayed.

2. Click the New button.

   **Step Result:** A validation scenario configuration dialog box is displayed.

   Figure 560. Validation Scenario Configuration Dialog Box

   This scenario configuration dialog box allows you to configure the following information and options:

   **Name**
   
   The name of the validation scenario.

   **Storage**
   
   You can choose between storing the scenario in the Project Options (on page 3286) or Global Options (on page 3283).

   **URL of the file to validate**
   
   The URL of the main module that includes the current module. It is also the entry module of the validation process when the current one is validated. To edit the URL,
double-click its cell and specify the URL of the main module by doing one of the following:

- Enter the URL in the text field or select it from the drop-down list.
- Use the Browse drop-down button to browse for a local, remote, or archived file.
- Use the Insert Editor Variable button to insert an editor variable (on page 276) or a custom editor variable (on page 284).

Figure 561. Insert an Editor Variable

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$(Desktop)</td>
<td>My Desktop</td>
</tr>
<tr>
<td>$(start-dir)</td>
<td>Start directory of custom validator</td>
</tr>
<tr>
<td>$(standard-params)</td>
<td>List of standard parameters for command line</td>
</tr>
<tr>
<td>$(fn)</td>
<td>The current file name without extension</td>
</tr>
<tr>
<td>$(currentFileURL)</td>
<td>The path of the currently edited file (URL)</td>
</tr>
<tr>
<td>$(cdui)</td>
<td>The path of current file directory (URL)</td>
</tr>
<tr>
<td>$(frameworks)</td>
<td>Oxygen frameworks directory (URL)</td>
</tr>
<tr>
<td>$(pbd)</td>
<td>Project directory (URL)</td>
</tr>
<tr>
<td>$(oxygenHome)</td>
<td>Oxygen installation directory (URL)</td>
</tr>
<tr>
<td>$(home)</td>
<td>The path to user home directory (URL)</td>
</tr>
<tr>
<td>$(proj)</td>
<td>Project name</td>
</tr>
<tr>
<td>$(env( VAR_NAME ))</td>
<td>Value of environment variable VAR_NAME</td>
</tr>
<tr>
<td>$(system(VAR_NAME))</td>
<td>Value of system variable VAR_NAME</td>
</tr>
</tbody>
</table>

**File type**

The type of the document that is validated in the current validation unit. Oxygen XML Editor automatically selects the file type depending on the value of the URL of the file to validate field.

**Validation engine**

For normal JSON documents, the Default engine should be used. For JSON Schemas, you could use the Default engine (if they have a schema version specified) or the JSON Schema Validator. The latter does not require a schema version to be specified. If the version is missing, JSON Schema draft-04 will be used as a default.

**Automatic validation**

If this option is selected, the validation operation defined by this row is also applied by the automatic validation feature (on page 1082). If the Automatic validation feature is disabled in the Document Checking preferences page (on page 180), then this option is ignored, as the preference setting has a higher priority.

**Schema**

Displays the specified schema.
Specify Schema

Opens the Specify Schema dialog box that allows you to set a schema to be used for validating JSON documents.

Move Up

Moves the selected scenario up one spot in the list.

Move Down

Moves the selected scenario down one spot in the list.

Add

Adds a new validation unit to the list.

Remove

Removes an existing validation unit from the list.

3. Configure any of the existing validation units according to the information above. You can use the buttons at the bottom of the table to add, remove, or move validation units.

4. Press OK.

Result: The newly created validation scenario will now be included in the list of scenarios in the Configure Validation Scenario(s) dialog box. You can select the scenario in this dialog box to associate it with the current document and press the Apply associated button to run the validation scenario.

Sharing JSON Validation Scenarios

The validation scenarios and their settings can be shared with other users by saving them at project level (on page 3286) or by exporting them to a specialized scenarios file (on page 276) that can then be imported. When you create a new validation scenario or edit an existing one, there is a Storage option to control whether the scenarios are stored in Project Options (on page 3286) or Global Options (on page 3283).

Selecting Project Options (on page 3286) stores the scenario in the project file and can be shared with other users that have access to the project. If your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) then your team will have access to the scenarios that you define. When you create a scenario at the project level, the URLs from the scenario become relative to the project URL.

Selecting Global Options (on page 3283) stores the scenario in the global options that are stored in the user home directory.
You can also change the storage options of existing validation scenarios by using the **Change storage** action from the contextual menu of the list of scenarios in the **Configure Validation Scenario(s)** dialog box.

**Resolving References with an XML Catalog**

If a reference to a remote JSON schema must be used but a local copy of the schema should actually be preferred for performance reasons, the reference can be resolved to the local copy with an **XML Catalog (on page 3289)**.

For example, if the JSON schema contains a reference to a remote schema such as:

```json
{"$ref": "http://json-schema.org/example/geo.json"}
```

the reference can be resolved to a local copy of the schema by inserting the following catalog entry:

```xml
<uri name="http://json-schema.org/example/geo.json" url="schemas/geo.json"/>
```

**Related Information:**

- Working with XML Catalogs (on page 1123)

**Associating a Schema to JSON Documents**

To provide as-you-type validation and to compute valid proposals for the **Content Completion Assistant (on page 3280)**, Oxygen XML Editor requires a schema to be associated with the JSON document. The schema specifies how the internal structure is defined.

**Detecting the Schema(s) for Validation and Content Completion**

For validation, Oxygen XML Editor tries to detect the JSON Schema by searching in the following order:

1. The schema referenced in validation stages from the validation scenario(s) (on page 1428) associated with the current JSON document.
2. If a schema is not detected, then it falls back to the schema associated directly in the JSON document (on page 1431).

**Tip:** To quickly open the schema used for validating the current document, select the **Open Associated Schema** action from the toolbar (or **Document > Schema** menu).
Associating a JSON Schema Through a Validation Scenario

Oxygen XML Editor uses the rules defined in the detected JSON schema to report errors and warnings during automatic and manual validations that help maintain the structural integrity of your JSON documents. There are several methods that can be used to validate with a JSON schema.

Configure a Validation Scenario and Specify the JSON Schema

You can specify the schema to be used for validation directly in the JSON validation scenario (on page 1424). To associate a JSON schema to a validation scenario to be used whenever the scenario is invoked, follow these steps:

1. Select the Configure Validation Scenario(s) from the Validation toolbar drop-down menu, from the Document > Validate menu, or from the Validate submenu when invoking the contextual menu on a file in the Project view (on page 333).
2. Press the New button to create a new validation scenario (on page 1424) or the Edit button to modify an existing one.
3. Add or configure validation units according to your needs and click the Specify Schema button.
4. Select the schema to be associated with the validation unit.
5. Click OK on both dialog boxes.

Result: The JSON schema is now associated with that validation scenario whenever it is invoked.

Use the Validate with Action to Specify a JSON Schema for Validating the Current Document

To validate the current document using a specified schema, follow these steps:

1. Select the Validation with action from the Validation drop-down menu on the toolbar (or Document > Validate menu).

Step Result: The Validate with dialog box is displayed:

Figure 562. Validate with Dialog Box
This dialog box contains the following options:

- **URL** - Allows you to specify or select a URL for the schema. It also keeps a history of the last used schemas. The URL must point to the schema file that can be loaded from the local disk or from a remote server through HTTP(S), FTP(S) or a custom protocol (on page 2610). You can specify the URL by using the text field, the history drop-down, the Insert Editor Variables (on page 276) button, or the browsing actions in the Browse drop-down list.
- **Schema type** - Select JSON for the schema type (other types of schema will not work with JSON documents).

2. Select the schema to be associated with the manual validation.
3. Click **OK**.

**Result:** The current document is validated using the JSON schema you specified.

**Use the Validate with Schema Action to Specify a JSON Schema for Validating all Selected JSON Documents**

To validate multiple JSON documents using a specified JSON schema, follow these steps:

1. Select all the JSON documents you want to validate in the Project view.
2. Invoke the contextual menu (right-click) and select the Validate with Schema action from the Validate submenu.

**Step Result:** The Validate with dialog box is displayed:

Figure 563. Validate with Dialog Box
This dialog box contains the following options:

- **URL** - Allows you to specify or select a URL for the schema. It also keeps a history of the last used schemas. The URL must point to the schema file that can be loaded from the local disk or from a remote server through HTTP(S), FTP(S) or a custom protocol (on page 2610). You can specify the URL by using the text field, the history drop-down, the Insert Editor Variables (on page 276) button, or the browsing actions in the Browse drop-down list.

- **Schema type** - Select JSON for the schema type (other types of schema will not work with JSON documents).

3. Select the JSON schema that you want to use to validate all selected JSON documents.

4. Click OK.

**Result:** The selected JSON documents are validated using the JSON schema you specified.

### Associating a Schema Directly in JSON Documents

**Associate Schema Action**

The schema used by the Content Completion Assistant (on page 3280) and document validation engine can be associated with the current document by using the Associate Schema action. The association can specify a relative file path or a URL of the schema.

To associate a JSON Schema to the current JSON document, follow these steps:

1. Select the Associate Schema action from the toolbar (or Document > Schema menu).

**Step Result:** The Associate Schema dialog box is displayed:

![Associate Schema Dialog Box](image)
This dialog box contains the following options for JSON documents:

- **URL** - Allows you to specify or select a URL for the schema. It also keeps a history of the last used schemas. The URL must point to the schema file that can be loaded from the local disk or from a remote server through HTTP(S), FTP(S) or a custom protocol (on page 2610).

- **Use path relative to file location** - Select this option if the JSON instance document and the associated schema contain relative paths. The location of the schema file is inserted in the JSON instance document as a relative file path. This practice allows you, for example, to share these documents with other users without running into problems caused by multiple project locations on physical disk.

2. Select the JSON Schema that will be associated with the JSON document.
3. Click **OK**.

**Result:** A `$schema` property is added at the beginning of the document with its value set to the specified URL. If the document already contained a schema association, the old association will be replaced with the new one.

**Tip:** To quickly open the schema used for validating the current document, select the **Open Associated Schema** action from the toolbar (or Document > Schema menu).

### Content Completion Assistant in JSON

Oxygen XML Editor includes an intelligent *Content Completion Assistant* (on page 3280) that offers proposals for inserting JSON structures that are valid at the current editing location.

The *Content Completion Assistant* is enabled by default. To disable it, open the **Preferences** dialog box (Options > Preferences) (on page 79), go to Editor > Content Completion, and deselect the **Enable content completion** option (on page 167).

**Figure 565. Content Completion Assistant in JSON**

### Content Completion and the Associated Schema

The *Content Completion Assistant* feature is schema-driven and the list of proposals in the *Content Completion Assistant* (on page 3280) depend on the associated JSON Schema. For information about ways to associate a schema to a JSON document, see the **Associating a Schema to JSON Documents** (on page 1428) section.
Using the Content Completion Assistant in JSON

The feature is activated in Text mode for JSON documents by:

- Typing a quote symbol (" ) to insert a property or value.
- Pressing Ctrl + Space (Command + Space on OS X) or Alt + ForwardSlash (Command + Alt + ForwardSlash on OS X).

You can navigate through the list of proposals by using the Up and Down keys on your keyboard. In some cases, the Content Completion Assistant displays a documentation window with information about the particular proposal (on page 1433). You can also change the size of the documentation window by dragging its top, right, and bottom borders.

To insert the selected proposal, press Enter or Tab.

Types of Proposals Listed in the Content Completion Assistant for JSON

The proposals that populate the Content Completion Assistant for JSON documents depend on the structure defined in the associated JSON Schema. The types of structure proposed in the content completion window include:

- JSON properties
- JSON values
- JSON arrays
- JSON objects

The number and type of proposals displayed by the Content Completion Assistant is dependent on the cursor’s current position in the JSON document and the child items displayed within a given context are defined by the structure of the specified JSON Schema.

Code Templates in the Content Completion

Oxygen XML Editor includes a set of built-in code templates for JSON documents that can be selected from the Content Completion Assistant. The code templates are displayed with a .tm symbol in the content completion list. You can also define your own code templates and share them with others. For more information, see Code Templates (on page 855).

Schema Annotations in JSON Content Completion

A schema annotation is a documentation snippet that appears in the Content Completion Assistant (on page 3280) offering more information about the current proposal.
This feature is enabled by default, but you can disable it by deselecting the Show annotations in Content Completion Assistant (on page 171) option in the Annotations preferences page.

Collecting Annotations from the JSON Schema

In a JSON Schema, the annotations are specified in the value of the title and description properties like this:

```
"idType": {
  "title": "The 'id' property",
  "description": "Specifies a required ID for this person.",
  "type": "string",
  "maxLength": 20
}
```

Syntax Highlighting in JSON Documents

Oxygen XML Editor supports syntax highlighting in Text mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for JSON files, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79).
2. Go to Editor > Syntax Highlight (on page 178).
3. Select and expand the JSON section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

You can see the effects of your changes in the Preview pane.

Related Information:

- Syntax Highlight Preferences (on page 178)

Folding in JSON

In a large JSON document, the data enclosed in the curly bracket characters {} can be collapsed so that only the needed data remains in focus. The folding features available for XML documents (on page 840) are also available in JSON documents.
JSON Outline View

The **Outline** view for JSON documents displays the list of all the components of the JSON document you are editing. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

Figure 566. JSON Outline View

Outline View Features

The **Outline** view allows you to:

- Quickly navigate through the document by selecting nodes in the **Outline** tree.
- Move elements by dragging them to a new position in the tree structure.
- Highlight elements in the editor area. It is synchronized with the editor area, so when you make a selection in the editor area, the corresponding nodes are highlighted in the **Outline** view, and vice versa.
- View document errors, as they are highlighted in the **Outline** view. A tooltip also provides more information about the nature of the error when you hover over the faulted element.

Outline View Interface

By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

The upper part of the **Outline** view contains a filter box that allows you to focus on the relevant components. Type a text fragment in the filter box and only the components that match it are
presented. For advanced usage you can use wildcard characters (such as *, ?) and separate multiple patterns with commas.

It also includes a Settings menu in the top-right corner that presents the following options to help you filter the view even further.

**Filter returns exact matches**

The text filter of the Outline view returns only exact matches.

**Selection update on cursor move**

Controls the synchronization between Outline view and source document. The selection in the Outline view can be synchronized with the cursor moves or the changes in the editor. Selecting one of the components from the Outline view also selects the corresponding item in the source document.

**Flat presentation mode of the filtered results**

When active, the application flattens the filtered result elements to a single level.

**Drop and Drop Actions in the Outline View**

Entire JSON properties, objects, and arrays can be moved or copied in the edited document using only the mouse in the Outline view with drag-and-drop operations. Several drag and drop actions are possible:

- If you drag a JSON node in the Outline view and drop it on another node, then the dragged node will be moved after the drop target.
- If you hold the mouse pointer over the drop target for a short time before the drop then the drop target node will be expanded first and the dragged node will be moved inside the drop target.
- You can also drop a node before or after another node if you hold the mouse pointer towards the upper or lower part of the target. A marker will indicate whether the drop will be performed before or after the target node.
- If you hold down the (Ctrl (Command on OS X)) key after dragging, a copy operation will be performed instead of a move.

**Contextual Menu Actions**

The following actions are available in the contextual menu of the JSON Outline view:

**Cut**

Cuts the currently selected component.

**Copy**
Copies the currently selected component.

Paste

Pastes the copied component.

Delete

Deletes the currently selected component.

Expand More

Expands the structure of a component in the Outline view.

Collapse All

Collapses the structure of all the component in the Outline view.

JSON to XML Converter

Oxygen XML Editor includes a useful and simple tool for converting JSON files to XML. It can be found in the Tools menu.

To convert a JSON document to XML, follow these steps:

1. Select the JSON to XML action from the Tools menu. The JSON to XML dialog box is displayed:

   Figure 567. JSON to XML Dialog Box

2. Choose or enter the Input URL of the JSON document.
3. Choose the path of the Output file that will contain the resulting XML document.
4. Select the Open in Editor option to open the resulting XML document in the main editing pane.
5. Click the Convert button.

The original JSON document is now converted to an XML document.

Figure 568. Example: XML to JSON Operation Result
Conversion Details

- If the JSON document has more than one property on the first level, the converted XML document will have an additional root element called `<JSON>`.

For example, the following JSON document:

```json
{
  "personnel": {
    "person": [
      {
        "name": "Boss"
      },
      {
        "name": "Worker"
      }
    ],
    "id": "personnel-id"
  }
}
```

it is converted to:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<JSON>
  <personnel>
```

```xml
```
• If the JSON document is an array, the converted XML document will have a root element called <array> and for each item within the array, another <array> is created.

```json
[
  {
    "name": "Boss",
  },
  {
    "name": "Worker"
  }
]
```

it is converted to:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<array>
  <array>
    <name>Boss</name>
  </array>
  <array>
    <name>Worker</name>
  </array>
</array>
```

• If the name of a JSON property contains characters that are not valid in XML element names (for example, $), then the invalid characters will be escaped as its hexadecimal equivalent in the converted XML.

```json
{"$id": "personnel-id"}
```

is converted to:

```xml
<_X24_id>personnel-id</_X24_id>
```

**Online JSON to XML Converter**

For a simple ONLINE tool for converting a single JSON file to XML, or vice versa, go to: https://www.oxygenxml.com/xml_json_converter.html.
XML to JSON Converter

Oxygen XML Editor includes a useful and simple tool for converting XML files to JSON. It can be found in the Tools menu.

To convert an XML document to JSON, follow these steps:

1. Select the XML to JSON action from the Tools menu. The XML to JSON dialog box is displayed:

   ![XML to JSON Dialog Box]

2. Choose or enter the Input URL of the XML document.
3. Choose the path of the Output file that will contain the resulting JSON document.
4. Select the Open in Editor option to open the resulting JSON document in the main editing pane.
5. Click the Convert button.

The original XML document is now converted to a JSON document.

![Example: XML to JSON Operation Result]
Conversion Details

- If any elements contain attributes in the XML document, the attributes are converted to properties in the converted JSON document. If the XML document contains more than one element with the same name, they will be converted into an array of object in the converted JSON document.

For example, the following XML document:

```xml
<personnel>
  <person id="person.one">
    <name>Boss</name>
  </person>
  <person id="person.two">
    <name>Worker</name>
  </person>
</personnel>
```

It is converted to:

```json
{
    "personnel": {},
    "person": [
        {
            "id": "person.one",
            "name": "Boss"
        },
        {
            "id": "person.two",
            "name": "Worker"
        }
    ]
}
```
{  
  "id": "person.one",
  "name": "Boss"
}
{
  "id": "person.two",
  "name": "Worker"
}

• If the XML document contains elements with mixed content (text plus elements), the converted JSON document will contain a `content` property with its value set as the text content.

```xml
<person>
  <name>Boss <i>One</i></name>
</person>
```

is converted to:

```json
{
  "person": {
    "name": {
      "content": "Boss",
      "i": "One"
    }
  }
}
```

• If the XML document contains element names that contains hexadecimal codes (for example, if they were escaped during a JSON to XML conversion (on page 1438)), it will be converted to the normal character value in the converted JSON document.

```xml
<_X24_id>personnel-id</_X24_id>
```

is converted to:

```json
{"$id": "personnel-id"}
```

**Online XML to JSON Converter**

For a simple ONLINE tool for converting a single XML file to JSON, or vice versa, go to: [https://www.oxygenxml.com/xml_json_converter.html](https://www.oxygenxml.com/xml_json_converter.html).
Contextual Menu Actions in JSON Documents

When editing JSON documents, Oxygen XML Editor provides the following actions in the contextual menu:

- **Cut, Copy, Paste**
  
  Executes the typical editing actions on the currently selected content.

- **Copy JSON Pointer**
  
  Creates a JSON Pointer at the current cursor location and copies the expression that denotes the JSON pointer to the system clipboard.

- **Copy XPath**
  
  Copies the XPath expression of the current property from the current editor to the clipboard.

- **Go to Matching Bracket (Ctrl + Shift + G)**
  
  Moves the cursor to the end bracket that matches the start bracket, or vice versa.

**Source submenu**

This submenu includes the following actions:

- **To Lower Case**
  
  Converts the content selection to lower case characters. This works with contiguous and multiple selections.

- **To Upper Case**
  
  Converts the selected content to upper case characters. This works with contiguous and multiple selections.

- **Capitalize Lines**
  
  It capitalizes the first letter found on every new line that is selected. Only the first letter is affected, the rest of the line remains the same. If the first character on the new line is not a letter then no changes are made.

- **Convert Hexadecimal Sequence to Character (Ctrl + Shift + X (Command + Shift + X on OS X))**
Converts a sequence of hexadecimal characters to the corresponding Unicode character (on page 770). The action can be invoked if there is a selection containing a valid hexadecimal sequence or if the cursor is placed at the right side of a valid hexadecimal sequence. A valid hexadecimal sequence can be composed of 2 to 4 hexadecimal characters and may or may not be preceded by the \texttt{0x} or \texttt{0X} prefix. Examples of valid sequences and the characters they will be converted to:

- \texttt{0x0045} will be converted to \texttt{E}
- \texttt{0X0125} to \texttt{#}
- \texttt{265} to \texttt{#}
- \texttt{2190} to \texttt{#}

\textbf{Note:} For more information about finding the hexadecimal value of a character, see Finding the Decimal, Hexadecimal, or Character Entity Equivalent (on page 779).

**Base64 Encode/Decode submenu**

This submenu include the following actions for encoding or decoding base 64 schemes:

**Import File to Encode and Insert**

Encodes a file and then inserts the encoded content into the current document at the cursor position.

**Decode Selection and Export to File**

Decodes a selection of text from the current document and then exports (saves) the result to another file.

**Encode Selection**

Replaces a selection of text with the result of encoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the Encoding for Base64, Base32, Hex conversions option in the Encoding preferences page (on page 125) will be used. Likewise, the same is true if the Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions option is not selected in the Messages preference page (on page 261).
**Decode Selection**

Replaces a selection of text with the result of decoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the *Encoding for Base64, Base32, Hex conversions* option in the *Encoding* preferences page (on page 125) will be used. Likewise, the same is true if the *Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions* option is not selected in the *Messages* preference page (on page 261).

**Modify All Matches**

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

**Base32 Encode/Decode submenu**

This submenu include the following actions for encoding or decoding base32 schemes:

- **Import File to Encode and Insert**

  Encodes a file and then inserts the encoded content into the current document at the cursor position.

- **Decode Selection and Export to File**

  Decodes a selection of text from the current document and then exports (saves) the result to another file.

- **Encode Selection**

  Replaces a selection of text with the result of encoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the *Encoding for Base64, Base32, Hex conversions* option in the *Encoding* preferences page (on page 125) will be used. Likewise, the same is true...
if the Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions option is not selected in the Messages preference page (on page 261).

**Decode Selection**

Replaces a selection of text with the result of decoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the Encoding for Base64, Base32, Hex conversions option in the Encoding preferences page (on page 125) will be used. Likewise, the same is true if the Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions option is not selected in the Messages preference page (on page 261).

**Modify All Matches**

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

**Hex Encode/Decode submenu**

This submenu include the following actions for encoding or decoding hex schemes:

**Import File to Encode and Insert**

Encodes a file and then inserts the encoded content into the current document at the cursor position.

**Decode Selection and Export to File**

Decodes a selection of text from the current document and then exports (saves) the result to another file.

**Encode Selection**

Replaces a selection of text with the result of encoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to
choose to not show this dialog box in the future. In this case, the encoding that is specified in the Encoding for Base64, Base32, Hex conversions option in the Encoding preferences page (on page 125) will be used. Likewise, the same is true if the Show the dialog box for choosing the encoding for Base64, Base32, Hex conversions option is not selected in the Messages preference page (on page 261).

**Decode Selection**

Replaces a selection of text with the result of decoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the Encoding for Base64, Base32, Hex conversions option in the Encoding preferences page (on page 125) will be used. Likewise, the same is true if the Show the dialog box for choosing the encoding for Base64, Base32, Hex conversions option is not selected in the Messages preference page (on page 261).

**Modify All Matches**

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

**Join and Normalize Lines (Ctrl + J (Command + J on OS X))**

For the current selection, this action joins the lines by replacing the line separator with a single space character. It also normalizes the whitespaces by replacing a sequence of such characters with a single space.

**Insert new line after (Ctrl + Alt + Enter (Command + Alt + Enter on OS X))**

This action has the same result as moving the cursor to the end of the current line and pressing the ENTER key.

**Modify All Matches**

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a
thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

**Open submenu**

The following actions are available in this submenu:

**Open File at Cursor**

Opens the file at the cursor position in a new panel. If the file path represents a directory path, it will be opened in system file browser. If the file at the specified location does not exist, an error dialog box is displayed and it includes a Create new file button that starts the New document wizard. This allows you to choose the type or the template for the file. If the action succeeds, the file is created with the referenced location and name and is opened in a new editor panel.

**Open File at Cursor in System Application**

Opens the file (identified by its link) or web page (identified by a web link) found at cursor position. The target is opened in the default system application associated with that file type.

**Compare**

Opens the current file in the Compare Files tool (on page 2770).

Transforming and Querying JSON Documents

Oxygen XML Editor provides the ability to transform JSON documents to XML or HTML through XSLT or XQuery processing. You also have access to some powerful tools for querying JSON through XPath expressions or XQuery.

For more information about transforming and querying in JSON, watch our video demonstration:

https://www.youtube.com/embed/1LHoMhEFagA

Transforming JSON Documents with XSLT

It is possible to transform JSON documents through XSLT processing. To do so, follow these steps:

1. Create an XSLT 3.0 stylesheet that has the xsl:initial-template. You can use one of the following two templates available in the New Document Wizard.
   - **XSLT Stylesheet for JSON** - Processes a JSON document by using a json-doc() function and matches the JSON properties from the JSON map.
• **XSLT Stylesheet for JSON to XML** - Processes a JSON document by using a `json-to-xml()` function and matches the converted XML content.

2. Create a new **XSLT transformation** scenario for your stylesheet.

3. Reference the JSON document that you want to transform using one of these two methods:
   - In the transformation scenario, click the **Parameters** button in the **XSLT** tab and add a parameter that specifies the URL to your JSON document in its value. For example, if you are transforming one of the built-in templates mentioned above, the `input` parameter is added by default and you could specify the URL in its value.
   - Specify the URL to your JSON document in the stylesheet you created. For example, if you use one of the built-in templates mentioned above, you would specify the URL in the value of the `input` parameter (in the `xsl:param` element).

4. Run the transformation.

ℹ️ **Tip:** There are some sample files in the `[OXYGEN_INSTALL_DIR]/samples/json/transform` folder that can be used to transform a JSON document to XML or HTML.

---

### Related Information:

- Blog: Transforming JSON
- XSLT Functions on JSON Data

---

### Transforming JSON Documents with XQuery

It is possible to transform JSON documents through XQuery processing. To do so, follow these steps:

2. Create a new **XQuery transformation** scenario for your XQuery file.
3. Reference the JSON document that you want to transform using one of these two methods:
   - In the transformation scenario, click the **Parameters** button in the **XQuery** tab and add a parameter that specifies the URL to your JSON document in its value.
   - Specify the URL to your JSON document in the XQuery file you created.
4. Run the transformation.

ℹ️ **Tip:** There is a sample XQuery file in the `[OXYGEN_INSTALL_DIR]/samples/json/transform` folder that can be used to transform a JSON document.
Querying JSON Documents with XPath or XQuery

Oxygen XML Editor provides an XPath toolbar that makes it easy to quickly query JSON documents using XPath expressions. You can also use the dedicated XPath/XQuery Builder view that allows you to compose more complex XPath or XQuery expressions and execute them over JSON documents.

**XPath Toolbar**

When an XPath expression is run over a JSON document, the document is converted to XML and the XPath is executed over the converted XML document. For more information about this toolbar, see [XPath Toolbar](on page 2182).

![Figure 571. XPath Toolbar for JSON](image)

**XPath/XQuery Builder View**

You can also use the XPath/XQuery view to run XPath and XQuery expressions over a JSON document. For XQuery, you need to reference the JSON document in your XQuery content. For more information about this view, see [XPath Builder View](on page 2185).

![Figure 572. XPath/XQuery Builder View for JSON](image)
Details About Querying JSON Documents Using XPath Expressions

To execute XPath expressions over a JSON document, the document is converted to XML and the XPath is executed over the converted XML document. For this conversion, Oxygen XML Editor uses the built-in JSON to XML Converter tool (on page 1437). The results are mapped back to the original JSON document.

For example, if you have the following JSON document:

```json
{
    "personnel": {
        "person": [
            {
                "name": "Boss"
            },
            {
                "name": "Worker"
            }
        ],
        "id": "personnel-id"
    }
}
```

and you want to match the name of the second person, the XPath expression would look like this:

```
/JSON/personnel/person[2]/name
```

The reason why the first element is JSON is because if the JSON document contains more than one property on the first level, the converted XML document will have an additional root element called <JSON> . For more information, see JSON to XML Conversion Details (on page 1438).

The [2] in the expression represents the index of the person in the array and in this case, it matches the second person because the index counting starts with 1.
Editing JSON Schema Documents

The purpose of the JSON schema is to define the legal properties and values of a JSON document to keep it valid and well formed. When editing JSON Schema, all of the same features in the JSON editor (on page 1417) are available.

Oxygen XML Editor includes a new document template to help you get started creating a JSON Schema document. The template is called JSON Schema and it can be found in the New Document folder in the New document wizard (on page 676). You can also customize your own JSON Schema templates (on page 685) and specify other versions (draft 04, 06, or 07).

For information about using a JSON Schema to validate documents, see Validating JSON Documents Against JSON Schema (on page 1421)

For information about how to associate a JSON schema for the purposes of validation, see Associating a JSON Schema Through a Validation Scenario (on page 1428).

Validating JSON Schema Documents

A Valid JSON Schema document is a Well-Formed document that also conforms to the JSON meta-schema rules that defines the legal syntax of a JSON Schema document.

If a JSON document includes a meta-schema URL in the document root with the "$schema" key, the file will be validated as a JSON Schema against the specified meta-schema.

Quick Reference

- If there is a "$schema": "http://json-schema.org/draft-04/schema" property in the schema root, then Draft 4 will be used.
- If there is a "$schema": "http://json-schema.org/draft-06/schema" property in the schema root, then Draft 6 will be used.
- If there is a "$schema": "http://json-schema.org/draft-07/schema" property in the schema root, then Draft 7 will be used.
- If there is a "$schema" property in the schema root, but with a different draft value, then an error will be displayed ("no meta-schema is known with URI").
- If none of these are found, then it is validated as a simple JSON instance.
- You could also select the JSON Schema Validator in a JSON validation scenario (on page 1424) and it will use the version specified in the JSON Schema, or if a version is not specified, the JSON Schema draft-04 will be used.

For information about how to associate a JSON schema for the purposes of validation, see Associating a JSON Schema Through a Validation Scenario (on page 1428).
Editing StratML Documents

Strategy Markup Language (StratML) is an XML vocabulary and schema for strategic plans. Oxygen XML Editor supports StratML Part 1 (Strategic Plan) and StratML Part 2 (Performance Plans and Reports) and provides templates for the following documents:

- **Strategic Plan** (StratML Part 1)
- **Performance Plan** (StratML Part 2)
- **Performance Report** - (StratML Part 2)
- **Strategic Plan** - (StratML Part 2)

You can view the components of a StratML document in the Outline view (on page 347). Oxygen XML Editor implements a default XML with XSLT transformation scenario for this document type, called StratML to HTML.

Editing XLIFF Documents

XLIFF (XML Localization Interchange File Format) is an XML-based format that was designed to standardize the way multilingual data is passed between tools during a localization process. Oxygen XML Editor provides the following support for editing XLIFF documents:

**XLIFF Version 1.2, 2.0, and 2.1 Support:**

- New document templates for XLIFF documents.
- A default CSS file (xliff.css) used for rendering XLIFF content in Author mode is stored in `/[OXYGEN_INSTALL_DIR]/frameworks/xliff/css/`
- Validation and content completion support using local catalogs.
  The default catalog (catalog.xml) for version 1.2 is stored in `/[OXYGEN_INSTALL_DIR]/frameworks/xliff/schemas/1.2`, for version 2.0 in `/[OXYGEN_INSTALL_DIR]/frameworks/xliff/schemas/2.0`, and for version 2.1 in `/[OXYGEN_INSTALL_DIR]/frameworks/xliff/schemas/2.1`.

**XLIFF Version 2.0 and 2.1 Enhanced Support:**

Support for validating XLIFF 2.0 and 2.1 documents using modules. For version 2.0, the default modules are stored in `/[OXYGEN_INSTALL_DIR]/frameworks/xliff/schemas/2.0/modules` and for version 2.1, they are stored in `/[OXYGEN_INSTALL_DIR]/frameworks/xliff/schemas/2.1`. 
Editing XLIFF Documents in Author Mode

By default, when you create a new XLIFF document from a template (on page 676), Oxygen XML Editor opens it in **Text** mode. Aside from the normal editing features found in **Text** mode, you can also switch to **Author** mode where Oxygen XML Editor offers some special form controls specifically for XLIFF documents. These form controls simply allow you to add or edit XLIFF attribute values and content in a visual mode.

For XLIFF version 2.0 and 2.1 documents, you can also change the style of the visual editing mode. The **Styles** drop-down menu on the toolbar offers the following styles that are specifically designed to render XLIFF 2.0 and 2.1 documents in **Author** mode:

- Default
- Classic
- Translate

Editing JavaScript Documents

This section explains the features of the Oxygen XML Editor JavaScript Editor and how you can use them.

JavaScript Editing Actions

Oxygen XML Editor allows you to create and edit JavaScript files and assists you with useful features such as syntax highlight, content completion, and outline view. To enhance your editing experience, you can select entire blocks (parts of text delimited by brackets) by double-clicking somewhere inside the brackets.

Figure 573. JavaScript Editor Text Mode

```javascript
function change_sides(front) {
  switch($(#
```
The contextual menu of the **JavaScript** editor offers the following actions:

- **Cut**
  
  Allows you to cut fragments of text from the editing area.

- **Copy**
  
  Allows you to copy fragments of text from the editing area.

- **Paste**
  
  Allows you to paste fragments of text in the editing area.

- **Toggle Comment**
  
  Allows you to comment a line or a fragment of the JavaScript document you are editing. This option inserts a single comment for the entire fragment you want to comment.

- **Toggle Line Comment**
  
  Allows you to comment a line or a fragment of the JavaScript document you are editing. This option inserts a comment for each line of the fragment you want to comment.

- **Go to Matching Bracket**
  
  Use this option to find the closing, or opening bracket, matching the bracket at the cursor position. When you select this option, Oxygen XML Editor moves the cursor to the matching bracket, highlights its row, and decorates the initial bracket with a rectangle.

  **Note:** A rectangle decorates the opening or closing bracket that matches the current one, at all times.

- **Source**
  
  Allows you to select one of the following actions:

  - **To Lower Case**
    
    Converts the selection content to lower case characters.

  - **To Upper Case**
    
    Converts the selection content to upper case characters.

  - **Capitalize Lines**
    
    Converts to upper case the first character of every selected line.

  - **Join and Normalize Lines**
    
    Joins all the rows you select to one row and normalizes the content.

  - **Insert new line after**
    
    Inserts a new line after the line at the cursor position.
Modify all matches

Use this option to modify (in-place) all the occurrences of the selected content. When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

Open

Allows you to select one of the following actions:

- **Open File at Cursor** - select this action to open the source of the file located at the cursor position
- **Open File at Cursor in System Application** - select this action to open the source of the file located at the cursor position with the application that the system associates with the file

Compare

Select this option to open the **Compare Files** tool to compare the file you are editing with a file you choose in the dialog box.

Folding

When you invoke the contextual menu from the folding (on page 3282) triangles in the stripe on the left side of the editor, the following actions are available:

- **Collapse Other Folds** *(Ctrl + NumPad/ (Command + NumPad/ on OS X))*
  
  Folds all the elements except the current element.

- **Collapse Child Folds** *(Ctrl + NumPad. (Command + NumPad. on OS X))*
  
  Folds the elements indented with one level inside the current element.

- **Expand Child Folds**
  
  Unfolds all child elements of the currently selected element.

- **Expand All** *(Ctrl + NumPad* (Command + NumPad* on OS X))*
  
  Unfolds all elements in the current document.

Validating JavaScript Files

You have the possibility to validate the JavaScript document you are editing. Oxygen XML Editor uses the Mozilla Rhino library for validation. For more information about this library, go to [http://www.mozilla.org/rhino/doc.html](http://www.mozilla.org/rhino/doc.html). The JavaScript validation process checks for errors in the syntax. Calling a function that is not defined is not treated as an error by the validation process. The
interpreter discovers this error when executing the faulted line. Oxygen XML Editor can validate a JavaScript document both on-request and automatically.

Content Completion in JavaScript Documents

When you edit a JavaScript document, the Content Completion Assistant (on page 3280) presents you a list of the elements you can insert at the cursor position. It can be manually activated with the Ctrl + Space (Command + Space on OS X) shortcut.

For an enhanced assistance, JQuery methods are also presented. The following icons decorate the elements in the content completion list of proposals depending on their type:

- • - function
- • v - variable
- • □ - object
- • e - property
- • . - method

Note: These icons decorate both the elements from the content completion list of proposals and from the Outline view (on page 1458).

Figure 574. JavaScript Content Completion Assistant

The Content Completion Assistant collects:
• Method names from the current file and from the library files.
• Functions and variables defined in the current file.

If you edit the content of a function, the content completion list of proposals contains all the local variables defined in the current function, or in the functions that contain the current one.

Syntax Highlighting in JavaScript Documents

Oxygen XML Editor supports syntax highlighting in Text mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for JavaScript files, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79).
2. Go to Editor > Syntax Highlight (on page 178).
3. Select and expand the JavaScript section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

You can see the effects of your changes in the Preview pane.

Related Information:

• Syntax Highlight Preferences (on page 178)

JavaScript Outline View

Oxygen XML Editor present a list of all the components of the JavaScript document you are editing in the Outline view. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Figure 575. JavaScript Outline View
The following icons decorate the elements in the **Outline** view depending on their type:

- 🛡 - function
- 📜 - variable
- 🏡 - object
- 🏁 - property
- 🛠 - method

The contextual menu of the JavaScript **Outline** view contains the usual Cut, Copy, Paste, and Delete actions. From the 🗿, Settings menu, you can select the Update selection on cursor move option to synchronize the **Outline** view with the editing area.

## Editing XProc Scripts

XProc is an XML pipeline language that can be used to script transformations. An XProc script is edited as an XML document that is validated against a RELAX NG schema, or if the script has an associated transformation scenario, then the XProc engine selected in the scenario is used as the validating engine (if the XProc engine supports validation). The default engine for XProc scenarios is a version of the Calabash engine that comes bundled with Oxygen XML Editor version 21.1.

### XProc Content Completion

Oxygen XML Editor helps you edit a XProc scripts through the Content Completion Assistant (on page 3280), offering proposals that are valid at the cursor position. It can be manually activated with the Ctrl + Space (Command + Space on OS X) shortcut.
The content completion inside the element `input/inline` from the XProc namespace `http://www.w3.org/ns/xproc` offers elements from the following schemas depending both on the `port` attribute and the parent of the `input` element. When invoking the content completion inside the XProc element `inline`, the list of content completion proposals is populated as follows:

- If the value of the `port` attribute is `stylesheet` and the `xslt` element is the parent of the `input` elements, the `Content Completion Assistant` offers XSLT elements.
- If the value of the `port` attribute is `schema` and the `validate-with-relax-ng` element is the parent of the `input` element, the `Content Completion Assistant` offers RELAX NG schema elements.
- If the value of the `port` attribute is `schema` and the `validate-with-xml-schema` element is the parent of the `input` element, the `Content Completion Assistant` offers XML Schema schema elements.
- If the value of the `port` attribute is `schema` and the `validate-with-schematron` element is the parent of the `input` element, the `Content Completion Assistant` offers either ISO Schematron elements or Schematron 1.5 schema elements.
- If the above cases do not apply, then the `Content Completion Assistant` offers elements from all the schemas from the above cases.

Figure 576. XProc Content Completion

```
<p:choose>
  <p:when test="not(contains(/item[1]/title, 'mysql'))">
    <p:xslt>
      <p:input port="source"/>
      <p:input port="stylesheet">
        <p:inline>
          <xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="2.0">
            <xsl:import href="/">
            <xsl:include href="/"/>
          </xsl:stylesheet>
        </p:inline>
        ...
      </p:stylesheet>
      <p:input port="empty"/>
      <p:input port="empty"/>
    </p:xslt>
  </p:when>
</p:choose>
```

XProc Syntax Highlighting

The XProc editor assists you in writing XPath expressions by offering dedicated coloring schemes for syntax highlighting.

To customize the colors or styles used for the syntax highlighting colors for XProc, follow these steps:
1. Open the Preferences dialog box (Options > Preferences) (on page 79).
2. Go to Editor > Syntax Highlight (on page 178).
3. Select and expand the XML section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.
5. Select the XML tab in the Preview pane to see the effects of your changes.

**Enabling Extensions in Calabash**

If you are using the default Calabash engine, it is possible to configure extensions (for a list of the valid extensions, see http://xmlcalabash.com/docs/reference/cfg.extension.html).

To configure an extension:

1. Edit the following file: OXYGEN_INSTALL_DIR/lib/xproc/calabash/engine.xml.
2. Add the extension and its value as a system-property, as in the following example:

   ```xml
   <system-property name="com.xmlcalabash.allow-text-results" value="true"/>
   ```

**Related Information:**

- Creating an XProc Transformation Scenario (on page 1742)
- Integrating an External XProc Engine (on page 1747)
- XProc Preferences (on page 198)

**Editing Schematron Schemas**

Schematron is a simple and powerful Structural Schema Language for making assertions about patterns found in XML documents. It relies almost entirely on XPath query patterns for defining rules and checks. Schematron validation rules allow you to specify a meaningful error message. This error message is provided to you if an error is encountered during the validation stage.

There are numerous online resources out there to help you get started with writing Schematron rules. Here are just a few that might help you:

- Guide to Schema Writing with Schematron
- Presentation: Schematron Development with Oxygen
Oxygen XML Editor assists you in editing Schematron documents with schema-based content completion, syntax highlight, search and refactor actions, and dedicated icons for the Outline view (on page 1470). You can create a new Schematron schema using one of the Schematron templates available in the New document wizard (on page 676).

For information about applying and detecting Schematron schemas, see Associating a Schema to XML Documents (on page 1112).

Validating XML Documents Against Schematron

The Skeleton XSLT processor is used for validation and conforms with ISO Schematron or Schematron 1.5. It allows you to validate XML documents against Schematron schemas (on page 1464) or against combined RELAX NG / W3C XML Schema and Schematron.

How to Specify the Query Language Binding

You can specify the query language binding to be used in the Schematron schema by doing the following:

• For embedded ISO Schematron, open the Preferences dialog box (Options > Preferences) (on page 79), go to XML > XML Parser > Schematron, and select it in the Embedded rules query language binding option (on page 195).

• For standalone ISO Schematron, specify the version by setting the query language to be used in a queryBinding attribute on the schema root element. For more information, see the Query Language Binding section of the Schematron specifications.

• For Schematron 1.5 (standalone and embedded), open the Preferences dialog box (Options > Preferences) (on page 79), go to XML > XML Parser > Schematron, and select the version in the XPath Version option (on page 196).

Multi-Lingual Support in Schematron Messages

You can specify the desired language for the validation messages in the Schematron Preferences page (on page 194). The Schematron validation messages can be presented in multiple languages by defining the language for each message using the Schematron diagnostics. For more information, see the Use of Schematron for Multi-Lingual Schemas specification.

How to Customize Color Schemes in Schematron

The Schematron editor renders the XPath expressions with dedicated color schemes. To customize the coloring schemes, open the Preferences dialog box (Options > Preferences) (on page 79) and go to Editor > Syntax Highlight.
Schematron Transformation Scenario

When you create a Schematron document, Oxygen XML Editor provides a built-in transformation scenario. You can use this scenario to obtain the XSLT style-sheet corresponding to the Schematron schema. You can apply this XSLT stylesheet to XML documents to obtain the Schematron validation results.

For more information about the Schematron support in Oxygen XML Editor, watch our video demonstrations:

https://www.youtube.com/embed/HdcZA3DJi7E

https://www.youtube.com/embed/y3u3wlO92e4

https://www.youtube.com/embed/FQNSsg57S4E

Related Information:

• Editing XML Documents in Text Mode (on page 828)

• Associating a Schema to XML Documents (on page 1112)

Editing Schematron Schema in the Master Files Context

Smaller interrelated modules that define a complex Schematron cannot be correctly edited or validated individually, due to their interdependency with other modules. For example, a diagnostic defined in a main schema document is not visible when you edit an included module. Oxygen XML Editor provides the support for defining the main module (or modules), thus allowing you to edit any of the imported/included schema files in the context of the larger schema structure.

You can set a main Schematron document either using the master files support from the Project view (on page 726), or using a validation scenario.

To set a main file using a validation scenario, add validation units that point to the main schemas. Oxygen XML Editor warns you if the current module is not part of the dependencies graph computed for the main schema. In this case, it considers the current module as the main schema.

The advantages of editing in the context of main file include:

• Correct validation of a module in the context of a larger schema structure.
• Content Completion Assistant (on page 3280) displays all the referable components valid in the current context. This include components defined in modules other than the currently edited one.

Presenting Schematron Validation Issues

The possible issues that might occur during the validation process when validating XML documents against Schematron are presented with colored underlines in the editing pane, colored markers in the right vertical stripe, and details about the issues are presented in the Errors panel at the bottom area of the Oxygen XML Editor window. Each error is flagged with a severity level that can be: warning, error, fatal or info.

To set a severity level, Oxygen XML Editor looks for the following information:

• The role attribute, which can have one of the following values:
  - warn or warning - Sets the severity level to warning. By default, underlined with a yellow squiggly line in the editing pane and a yellow marker in the right vertical stripe.
  - error - Sets the severity level to error. By default, underlined with a red squiggly line in the editing pane and a red marker in the right vertical stripe.
  - fatal - Sets the severity level to fatal. By default, underlined with a red squiggly line in the editing pane and a red marker in the right vertical stripe.
  - info or information - Sets the severity level to information. By default, underlined with a blue squiggly line in the editing pane and a blue marker in the right vertical stripe.

• The start of the message, after trimming leading white-spaces. Oxygen XML Editor looks to match the following exact string of characters (case-sensitive):
  - Warning: - Sets the severity level to warning. By default, underlined with a yellow squiggly line in the editing pane and a yellow marker in the right vertical stripe.
  - Error: - Sets the severity level to error. By default, underlined with a red squiggly line in the editing pane and a red marker in the right vertical stripe.
  - Fatal: - Sets the severity level to fatal. By default, underlined with a red squiggly line in the editing pane and a red marker in the right vertical stripe.
  - Info: - Sets the severity level to info. By default, underlined with a blue squiggly line in the editing pane and a blue marker in the right vertical stripe.

• If none of the previous rules match, Oxygen XML Editor sets the severity level to error. By default, underlined with a red squiggly line in the editing pane and a red marker in the right vertical stripe.

Tip: You can configure the color for each type in the Document Checking preferences page (on page 180).
Integrating Schematron Rules in a Framework and Sharing Them

Custom **Schematron** rules are a great way to ensure consistency for XML authoring, especially when there is a large team working on the same set of documents. You can use **Schematron** for numerous use cases. For example, to restrict certain elements from being used, to impose restrictions on the amount of text for an element, or to impose restrictions on certain elements based on various attribute values or text content set in other elements. Furthermore, you can define quick fixes for each **Schematron** rule (on page 1482) to offer technical writers proposed solutions for reported problems.

Once you define the **Schematron** rules, they can be shared with the other members of your team by integrating them in a **framework** (on page 3282) (document type) configuration.

**How to Integrate Schematron Rules in a Framework**

To integrate a Schematron rule in an existing framework bundled with the application, follow these steps:

1. Create a folder structure for an extended framework and save it somewhere on disk where you have full write access (for example, `custom_frameworks/dita-extension`).
2. In that new folder structure, create another folder that will contain all of your custom Schematron files (for example, `custom_frameworks/dita-extension/rules`).
3. Define the Schematron rules in an existing or new Schematron file and save it in the folder you created in step 2. There are numerous online resources out there to help you get started with writing Schematron rules. Here are just a few that might help you:
   - **Guide to Schema Writing with Schematron**
   - **Presentation: Schematron Development with Oxygen**
4. Open the **Preferences** dialog box (Options > Preferences) (on page 79) and go to **Document Type Association > Locations** (on page 94). In this preferences page, add the path to your
custom_frameworks folder in the Additional frameworks directories list, then click OK or Apply to save your changes.

5. Go to the Document Type Association preferences page (on page 92) and select a framework configuration (for example, DITA) and use the Extend button to create an extension for it.

6. Give the extension an appropriate name (for example, DITA - Custom), select External for the Storage option, and specify an appropriate path to your framework configuration file (for example, path/to/.../custom_frameworks/dita-extension/dita-extension.framework).

7. Make whatever changes you desire to the extension, then go to the Validation tab, edit the default validation scenario (select the scenario and click the Edit button), and add an extra validation unit to it (one that uses your custom Schematron file). For more details about editing validation scenarios, see Configuring Validation Scenarios for a Framework (on page 2339).

8. Click OK to close the dialog box and then OK or Apply to save the changes to the Document Type Association preferences page (on page 92).

9. Open an XML document that matches your framework configuration and test the new rule.

10. You can continue to refine the Schematron and develop additional rules as needed.

Sharing Schematron Rules

To share Schematron rules with other members of your team, you simply need to share the framework where you integrated the Schematron rules. There are several methods for sharing frameworks and you can find details here: Sharing a Custom Framework (on page 2371).

Related Information:

- Defining Schematron Quick Fixes (on page 1482)

  Associating a Schema in Validation Scenarios Defined in the Document Type (on page 1118)

- Sharing a Custom Framework (on page 2371)

Validating Schematron Documents

By default, a Schematron schema is validated as you type. To change this, open the Preferences dialog box (Options > Preferences) (on page 79), go to Editor > Document Checking, and deselect the Enable automatic validation option (on page 181).
To validate a Schematron document manually, select the Validate action from the Validation toolbar drop-down menu or the Document > Validate menu. When Oxygen XML Editor validates a Schematron schema, it expands all the included modules so the entire schema hierarchy is validated. The validation problems are highlighted directly in the editor, making it easy to locate and fix any issues.

Oxygen XML Editor offers an error management mechanism capable of pinpointing errors in XPath expressions and in the included schema modules.

Related Information:
- Presenting Schematron Validation Issues (on page 1464)

Content Completion in Schematron Documents

Oxygen XML Editor helps you edit a Schematron schema through the Content Completion Assistant (on page 3280), offering proposals that are valid at the cursor position. It can be manually activated with the Ctrl + Space (Command + Space on OS X) shortcut.

When you edit the value of an attribute that refers a component, the proposed components are collected from the entire schema hierarchy. For example, if the editing context is phase/active/@pattern, the Content Completion Assistant proposes all the defined patterns.

Note: For Schematron resources, the Content Completion Assistant collects its components starting from the master files (on page 3284). The master files can be defined in the project or in the associated validation scenario. For further details about the Master Files support go to Defining Master Files at Project Level (on page 726).

If the editing context is an attribute value that is an XPath expression (such as assert/@test or report/@test), the Content Completion Assistant offers the names of XPath functions, the XPath axes, and user-defined variables.

The Content Completion Assistant displays XSLT 1.0 functions and optionally XSLT 2.0 / 3.0 functions in the attributes path, select, context, subject, test depending on the Schematron options (on page 194) that are set in Preferences pages. If the Saxon 6.5.5 namespace (xmlns:saxon="http://icl.com/saxon") or the Saxon 9.8.0.12 namespace is declared in the Schematron schema (xmlns:saxon="http://saxon.sf.net/") the content completion also displays the XSLT Saxon extension functions as in the following figure:

Figure 577. XSLT Extension Functions in Schematron Schema Content Completion
The Content Completion Assistant also includes code templates that can be used to quickly insert code fragments (on page 855) into Schematron documents.

Syntax Highlighting in Schematron

Oxygen XML Editor supports syntax highlighting in Text mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for Schematron schemas, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79).
2. Go to Editor > Syntax Highlight (on page 178).
3. Select and expand the XML section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.
5. Select the XML tab in the Preview pane to see the effects of your changes.

Tip: Oxygen XML Editor also allows you to specify syntax highlighting colors for specific XML elements and attributes with specific namespace prefixes. This can be done in the Editor > Syntax Highlight > Elements/Attributes by Prefix preferences page (on page 179).

Related Information:
Embedding Schematron Rules in XML Schema or RELAX NG

Schematron rules can be embedded into an XML Schema through annotations (using the `appinfo` element), or in any element on any level of a RELAX NG Schema (taking into account that the RELAX NG validator ignores all elements that are not in the RELAX NG namespace).

Oxygen XML Editor accepts such documents as Schematron validation schemas and it is able to extract and use the embedded rules.

Validating XML Documents with XML Schema and Embedded Schematron

To validate an XML document with XML Schema and its embedded Schematron, you can associate the document like this:

```xml
<?xml-model href="percent.xsd" type="application/xml"
         schematypens="http://purl.oclc.org/dsdl/schematron"?>
```

Validating XML Documents with Relax NG and Embedded Schematron

To validate an XML document with RELAX NG schema and its embedded Schematron rules, you need to associate the document with both schemas like this:

```xml
<?xml-model href="percent.rng" type="application/xml"
         schematypens="http://relaxng.org/ns/structure/1.0"?>
<?xml-model href="percent.rng" type="application/xml"
         schematypens="http://purl.oclc.org/dsdl/schematron"?>
```

The second association validates your document with Schematron rules extracted from the RELAX NG Schema.

Note: When you work with XML Schema or Relax NG documents that have embedded Schematron rules Oxygen XML Editor provides two built-in validation scenarios: Validate XML Schema with embedded Schematron for XML schema, and Validate Relax NG with embedded Schematron for Relax NG. You can use one of these scenarios to validate the embedded Schematron rules.

Example: Embedded Schematron in XML Schema

```xml
<xsd:appinfo>
  <sch:pattern>
```
Example: Embedded Schematron in Relax NG Schema

```xml
<grammar
    xmlns="http://relaxng.org/ns/structure/1.0"
    xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <sch:pattern>
    <sch:rule context="...">
      <sch:assert test="...">Message.</sch:assert>
    </sch:rule>
  </sch:pattern>
  <start>..............</start>
</grammar>
```

Schematron Outline View

The **Outline** view for Schematron schemas presents a list of components in a tree-like structure and it allows for quick access to a component by name. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

Figure 578. Schematron Outline View
The following actions are available in the Settings menu on the Outline view toolbar:

**Filter returns exact matches**

The text filter of the Outline view returns only exact matches.

**Selection update on cursor move**

Controls the synchronization between Outline view and source document. The selection in the Outline view can be synchronized with the cursor moves or the changes in the editor. Selecting one of the components from the Outline view also selects the corresponding item in the source document.

**Flat presentation mode of the filtered results**

When active, the application flattens the filtered result elements to a single level.

**Show comments and processing instructions**

Show/hide comments and processing instructions in the Outline view.

**Show element name**

Show/hide element name.

**Show text**

Show/hide additional text content for the displayed elements.

**Show attributes**

Show/hide attribute values for the displayed elements. The displayed attribute values can be changed from the Outline preferences panel (on page 259).

**Configure displayed attributes**

Displays the XML Structured Outline preferences page (on page 259).

The following contextual menu actions are also available in the Outline view:
Append Child
Displays a list of elements that you can insert as children of the current element.

Insert Before
Displays a list of elements that you can insert as siblings of the current element, before the current element.

Insert After
Displays a list of elements that you can insert as siblings of the current element, after the current element.

Edit Attributes
Opens a dialog box that allows you to edit the attributes of the currently selected component.

Toggle Comment
Comments/uncomments the currently selected element.

Cut
Cuts the currently selected component.

Copy
Copies the currently selected component.

Delete
Deletes the currently selected component.

Expand More
Expands the structure of a component in the Outline view.

Collapse All
Collapses the structure of all the component in the Outline view.

The upper part of the Outline view contains a filter box that allows you to focus on the relevant components. Type a text fragment in the filter box and only the components that match it are presented. For advanced usage you can use wildcard characters (such as *, ?) and separate multiple patterns with commas.

Schematron Resource Hierarchy/Dependencies View
The Resource Hierarchy/Dependencies view displays the hierarchy/dependencies for a Schematron schema. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.
If you want to see the hierarchy of a schema, select the desired schema in the Project view (on page 333) and choose Resource Hierarchy from the contextual menu.

Figure 579. Resource Hierarchy

If you want to see the dependencies of a schema, select the desired schema in the Project view (on page 333) and choose Resource Dependencies from the contextual menu.

Figure 580. Resource Dependencies

The following actions are available on the toolbar of the Resource Hierarchy/Dependencies view:

- **Refresh**
  Refreshes the Hierarchy/Dependencies structure.

- **Stop**
  Stops the hierarchy/dependencies computing.

- **Show Hierarchy**
  Allows you to choose a resource to compute the hierarchy structure.

- **Show Dependencies**
  Allows you to choose a resource to compute the dependencies structure.

- **Configure dependencies search scope**
  Allows you to configure a scope to compute the dependencies structure. There is also an option for automatically using the defined scope for future operations.

- **History**
Provides access to the list of previously computed dependencies. Use the Clear history button to remove all items from this list.

The contextual menu for a resource listed in the Resource Hierarchy/Dependencies view contains the following actions:

**Open**

Opens the resource. You can also double-click a resource in the Hierarchy/Dependencies structure to open it.

**Go to reference**

Opens the source document where the resource is referenced.

**Copy location**

Copies the location of the resource.

**Move resource**

Moves the selected resource.

**Rename resource**

Renames the selected resource.

**Show Resource Hierarchy**

Shows the hierarchy for the selected resource.

**Show Resource Dependencies**

Shows the dependencies for the selected resource.

**Add to Master Files**

Adds the currently selected resource in the Master Files directory (on page 726).

**Expand All**

Expands all the children of the selected resource from the Hierarchy/Dependencies structure.

**Collapse All**

Collapses all children of the selected resource from the Hierarchy/Dependencies structure.

**Tip:** When a recursive reference is encountered in the Hierarchy view, the reference is marked with a special icon.

**Note:** The Move resource or Rename resource actions give you the option to update the references to the resource (on page 1474).
Moving/Renaming Schematron Resources

You can move and rename a resource presented in the Resource/Hierarchy Dependencies view, using the Rename resource and Move resource refactoring actions from the contextual menu.

When you select the Rename action in the contextual menu of the Resource/Hierarchy Dependencies view, the Rename resource dialog box is displayed. The following fields are available:

- **New name** - Presents the current name of the edited resource and allows you to modify it.
- **Update references of the renamed resource(s)** - Select this option to update the references to the resource you are renaming. A Preview option is available that allows you to see what will be updated before selecting Rename to process the operation.

When you select the Move action from the contextual menu of the Resource/Hierarchy Dependencies view, the Move resource dialog box is displayed. The following fields are available:

- **Destination** - Presents the path to the current location of the resource you want to move and gives you the option to introduce a new location.
- **New name** - Presents the current name of the moved resource and gives you the option to change it.
- **Update references of the moved resource(s)** - Select this option to update the references to the resource you are moving, in accordance with the new location and name. A Preview option is available that allows you to see what will be updated before selecting Move to process the operation.

Highlight Component Occurrences in Schematron Documents

When you position your mouse cursor over a component in a Schematron document, Oxygen XML Editor searches for the component declaration and all its references and highlights them automatically.

Customizable colors are used: one for the component definition and another one for component references. Occurrences are displayed until another component is selected.

To change the default behavior of Highlight Component Occurrences, open the Preferences dialog box (Options > Preferences) (on page 79) and go to Editor > Mark Occurrences. You can also trigger a search using the Search > Search Occurrences in File Ctrl + Shift + U (Command + Shift + U on OS X) action from contextual menu. Matches are displayed in separate tabs of the Results view (on page 357).
Searching and Refactoring Operations in Schematron Documents

Search Actions

The following search actions can be applied on pattern, phase, or diagnostic types and are available from the Search submenu in the contextual menu of the current editor or from the Document menu:

- **Search References**
  Searches all references of the item found at current cursor position in the defined scope, if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box is displayed and you have the possibility to define another search scope.

- **Search References in**
  Searches all references of the item found at current cursor position in the file or files that you specify when define a scope in the Search References dialog box.

- **Search Declarations**
  Searches all declarations of the item found at current cursor position in the defined scope if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box will be displayed and you have the possibility to define another search scope.

- **Search Declarations in**
  Searches all declarations of the item found at current cursor position in the file or files that you specify when you define a scope for the search operation.

- **Search Occurrences in File**
  Searches all occurrences of the item at the cursor position in the currently edited file.

Refactoring Actions

The following refactoring actions can be applied on pattern, phase, or diagnostic types and are available from the Refactoring submenu in the contextual menu of the current editor or from the Document > Refactoring menu:

- **Rename Component**
  Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the Esc or Enter key on your keyboard.
**Rename Component in**

Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the **Preview** button, you can view the files to be affected by the action.

Figure 581. Rename Identity Constraint Dialog Box

![Rename Identity Constraint Dialog Box](image)

---

**Searching and Refactoring Operations Scope in Schematron Documents**

The **scope** is a collection of documents that define the context of a search and refactor operation. To control it you can use the **Change scope** operation, available in the **Quick Assist** action set or on the **Resource Hierarchy/Dependency View** toolbar. You can restrict the scope to the current project or to one or multiple **working sets (on page 3288)**. The **Use only Master Files, if enabled** checkbox allows you to restrict the scope of the search and refactor operations to the resources from the **Master Files** directory. Click **read more** for details about the **Master Files support (on page 726)**.

Figure 582. Change Scope Dialog Box
The scope you define is applied to all future search and refactor operations until you modify it. Contextual menu actions allow you to add or delete files, folders, and other resources to the working set (on page 3288) structure.

Quick Assist Support in Schematron Documents

The Quick Assist support (on page 3286) improves the development work flow, offering fast access to the most commonly used actions when you edit schema documents.

The Quick Assist feature (on page 3286) is activated automatically when the cursor is positioned over the name of a component. It is accessible via a yellow bulb icon ((Roles) placed at the current line in the stripe on the left side of the editor. Also, you can invoke the quick assist menu by using the Alt + 1 (Meta + Alt + 1 on Mac OS X) keyboard shortcuts.

Figure 583. Schematron Quick Assist Support

The Quick Assist support offers direct access to the following actions:

- Rename Component in
Renames the component and all its dependencies.

- **Search Declarations**
  Searches the declaration of the component in a predefined scope. It is available only when the context represents a component name reference.

- **Search References**
  Searches all references of the component in a predefined scope.

- **Component Dependencies**
  Searches the component dependencies in a predefined scope.

- **Change Scope**
  Configures the scope that will be used for future search or refactor operations.

- **Rename Component**
  Allows you to rename the current component in-place.

- **Search Occurrences**
  Searches all occurrences of the component within the current file.

### Schematron Unit Test (XSpec)

XSpec is a behavior driven development (BDD) framework for XSLT, XQuery, and Schematron. XSpec consists of syntax for describing the behavior of your XSLT, XQuery, or Schematron code, and some code that enables you to test your code against those descriptions.

#### Creating a Schematron Unit Test

To create a Schematron Unit Test, go to File > New > Schematron Unit Test. This is simple document template to help you get started.

#### Running a Schematron Unit Test

To run a Unit Test, open the XSpec file in an editor and click **Apply Transformation Scenario(s)** on the main toolbar. This will run the built-in **Run XSpec Test** transformation scenario that is defined in the XSpec framework (on page 3282).

#### Testing a Stylesheet

An XSpec file contains one or more test scenarios.

**Example**
Suppose you have this Schematron rule that says sections should have a title:

```
<sch:pattern>
  <sch:rule context="section">
    <sch:assert test="title" id="a002">
      section should have a title
    </sch:assert>
  </sch:rule>
</sch:pattern>
```

The XSpec test could look like this:

```
<x:description xmlns:x="http://www.jenitennison.com/xslt/xspec" schematron="demo-01.sch">
  <x:scenario label="section should have a title">
    <x:context>
      <article>
        <section>
          <title>Introduction</title>
          <p>This is an example.</p>
        </section>
        <section>
          <p>This is an example.</p>
        </section>
      </article>
    </x:context>
    <x:expect-not-assert id="a002" location="/article[1]/section[1]"/>
    <x:expect-assert id="a002" location="/article[1]/section[2]"/>
  </x:scenario>
</x:description>
```

The `sch:assert` with the `id="a002"` is not expected to be triggered on the first section since it includes a title. This requirement is expressed with the `x:expect-not-assert` element.

Since the second section does not have a title, you would expect the Schematron rule to be triggered and this requirement is expressed with the `x:expect-assert` element.

For more details about how to write Schematron tests and various samples, see [https://github.com/xspec/xspec/wiki/Writing-Scenarios-for-Schematron#writing-tests](https://github.com/xspec/xspec/wiki/Writing-Scenarios-for-Schematron#writing-tests).
Adding a Catalog to an XSpec Transformation

If your Schematron needs a catalog, you can add one to the XSpec transformation by doing one of the following:

- If you are using a project (on page 707) in Oxygen XML Editor, create a catalog.xml file in the project directory. This catalog will then be loaded automatically.
- Edit (on page 1758) the Run XSpec Test transformation scenario, go to the Parameters tab (on page 1720), and set the value of the catalog parameter to the location of your catalog file.

Editing Schematron Quick Fixes

Oxygen XML Editor provides support for editing the Schematron Quick Fixes (on page 1111). You can define a library of Quick Fixes by editing them directly in the current Schematron file or in a separate file. Oxygen XML Editor assists you in editing Schematron Quick Fixes with schema-based content completion, syntax highlighting, and validation as you type.

For information about applying and detecting the Schematron schemas that include SQF, see Associating a Schema to XML Documents (on page 1112).

### Related Information:

- Oxygen XML Blog: Schematron Checks to Help Technical Writing

### Schematron Quick Fixes (SQF)

Oxygen XML Editor provides support for Schematron Quick Fixes (on page 3287) (SQF). They help you resolve issues that appear in XML documents that are validated against Schematron schemas by offering you solution proposals. The Schematron Quick Fixes are an extension of the Schematron language and they allow you to define fixes for Schematron validation messages. Specifically, they are associated with assert or report messages.

A typical use case is using Schematron Quick Fixes to assist content authors with common editing tasks. For example, you can use Schematron rules to automatically report certain validation warnings (or errors) when performing regular editing tasks, such as inserting specific elements or changing IDs to match specific naming conventions. For more details and examples, see the following blog post: [http://blog.oxygenxml.com/2015/05/schematron-checks-to-help-technical.html](http://blog.oxygenxml.com/2015/05/schematron-checks-to-help-technical.html).
Displaying the Schematron Quick Fix Proposals

The defined Schematron Quick Fixes are displayed on validation errors in Text mode and Author mode.

Figure 584. Example of a Schematron Quick Fix

Related Information:

- Editing Schematron Quick Fixes (on page 1481)
- Schematron Quick Fix Specifications
- Presenting Schematron Validation Issues (on page 1464)

Defining Schematron Quick Fixes

You can define and customize Schematron Quick Fixes (on page 3287) directly in the current Schematron file or in a separate Schematron file. The Schematron Quick Fixes are an extension of the Schematron language and they allow you to define fixes for Schematron error messages. You can refer the Quick Fixes from the assert or report elements in the values of the sqf:fix attributes.

Defining a Schematron Quick Fix

The basics of a Schematron Quick Fix is defined by an ID, name, description, and the operations to be executed.

- **ID** - Defined by the id attribute from the fix element and must be unique in the current context. It is used to refer the Quick Fix from a report or assert element.
- **Name** - The name of the Quick Fix is defined by the title element.
- **Description** - Defined by the text in the paragraphs (p) of the description element.
- **Operations** - The following basic types of operations (elements) (on page 1484) are supported:
  - `<sqf:add>` Element - To add a new node or fragment in the document.
  - `<sqf:delete>` Element - To remove a node from the document.
Figure 585. Schematron Quick Fix Components

The assertion message that generates the Quick Fix is added as the description of the problem to be fixed. The title is presented as the name of the Quick Fix. The content of the paragraphs (p) within the description element are presented in the tooltip message when the Quick Fix is selected.

Additional Elements Supported in the Schematron Quick Fixes

<sqf:user-entry>

This element defines a value that must be set manually by the user. For more information, see User Entry SQF Operation (on page 1488).

</sqf:user-entry>

<sqf:call-fix>

This element calls another Quick Fix within a Quick Fix. The called Quick Fix must be defined globally or in the same Schematron rule as the calling Quick Fix. A calling Quick Fix adopts the activity elements of the called Quick Fix and should not include other activity elements. You can also specify which parameters are sent by using the <sqf:with-param> child element.

</sqf:call-fix>

<sqf:group>

Allows you to group multiple Quick Fixes and refer them from an assert or report element.

</sqf:group>

<sqf:fixes>

Is defined globally and contains global fixes and groups of fixes.

</sqf:fixes>
Used to copy the selected nodes that are specified by the `select` attribute. The element with its attribute is treated as an `xsl:copy-of` with a `select` attribute, as defined in the XSLT specification.

```
<sqf:param>
  Defines a parameter for a Quick Fix. If the parameter is defined as `abstract` then the `type` and default value should not be specified and the fix can be called from an abstract pattern that defines this parameter.
```

Other SQF Notes

Note: The `sqf:default-fix` attribute is ignored in Oxygen XML Editor.

For more details on editing Schematron Quick Fixes, go to: Schematron Quick Fix Specifications

Basic Schematron Quick Fix Operations

There are four basic operations that can be executed in a Schematron Quick Fix (on page 3287): **Add**, **Delete**, **Replace**, and **String Replace**.

**Add**

The `<sqf:add>` element allows you to add a node to the instance. An `anchor` node is required to select the position for the new node. The `anchor` node can be selected by the `match` attribute. Otherwise, it is selected by the `context` attribute of the rule.

The `target` attribute defines the name of the node to be added. It is required if the value of the `node-type` attribute is set to anything other than "comment".

The `<sqf:add>` element has a `position` attribute and it determines the position relative to the `anchor` node. The new node could be specified as the first child of the `anchor` node, the last child of the `anchor` node, before the `anchor` node, or after the `anchor` node (`first-child` is the default value). If you want to add an attribute to the `anchor` node, do not use the `position` attribute.

Note: If you insert an element and its content is empty, Oxygen XML Editor will insert the required element content.

**An Example of the `<sqf:add>` Element:**

```
<schema xmlns="http://purl.oclc.org/dsdl/schematron"
  xmlns:sqf="http://www.schematron-quickfix.com/validator/process"
  queryBinding="xslt2">
  <pattern>
    <rule context="head">
```

Specific Add Operations:

- **Insert Element** - To insert an element, use the `<sqf:add>` element, set the value of the `node-type` to "element", and specify the element `QName (on page 3286)` with the `target` attribute. If the element has a prefix, it must be defined in the Schematron using a namespace declaration (`<ns uri="namespace" prefix="prefix"/>`).

- **Insert Attribute** - To insert an attribute, use the `<sqf:add>` element, set the value of the `node-type` to "attribute", and specify the attribute `QName (on page 3286)` with the `target` attribute. If the attribute has a prefix, it must be defined in the Schematron using a namespace declaration (`<ns uri="namespace" prefix="prefix"/>`).

- **Insert Fragment** - If the `node-type` is not specified, the `<sqf:add>` element will insert an XML fragment. The XML fragment must be well formed. You can specify the fragment in the `add` element or by using the `select` attribute.

- **Insert Comment** - To insert a comment, use the `<sqf:add>` element and set the value of the `node-type` to "comment".

- **Insert Processing Instruction** - To insert a processing instruction, use the `<sqf:add>` element, set the value of the `node-type` to "pi" or "processing-instruction", and specify the name of the processing instruction in the `target` attribute.

**Delete**

The `<sqf:delete>` element allows you to remove any type of node (such as elements, attributes, text, comments, or processing instructions). To specify nodes for deletion the `<sqf:delete>` element can include a `match` attribute that is an XPath expression (the default value is `.`). If the `match` attribute is not included, it deletes the context node of the Schematron rule.
An Example of the `<sqf:delete>` Element:

```xml
<schema xmlns="http://purl.oclc.org/dsdl/schematron" queryBinding="xslt2"
       xmlns:sqf="http://www.schematron-quickfix.com/validator/process">
    <pattern>
        <rule context="*[@xml:lang]">
            <report test="@xml:lang" sqf:fix="remove_lang">
                The attribute "xml:lang" is forbidden.</report>
            <sqf:fix id="remove_lang">
                <sqf:description>
                    <sqf:title>Remove "xml:lang" attribute</sqf:title>
                </sqf:description>
                <sqf:delete match="@xml:lang"/>
            </sqf:fix>
        </rule>
    </pattern>
</schema>
```

Replace

The `<sqf:replace>` element allows you to replace nodes. Similar to the `<sqf:delete>` element, it can include a `match` attribute. Otherwise, it replaces the context node of the rule. The `<sqf:replace>` element has three tasks. It identifies the nodes to be replaced, defines the replacing nodes, and defines their content.

An Example of the `<sqf:replace>` Element:

```xml
<schema xmlns="http://purl.oclc.org/dsdl/schematron"
        xmlns:sqf="http://www.schematron-quickfix.com/validator/process"
        queryBinding="xslt2">
    <pattern>
        <rule context="title">
            <report test="exists(ph)" sqf:fix="resolvePh" role="warn">
                ph element is not allowed in title.</report>
            <sqf:fix id="resolvePh">
                <sqf:description>
                    <sqf:title>Change the ph element into text</sqf:title>
                </sqf:description>
                <sqf:replace match="ph">
                    <value-of select="."/>
                </sqf:replace>
            </sqf:fix>
        </rule>
    </pattern>
</schema>
```
Other Attributes for Replace Operations:

- **node-type** - Determines the type of the replacing node. The permitted values include:
  - keep - Keeps the node type of the node to be replaced.
  - element - Replaces the node with an element.
  - attribute - Replaces the node with an attribute.
  - pi - Replaces the node with a processing instruction.
  - comment - Replaces the node with a comment.

- **target** - By using a QName (on page 3286) it gives the replacing node a name. This is necessary when the value of the node-type attribute is anything other than "comment".

- **select** - Allows you to choose the content of the replacing nodes. You can use XPath expressions with the select attribute. If the select attribute is not specified then the content of the <sqf:replace> element is used instead.

**String Replace**

The <sqf:stringReplace> element is different from the others. It can be used to find a sub-string of text content and replace it with nodes or other strings.

**Attributes for the String Replace Operation:**

- **match** - Allows you to select text nodes that contain the sub-strings you want to replace.
- **select** - Allows you to select the replacing fragment, in case you do not want to set it in the content of the stringReplace element.
- **regex** - Matches the sub-strings using a regular expression.

**Note:** Consider the following information about using regular expressions in the stringReplace element:

- The regular expressions from this operation are compiled as Java regular expressions. For more information, see [https://docs.oracle.com/javase/7/docs/api/java/util/regex/Pattern.html](https://docs.oracle.com/javase/7/docs/api/java/util/regex/Pattern.html).
- The j flag allows you to use the standard Java regular expression engine, which allows native Java regular expression syntax. This allows, for example, the use of \b in a regular expression to match word boundaries. For more information, see [http://www.saxonica.com/html/documentation/functions/fn/matches.html](http://www.saxonica.com/html/documentation/functions/fn/matches.html).
Regular expressions in the `<sqf:stringReplace>` element always have the `dot matches all` flag set to "true". Therefore, the line terminator will also be matched by the regular expression.

- **flags** - Specifies flags to control the interpretation of the regular expression (given in the `regex` attribute).

⚠️ **Attention:** The context of the content within the `<sqf:stringReplace>` element is set to the whole text node, rather than the current sub-string.

**An Example of the `<sqf:stringReplace>` Element:**

```xml
<?xml version="1.0" encoding="UTF-8"?>
<sch:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron"
            xmlns:sqf="http://www.schematron-quickfix.com/validator/process"
            queryBinding="xslt2">
    <sch:pattern>
        <sch:rule context="text()">
            <sch:report test="matches(., 'Oxygen', 'i')">
                The oXygen word is not allowed</sch:report>
            <sqf:fix id="changeWord">
                <sqf:description>
                    <sqf:title>Replace word with product</sqf:title>
                </sqf:description>
                <sqf:stringReplace regex="Oxygen" flags="i">
                    <ph keyref="product"/>
                </sqf:stringReplace>
            </sqf:fix>
        </sch:rule>
    </sch:pattern>
</sch:schema>
```

**Related Information:**

- User Entry SQF Operation (on page 1488)
- Restricting Quick Fix Operations (on page 1489)
User Entry SQF Operation

The `<sqf:user-entry>` element defines a value that must be set manually by the user. If multiple `<user-entry>` elements are defined, Oxygen XML Editor will display a dialog box for each one, in which the user can specify values. Also, the `<user-entry>` element can be used as an XPath variable where the XPath variable is the name of the `<user-entry>`. Note that the `default` attribute defines a default value for the operation by using an XPath expression (as in the example below) and its value will be presented in the user entry dialog box.

**An Example of the `<sqf:user-entry>` Element:**

```xml
<sqf:fix id="editTitle">
  <sqf:description>
    <sqf:title>Edit the journal title</sqf:title>
  </sqf:description>
  <sqf:user-entry name="newTitle" default="@title">
    <sqf:description>
      <sqf:title>Edit the title:</sqf:title>
    </sqf:description>
  </sqf:user-entry>
  <sqf:replace match="@title" target="title" node-type="keep" select="$newTitle"/>
</sqf:fix>
```

**Related Information:**

- Basic Schematron Quick Fix Operations *(on page 1484)*

Restricting Quick Fix Operations

To restrict a *Quick Fix *(on page 3287) or a specific operation to only be available if certain conditions are met, the `use-when` attribute can be included in the `<sqf:fix>` element or any of the SQF operation elements. The condition of the `use-when` attribute is an XPath expression and the fix or operation will be performed only if the condition is satisfied. In the following example, the `use-when` condition is applied to the `<sqf:fix>` element:

```xml
<sqf:fix id="last" use-when="$colWidthSummarized - 100 lt $lastWidth" role="replace">
  <sqf:description>
    <sqf:title>Subtract excessive width from the last element.</sqf:title>
  </sqf:description>
  <let name="delta" value="$colWidthSummarized - 100"/>
</sqf:fix>
```
Related Information:

- Basic Schematron Quick Fix Operations *(on page 1484)*

Formatting/Indenting Content Inserted by SQF Operations

Content that is inserted by the **Add**, **Replace**, or **String Replace** Schematron Quick Fix *(on page 3287)* operations is automatically indented unless you set the value of the `xml:space` attribute to `preserve` on the operation element. There are several methods available to format the content that is inserted:

- **xsl:text** - You can use an `xsl:text` element to format the inserted content and keep the automatic indentation, as in the following example:

```
<sqf:add position="last-child">
    <row><xsl:text>
        <entry>First column</entry><xsl:text>
        <entry>Second column</entry><xsl:text>
    </row><xsl:text>
</sqf:add>
```

- **xml:space** - Use the `xml:space` attribute and set its value to `preserve` to format the content and specify the spacing between elements, as in the following example:

```
<sqf:add node-type="element" target="codeblock" xml:space="preserve">
    /* a long sample program */
    Do forever
    Say "Hello, World"
    End</sqf:add>
```
Executing Schematron Quick Fixes in Other Documents

You can apply Schematron Quick Fixes (on page 3287) over nodes from referenced documents (using XInclude or external entities), and you can access them as nodes in your current document.

Also, you can apply the Quick Fixes over other documents using the doc() function in the value of the match attribute. For example, you can add a new key in the keylist.xml file using the following operation:

```xml
<sqf:add match="doc('keylist.xml')/KeyList" target="Key"
node-type="element" select="Key2">
</sqf:add>
```

Generate Multiple Similar Quick Fixes

You can generate the same Schematron Quick Fix (on page 3287) for multiple matches. To do this, you can add the use-for-each attribute inside the sqf:fix element and for each match of the XPath expression in the value of the use-for-each attribute, a Quick Fix will be presented to the user. The XPath expression does not change the context of the Quick Fix. If you want to access the current match from the XPath expression, you can use the $sqf:current variable.

**Example:**

Suppose you want to restrict the user from entering more than 4 list items in a list. The following example presents an error on any list that has more than 4 list items and offers a Quick Fix with multiple proposals where the user would specify which list item to remove.

```xml
<sch:rule context="ul">
  <sch:report test="count(li) gt 4" sqf:fix="removeAnyItem">
    The list cannot contain more than 4 entries.
  </sch:report>
  <sqf:fix id="removeAnyItem" use-for-each="1 to count(li)">
    <sqf:description>
      <sqf:title>Remove item #<sch:value-of select="$sqf:current"/></sch:title>
    </sqf:description>
    <sqf:delete match="li[$sqf:current]"/>
  </sqf:fix>
</sch:rule>
```
Localizing SQF Messages

Oxygen XML Editor provides support for presenting Schematron Quick Fix messages in multiple languages. The language used for the SQF messages is the language specified in the `Message Language` option in the Schematron preferences page (on page 195). If you want to provide an alternative message for a specific language, you can reference IDs or key values for the specific alternate text phrase. In Oxygen XML Editor, the alternate text phrase is defined in a `sch:diagnostic` element and it can be used in conjunction with `sch:assert` or `sch:report` elements.

**Example:**

The following example presents a quick fix with a different message depending on whether the user's language is English or German.

```xml
<sch:rule context="dog">
  <sch:assert test="bone" diagnostics="d_en d_de" sqf:fix="addBone">
    A dog should have a bone. </sch:assert>

  <sqf:fix id="addBone">
    <sqf:description>
      <sqf:title ref="fix_en fix_de" xml:lang="en">Add a bone</sqf:title>
      <sqf:p ref="fix_desc_en fix_desc_de" xml:lang="en">Add bone element as child</sqf:p>
    </sqf:description>
    <sqf:add node-type="element" target="bone"/>
  </sqf:fix>
</sch:rule>

....

<sch:diagnostics xml:lang="en">
  <sch:diagnostic id="d_en"> A dog should have a bone. </sch:diagnostic>
  <sch:diagnostic id="fix_en"> Add a bone </sch:diagnostic>
  <sch:diagnostic id="fix_desc_en">Add a bone element as child</sch:diagnostic>
</sch:diagnostics>

<sch:diagnostics xml:lang="de">
  <sch:diagnostic id="d_de"> Ein Hund sollte ein Bein haben. </sch:diagnostic>
  <sch:diagnostic id="fix_de"> Fugen Sie einen Knochen hinzu </sch:diagnostic>
  <sch:diagnostic id="fix_desc_de">Fugen Sie ein Knochenelement als untergeordnetes Element hinzu</sch:diagnostic>
</sch:diagnostics>
```
Integrating SQF in a Framework and Sharing Them

You can use Schematron Quick Fixes (on page 3287) to assist your content authors by imposing rules for an entire framework (on page 3282) (document type) and offering fixes when a rule violation is detected.

For example, if you are using DITA, you may want your contributors to avoid inserting a figure (fig element) inside a paragraph (p element) that contains other content since it may result in undesirable placement or spacing in the output. The Schematron rule and its Quick Fix for this particular use-case could look like this:

```xml
<schema xmlns="http://purl.oclc.org/dsdl/schematron"
    xmlns:sqf="http://www.schematron-quickfix.com/validator/process"
    queryBinding="xslt2">
  <pattern id="check.figure.location">
    <rule context="p/fig">
      <report test="true()" role="warn" sqf:fix="moveAfter">
        A figure inside a paragraph doesn't transform well into PDF. </report>
      <sqf:fix id="moveAfter">
        <sqf:description>
          <sqf:title>Move after the paragraph.</sqf:title>
        </sqf:description>
        <let name="figToMove" value="."/>
        <sqf:add match="parent::p" select="$figToMove" position="after"/>
        <sqf:delete match="."/>
      </sqf:fix>
    </rule>
  </pattern>
</schema>
```

The result of this example would be that the user will see a warning if they insert a fig element inside a p element and they are presented with the option of selecting the Quick Fix that would move the figure outside the paragraph.

How to Integrate SQF in a Framework

To integrate a Schematron Quick Fix in a framework (on page 3282), follow these steps:

1. Create a folder structure for an extended framework and save it somewhere on disk where you have full write access (for example, custom_frameworks/dita-extension).
2. In that new folder structure, create another folder that will contain all of your custom Schematron files (for example, custom_frameworks/dita-extension/rules).
3. Define the Schematron *Quick Fix for a rule* (on page 1482) in an existing or new Schematron file and save it in the folder you created in step 2.

4. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Document Type Association > Locations (on page 94). In this preferences page, add the path to your customFrameworks folder in the Additional frameworks directories list, then click OK or Apply to save your changes.

5. Go to the Document Type Association preferences page (on page 92) and select a framework configuration (for example, DITA) and use the Extend button to create an extension for it.

6. Give the extension an appropriate name (for example, DITA - Custom), select External for the Storage option, and specify an appropriate path to your framework configuration file (for example, path/to/.../custom_frameworks/dita-extension/dita-extension.framework).

7. Make whatever changes you desire to the extension, then go to the Validation tab, edit the default validation scenario (select the scenario and click the Edit button), and add an extra validation unit to it (one that uses your custom Schematron file that includes the SQF). For more details about editing validation scenarios, see Configuring Validation Scenarios for a Framework (on page 2339).

8. Click OK to close the dialog box and then OK or Apply to save the changes to the Document Type Association preferences page (on page 92).

9. Add a reference to the Schematron file that includes the SQF in your framework by following the procedure in Associating a Schema in Validation Scenarios Defined in the Document Type (on page 1118).

10. Open a document in your framework and test the new rule and Quick Fix.

11. You can continue to refine the Schematron and develop additional rules as needed.

**Sharing Schematron Quick Fixes**

To share Schematron Quick Fixes with other members of your team, you simply need to share the framework where you integrated the SQF. There are several methods for sharing frameworks and you can find details here: Sharing a Custom Framework (on page 2371).

**Related Information:**

- Defining Schematron Quick Fixes (on page 1482)
- Basic Schematron Quick Fix Operations (on page 1484)

  Associating a Schema in Validation Scenarios Defined in the Document Type (on page 1118)
Validating Schematron Quick Fixes

By default, Schematron Quick Fixes are validated as you edit them within the Schematron file or while editing them in a separate file. To change this, open the Preferences dialog box (Options > Preferences) (on page 79), go to Editor > Document Checking, and deselect the Enable automatic validation option (on page 181).

To validate Schematron Quick Fixes manually, select the Validate action from the Validation toolbar drop-down menu or the Document > Validate menu. The validation problems are highlighted directly in the editor, making it easy to locate and fix any issues.

Related Information:

• Validating XML Documents Against a Schema (on page 1081)

• Validation Scenario (on page 1093)

• Presenting Validation Errors in Author Mode (on page 445)

• Presenting Validation Errors in Text Mode (on page 364)

Content Completion in SQF

Oxygen XML Editor helps you edit Schematron Quick Fixes embedded in a Schematron document by offering proposals that are valid at the cursor position in a Content Completion Assistant (on page 3280). It can be manually activated with the Ctrl + Space (Command + Space on OS X) shortcut.

When you edit the value of an attribute that references a Quick Fix ID, the ids are collected from the entire definition scope. For example, if the editing context is assert/@sqf:fix, the Content Completion Assistant proposes all fixes defined locally and globally.

If the editing context is an attribute value that is an XPath expression (such as sqf:add/@match or replace/@select), the Content Completion Assistant offers the names of XPath functions, the XPath axes, and user-defined variables and parameters.
The *Content Completion Assistant* displays XSLT 1.0 functions (and optionally XSLT 2.0 / 3.0 functions) in the attributes *path*, *select*, *context*, *subject*, and *test*, depending on the Schematron options *(on page 194)* that are set in Preferences pages. If the Saxon 6.5.5 namespace *(xmlns:saxon="http://icl.com/saxon")* or the Saxon 9.8.0.12 namespace is declared in the Schematron schema *(xmlns:saxon="http://saxon.sf.net/")* the content completion also displays the XSLT Saxon extension functions.

**Highlight Quick Fix Occurrences in SQF**

When you position your mouse cursor over a *Quick Fix (on page 3287)* ID in a Schematron document, Oxygen XML Editor searches for the *Quick Fix* declaration and all its references and highlights them automatically.

Customizable colors are used: one for the *Quick Fix* definition and another one for its references. Occurrences are displayed until another *Quick Fix* is selected.

To change the default behavior of **Highlight Component Occurrences**, open the *Preferences* dialog box *(Options > Preferences) (on page 79)* and go to Editor > Mark Occurrences. You can also trigger a search using the *Search > Search Occurrences in File (Ctrl + Shift + U (Command + Shift + U on OS X))* action from contextual menu. Matches are displayed in separate tabs of the *Results view (on page 357)*.

**Searching and Refactoring Operations in SQF**

**Search Actions**

The following search actions can be applied on *Quick Fix (on page 3287)* IDs and are available from the *Search* submenu in the contextual menu of the current editor or from the *Document > References* menu:

- **Search References**
  
  Searches all references of the item found at current cursor position in the defined scope, if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box is displayed and you have the possibility to define another search scope.

- **Search References in**
  
  Searches all references of the item found at current cursor position in the file or files that you specify when define a scope in the *Search References* dialog box.

- **Search Declarations**
Searches all declarations of the item found at current cursor position in the defined scope if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box will be displayed and you have the possibility to define another search scope.

Search Declarations in

Searches all declarations of the item found at current cursor position in the file or files that you specify when you define a scope for the search operation.

Search Occurrences in File

Searches all occurrences of the item at the cursor position in the currently edited file.

Refactoring Actions

The following refactoring actions can be applied on Quick Fix IDs and are available from the Refactoring submenu in the contextual menu of the current editor or from the Document > Refactoring menu:

Rename Component

Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the Esc or Enter key on your keyboard.

Rename Component in

Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the Preview button, you can view the files to be affected by the action.

Figure 586. Rename Identity Constraint Dialog Box
Embedding Schematron Quick Fixes in Relax NG or XML Schema

Schematron Quick Fixes (on page 3287) can be embedded into an XML Schema through annotations (using the appinfo element), or in a Schematron rule embedded in the RELAX NG Schema. For more information about embedding Schematron in XML Schema or Relax NG, see Embedding Schematron Rules in XML Schema or RELAX NG (on page 1469).

Oxygen XML Editor is able to extract and use the embedded Schematron Quick Fixes. To make the embedded Schematron Quick Fixes available, follow these steps:

1. Define a validation against a schema (on page 1081).
2. For the Schema type, choose XML Schema or Relax NG.
3. Select the Embedded Schematron rules option.

Example: Embedded Schematron Quick Fix in XML Schema

```xml
<xsd:appinfo>
  <sch:pattern>
    <sch:rule context="...">
      <sch:assert test="..." sqf:fix="fixId">Message.</sch:assert>
      <sqf:fix id="fixId">
        ........
      </sqf:fix>
    </sch:rule>
  </sch:pattern>
</xsd:appinfo>
```
Example: Embedded Schematron Quick Fix in Relax NG

```xml
<grammar
    xmlns="http://relaxng.org/ns/structure/1.0"
    xmlns:sch="http://purl.oclc.org/dsdl/schematron">
    <sch:pattern>
        <sch:rule context="...">
            <sch:assert test="..." sqf:fix="fixId">Message.</sch:assert>
            <sqf:fix id="fixId">
                ......
            </sqf:fix>
        </sch:rule>
    </sch:pattern>
</grammar>
```

**Tip:** For more extensive examples, see the samples in the [OXYGEN_INSTALL_DIR]/samples/schematron folder.

- Embedding Schematron Rules in XML Schema or RELAX NG *(on page 1469)*
- Defining Schematron Quick Fixes *(on page 1482)*

Editing SVG Files

SVG (Scalable Vector Graphics) is a platform for two-dimensional graphics. It has two parts: an XML-based file format and a programming API for graphical applications. Some of the key features include support for shapes, text, and embedded raster graphics with many painting styles, scripting through languages such as ECMAScript, and support for animation.

SVG is a vendor-neutral, open standard that has important industry support. Companies such as Adobe, Apple, and IBM have contributed to its W3C specifications. Many documentation frameworks...
(on page 3282) (including DocBook) have support for SVG by defining the graphics directly in the document.

Oxygen XML Editor adds SVG support by using the Batik distribution package (an open source project developed by the Apache Software Foundation) and the default XML Catalog (on page 1123) resolves the SVG DTD.

**Note:** Batik partially supports SVG 1.1. For a detailed list of supported elements, attributes, and properties, see the Batik Implementation Status page.

**How to Render SVG Images that Use Java Scripting**

1. Copy the js.jar library from the Batik distribution into the Oxygen XML Editor lib folder.
2. Restart the application.

**SVG 1.2 Rendering Issues**

Oxygen XML Editor uses the Apache Batik open source library to render SVG images and it only has partial support for SVG 1.2. For more information, see http://xmlgraphics.apache.org/batik/dev/svg12.html.

This partial support could lead to some rendering issues in Oxygen XML Editor. For example, if you are using the Inkscape SVG editor, it is possible for it to save the SVG as 1.1, while using SVG 1.2 elements (such as flowRoot) inside it. This means that the image will not be properly rendered inside the application.

**Note:** SVG images shown in the Author visual editing mode are rendered as static images, without support for animations and JavaScript.

**Standalone SVG Viewer**

Oxygen XML Editor includes a simple SVG Viewer that allows you to work with SVG images.

To open the viewer, select SVG Viewer from the Tools menu.

Figure 587. SVG Viewer
You can browse for and open any SVG file that has the .svg or .svgz extension.

If the file is included in the current project, you can open it in the viewer by right-clicking the image file in the Project view (on page 333) and selecting Open with > SVG Viewer.

**Actions Available in the SVG Viewer**

The following actions are available in the SVG Viewer:

**Zoom in**

To zoom in on an image, use any of the following methods:

- Scroll forward with the mouse wheel.
- Select Zoom in from the contextual menu.
- Use the Ctrl + I (Command + I on OS X) keyboard shortcut.

**Zoom out**

To zoom in on an image, use any of the following methods:

- Scroll backward with the mouse wheel.
- Use the Ctrl + O (Command + O on OS X) keyboard shortcut.
- Select Zoom out from the contextual menu.

**Rotate**

To rotate an image, use either of the following methods:

- Use the Ctrl + Right-Click + Drag (Command + Right-Click + Drag on OS X) shortcut.
- Select Rotate from the contextual menu. This rotates the image exactly 90 degrees clockwise.
Refresh

To refresh (or reset) an image, use either of the following methods:

• Use the **Ctrl + T (Command + T on OS X)** keyboard shortcut.
• Select **Refresh** from the contextual menu.

Move

To move an image, use either of the following methods:

• Use the **Arrow Keys** on your keyboard.
• Use the **Shift + Left-Click + Drag** shortcut.

Pan

To pan an image, **click and drag** the image with your mouse.

Related Information:

• **Editing SVG Files (on page 1499)**

Integrated SVG Viewer in the Results Panel

Oxygen XML Editor includes an integrated **SVG Viewer** that can render the results of an XSLT transformation scenario that generates SVG images in the **Results panel (on page 357)** at the bottom of the editor. This is useful for developing XSL stylesheets with the capability of producing SVG graphics.

To enable this feature, select **Show in results view as > SVG** in the **Output tab of the XSLT transformation scenario configuration dialog box (on page 1685)**. When you run the transformation, the SVG result is then rendered in an integrated SVG viewer in the **Results panel (on page 357)**.

Example of a Use-Case

Suppose you have an XML document that describes the evolution of your sales over a time period and you want to create a graphic for it. You could use the following steps to accomplish this task:

1. Start with a static SVG image, written directly in Oxygen XML Editor or exported from a external graphics tool.
2. Extract the parts that are dependent upon the data from the XML document and create an XSL template to produce the image.
3. Create an **XML transformation with XSLT scenario (on page 1674)**.
4. While configuring the transformation scenario, select **Show in results view as > SVG in the Output tab (on page 1685)** of the configuration dialog box.

5. Run the transformation.

The SVG image is rendered in an integrated SVG viewer in the **Results panel (on page 357)** at the bottom of the editor.

**Figure 588. Integrated SVG Viewer**

---

**Editing HTML Documents**

Oxygen XML Editor provides a special framework for editing HTML files (`html` or `htm` file extensions) with a variety of specialized editing features, including validation, content completion, syntax highlighting, HTML-specific actions, and more.

Oxygen XML Editor also includes a **built-in XHTML framework (on page 1604)** (files with the `http://www.w3.org/1999/xhtml` namespace or with the `xhtml` or `xht` file extension) that has a full set of features (full editing support, document templates, enhanced CSS rendering, specific actions, validation, content completion, transformation scenarios, and more). Oxygen XML Editor also includes support for importing HTML files as an XML document (on page 2285).

**Related Information:**

- XHTML Document Type (Framework) (on page 1604)
HTML Editor

Oxygen XML Editor includes a specialized HTML editor and various editing features for files that have the `html` or `htm` file extensions. The encoding is detected automatically based on the value specified in the `charset` attribute of the `meta` element.

New Document Template

Oxygen XML Editor includes a new document template to help you get started creating HTML content. It is available when creating new documents from templates (on page 676) and can be found in the New Document folder or by typing `html` in the search field.

Text Mode Editor

You can edit HTML files in the Text editing mode (on page 828) using all of its useful features (on page 828). It includes content completion (on page 1505) based on a special HTML schema, syntax highlighting (on page 1505), a specialized Outline view (on page 1506) that presents the structure, and folding support (on page 1506).

In addition, there is a View in Browser/System Application action available when you right-click anywhere in an HTML document opened in Text mode and it opens the document in your default browser.

Grid Mode

You can use the Grid mode (on page 886) where the document is displayed as a structured grid of nested tables where the text content can be modified without directly interacting with the markup, but the documents must be XML well-formed.

Author Visual Editor

You can edit HTML files in the visual Author editing mode (on page 893) but in this mode, the documents must be XML well-formed because this editor uses the XHTML authoring features and actions (on page 1605).

HTML Validation

Oxygen XML Editor includes a built-in validator used for validating HTML documents. It is based upon the W3C HTML Validator and the HTML documents are validated against the W3C HTML5 specification. The validator in Oxygen XML Editor only supports HTML5 structure. It presents the
errors in the editor similar to XML documents (on page 364). It also checks the embedded CSS content and the warnings and errors are presented similar to the CSS editor (on page 1381).

By default, HTML documents are validated using the W3C HTML Validator engine, but you can create or edit a validation scenario (on page 1093) to specify that they are validated using the default engine that validates against the Relax NG-Compact Schema specified in the HTML framework.

**HTML Content Completion Assistant**

Oxygen XML Editor includes an intelligent Content Completion Assistant (on page 3280) that offers proposals for inserting HTML structures that are valid at the current editing location.

The Content Completion Assistant is enabled by default. To disable it, open the Preferences dialog box (Options > Preferences) (on page 79), go to Editor > Content Completion, and deselect the Enable content completion option (on page 167).

Figure 589. Content Completion Assistant in HTML

Using the Content Completion in HTML

For HTML documents, the Content Completion Assistant uses a built-in schema and the list of proposals depend on the RELAX NG schema specified in the HTML framework. Using the content completion feature is the same as with any other XML document. For more details, see:

- Using the Content Completion Assistant in Text Mode (on page 844)
- Using the Content Completion Assistant in Author Mode (on page 922)

**Syntax Highlighting in HTML Documents**

Oxygen XML Editor supports syntax highlighting in Text mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

For HTML documents, it handles attributes without quotes, unclosed or void elements, and it also offers highlighting for embedded CSS or JavaScript content.

To customize the colors or styles used for the syntax highlighting colors for HTML files, follow these steps:
1. Open the Preferences dialog box (Options > Preferences) (on page 79).
2. Go to Editor > Syntax Highlight (on page 178).
3. Select and expand the XHTML section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

You can see the effects of your changes in the Preview pane.

Related Information:

- Syntax Highlight Preferences (on page 178)

Folding in HTML

In a large HTML document, elements can be collapsed so that only the needed data remains in focus. The folding features available for XML documents (on page 840) are also available in HTML documents, but it also provides folding for nested elements that are not closed.

HTML Outline View

The Outline view for HTML documents displays the structure of the HTML document you are editing. By default, it is displayed on the left side of the editor. In addition to the normal features available in the Outline view for XML documents (on page 347), the HTML Outline view also handles void elements, elements that are not closed, or attributes without quotes, and presents the tree structure of the HTML document correctly.

Figure 590. HTML Outline View
Editing Markdown Documents

Markdown was created as a lightweight markup language with plain text formatting syntax designed to provide syntax that is very easy to read and write, and to convert it to HTML and other formats. It is often used by content contributors who want a quick and easy way to write content without having to take their fingers off the keyboard and without having to learn numerous codes or shortcuts, and it can easily be shared interchangeably between virtually any types of contributor and system.

Oxygen XML Editor provides a built-in Markdown editor that allows you to convert Markdown syntax to HTML or DITA and it includes a preview panel to help you visualize the final output. Aside from the plain text syntax that is common among most Markdown applications, the editor in Oxygen XML Editor also integrates many other powerful features that content authors are accustomed to using for other types of documents. Some of these additional unique features include:

- Additional toolbar and contextual menu actions.
- Automatic validation to help keep the syntax valid.
- Dedicated syntax highlighting to make Markdown documents even easier to read and write.
- Unique features for creating Markdown documents directly in DITA maps (on page 3281) and converting Markdown documents to DITA topics.
- Specialized syntax rules to combine popular syntax features from several specifications.

Markdown Editor

Oxygen XML Editor provides an intuitive, dynamic, and easy-to-use Markdown editor for writing and converting Markdown documents. It is a split-screen editor with two panels that are synchronized in
real-time. The left side is a simple text editor that is specially designed for writing Markdown syntax. The right side is a WYSIWYG style preview of how changes will look in the output.

**Markdown Text Editor Pane (Left Side)**

The left pane is a simple text editor that is refined to accept Markdown syntax. At the same time, you still have many of the actions, options, and features that you are used to when editing any other type of document in Oxygen XML Editor.

The features of this special editor that are unique for Markdown documents include:

- **Unique Markdown Syntax Rules** - The Markdown editor in Oxygen XML Editor uses an integration of rules (on page 1522) that combine rules from common default Markdown syntax along with many of the rules used in the GitHub Flavored Markdown syntax.
- **Syntax Highlighting** - The Oxygen XML Editor syntax highlighting feature is integrated into the Markdown text editor to make it easier to read and write Markdown syntax. You can even customize the colors and styles for the syntax highlighting (on page 1519).
- **Automatic Spell Checking** - The Markdown editor supports the Oxygen XML Editor automatic spell checking feature (on page 764) that reports possible misspelled words as you type. You simply need to select the Automatic spell check option in the Spell Check preferences page (on page 184), then click the Select editors button and select Markdown Editor.
- **Helpful Toolbar and Contextual Menu Actions** - A variety of unique actions (on page 1510) are available from the toolbar to help you insert proper Markdown syntax. The contextual menu also includes some common editing actions, as well as unique actions to export (convert) Markdown documents to HTML or DITA.
- **Shortcut Keys** - Many of the shortcut keys that are most commonly used (on page 27) in Oxygen XML Editor also work in the Markdown editor.

**WYSIWYG Preview Pane (Right Side)**

The right pane is a WYSIWYG Preview pane that shows a visual representation of how changes made in the left-side text editor will be converted to HTML or DITA output. The changes you make in the text editor are parsed continually and they are immediately visible in the Preview pane. There are two tabs available in the Preview pane, one for visualizing DITA output and one for visualizing HTML output. You can switch between the two tabs at the bottom of the pane.

The Preview pane includes the following unique features:

- **WYSIWYG Visualization** - This pane presents the Markdown syntax from the left-side text editor in a visual WYSIWYG style interface that is automatically synchronized as you type.
• **Export Options** - The DITA tab includes a contextual menu action to export (convert) the current Markdown document to a DITA topic (on page 1518). Similarly, the HTML tab includes a contextual menu action to export (convert) it to an XHTML document (on page 1518).

• **Automatic Validation** - As you edit Markdown documents, they are validated automatically (on page 1519). The conversion engine constantly tries to parse your changes and if a change results in an error that prevents the parser from converting the syntax, an error message will be displayed in the **Preview pane or Results view (on page 357)** at the bottom of the editor.

• **Print Feature** - The Markdown editor includes a **Print** action that is available in the contextual menu and it allows you to configure options for printing the current document as you see it in the **Preview pane**.

• **Preview Markup** - The Markdown editor includes a **Tags Display Mode** drop-down menu (on page 1512) that is available on the toolbar and it allows you to control the amount of markup that is displayed in the **Preview pane**.

• **Specialized DITA Features** - The Markdown editor includes some unique, specialized features to integrate it with the powerful DITA support (on page 1520) in Oxygen XML Editor.

Creating New Markdown Documents

To create a new Markdown document in Oxygen XML Editor, follow these steps:

1. Click the New button on the toolbar or select File > New.
3. Click the Create button.

Result: A new Markdown document is created and it is opened in the specialized Markdown Editor (on page 1507).

Related Information:

- Markdown Editor (on page 1507)

Actions Available in the Markdown Editor

Aside from the actions that are available in Oxygen XML Editor for any type of document (such as the actions in the various menus and the common sections of the toolbar), a variety of unique actions are also available in the Markdown editor, from the toolbar and contextual menu.

**Toolbar Actions**

The following default actions are readily available on the toolbar when editing Markdown documents:

- **Header (1st Level)**
  
  Inserts an *atx-style first level header (on page 1523)* at the cursor position.

- **Header (2st Level)**
  
  Inserts an *atx-style second level header (on page 1523)* at the cursor position.

- **Header (3rd Level)**
Inserts an *atx-style third level header (on page 1523)* at the cursor position.

---

**Horizontal Rule**

Inserts a *horizontal rule (on page 1523)* at the cursor position.

**Bold (Strong)**

Marks the selected text with *bold (on page 1524)*.

**Italic (Emphasis)**

Marks the selected text with *italics (on page 1524)*.

**Strikethrough**

Marks the selected text with a *strikethrough (on page 1524)*.

**Code Block**

Inserts (or surrounds selected text in) a *codeblock (on page 1529)*.

**Blockquote**

Inserts a *blockquote (on page 1528)* at the cursor position.

**Insert Link**

Opens the *Insert Link* dialog box that allows you to define a *link (on page 1525)* to insert at the cursor position.

Figure 592. Insert Link Dialog Box

![Insert Link Dialog Box](image)

**Insert Image**

Opens the *Insert Image* dialog box that allows you to define an *image (on page 1527)* to insert at the cursor position. You can type the URL of the image you want to insert or use browsing actions in the *Browse drop-down menu.*

Figure 593. Insert Link Dialog Box
Insert Ordered List

Inserts an ordered list (on page 1530) at the cursor position. Three child list items are also automatically inserted by default. You can also use this action to convert selected content to an ordered list.

Insert Unordered List

Inserts an unordered list (on page 1530) at the cursor position. Three child list items are also automatically inserted by default. You can also use this action to convert selected content to an unordered list.

Insert Task List

Inserts a task list (on page 1532) at the cursor position. Three child list items are also automatically inserted by default. You can also use this action to convert selected content to a task list.

Insert Table

Inserts a table (on page 1533) at the cursor position.

Tags Display Mode drop-down menu

Allows you to control the amount of markup that is displayed in the Preview pane and offers the following choices:

- **Full Tags with Attributes**
  
  Displays full tag names with attributes for both block and inline elements.

- **Full Tags**
  
  Displays full tag names without attributes for both block and inline elements.

- **Block Tags**
  
  Displays full tag names for block elements and simple tags without names for inline elements.

- **Inline Tags**
Displays full tag names for *inline elements*, while *block elements* are not displayed.

**Partial Tags**

Displays simple tags without names for *inline elements*, while *block elements* are not displayed.

**No Tags**

No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

**Configure Tags Display Mode**

Opens the Author preferences page (on page 131) where you can configure options regarding *tags*, such as the default *Tags Display Mode*, *Tags Background Color*, *Tags Foreground Color*, and *Tags Font*.

**Contextual Menu Actions**

The following default actions are available in the contextual menu when editing Markdown documents:

- **Cut, Copy, Paste**

  Use these actions to execute the typical editing actions on the currently selected content.

- **Source submenu**

  This submenu includes the following actions:

  - **To Upper Case**

    Converts the content selection to upper case characters.

  - **To Lower Case**

    Converts the content selection to lower case characters.

  - **Capitalize Lines**

    It capitalizes the first letter found on every new line that is selected. Only the first letter is affected, the rest of the line remains the same. If the first character on the new line is not a letter then no changes are made.

  - **Convert Hexadecimal Sequence to Character** (*Ctrl + Shift + X* (Command + Shift + X on OS X))

    Converts a sequence of hexadecimal characters to the corresponding Unicode character (on page 770). The action can be invoked if there
is a selection containing a valid hexadecimal sequence or if the cursor is placed at the right side of a valid hexadecimal sequence. A valid hexadecimal sequence can be composed of 2 to 4 hexadecimal characters and may or may not be preceded by the \texttt{0x} or \texttt{0X} prefix. Examples of valid sequences and the characters they will be converted to:

- \texttt{0x0045} will be converted to \texttt{E}
- \texttt{0X0125} to \texttt{#}
- \texttt{265} to \texttt{#}
- \texttt{2190} to \texttt{#}

\textbf{Note:} For more information about finding the hexadecimal value of a character, see \textit{Finding the Decimal, Hexadecimal, or Character Entity Equivalent (on page 779)}.

**Base64 Encode/Decode submenu**

This submenu includes the following actions for encoding or decoding base 64 schemes:

**Import File to Encode and Insert**

Encodes a file and then inserts the encoded content into the current document at the cursor position.

**Decode Selection and Export to File**

Decodes a selection of text from the current document and then exports (saves) the result to another file.

**Encode Selection**

Replaces a selection of text with the result of encoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the \textit{Encoding for Base64, Base32, Hex conversions} option in the \textit{Encoding preferences page (on page 125)} will be used. Likewise, the same is true if the \textit{Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions} option is not selected in the \textit{Messages preference page (on page 261)}.

**Decode Selection**
Replaces a selection of text with the result of decoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the Encoding for Base64, Base32, Hex conversions option in the Encoding preferences page (on page 125) will be used. Likewise, the same is true if the Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions option is not selected in the Messages preference page (on page 261).

Modify All Matches

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

Base32 Encode/Decode submenu

This submenu includes the following actions for encoding or decoding base32 schemes:

Import File to Encode and Insert

Encodes a file and then inserts the encoded content into the current document at the cursor position.

Decode Selection and Export to File

Decodes a selection of text from the current document and then exports (saves) the result to another file.

Encode Selection

Replaces a selection of text with the result of encoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the Encoding for Base64, Base32, Hex conversions option in the Encoding preferences page (on page 125) will be used. Likewise, the same is true if the Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions option is not selected in the Messages preference page (on page 261).
Base64, Base 32, Hex conversions option is not selected in the Messages preference page (on page 261).

Decode Selection

Replaces a selection of text with the result of decoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the Encoding for Base64, Base32, Hex conversions option in the Encoding preferences page (on page 125) will be used. Likewise, the same is true if the Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions option is not selected in the Messages preference page (on page 261).

Modify All Matches

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

Hex Encode/Decode submenu

This submenu includes the following actions for encoding or decoding hex schemes:

Import File to Encode and Insert

Encodes a file and then inserts the encoded content into the current document at the cursor position.

Decode Selection and Export to File

Decodes a selection of text from the current document and then exports (saves) the result to another file.

Encode Selection

Replaces a selection of text with the result of encoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case,
the encoding that is specified in the **Encoding for Base64, Base32, Hex conversions** option in the **Encoding** preferences page (on page 125) will be used. Likewise, the same is true if the **Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions** option is not selected in the **Messages** preference page (on page 261).

**Decode Selection**

Replaces a selection of text with the result of decoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the **Encoding for Base64, Base32, Hex conversions** option in the **Encoding** preferences page (on page 125) will be used. Likewise, the same is true if the **Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions** option is not selected in the **Messages** preference page (on page 261).

**Modify All Matches**

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

**Join and Normalize Lines** (**Ctrl + J** (**Command + J** on OS X))

For the current selection, this action joins the lines by replacing the *line separator* with a single space character. It also normalizes the whitespaces by replacing a sequence of such characters with a single space.

**Insert new line after** (**Ctrl + Alt + Enter** (**Command + Alt + Enter** on OS X))

This action has the same result as moving the cursor to the end of the current line and pressing the **ENTER** key.

**Modify All Matches**

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with
different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

**Open submenu**

The following actions are available in this submenu:

**Open File at Cursor**

Opens the file at the cursor position in a new panel. If the file path represents a directory path, it will be opened in system file browser. If the file at the specified location does not exist, an error dialog box is displayed and it includes a **Create new file** button that starts the **New document** wizard. This allows you to choose the type or the template for the file. If the action succeeds, the file is created with the referenced location and name and is opened in a new editor panel.

**Open File at Cursor in System Application**

Opens the file (identified by its link) or web page (identified by a web link) found at cursor position. The target is opened in the default system application associated with that file type.

**Compare**

Opens the current file in the **Compare Files tool (on page 2770)**.

**Show/Hide Preview**

A toggle action that shows or hides the **Preview** pane.

**Export as DITA Topic**

Converts the current Markdown document into a DITA topic.

**Export as HTML**

Converts the current Markdown document into an XHTML document.

**Print (Available in the Preview pane)**

Opens a page setup dialog box that allows you to configure printing options for the current document.

**Related Information:**

- Working with Markdown Documents in DITA *(on page 1520)*
Syntax Highlighting in the Markdown Editor

Oxygen XML Editor supports syntax highlighting in the Markdown editor to make it easier to read the semantics of the structured content by displaying each type of XML code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for Markdown documents, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79).
2. Go to Editor > Syntax Highlight (on page 178).
3. Select and expand the Markdown section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

You can see the effects of your changes in the Preview pane.

Related Information:

- Syntax Highlight Preferences (on page 178)
- Markdown Editor (on page 1507)

Automatic Validation in Markdown Documents

Markdown documents are validated automatically as you type. The conversion engine constantly tries to parse your changes to display the results in the Preview pane. If a change results in an error that prevents the parser from converting the syntax, an error message will be displayed in the DITA tab or in the Results view (on page 357) at the bottom of the editor.

The types of errors that will be reported include the following:

- Improper order of headers.
- The syntax in a documents begins with something other than a 1st level header.
- Tags are not closed properly if XHTML markup is used in the document.
- Invalid tag names if XHTML markup is used in the document.
- Markup is not well formed if XHTML markup is used in the document.
Working with Markdown Documents in DITA

Oxygen XML Editor includes some unique features that allow you to easily integrate Markdown documents in a DITA project. This is especially helpful for teams that have contributors who are familiar with the Markdown syntax, but they want their output to be generated from DITA projects. The integration between the Markdown editor and DITA includes actions to export or convert Markdown documents to DITA topics and the DITA tab in the Preview pane provides a visualization of how the topic will look after conversion.

**Export Markdown as a DITA Topic**

The Markdown editor includes an option to quickly convert the current Markdown document into a DITA topic. The Export as DITA Topic action is available in the contextual menu.

The conversion creates a new XML file that is defined as a DITA topic and opens it in the Text editing mode. You can then work with the document as you would with any other DITA topic, although you may need to manually correct some issues where the parser could not properly map Markdown syntax to DITA markup.

**Working with Markdown Documents in the DITA Maps Manager**

Oxygen XML Editor has some specialized features that allow you to integrate Markdown documents directly into your DITA project using the DITA Maps Manager. The following features are available for Markdown documents in the DITA Maps Manager view:

- **Insert Reference to Markdown Document** - You can use the New, Reference, and Reference to the currently edited file actions from the Append Child, Insert Before, or Insert After submenu when invoking the contextual menu in the DITA Maps Manager to insert a reference to a Markdown document at the selected location in the map. Markdown documents will be inserted as a topic reference (topicref element) with the format attribute set to markdown.

- **Validate Markdown Documents in DITA Maps** - When you use the Validate and Check for Completeness action from the DITA Maps Manager toolbar to check the integrity of the structure of a DITA map, Markdown documents that are referenced in the DITA map will be converted to DITA topics in the background and validated the same as any other DITA topic.
- **Transforming DITA Maps with Markdown Documents** - When transforming *DITA maps* that have Markdown documents referenced, the transformation will convert the Markdown documents to normal DITA output without you needing to manually convert the Markdown documents to DITA topics.

- **Manually Convert Markdown Documents to DITA Topics** - If you need to use DITA semantics that are not possible in Markdown syntax (such as content references, related links, and other DITA-specific syntax), you can manually convert the Markdown document into a DITA topic. To do so, right-click the Markdown document in the DITA Maps Manager and select **Refactoring > Convert Markdown to DITA Topic.** This will open a dialog box that allows you to configure options for converting the document to an XML file that is defined as a DITA topic.

![Figure 594. Convert Markdown to DITA Topic Dialog Box](image)

This dialog box includes the following options:

**Destination**

The destination path for the new DITA topic.

**File Name**

Presents the current name and allows you to change it.

**Update references**

Select this option to update all references of the file in the *DITA map* and in the files referenced from the *DITA map.*

**Delete Markdown file**

If selected, the Markdown version of the file is deleted when the document is converted into a DITA file. If deselected (default value), when the document is converted into a DITA file, the original Markdown file is also preserved in its current location.

**Preview**

Select this button to display a preview of the changes Oxygen XML Editor is about to make.
Convert

Select this button to perform the conversion. If the Markdown file has `format="markdown"`, it will be converted to a DITA topic. If it has `format="mdita"`, it will be converted to a LightWeight DITA topic.

Tip: Oxygen XML Editor comes with a sample ditamap project for converting Markdown to DITA. Go to the Project view (on page 333), open the sample.xpr project, and navigate to the dita/markdown-dita folder.

Converting Multiple Markdown Documents to DITA

Oxygen XML Editor offers an add-on that contributes actions in the Tools menu and contextual menu to enable batch conversion between various formats, including Markdown to DITA. For more information and instructions for installing the add-on, see Batch Converter Add-on (on page 2677).

Related Information:

- Markdown Editor (on page 1507)
- Actions Available in the Markdown Editor (on page 1510)
- Markdown Editor Syntax Rules and Specifications (on page 1522)
- Automatic Validation in Markdown Documents (on page 1519)
- Markdown DITA Syntax Reference

Markdown Editor Syntax Rules and Specifications

The Markdown editor in Oxygen XML Editor uses rules that were integrated from the most common set of default Markdown syntax rules along with many of the GitHub Flavored Markdown rules.

This topic lists the Oxygen XML Editor implementation of the most commonly used syntax rules.

Headers

The Markdown editor supports two styles of headers, Setext and Atx.

- Setext Style
Setext-style headers are underlined using equal signs (for first-level headers) and dashes (for second-level headers). Any number of equal signs or dashes will result in the same output.

**Example: Setext Style Headers**

```
First-Level Header (H1)
--------

Second-Level Header (H2)
-------------
```

- **Atx Style**

Atx-style headers use 1-6 hash characters at the start of the line, corresponding to header levels 1-6. Optionally, you may close atx-style headers. This is purely cosmetic and the closing hashes do not need to match the number of hashes used to open the header. It is the number of opening hashes that determines the header level.

**Example: Atx Style Headers**

```
# H1 text #
## H2 text
### H3 text ######
#### H4 text
##### H5 text ####
###### H6 text
```

**Horizontal Rules (for HTML output only)**

You can produce a horizontal rule tag (`<hr />`) by placing three or more hyphens, asterisks, or underscores on a line by themselves (they also need to be preceded and followed by a blank line). Optionally, they can be separated by spaces.

**Example: Horizontal Rules**

```
* * *
*****
--------------------------
_ _ _ _
```
Paragraphs and Line Breaks

A paragraph is simply one or more consecutive lines of text, separated by one or more blank lines. The text at the beginning of a paragraph should not be indented with spaces or tabs. To create a new paragraph, simply insert a blank line in between them.

⚠️ Important: When converting to HTML, if you break a paragraph on multiple lines (without a blank line in between them), it will create a break tag (`<br />`). When converting to DITA, the text is kept in a single paragraph in this case and a blank line is required to break a paragraph. This behavior differs slightly from the default Markdown rules.

Example: Paragraphs

```
This is a paragraph that contains
two lines of text. (In HTML, a break tag is created in between the two lines)

This is a new paragraph.
```

Styling Text

The Markdown editor supports some syntax rules for styling text (such as bold, italic, or strikethrough).

- **Italic (Emphasis)** - Text wrapped with one asterisk or underscore produces an italic (emphasis) tag.
  
  `*italic*`
  `_italic_`

- **Bold (Strong)** - Text wrapped with two asterisks or underscores produces a bold (strong) tag.
  
  `**bold**`
  `__bold__`

- **Strikethrough** - In HTML only, text wrapped with two tildes (`~~`) produces a strikethrough tag.

  `~~strikethrough~~`

Tip: You can also combine these styling rules. For example, `**BoldText _ItalicText_` would produce italicized text within bold text. Also, if you surround an asterisk or underscore with spaces, it will be treated as a literal asterisk or underscore. To produce a literal asterisk or underscore at a position where it would otherwise be used as a styling delimiter, you can escape it with a backslash (for example, `\*literal asterisks\*`).
Links

The Markdown editor supports two types of links, *inline* and *reference*. In both cases, it begins with link text that is delimited by [square brackets].

- **Inline Links**

  To create an inline link, use a set of regular parentheses immediately after the closing square bracket for the link text. Inside the parentheses, put the URL where you want the link to point, and optionally a title surrounded in quotes. Also, if you reference a local resource on the same server, you can use relative paths.

  **Examples: Inline Link**

  With a title:

  ```markdown
  Text with [example link text](http://www.example.com/path "Title") inline link and title.
  ```

  Without a title:

  ```markdown
  Text with [example link text](http://www.example.com/path) inline link without a title.
  ```

  Relative path:

  ```markdown
  Text with [example link text](/relative_path/) inline link with relative path.
  ```

- **Reference Links**

  Reference-type links use a second set of square brackets that include a label (link identifier) to identify the link (it may consist of letters, numbers, spaces, and punctuation and it is not case-sensitive). You can optionally use a space to separate the sets of brackets. The labels (link identifiers) are only used for creating the links and do not appear in the output.

  ```markdown
  Text with [link text1][id 1] a reference-type link and [link text2][id_2] another one.
  ```

  Then, somewhere in the document, you need to define your link label on a line by itself. The link identifier must be within square brackets followed by a colon, then after one or more spaces the URL for the link. Optionally this can be followed by a title enclosed in single quotes, double quotes, or parentheses. Also, the link may optionally be enclosed in angle brackets (< >).

  ```markdown
  [id 1]: http://example1.com/ "Optional Title"
  [id_2]: <http://example2.com/> "Optional Title2"
  ```
Other notes about Reference Links:

- You can put the title on a second line and use extra spaces or tabs for padding. This is useful for aesthetics when the URL is long.

  ```
  [id]: http://example.com/long/path/to/resource/here
  "Optional Title Here"
  ```

- The label (link identifier) can be missing, in which case the link text (in square brackets) is used as the name.

  ```
  [My Link][]
  ```

  and then defined as:

  ```
  [My Link]: http://example.com/
  ```

**Automatic Links**

The Markdown editor supports a shortcut style for creating automatic links for URLs and email addresses. You simply surround the URL or email address with angle brackets.

**Note:** These automatic links only work properly in HTML conversions. The *Preview* pane may display them properly in the DITA tab, but the DITA output will not properly recognize the format.

- **URLs**

  By surrounding a URL with angle brackets, you can show the actual text of the URL while also making it clickable in the output.

  ```
  <http://example.com/>
  ```

  For example, in HTML it is converted to:

  ```
  <a href="http://example.com">http://example.com</a>
  ```

- **Email Addresses**

  Automatic links for email addresses work similarly, except that Markdown will also perform a bit of randomized decimal and hex entity-encoding to help obscure your address from address-harvesting *spambots*.

  ```
  <address@example.com>
  ```

  In HTML, it is converted to something like:

  ```
  <a href="&#x6D;&#x61;l&amp;x6C;&#x74;&amp;x6F;&#x61;64;&#x672;&amp;x65;">
  ```
Images

The Markdown editor uses an image syntax that is intended to resemble the syntax for links, allowing for the same two types: inline and reference. In both cases, the syntax for images begins with an exclamation mark, followed by alt attribute text surrounded by square brackets, and then followed by a set of parentheses that contain the URL or path to the image.

**Inline Images**

For inline images, use a set of regular parentheses immediately after the closing square bracket for the alt attribute text. Inside the parentheses, put the URL or path of the image, and optionally a title surrounded in quotes.

**Examples: Inline Images**

With a title:

Text with ![Alt text](/path/to/img.jpg "Optional title") inline image and a title.

Without a title:

Text with ![Alt text](/path/to/img.jpg) inline link without a title.

**Reference Images**

For reference-type images, use a second set of square brackets that include a label (image identifier) to identify the image (it may consist of letters, numbers, spaces, and punctuation and it is not case-sensitive). You can optionally use a space to separate the sets of brackets. The labels (image identifiers) do not appear in the output.

Text with ![Alt text1][id] a reference-type image.

Then, somewhere in the document, you need to define your image label on a line by itself. The image identifier must be within square brackets followed by a colon, then after one or more spaces the URL or path of the image. Optionally this can be followed by a title enclosed in single quotes, double quotes, or parentheses.

[id]: url/to/image "Optional Title"
Blockquotes

The Markdown editor uses email-style greater than characters (>) for blockquotes. You only need to put the > before the first line of a hard-wrapped paragraph, but it looks better (and is clearer) if you put a > before every line.

- **Example: Blockquotes**
  
  ```
  > This is a blockquote with two paragraphs. Lorem ipsum dolor sit amet,
  > consectetur adipiscing elit. Aliquam hendrerit mi posuere lectus.
  > Vestibulum enim wisi, viverra nec, fringilla in, laoreet vitae, risus.
  >
  > Donec sit amet nisl. Aliquam semper ipsum sit amet velit. Suspendisse
  > id sem consectetur libero luctus adipiscing.
  ```

- **Blockquotes** can be nested by adding additional levels of > characters.

  **Example: Nested Blockquotes**
  
  ```
  > This is the first level of quoting.
  >
  > > This is nested blockquote.
  >
  > Back to the first level.
  ```

- **Blockquotes** can also contain other Markdown elements (such as headers, lists, and code blocks).

  **Example: Blockquotes with Other Markdown Elements**
  
  ```
  > ## This is a header.
  >
  > 1. This is the first list item.
  > 2. This is the second list item.
  >
  > Here's some example code:
  >
  > return shell_exec("echo \$input | \$markdown_script")
  ```

Quoting Code (Inline and Code Blocks)

The Markdown editor supports quoting code or commands inline within a sentence or in distinct blocks.
• Inline

You can quote or emphasize code within a sentence (inline) with single backticks (`). The text within the backticks will not be formatted.

**Example: Inline Code Emphasis**

```
This is a normal sentence with a `code` in the middle.
```

• Code Blocks

You can format code or text into its own distinct block by inserting a blank line before and after the content and using at least 4 spaces (or 1 tab), or by using opening and closing triple backticks (```) on separate lines.

**Example: Code Block**

```
This is a normal paragraph:

    This is a code block

This is a normal paragraph:

    ... 

This is a code block

    ...
```

One level of indentation is removed from each line of a codeblock and it continues until it reaches a line that is not indented (or until the closing backticks).

**Example: Code Block with Indentation**

```
tell application "something"
    beep
end tell
```

For example, in HTML the result would look like this:

```
<pre><code>tell application "Foo"
    beep
end tell</code></pre>
```

You can also add an optional language identifier to enable syntax highlighting in your code blocks. The Oxygen XML Editor Markdown editor supports the following languages: Java, JavaScript, CSS, and Python.
Example: Syntax Highlighting in Code Block

```
```
```css
input[type="submit"] {
  color: white;
  font-weight: bold;
...```

Inline XHTML (for HTML output only)

The Markdown editor supports writing inline XHTML. Since Markdown is just a writing format, it requires a conversion for publishing purposes. If you are using the HTML conversion, for any markup that is not covered by Markdown syntax, you can simply use XHTML syntax.

Example: Inline XHTML

This is a regular paragraph.

```xml
<table>
  <tr>
    <td>Col 1</td>
    <td>Col 2</td>
  </tr>
</table>
```

This is another regular paragraph.

Lists

The Markdown editor supports ordered and unordered lists. You can also insert blockquotes (on page 1528) and code blocks (on page 1528) inside list items. List markers typically start at the left margin, but may be indented by up to three spaces.

- Unordered Lists

For unordered lists, you can use asterisks (*), plus signs (+), and hyphens (-) interchangeably.

* List item 1
+ List item 2
- List item 3

- Ordered Lists
For ordered lists, use numbers followed by periods. The actual numbers you use have no effect on the output. It simply converts them to list items within an ordered list and the actual number of list items will determine the numbers in the output.

1. List item 1
2. List item 2
3. List item 3

• **Nested Lists**

You can create nested lists by indenting lines by two spaces.

1. Ordered list item 1
   1. Nested ordered list item 1
   2. Nested ordered list item 2
      * 2nd level nested unordered list item 1
      * 2nd level nested unordered list item 2
      * 3rd level nested unordered list item 1
   2. Ordered list item 2

• **Paragraphs Inside Lists**

If list items are separated by blank lines, Markdown will wrap the items in a paragraph in the output.

* List item 1
* List item 2

For both DITA and HTML output, this would result in:

```html
<ul>
  <li><p>List item 1</p></li>
  <li><p>List item 2</p></li>
</ul>
```

• **Multiple Paragraphs Inside Lists**

List items may consist of multiple paragraphs. Each subsequent paragraph in a list item must be indented by either 4 spaces or one tab. Optionally, you can also indent each line of a paragraph to make it look nicer.

1. This is a list item with two paragraphs. Lorem ipsum dolor sit amet, consectetur adipiscing elit. Aliquam hendrerit mi posuere lectus.
Vestibulum enim wisi, viverra nec, fringilla in, laoreet vitae, risus. Donec sit amet nisl. Aliquam semper ipsum sit amet velit.

2. Suspendisse id sem consectetuer libero luctus adipiscing.

• Blockquotes Inside Lists

To put a *blockquote* within a list item, the blockquote delimiters (`>`) need to be indented so that it is under the first letter of the text after the list item marker.

* A list item with a blockquote:
  > This is a blockquote
  > inside a list item.

• Code Blocks Inside Lists

To put a code block within a list item, insert an empty line in between the list item and the code block, and the code block needs to be indented twice (with 8 spaces or 2 tabs), or if you are using the triple backticks method, the opening triple backtick needs to be indented with 4 spaces or 1 tab.

* A list item with a code block:

```
This is a code block inside a list item
```

...  

```
This is a code block inside a list item using the backticks method
```

**Task Lists**

You can create task lists by prefacing list items with a hyphen followed by a space followed by square brackets (`- [ ]`). To mark a task as complete, use `- [x].`

**Example: Task Lists**

- [ ] Unfinished task 1
- [x] Finished task 2

**Definition Lists**

You can create definition lists by using a colon plus a space for each list item.

**Example: Definition Lists**
Tables

You can create tables in the Markdown editor by using pipes (|) and hyphens (-).

- **Creating a Table**

  Pipes are used to separate each column, while hyphens are used to create column headers. The pipes on either end of the table are optional. Cells can vary in width and do not need to be perfectly aligned within columns, but there must be at least three hyphens in each column of the header row.

<table>
<thead>
<tr>
<th>First Header</th>
<th>Second Header</th>
</tr>
</thead>
<tbody>
<tr>
<td>Column 1 Row 1 Cell</td>
<td>Column 2 Row 1 Cell</td>
</tr>
<tr>
<td>Column 1 Row 2 Cell</td>
<td>Column 2 Row 2 Cell</td>
</tr>
</tbody>
</table>

- **Formatting Rules in Table Cells**

  You can use formatting rules inside the cells of the table (such as links, inline code blocks, and text styling).

<table>
<thead>
<tr>
<th>First Header</th>
<th>Second Header</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>inline code</code></td>
<td>Content with <strong>bold text</strong> inside cell</td>
</tr>
</tbody>
</table>

- **Aligning Text in Tables**

  You can align text to the left, right, or center of a column by including colons (:) to the left, right, or on both sides of the hyphens within the header row.

<table>
<thead>
<tr>
<th align="left">Left-aligned</th>
<th align="center">Center-aligned</th>
<th align="right">Right-aligned</th>
</tr>
</thead>
<tbody>
<tr>
<td align="left">Content Cell</td>
<td align="center">Content Cell</td>
<td align="right">Content Cell</td>
</tr>
</tbody>
</table>

- **Joining Cells (Span a Cell Over Multiple Columns)**

  You can join cells horizontally (span a cell over multiple columns) by using multiple consecutive pipe characters (|) to the right of the particular cell. The number of consecutive pipes indicate the number of columns the cell will span (|| for two, ||| for three, and so on).

<table>
<thead>
<tr>
<th>First Header</th>
<th>Second Header</th>
<th>Third Header</th>
<th>Fourth Header</th>
</tr>
</thead>
</table>
Emoji

You can add *emoji* in the Markdown editor by surrounding the EMOJICODE with colons (`:EMOJICODE:`).

**Example: Emoji**

```markdown
:smile:
:laughing:
```

The resulting emoticons will appear in the output, but they are not displayed in the *Preview* pane.

For a full list of available emoji codes, see [Emoji Cheat Sheet](#).

Backslash Escapes

You can ignore Markdown formatting by using backslash escapes (\) to generate literal characters that would otherwise have special meaning in the Markdown syntax. For example, if you want to surround a word with literal asterisks (instead of an italic or emphasis tag), you can use backslashes to escape the asterisks.

```
\ literal asterisks\`
```

The Markdown editor provides backslash escapes for the following characters:

- \  backslash
- `  backtick
- *  asterisk
- _  underscore
- {}  curly braces
- []  square brackets
- ()  parentheses
- #  hash mark
- +  plus sign
- -  minus sign (hyphen)
- .  dot
- !  exclamation mark

Automatic Escaping for Special Characters

The Markdown editor includes support for automatically escaping special characters such as angle brackets (< >) and ampersands (&). If you want to use them as literal characters, you must
escape them as entities, as in the table below. The exception to this is in HTML output, if the special characters for a valid tag (for example, `<b>`), they are treated as literal characters and escaping is not necessary.

<table>
<thead>
<tr>
<th>Literal Character</th>
<th>Escaping Code</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;</code></td>
<td><code>&amp;lt;</code></td>
</tr>
<tr>
<td><code>&gt;</code></td>
<td><code>&amp;gt;</code></td>
</tr>
<tr>
<td><code>&amp;</code></td>
<td><code>&amp;amp;</code></td>
</tr>
</tbody>
</table>

Footnotes

The Markdown editor in Oxygen XML Editor supports normal and inline footnotes. The following examples show the required syntax.

• **Example: Normal Footnote**

Here is a footnote reference,[^1]

[^1]: Here is the footnote.

• **Example: Normal Footnote with Multiple Blocks**

Here is a footnote reference,[^longnote]

[^longnote]: Here is the footnote with multiple blocks.

Subsequent paragraphs are indented with 4 spaces or 1 tab to show that they belong to the previous footnote.

• **Example: Inline Footnote**

Here is an inline note.[^Inlines notes are easier to write, since you don’t have to pick an identifier and move down to type the note.]

Related Information:

• Default Markdown Syntax

• GitHub Flavored Markdown Rules

• Markdown Editor (on page 1507)
• Actions Available in the Markdown Editor (on page 1510)
Oxygen XML Editor includes a variety of specialized editors, views, and features that are dynamic according to the type of document that you open or create. Oxygen XML Editor includes fully supported built-in frameworks for the most popular XML document types (DITA, DocBook, TEI, XHTML, JATS) with a full set of features, as well as support for other document types with more generic features.

The built-in frameworks are defined according to a set of rules and a variety of settings that improve editing capabilities for its particular file type. These settings include:

- A default grammar used for validation and content completion in both Author mode and Text mode.
- CSS stylesheets for rendering XML documents in Author mode.
- User actions invoked from toolbars or menus in Author mode.
- Built-in transformation scenarios used for publishing XML documents.
- XML Catalogs used for mapping resources.
- New document templates to make it easy to create XML documents.
- User-defined extensions for customizing the interaction with the content author in Author mode.

It is also possible to create and configure your own custom frameworks (document types). For more information, see the Creating and Configuring Custom Frameworks section.

For extensive details about the DITA editing features included in Oxygen XML Editor, see the DITA Authoring chapter.

**DocBook 4 Document Type (Framework)**

DocBook is a very popular set of tags for describing books, articles, and other prose documents, particularly technical documentation. DocBook provides a vast number of semantic element tags, divided into three broad categories: structural, block-level, and inline. DocBook content can then be published in a variety of formats, including HTML, PDF, WebHelp, and EPUB.

**File Definition**

A file is considered to be a DocBook 4 document when one of the following conditions are true:
• The root element name is `book` or `article`.
• The PUBLIC ID of the document contains the string `-//OASIS//DTD DocBook XML`.

**Default Document Templates**

There are a variety of default DocBook 4 templates available when creating new documents from templates *(on page 676)* and they can be found in: Framework Templates > DocBook 4.

The default templates for DocBook 4 documents are located in the `{OXYGEN_INSTALL_DIR}/frameworks/docbook/templates/Docbook 4` folder.

**Default Schema for Validation and Content Completion**

The default schema that is used if one is not detected in the DocBook 4 file is `docbookxi.dtd` and it is stored in `{OXYGEN_INSTALL_DIR}/frameworks/docbook/4.5/dtd/`.

**Default CSS**

The default CSS files used for rendering DocBook content in Author mode are stored in `{OXYGEN_INSTALL_DIR}/frameworks/docbook/css/`.

By default, these default CSS files are merged with any that are specified in the document. For more information, see Configuring and Managing Multiple CSS Styles for a Framework *(on page 2348)*.

**Default XML Catalog**

The default XML Catalog *(on page 3289)*, `catalog.xml`, is stored in `{OXYGEN_INSTALL_DIR}/frameworks/docbook/`.

**Transformation Scenarios**

Oxygen XML Editor includes numerous built-in DocBook transformation scenarios that allow you to transform DocBook 4 documents to a variety of outputs, such as WebHelp, PDF, HTML, HTML Chunk, XHTML, XHTML Chunk, and EPUB. All of them are listed in the DocBook 4 section in the Configure Transformation Scenario(s) dialog box *(on page 1762)*.

For more information, see the DocBook Transformation Scenarios *(on page 1667)* section.

DocBook 4 Author Mode Actions

A variety of actions are available in the DocBook 4 framework that can be added to the DocBook4 menu, the Author Custom Actions toolbar, the contextual menu, and the Content Completion Assistant.

DocBook 4 Toolbar Actions

The following default actions are readily available on the DocBook (Author Custom Actions) toolbar when editing in Author mode (by default, most of them are also available in the DocBook4 menu and in various submenus of the contextual menu):

- **Bold**
  Emphasizes the selected text by surrounding it with `<emphasis role="bold">` tag. You can use this action on multiple non-contiguous selections.

- **Italic**
  Emphasizes the selected text by surrounding it with `<emphasis role="italic">` tag. You can use this action on multiple non-contiguous selections.

- **Underline**
  Emphasizes the selected text by surrounding it with `<emphasis role="underline">` tag. You can use this action on multiple non-contiguous selections.

- **Link Actions Drop-Down Menu**
  The following link actions are available from this menu:
  
  - **Cross reference (link)**
    Opens a dialog box that allows you to select a target to insert as a hypertext link.
  
  - **Cross reference (xref)**
Inserts a cross reference to other parts of the document.

Web Link (ulink)

Inserts a link that addresses its target with a URL (Universal Resource Locator).

Insert OLink

Opens an OLink dialog box that allows you to insert a link that addresses its target indirectly, using the `targetdoc` and `targetptr` values that are present in a Targetset (on page 1572) file.

Figure 595. Insert OLink Dialog Box

After you choose the Targetset URL, the structure of the target documents is presented. For each target document (targetdoc), its content is displayed allowing you to easily identify the `targetptr` for the `olink` element that will be inserted. You can also use the search fields to quickly identify a target. If you already know the values for `targetdoc` and `targetptr`, you can insert them directly in the corresponding fields. You can also edit an `olink` using the Edit OLink action that is available on the contextual menu. The last used Targetset URL will be used to identify the edited target.
To insert XREF text into the olink, enter the text in the xreftext field and make sure the Insert xreftext in the OLink option is selected.

**Insert URI**

Inserts a URI element. The URI identifies a Uniform Resource Identifier (URI) in content.

![Insert Image](image)

Opens a dialog box that allows you to select the path of an image to insert at the cursor position (on page 1021). Depending on the current location, an image-type element is inserted. If the action is invoked between two block elements (such as paragraphs), the dialog box also allows you to provide a title.

![Insert Media Resource](image)

Opens a Choose Media dialog box (on page 1055) that allows you to select the URL of a media object to be inserted into a document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted and rendered in Author mode so that it can be played directly from there.

![Insert XInclude](image)

Opens a dialog box that allows you to browse and select content to be included and automatically generates the corresponding XInclude instruction.

### Section Drop-Down Menu

The following actions are available from this menu:

- **Insert Section**

  Inserts a new section or subsection in the document, depending on the current context. For example, if the current context is sect1, then a sect2 is inserted. By default, this action also inserts a para element as a child node. The para element can be deleted if it is not needed.

- **Promote Section (Ctrl + Alt + LeftArrow (Command + Alt + LeftArrow on OS X))**

  Promotes the current node as a sibling of the parent node.

- **Demote Section (Ctrl + Alt + RightArrow (Command + Alt + RightArrow on OS X))**

  Demotes the current node a child of the previous node.

- **Insert Paragraph**

  Insert a new paragraph element at current cursor position.

- **Insert Equation**
Opens the **XML Fragment Editor** that allows you to insert and edit MathML notations *(on page 1057)*.

**Insert List Item**

Inserts a list item in the current list type.

**Insert Ordered List**

Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

**Insert Itemized List**

Inserts an itemized list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an itemized list.

**Insert Variable List**

Inserts a DocBook variable list. A child list item is also inserted automatically by default. You can also use this action to convert selected paragraphs or other types of lists to a variable list.

**Insert Procedure List**

Inserts a DocBook procedure element. A step child item is also inserted automatically. You can also use this action to convert selected paragraphs or other types of lists to a procedure list.

**Sort**

 Sorts cells or list items in a table.

**Insert Table**

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a block element *(on page 3280)*) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

**Note:** If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that **Only lists, paragraphs, or inline content can be converted to tables**.

**Insert Row Below**
Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

Delete Row(s)
Deletes the table row located at cursor position or multiple rows in a selection.

Insert Column After
Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

Delete Column(s)
Deletes the table column located at cursor position or multiple columns in a selection.

Table Properties
Opens the Table properties dialog box that allows you to configure properties of a table (such as frame borders).

Join Cells
Joins the content of the selected cells (both horizontally and vertically).

Split Cell
Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

DocBook4 Menu Actions
The following additional actions can be found in the DocBook4 menu when editing in Author mode:

Paste special submenu
This submenu includes the following special paste actions that are specific to the DocBook 4 framework:

Paste As XInclude
Allows you to create an xi:include element that references a DocBook element copied from Author mode. The operation fails if the copied element does not have a declared ID.

Paste as link
Allows you to create a link element that references a DocBook element copied from Author mode. The operation fails if the copied element does not have a declared ID.
Paste as xref

Allows you to create an `<xref>` element that references a DocBook element copied from Author mode. The operation fails if the copied element does not have a declared ID.

Subscript

Surrounds the selected text with a `<subscript>` tag, used for inserting a character (number, letter, or symbol) that will appear slightly below the baseline and slightly smaller than the rest of the text.

Superscript

Surrounds the selected text with a `<superscript>` tag, used for inserting a character (number, letter, or symbol) that will appear slightly above the baseline and slightly smaller than the rest of the text.

Table submenu

In addition to the table actions available on the toolbar, the following actions are available in this submenu:

- **Insert Row Above**
  
  Inserts a new table row with empty cells above the current row. This action is available when the cursor is positioned inside a table.

- **Insert Rows**
  
  Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (Above or Below the current row).

- **Insert Column Before**
  
  Inserts a column before the current one.

- **Insert Columns**
  
  Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (Above or Below the current column).

- **Insert Cell**
  
  Inserts a new empty cell depending on the current context. If the cursor is positioned between two cells, Oxygen XML Editor inserts a new cell at cursor position. If the cursor is inside a cell, the new cell is created after the current cell.

ID Options
Opens the **ID Options** dialog box that allows you to configure options for generating IDs in **Author** mode. The dialog box includes the following:

**ID Pattern**

The pattern for the ID values that will be generated. This text field can be customized using constant strings or any of the Oxygen XML Editor Editor Variables *(on page 276)*.

**Element name or class value to generate ID for**

The elements for which ID values will be generated, specified using class attribute values. To customize the list, use the **Add**, **Edit**, or **Remove** buttons.

**Auto generate IDs for elements**

If selected, Oxygen XML Editor will automatically generate unique IDs for the elements listed in this dialog box when they are created in **Author** mode.

**Remove IDs when copying content**

This option allows you to control whether or not pasted elements that are listed in this dialog box should retain their existing IDs. If this option is not selected, IDs are always retained when you copy or cut content and paste it in the same document or other documents. If this option is selected, IDs are never retained for copied content, but if you cut the content, they are preserved for the first paste action (and not retained for any subsequent paste actions).

**Generate IDs**

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the **ID Options** dialog box that are found in the current selection.

**Note:** The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `id` attribute.

**Refresh References**
You can use this action to manually trigger a refresh and update of all referenced resources.

**Tags display mode Submenu**

- **Full Tags with Attributes**
  Displays full tag names with attributes for both block (on page 3280) and inline elements (on page 3283). Oxygen XML Editor

- **Full Tags**
  Displays full tag names without attributes for both block and inline elements.

- **Block Tags**
  Displays full tag names for block elements and simple tags without names for inline elements.

- **Inline Tags**
  Displays full tag names for inline elements, while block elements are not displayed.

- **Partial Tags**
  Displays simple tags without names for inline elements, while block elements are not displayed.

- **No Tags**
  No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

**Configure Tags Display Mode**

Use this option to go to the Author preferences page (on page 131) where you can configure the Tags Display Mode options.

**Profiling/Conditional Text Submenu**

- **Edit Profiling Attributes**
  Allows you to configure the profiling attributes (on page 969) and their values.

- **Show Profiling Colors and Styles**
  Select this option to turn on conditional styling.

- **Show Profiling Attributes**
Select this option to turn on conditional text markers. They are displayed at the end of conditional text blocks, as a list of attribute name and their currently set values.

**Show Excluded Content**

When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.

**List of all profiling condition sets that match the current document type**

You can click a listed *condition set* *(on page 975)* to activate it.

**= Profiling Settings**

Opens the *profiling options preferences page* *(on page 144)*, where you can manage profiling attributes and profiling conditions sets. You can also configure the profiling styles and colors options from the *colors/styles preferences page* *(on page 146)* and the *attributes rendering preferences page* *(on page 148)*.

**DocBook 4 Contextual Menu Actions**

In addition to many of the *DocBook 4 toolbar actions* *(on page 1539)* and the *general Author mode contextual menu actions* *(on page 1065)*, the following DocBook 4 framework-specific actions are also available in the contextual menu when editing in *Author* mode:

**Paste special submenu**

This submenu includes the following special paste actions that are specific to the DocBook 4 framework:

**Paste As XInclude**

Allows you to create an `xi:include` element that references a DocBook element copied from *Author* mode. The operation fails if the copied element does not have a declared ID.

**Paste as link**

Allows you to create a `link` element that references a DocBook element copied from *Author* mode. The operation fails if the copied element does not have a declared ID.

**Paste as xref**
Allows you to create an `<xref>` element that references a DocBook element copied from Author mode. The operation fails if the copied element does not have a declared ID.

**Image Map Editor**

This action is available in the contextual menu when it is invoked on an image. This action applies an image map to the current image (if one does not already exist) and opens the Image Map Editor dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

**Table Actions**

The following table editing actions are available in the contextual menu when it is invoked on a table:

- **Insert Rows**
  
  Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (Above or Below the current row).

- **Delete Row(s)**
  
  Deletes the table row located at cursor position or multiple rows in a selection.

- **Insert Columns**
  
  Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (Above or Below the current column).

- **Delete Column(s)**
  
  Deletes the table column located at cursor position or multiple columns in a selection.

- **Join Cells**
  
  Joins the content of the selected cells (both horizontally and vertically).

- **Split Cell**
  
  Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

- **Sort**
  
  Sorts cells or list items in a table.

- **Table Properties**
Opens the **Table properties** dialog box that allows you to configure properties of a table (such as frame borders).

### Other Actions submenu

This submenu gives you access to all the usual contextual menu actions.

**Link > Edit OLink**

Opens a dialog box that allows you to edit an existing OLink. See the **Insert OLink** action for more information.

**Generate IDs**

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the **ID Options** dialog box that are found in the current selection.

**Note:** The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `id` attribute.

### DocBook 4 Drag/Drop (or Copy/Paste) Actions

Dragging a file from the **Project view (on page 333)** or **DITA Maps Manager view (on page 2990)** and dropping it into a DocBook 4 document that is edited in **Author** mode, creates a link to the dragged file (the `ulink` DocBook element) at the drop location. Copy and paste actions work the same.

You can also drag images or media files from your system explorer or the **Project view (on page 333)** and drop them into a DocBook 4 document (or copy and paste). This will insert the appropriate element at the drop or paste location (for example, dropping/pasting an image will insert the `inlinegraphic` DocBook element with a `fileref` attribute).

**Tip:** For information about customizing **Author** mode actions for a particular framework (on page 3282) (document type), see the Configuring Actions, Menus, Toolbars, Content Completion for a Framework (on page 2323) section.

### Related Information:

- Configuring Actions, Menus, Toolbars, Content Completion for a Framework (on page 2323)
Inserting an Olink in DocBook Documents

The `olink` element is used for linking to resources outside the current DocBook document. The `targetdoc` attribute is used for the document ID that contains the target element and the `targetptr` attribute for the ID of the target element (the value of an `id` or `xml:id` attribute). The combination of those two attributes provides a unique identifier to locate cross references.

For example, a *Mail Administrator Guide* with the document ID `MailAdminGuide` might contain a chapter about user accounts, like this:

```xml
<chapter id="user_accounts">
  <title>Administering User Accounts</title>
  <para>blah blah</para>
</chapter>
```

You can form a cross reference to that chapter by adding an `olink`, as in the following example:

```xml
<olink targetdoc="MailAdminGuide" targetptr="user_accounts">user accounts</olink>
```

You may need to update your when you get a new machine.

To use an `olink` to create links between documents, follow these steps:

1. Decide which documents are to be included in the domain for cross referencing. A unique ID must be assigned to each document that will be referenced with an `olink`. It is usually added as an `id` (or `xml:id` for DocBook5) attribute to the root element of the document.

2. Decide on your output hierarchy. For creating links between documents, the relative locations of the output documents must be known. Before going further you must decide the names and locations of the output directories for all the documents from the domain. Each directory will be represented by an element: `<dir name="directory_name">`, in the target database document.

3. Create the target database document. Each collection of documents has a master target database document that is used to resolve all `olinks` from that collection. The target database document is an XML file that is created once. It provides a means for pulling in the target data for each document. The database document is static and all the document data is pulled in dynamically.

   **Tip:** Oxygen XML Editor includes a built-in new document template called *DocBook Targetset Map* available in the New document wizard (on page 676) that will help you get started.

   **Example:** The following is an example of a target database document. It structures a collection of documents in a `sitemap` element that provides the relative locations of the outputs (HTML in
this example). Then it pulls in the individual target data using system entity references to target data files that will be created in the next step.

```xml
<?xml version="1.0" encoding="utf-8"?>
<!DOCTYPE targetset [ 
 <!ENTITY ugtargets SYSTEM "file:///doc/userguide/target.db">  
 <!ENTITY agtargets SYSTEM "file:///doc/adminguide/target.db">  
 <!ENTITY reftargets SYSTEM "file:///doc/man/target.db"> ]>
<targetset>
  <targetsetinfo>
    Description of this target database document, which is for the examples in olink doc.
  </targetsetinfo>

<!-- Site map for generating relative paths between documents -->
<sitemap>
  <dir name="documentation">
    <dir name="guides">
      <dir name="mailuser">
        <document targetdoc="MailUserGuide" baseuri="userguide.html">
          &ugtargets;
        </document>
      </dir>
    </dir>
  </dir>
  <dir name="mailadmin">
    <document targetdoc="MailAdminGuide">
      &agtargets;
    </document>
  </dir>
  <dir name="reference">
    <dir name="mailref">
      <document targetdoc="MailReference">
        &reftargets;
      </document>
    </dir>
  </dir>
</sitemap>
</targetset>
```
4. Generate the target data files by executing a DocBook transformation scenario. Before applying the transformation, you need to edit the transformation scenario, go to the Parameters tab, and make sure the value of the collect.xref.targets parameter is set to yes. The default name of a target data file is target.db, but it can be changed by setting an absolute file path in the targets.filename parameter.

Example: An example of a target.db file:

```xml
<div element="book" href="#MailAdminGuide" number="1" targetptr="user_accounts">
  <ttl>Administering User Accounts</ttl>
  <xreftext>How to administer user accounts</xreftext>
  <div element="part" href="#d5e4" number="I">
    <ttl>First Part</ttl>
    <xreftext>Part I, "First Part"</xreftext>
    <div element="chapter" href="#d5e6" number="I">
      <ttl>Chapter Title</ttl>
      <xreftext>Chapter 1, Chapter Title</xreftext>
      <div element="sect1" href="#src_chapter" number="1" targetptr="src_chapter">
        <ttl>Section1 Title</ttl>
        <xreftext>xreflabel_here</xreftext>
      </div>
    </div>
  </div>
</div>
```

When editing a DocBook XML document in Author mode, the Insert OLink action is available in the Link drop-down menu from the toolbar. This action opens the Insert OLink dialog box that allows you to select the target of an olink from the list of all possible targets from a specified target database document (specified in the Targetset URL field). Once a Targetset URL is selected, the structure of the target documents is presented. For each target document (targetdoc), its content is displayed, allowing you to easily identify the appropriate targetptr. You can also use the search fields to quickly identify a target. If you already know the values for the targetdoc and targetptr attributes, you can insert them directly in the corresponding fields.

Example: In the following image, the target database document is called target.xml, dbadmin is selected for the target document (targetdoc), and bldinit is selected as the value for the targetptr attribute. Notice that you can also add XREF text into the olink by using the xreftext field.

Figure 596. Insert OLink Dialog Box
6. Process a DocBook transformation for each document to generate the output.
   a. Edit the transformation scenario and set the value of the `target.database.document` parameter to be the URL of the target database document.
   b. Apply the transformation scenario.

DocBook 5 Document Type (Framework)

DocBook is a very popular set of tags for describing books, articles, and other prose documents, particularly technical documentation. DocBook provides a vast number of semantic element tags, divided into three broad categories: structural, block-level, and inline. DocBook content can then be published in a variety of formats, including HTML, PDF, WebHelp, and EPUB.

File Definition

A file is considered to be a DocBook 5 document when the namespace is `http://docbook.org/ns/docbook`.
Default Document Templates

There are a variety of default DocBook 5 templates available when creating new documents from templates (on page 676) and they can be found in: Framework Templates > DocBook 5 > DocBook 5.0 and Framework Templates > DocBook 5 > DocBook 5.1.

New document templates for both DocBook 5 documents are located in the
\[OXYGEN_INSTALL_DIR\]/frameworks/docbook/templates/Docbook5.0 folder.

New document templates for both DocBook 5.1 documents are located in the
\[OXYGEN_INSTALL_DIR\]/frameworks/docbook/templates/Docbook5.1 folder.

Default Schema for Validation and Content Completion

The default schema that is used if one is not detected is docbookxi.rng and it is stored in \[OXYGEN_INSTALL_DIR\]/frameworks/docbook/5.0/rng/ (or for DocBook 5.1 in \[OXYGEN_INSTALL_DIR\]/frameworks/docbook/5.1/rng/). Other types of schemas for various DocBook versions are also located in various folders inside the \[OXYGEN_INSTALL_DIR\]/frameworks/docbook/ directory.

Default CSS

The default CSS files used for rendering DocBook content in Author mode is stored in \[OXYGEN_INSTALL_DIR\]/frameworks/docbook/css/.

By default, these default CSS files are merged with any that are specified in the document. For more information, see Configuring and Managing Multiple CSS Styles for a Framework (on page 2348).

Transformation Scenarios

Oxygen XML Editor includes numerous built-in DocBook transformation scenarios that allow you to transform DocBook 5 documents to a variety of outputs, such as WebHelp, PDF, HTML, HTML Chunk, XHTML, XHTML Chunk, and EPUB. Oxygen XML Editor also includes a DocBook 5.1 transformation scenario for Assembly documents (on page 1569). All of them are listed in the DocBook 5 section in the Configure Transformation Scenario(s) dialog box (on page 1762).

For more information, see the DocBook Transformation Scenarios (on page 1667) section.

Resources

- Oxygen Video Tutorial: Editing DocBook Documents in Author Mode
- DocBook 5.0 (and older) Specifications
DocBook 5 Author Mode Actions

A variety of actions are available in the DocBook 5 framework (on page 3282) that can be added to the DocBook5 menu, the Author Custom Actions toolbar, the contextual menu, and the Content Completion Assistant (on page 3280).

DocBook 5 Toolbar Actions

The following default actions are readily available on the DocBook (Author Custom Actions) toolbar when editing in Author mode (by default, most of them are also available in the DocBook5 menu and in various submenus of the contextual menu):

- **Bold**
  Emphasizes the selected text by surrounding it with `<emphasis role="bold">` tag. You can use this action on multiple non-contiguous selections.

- **Italic**
  Emphasizes the selected text by surrounding it with `<emphasis role="italic">` tag. You can use this action on multiple non-contiguous selections.

- **Underline**
  Emphasizes the selected text by surrounding it with `<emphasis role="underline">` tag. You can use this action on multiple non-contiguous selections.
- **Link Actions Drop-Down Menu**

The following link actions are available from this menu:

- **Cross reference (link)**
  
  Opens a dialog box that allows you to select a target to insert as a hypertext link.

- **Cross reference (xref)**
  
  Inserts a cross reference to other parts of the document.

- **Web Link (ulink)**
  
  Inserts a link that addresses its target with a URL (Universal Resource Locator).

- **Insert OLink**
  
  Opens an OLink dialog box that allows you to insert a link that addresses its target indirectly, using the `targetdoc` and `targetptr` values that are present in a Targetset. (on page 1572) file.

Figure 597. Insert OLink Dialog Box

After you choose the Targetset URL, the structure of the target documents is presented. For each target document (`targetdoc`), its content is displayed allowing you to easily identify the `targetptr` for the `olink`
element that will be inserted. You can also use the search fields to quickly identify a target. If you already know the values for \texttt{targetdoc} and \texttt{targetptr}, you can insert them directly in the corresponding fields. You can also edit an \texttt{olink} using the \texttt{Edit OLink} action that is available on the contextual menu. The last used \texttt{Targetset} URL will be used to identify the edited target.

To insert XREF text into the \texttt{olink}, enter the text in the \texttt{xreftext} field and make sure the \texttt{Insert xreftext in the OLink} option is selected.

\textbf{Insert URI}

Inserts a URI element. The URI identifies a Uniform Resource Identifier (URI) in content.

\textbf{Insert Image}

Opens a dialog box that allows you to select the path of an image to insert at the cursor position (on page \pageref{page-1021}). Depending on the current location, an image-type element is inserted. If the action is invoked between two block elements (such as paragraphs), the dialog box also allows you to provide a title.

\textbf{Insert Media Resource}

Opens a \texttt{Choose Media} dialog box (on page \pageref{page-1055}) that allows you to select the URL of a media object to be inserted into a document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted and rendered in \texttt{Author} mode so that it can be played directly from there.

\textbf{Insert XInclude}

Opens a dialog box that allows you to browse and select content to be included and automatically generates the corresponding XInclude instruction.

\section*{Section Drop-Down Menu}

The following actions are available from this menu:

\subsection*{Insert Section}

Inserts a new section or subsection in the document, depending on the current context. For example, if the current context is \texttt{sect1}, then a \texttt{sect2} is inserted. By default, this action also inserts a \texttt{para} element as a child node. The \texttt{para} element can be deleted if it is not needed.

\textbf{Promote Section (Ctrl + Alt + LeftArrow (Command + Alt + LeftArrow on OS X))}

Promotes the current node as a sibling of the parent node.
Demote Section (Ctrl + Alt + RightArrow (Command + Alt + RightArrow on OS X))

Demotes the current node a child of the previous node.

Insert Paragraph

Insert a new paragraph element at current cursor position.

Insert Equation

Opens the XML Fragment Editor that allows you to insert and edit MathML notations (on page 1057).

Insert List Item

Inserts a list item in the current list type.

Insert Ordered List

Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

Insert Itemized List

Inserts an itemized list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an itemized list.

Insert Variable List

Inserts a DocBook variable list. A child list item is also inserted automatically by default. You can also use this action to convert selected paragraphs or other types of lists to a variable list.

Insert Procedure List

Inserts a DocBook procedure element. A step child item is also inserted automatically. You can also use this action to convert selected paragraphs or other types of lists to a procedure list.

Sort

Sorts cells or list items in a table.

Insert Table

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a block element.
(on page 3280) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

**Note:** If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that *Only lists, paragraphs, or inline content can be converted to tables.*

- **Insert Row Below**
  Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

- **Delete Row(s)**
  Deletes the table row located at cursor position or multiple rows in a selection.

- **Insert Column After**
  Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

- **Delete Column(s)**
  Deletes the table column located at cursor position or multiple columns in a selection.

- **Table Properties**
  Opens the Table properties dialog box that allows you to configure properties of a table (such as frame borders).

- **Join Cells**
  Joins the content of the selected cells (both horizontally and vertically).

- **Split Cell**
  Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

**DocBook5 Menu Actions**

The following additional actions can be found in the DocBook5 menu when editing in Author mode:

- **Paste special submenu**
  This submenu includes the following special paste actions that are specific to the DocBook 5 framework:

  - Paste As XInclude
Allows you to create an `xi:include` element that references a DocBook element copied from **Author** mode. The operation fails if the copied element does not have a declared ID.

**Paste as link**

Allows you to create a `link` element that references a DocBook element copied from **Author** mode. The operation fails if the copied element does not have a declared ID.

**Paste as xref**

Allows you to create an `xref` element that references a DocBook element copied from **Author** mode. The operation fails if the copied element does not have a declared ID.

**T₂ Subscript**

Surrounds the selected text with a `subscript` tag, used for inserting a character (number, letter, or symbol) that will appear slightly below the baseline and slightly smaller than the rest of the text.

**T₆ Superscript**

Surrounds the selected text with a `superscript` tag, used for inserting a character (number, letter, or symbol) that will appear slightly above the baseline and slightly smaller than the rest of the text.

**Table submenu**

In addition to the table actions available on the toolbar, the following actions are available in this submenu:

- **Insert Row Above**
  
  Inserts a new table row with empty cells above the current row. This action is available when the cursor is positioned inside a table.

- **Insert Rows**
  
  Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (**Above** or **Below** the current row).

- **Insert Column Before**
  
  Inserts a column before the current one.
Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (Above or Below the current column).

**Insert Cell**

Inserts a new empty cell depending on the current context. If the cursor is positioned between two cells, Oxygen XML Editor a new cell at cursor position. If the cursor is inside a cell, the new cell is created after the current cell.

**ID Options**

Opens the **ID Options** dialog box that allows you to configure options for generating IDs in **Author** mode. The dialog box includes the following:

**ID Pattern**

The pattern for the ID values that will be generated. This text field can be customized using constant strings or any of the Oxygen XML Editor **Editor Variables** *(on page 276)*.

**Element name or class value to generate ID for**

The elements for which ID values will be generated, specified using class attribute values. To customize the list, use the **Add**, **Edit**, or **Remove** buttons.

**Auto generate IDs for elements**

If selected, Oxygen XML Editor will automatically generate unique IDs for the elements listed in this dialog box when they are created in **Author** mode.

**Remove IDs when copying content**

This option allows you to control whether or not pasted elements that are listed in this dialog box should retain their existing IDs. If this option is not selected, IDs are always retained when you copy or cut content and paste it in the same document or other documents. If this option is selected, IDs are never retained for copied content, but if you cut the content, they are preserved for the first paste action (and not retained for any subsequent paste actions).

**Generate IDs**

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:
• When invoked on a single selection, an ID is generated for the selected element at the cursor position.
• When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the ID Options dialog box that are found in the current selection.

Note: The Generate IDs action does not overwrite existing ID values. It only affects elements that do not already have an id attribute.

Refresh References
You can use this action to manually trigger a refresh and update of all referenced resources.

Tags display mode Submenu

- Full Tags with Attributes
  
  Displays full tag names with attributes for both block (on page 3280) and inline elements (on page 3283).

- Full Tags
  
  Displays full tag names without attributes for both block and inline elements.

- Block Tags
  
  Displays full tag names for block elements and simple tags without names for inline elements.

- Inline Tags
  
  Displays full tag names for inline elements, while block elements are not displayed.

- Partial Tags
  
  Displays simple tags without names for inline elements, while block elements are not displayed.

- No Tags
  
  No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

Configure Tags Display Mode

Use this option to go to the Author preferences page (on page 131) where you can configure the Tags Display Mode options.
Profiling/Conditional Text Submenu

Edit Profiling Attributes

Allows you to configure the profiling attributes (on page 969) and their values.

Show Profiling Colors and Styles

Select this option to turn on conditional styling.

Show Profiling Attributes

Select this option to turn on conditional text markers. They are displayed at the end of conditional text blocks, as a list of attribute name and their currently set values.

Show Excluded Content

When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.

List of all profiling condition sets that match the current document type

You can click a listed condition set (on page 975) to activate it.

Profiling Settings

Opens the profiling options preferences page (on page 144), where you can manage profiling attributes and profiling conditions sets. You can also configure the profiling styles and colors options from the colors/styles preferences page (on page 146) and the attributes rendering preferences page (on page 148).

DocBook 5 Contextual Menu Actions

In addition to many of the DocBook 5 toolbar actions (on page 1555) and the general Author mode contextual menu actions (on page 1065), the following DocBook 5 framework-specific actions are also available in the contextual menu when editing in Author mode:

Paste special submenu

This submenu includes the following special paste actions that are specific to the DocBook 5 framework:

Paste As XInclude

Allows you to create an \texttt{xinclude} element that references a DocBook element copied from Author mode. The operation fails if the copied element does not have a declared ID.
**Paste as link**

Allows you to create a `link` element that references a DocBook element copied from **Author** mode. The operation fails if the copied element does not have a declared ID.

**Paste as xref**

Allows you to create an `xref` element that references a DocBook element copied from **Author** mode. The operation fails if the copied element does not have a declared ID.

**Image Map Editor**

This action is available in the contextual menu when it is invoked on an image. This action applies an *image map* to the current image (if one does not already exist) and opens the **Image Map Editor** dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

**Table Actions**

The following table editing actions are available in the contextual menu when it is invoked on a table:

**Insert Rows**

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (**Above** or **Below** the current row).

**Delete Row(s)**

Deletes the table row located at cursor position or multiple rows in a selection.

**Insert Columns**

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (**Above** or **Below** the current column).

**Delete Column(s)**

Deletes the table column located at cursor position or multiple columns in a selection.

**Join Cells**

Joins the content of the selected cells (both horizontally and vertically).

**Split Cell**
Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

Sort
Sorts cells or list items in a table.

Table Properties
Opens the Table properties dialog box that allows you to configure properties of a table (such as frame borders).

Other Actions submenu
This submenu give you access to all the usual contextual menu actions.

Link > Edit OLink
Opens a dialog box that allows you edit an existing OLink. See the Insert OLink action for more information.

Generate IDs
Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the ID Options dialog box that are found in the current selection.

Note: The Generate IDs action does not overwrite existing ID values. It only affects elements that do not already have an id attribute.

DocBook 5 Drag/Drop (or Copy/Paste) Actions
Dragging a file from the Project view (on page 333) or DITA Maps Manager view (on page 2990) and dropping it into a DocBook 5 document that is edited in Author mode, creates a link to the dragged file (the link DocBook element) at the drop location. Copy and paste actions work the same.

You can also drag images or media files from your system explorer or the Project view (on page 333) and drop them into a DocBook 5 document (or copy and paste). This will insert the appropriate element at the drop or paste location (for example, dropping/pasting an image will insert the imageobject DocBook element with an imagedata child element and a fileref attribute).
Tip: For information about customizing Author mode actions for a particular framework (on page 3282) (document type), see the Configuring Actions, Menus, Toolbars, Content Completion for a Framework (on page 2323) section.

Related Information:

- Configuring Actions, Menus, Toolbars, Content Completion for a Framework (on page 2323)

Inserting an Olink in DocBook Documents

The `olink` element is used for linking to resources outside the current DocBook document. The `targetdoc` attribute is used for the document ID that contains the target element and the `targetptr` attribute for the ID of the target element (the value of an `id` or `xml:id` attribute). The combination of those two attributes provides a unique identifier to locate cross references.

For example, a Mail Administrator Guide with the document ID `MailAdminGuide` might contain a chapter about user accounts, like this:

```xml
<chapter id="user_accounts">
  <title>Administering User Accounts</title>
  <para>blah blah</para>
</chapter>
```

You can form a cross reference to that chapter by adding an `olink`, as in the following example:

```xml
<olink targetdoc="MailAdminGuide" targetptr="user_accounts">user accounts</olink>
```

You may need to update your

To use an `olink` to create links between documents, follow these steps:

1. Decide which documents are to be included in the domain for cross referencing.
   A unique ID must be assigned to each document that will be referenced with an `olink`. It is usually added as an `id` (or `xml:id` for DocBook5) attribute to the root element of the document.

2. Decide on your output hierarchy.
   For creating links between documents, the relative locations of the output documents must be known. Before going further you must decide the names and locations of the output directories for all the documents from the domain. Each directory will be represented by an element: `<dir name="directory_name">`, in the target database document.

3. Create the target database document.
Each collection of documents has a master target database document that is used to resolve all olinks from that collection. The target database document is an XML file that is created once. It provides a means for pulling in the target data for each document. The database document is static and all the document data is pulled in dynamically.

**Tip:** Oxygen XML Editor includes a built-in new document template called **DocBook Targetset Map** available in the **New document wizard** *(on page 676)* that will help you get started.

**Example:** The following is an example of a target database document. It structures a collection of documents in a sitemap element that provides the relative locations of the outputs (HTML in this example). Then it pulls in the individual target data using system entity references to target data files that will be created in the next step.

```xml
<?xml version="1.0" encoding="utf-8"?>
<!DOCTYPE targetset [  
<!ENTITY ugtargets SYSTEM "file:///doc/userguide/target.db">  
<!ENTITY agtargets SYSTEM "file:///doc/adminguide/target.db">  
<!ENTITY reftargets SYSTEM "file:///doc/man/target.db">  
]>
<targetset>
  <targetsetinfo>
    Description of this target database document, which is for the examples in olink doc.
  </targetsetinfo>

  <!-- Site map for generating relative paths between documents -->
  <sitemap>
    <dir name="documentation">
      <dir name="guides">
        <dir name="mailuser">
          <document targetdoc="MailUserGuide" baseuri="userguide.html">
            &ugtargets;
          </document>
        </dir>
        <dir name="mailadmin">
          <document targetdoc="MailAdminGuide">
            &agtargets;
          </document>
        </dir>
      </dir>
    </dir>
  </sitemap>
</targetset>
```
4. Generate the target data files by executing a DocBook transformation scenario.
   Before applying the transformation, you need to edit the transformation scenario, go to the
   Parameters tab, and make sure the value of the collect.xref.targets parameter is set to yes.
   The default name of a target data file is target.db, but it can be changed by setting an absolute
   file path in the targets.filename parameter.

   **Example:** An example of a target.db file:

   ```xml
   <dir name="mailref">
     <document targetdoc="MailReference">
       &reftargets;
     </document>
   </dir>
   
   4. Generate the target data files by executing a DocBook transformation scenario.
   Before applying the transformation, you need to edit the transformation scenario, go to the
   Parameters tab, and make sure the value of the collect.xref.targets parameter is set to yes.
   The default name of a target data file is target.db, but it can be changed by setting an absolute
   file path in the targets.filename parameter.

   **Example:** An example of a target.db file:

   ```xml
   <dir name="mailref">
     <document targetdoc="MailReference">
       &reftargets;
     </document>
   </dir>
   
   4. Generate the target data files by executing a DocBook transformation scenario.
   Before applying the transformation, you need to edit the transformation scenario, go to the
   Parameters tab, and make sure the value of the collect.xref.targets parameter is set to yes.
   The default name of a target data file is target.db, but it can be changed by setting an absolute
   file path in the targets.filename parameter.

   **Example:** An example of a target.db file:

   ```xml
   <dir name="mailref">
     <document targetdoc="MailReference">
       &reftargets;
     </document>
   </dir>
   
   4. Generate the target data files by executing a DocBook transformation scenario.
   Before applying the transformation, you need to edit the transformation scenario, go to the
   Parameters tab, and make sure the value of the collect.xref.targets parameter is set to yes.
   The default name of a target data file is target.db, but it can be changed by setting an absolute
   file path in the targets.filename parameter.

   **Example:** An example of a target.db file:

   ```xml
   <dir name="mailref">
     <document targetdoc="MailReference">
       &reftargets;
     </document>
   </dir>
   
   4. Generate the target data files by executing a DocBook transformation scenario.
   Before applying the transformation, you need to edit the transformation scenario, go to the
   Parameters tab, and make sure the value of the collect.xref.targets parameter is set to yes.
   The default name of a target data file is target.db, but it can be changed by setting an absolute
   file path in the targets.filename parameter.

   **Example:** An example of a target.db file:

   ```xml
   <dir name="mailref">
     <document targetdoc="MailReference">
       &reftargets;
     </document>
   </dir>
   
   4. Generate the target data files by executing a DocBook transformation scenario.
   Before applying the transformation, you need to edit the transformation scenario, go to the
   Parameters tab, and make sure the value of the collect.xref.targets parameter is set to yes.
   The default name of a target data file is target.db, but it can be changed by setting an absolute
   file path in the targets.filename parameter.

   **Example:** An example of a target.db file:

   ```xml
   <dir name="mailref">
     <document targetdoc="MailReference">
       &reftargets;
     </document>
   </dir>
   
   4. Generate the target data files by executing a DocBook transformation scenario.
   Before applying the transformation, you need to edit the transformation scenario, go to the
   Parameters tab, and make sure the value of the collect.xref.targets parameter is set to yes.
   The default name of a target data file is target.db, but it can be changed by setting an absolute
   file path in the targets.filename parameter.

   **Example:** An example of a target.db file:

   ```xml
   <dir name="mailref">
     <document targetdoc="MailReference">
       &reftargets;
     </document>
   </dir>
   
   4. Generate the target data files by executing a DocBook transformation scenario.
   Before applying the transformation, you need to edit the transformation scenario, go to the
   Parameters tab, and make sure the value of the collect.xref.targets parameter is set to yes.
   The default name of a target data file is target.db, but it can be changed by setting an absolute
   file path in the targets.filename parameter.

   **Example:** An example of a target.db file:

   ```xml
   <dir name="mailref">
     <document targetdoc="MailReference">
       &reftargets;
     </document>
   </dir>
   
   4. Generate the target data files by executing a DocBook transformation scenario.
   Before applying the transformation, you need to edit the transformation scenario, go to the
   Parameters tab, and make sure the value of the collect.xref.targets parameter is set to yes.
   The default name of a target data file is target.db, but it can be changed by setting an absolute
   file path in the targets.filename parameter.

   **Example:** An example of a target.db file:

   ```xml
   <dir name="mailref">
     <document targetdoc="MailReference">
       &reftargets;
     </document>
   </dir>
   
   4. Generate the target data files by executing a DocBook transformation scenario.
   Before applying the transformation, you need to edit the transformation scenario, go to the
   Parameters tab, and make sure the value of the collect.xref.targets parameter is set to yes.
   The default name of a target data file is target.db, but it can be changed by setting an absolute
   file path in the targets.filename parameter.

   **Example:** An example of a target.db file:

   ```xml
   <dir name="mailref">
     <document targetdoc="MailReference">
       &reftargets;
     </document>
   </dir>
   
   4. Generate the target data files by executing a DocBook transformation scenario.
   Before applying the transformation, you need to edit the transformation scenario, go to the
   Parameters tab, and make sure the value of the collect.xref.targets parameter is set to yes.
   The default name of a target data file is target.db, but it can be changed by setting an absolute
   file path in the targets.filename parameter.

   **Example:** An example of a target.db file:

   ```xml
   <dir name="mailref">
     <document targetdoc="MailReference">
       &reftargets;
     </document>
   </dir>
   
   4. Generate the target data files by executing a DocBook transformation scenario.
   Before applying the transformation, you need to edit the transformation scenario, go to the
   Parameters tab, and make sure the value of the collect.xref.targets parameter is set to yes.
   The default name of a target data file is target.db, but it can be changed by setting an absolute
   file path in the targets.filename parameter.

   **Example:** An example of a target.db file:

   ```xml
   <dir name="mailref">
     <document targetdoc="MailReference">
       &reftargets;
     </document>
   </dir>
   
   4. Generate the target data files by executing a DocBook transformation scenario.
   Before applying the transformation, you need to edit the transformation scenario, go to the
   Parameters tab, and make sure the value of the collect.xref.targets parameter is set to yes.
   The default name of a target data file is target.db, but it can be changed by setting an absolute
   file path in the targets.filename parameter.

   **Example:** An example of a target.db file:

   ```xml
   <dir name="mailref">
     <document targetdoc="MailReference">
       &reftargets;
     </document>
   </dir>
   
   4. Generate the target data files by executing a DocBook transformation scenario.
   Before applying the transformation, you need to edit the transformation scenario, go to the
   Parameters tab, and make sure the value of the collect.xref.targets parameter is set to yes.
   The default name of a target data file is target.db, but it can be changed by setting an absolute
   file path in the targets.filename parameter.

   **Example:** An example of a target.db file:

   ```xml
   <dir name="mailref">
     <document targetdoc="MailReference">
       &reftargets;
     </document>
   </dir>
   
   4. Generate the target data files by executing a DocBook transformation scenario.
   Before applying the transformation, you need to edit the transformation scenario, go to the
   Parameters tab, and make sure the value of the collect.xref.targets parameter is set to yes.
   The default name of a target data file is target.db, but it can be changed by setting an absolute
   file path in the targets.filename parameter.

   **Example:** An example of a target.db file:

   ```xml
   <dir name="mailref">
     <document targetdoc="MailReference">
       &reftargets;
     </document>
   </dir>
You can also use the search fields to quickly identify a target. If you already know the values for the `targetdoc` and `targetptr` attributes, you can insert them directly in the corresponding fields.

**Example:** In the following image, the target database document is called `target.xml`, `dbadmin` is selected for the target document (`targetdoc`), and `bldinit` is selected as the value for the `targetptr` attribute. Notice that you can also add XREF text into the `olink` by using the `xreftext` field.

Figure 598. Insert OLink Dialog Box

6. Process a DocBook transformation for each document to generate the output.
   a. Edit the transformation scenario and set the value of the `target.database.document` parameter to be the URL of the target database document.
   b. Apply the transformation scenario.
DocBook 5.1 Assembly

The DocBook Assembly document type was introduced with DocBook 5.1 and it is used to define the hierarchy and relationships for a collection of resources. It is especially helpful for topic-oriented authoring scenarios since it assembles a set of resources (such as DocBook 5.1 topics) to form a hierarchical structure for a larger publication.

An Assembly document usually has four major parts:

- **Resources** - Identifies a collection of resources (such as topics). An Assembly may identify one or more collections.
- **Structure** - Identifies an artifact to be assembled. A document in this case is the particular collection of resources (such as topics) that forms the documentation. Within the structure element, an output element can be used to identify the type of output to be generated and module elements can be used to identify the resources to be included. An Assembly may identify one or more structures.
- **Relationships** - Identifies relationships between resources. These relationships may be manifested in any number of structures during assembly. An Assembly may identify any number of relationships.
- **Transformations** - Identifies transformations that can be applied during assembly. An Assembly may identify any number of transformations.

For detailed information about the DocBook Assembly document type, see DocBook 5.1: The Definitive Guide - DocBook Assemblies.

File Definition

A file is considered to be an Assembly when the root name is assembly.

Default Document Templates

A default Assembly document template is available when creating new documents from templates (on page 676) and it can be found in: Framework Templates > DocBook 5 > DocBook 5.1.

The default template for DocBook Assembly documents is located in the [OXYGEN_INSTALL_DIR]/frameworks/docbook/templates/Docbook5.1 folder.

Default Schema for Validation and Content Completion

The default schema that is used if one is not detected is docbookxi.rng and it is stored in [OXYGEN_INSTALL_DIR]/frameworks/docbook/5.1/rng/.
Transformation Scenarios

Oxygen XML Editor includes a built-in transformation scenario that can be applied on an Assembly file to generate an assembled (merged) DocBook file. The scenario is called DocBook Assembly and is found in the DocBook 5 section in the Configure Transformation Scenario(s) dialog box (on page 1762).

Resources

- Sample files: \[OXYGEN_INSTALL_DIR]/samples/docbook/v5/assembly/

DocBook 5.1 Topic

The DocBook Topic document type was introduced with DocBook 5.1 and it is used as a modular unit of documentation. It is similar to the concept of the DITA Topic and can be used as modular resources in conjunction with DocBook 5.1 Assembly (on page 1569) documents.

File Definition

A DocBook file is considered to be a Topic when the root name is topic.

Default Document Templates

A default Topic document template is available when creating new documents from templates (on page 676) and it can be found in: Framework Templates > DocBook 5 > DocBook 5.1.

The default template for DocBook Assembly documents is located in the [OXYGEN_INSTALL_DIR]/frameworks/docbook/templates/Docbook5.1 folder.

Default Schema for Validation and Content Completion

The default schema that is used if one is not detected is docbookxi.rng and it is stored in [OXYGEN_INSTALL_DIR]/frameworks/docbook/5.1/rng/.
**Transformation Scenarios**

Since DocBook *Topics* are modular resources, they are *assembled* and transformed in the *DocBook Assembly* transformation process *(on page 1571)*. You can also use any of the built-in DocBook transformation scenarios to transform individual DocBook Topics to a variety of outputs, such as PDF, HTML, EPUB, and more. They are found in the *DocBook 5* section in the *Configure Transformation Scenario(s)* dialog box *(on page 1762)*.

**Resources**

- Sample files: `[OXYGEN_INSTALL_DIR]/samples/docbook/v5/assembly/

**Related Information:**

- DocBook 5.1 Assembly *(on page 1569)*

**DocBook Targetset Document Type (Framework)**

DocBook *Targetset* documents are used to resolve cross references with the DocBook *olink*.

**File Definition**

A file is considered to be a *Targetset* when the root name is `targetset`.

**Default Document Templates**

A default *DocBook Targetset Map* document template is available when creating new documents from templates *(on page 676)* and it can be found in: Framework Templates > DocBook Targetset.

The default template for DocBook Targetset documents is located in the `[OXYGEN_INSTALL_DIR]/frameworks/docbook/templates/Targetset` folder.

**Default Schema for Validation and Content Completion**

The default schema, `targetdatabase.dtd`, for this type of document is stored in `[OXYGEN_INSTALL_DIR]/frameworks/docbook/xsl/common/`. 
DITA Topics Document Type (Framework)

The Darwin Information Typing Architecture (DITA) is an XML-based architecture for authoring, producing, and delivering technical information. It divides content into small, self-contained topics that you can reuse in various deliverables. The extensibility of DITA permits organizations to define specific information structures while still using standard tools to work with them. DITA content is created as topics, each an individual XML file. Typically, each topic has a defined primary objective and structure, and DITA also includes several specialized topic types (task, concept, reference, glossary entry).

For much more detailed information, resources, and instructions, see the DITA Authoring (on page 2981) chapter.

File Definition

A file is considered to be a DITA topic document when one of the following conditions are true:

- The root element name is one of the following: concept, task, reference, dita, or topic.
- The PUBLIC ID of the document is a PUBLIC ID for the elements listed above.
- The root element of the file has an attribute named DITAArchVersion for the "http://dita.oasis-open.org/architecture/2005/" namespace. This enhanced case of matching is only applied when the Enable DTD/XML Schema processing in document type detection option (on page 94) is selected from the Document Type Association preferences page (on page 92).

Default Document Templates

There are a variety of default DITA topic templates available when creating new documents from templates (on page 676) and they can be found in various folders inside: Framework Templates > DITA.

The default templates for DITA topic documents are located in the [OXYGEN_INSTALL_DIR]/frameworks/dita/templates/topic folder.
Default Schema for Validation and Content Completion

Default schemas that are used if one is not detected in the DITA documents are stored in the various folders inside `DITA-OT-DIR/dtd/` or `DITA-OT-DIR/schema/`.

Default CSS

The default CSS files used for rendering DITA content in Author mode are stored in the various folders inside: `OXYGEN_INSTALL_DIR/frameworks/dita/css/`. By default, these default CSS files are merged with any that are specified in the document. For more information, see Configuring and Managing Multiple CSS Styles for a Framework (on page 2348).

Default XML Catalogs

The default XML Catalogs (on page 3289) for the DITA topic document type are as follows:

- `DITA-OT-DIR/catalog-dita.xml`
- `OXYGEN_INSTALL_DIR/frameworks/dita/catalog.xml`
- `OXYGEN_INSTALL_DIR/frameworks/dita/plugin/catalog.xml`
- `OXYGEN_INSTALL_DIR/frameworks/dita/styleguide/catalog.xml`

Transformation Scenarios

Oxygen XML Editor includes built-in transformation scenarios that allow you to transform individual DITA Topics to a XHTML or PDF output. They can be found in the DITA section in the Configure Transformation Scenario(s) dialog box (on page 1762).

DITA Topic Author Mode Actions

A variety of actions are available for the DITA framework that can be found on the toolbar, the contextual menu, or the DITA menu.

**DITA Toolbar Actions**

The following default actions are readily available on the DITA (Author Custom Actions) toolbar when editing in Author mode (by default, most of them are also available in the DITA menu and in various submenus of the contextual menu):

- **Bold**
  Surrounds the selected text with a `b` tag. You can use this action on multiple non-contiguous selections.

- **Italic**
  Surrounds the selected text with an `i` tag. You can use this action on multiple non-contiguous selections.

- **Underline**
  Surrounds the selected text with a `u` tag. You can use this action on multiple non-contiguous selections.

- **Link Actions Drop-Down Menu**

  The following link actions are available from this menu:

  - **Cross Reference**
    Opens the Cross Reference (xref) dialog box that allows you to insert a link to a target DITA resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your DITA map structure. Once the target resource has been selected, you can also target specific elements within that resource. For more information, see Linking in DITA Topics.

  - **File Reference**
Opens the **File Reference** dialog box *(on page 3164)* that allows you to insert a link to a target non-DITA file resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. For more information, see **Linking in DITA Topics** *(on page 3163)*.

**Web Link**

Opens the **Web Link** dialog box *(on page 3164)* that allows you to insert a link to a target web-related resource at the current location within a document. The target resource can be a URL or a key that is already defined in your *DITA map* structure. For more information, see **Linking in DITA Topics** *(on page 3163)*.

**Related Link to Topic**

Opens the **Cross Reference (xref)** dialog box *(on page 3165)* that allows you to insert a link to a target DITA resource in a related links section at the bottom of the current document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. Once the target resource has been selected, you can also target specific elements within that resource. If a related links section does not already exist, this action creates one. For more information, see **Linking in DITA Topics** *(on page 3163)*.

**Tip:** You can use the **Find Similar Topics** action that available in the *DITA* menu to quickly find related topics that can be added as related links. It opens the **Open/Find Resource** view and performs a search using text content from the `<title>`, `<shortdesc>`, `<keyword>`, and `<indexterm>` elements.

**Related Link to File**

Opens the **File Reference** dialog box *(on page 3165)* that allows you to insert a link to a target non-DITA file resource in a related links section at the bottom of the current document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. If a related links section does not already exist, this action creates one. For more information, see **Linking in DITA Topics** *(on page 3163)*.

**Related Link to Web Page**

Opens the **Web Link** dialog box *(on page 3165)* that allows you to insert a link to a target web-related resource in a related links section at the bottom of the current document. The target resource can be a URL or a key that
is already defined in your DITA map structure. If a related links section does not already exist, this action creates one. For more information, see Linking in DITA Topics (on page 3163).

**Insert Image**

Opens the Insert Image dialog box (on page 3062) that allows you to configure the properties of an image to be inserted into a DITA document at the cursor position.

**Insert Media Resource**

Opens the Insert Media dialog box (on page 3066) that allows you to select and configure the properties of a media object to be inserted into a DITA document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted in an object element and it is rendered in Author mode so that it can be played directly from there.

### § • Insert Section Drop-Down Menu

The following insert actions are available from this menu:

- **Insert Section**
  
  Inserts a new section element in the document, depending on the current context.

- **Insert Concept**
  
  Inserts a new concept element, depending on the current context. Concepts provide background information that users must know before they can successfully work with a product or interface.

- **Insert Task**
  
  Inserts a new task element, depending on the current context. Tasks are the main building blocks for task-oriented user assistance. They generally provide step-by-step instructions that will help a user to perform a task.

- **Insert Topic**
  
  Inserts a new topic element, depending on the current context. Topics are the basic units of DITA content and are usually organized around a single subject.

- **Insert Reference**
  
  Inserts a new reference element, depending on the current context. A reference is a top-level container for a reference topic.

- **Insert Paragraph**
  
  Inserts a new paragraph at current cursor position.
Reuse Content

This action provides a mechanism for reusing content fragments. It opens the **Reuse Content** dialog box (on page 3135) that allows you to insert several types of references to reusable content at the cursor position. The types of references that you can insert using this dialog box include content references (conref (on page 3136)), content key references (conkeyref (on page 3137)), or key references to metadata (keyref (on page 3141)).

Insert step or list item

Inserts a new list or step item in the current list type.

Insert Unordered List

Inserts an unordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an unordered list.

Insert Ordered List

Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

Sort

Sorts cells or list items in a table.

Insert Table

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a block element (on page 3280)) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

**Note:** If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that Only lists, paragraphs, or inline content can be converted to tables.

Insert Row Below

Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

Delete Row(s)

Deletes the table row located at cursor position or multiple rows in a selection.
**Insert Column After**

Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

**Delete Column(s)**

Deletes the table column located at cursor position or multiple columns in a selection.

**Table Properties**

Opens the Table properties dialog box that allows you to configure properties of a table (such as frame borders).

**Join Cells**

Joins the content of the selected cells (both horizontally and vertically).

**Split Cell**

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

### DITA Contextual Menu Actions

In addition to many of the DITA toolbar actions (on page 1575) and the general Author mode contextual menu actions (on page 1065), there are numerous DITA-specific actions that are available in the contextual menu when editing DITA documents in Author mode (most of them are also available in the DITA menu at the top of the interface):

**Add File to Review Task**

This action can be used to add the current document to a task in the Content Fusion Tasks Manager view. Oxygen Content Fusion is a flexible, intuitive collaboration platform designed to adapt to any type of documentation review workflow. This functionality is available through a pre-installed connector add-on (on page 2679). To fully take advantage of all of the benefits and features of Content Fusion, your organization will need an Oxygen Content Fusion Enterprise Server. For more information, see the Oxygen Content Fusion website.

**Edit Attributes**

Displays an in-place attributes editor (on page 429) that allows you to manage the attributes of an element.

**Edit Profiling Attributes**

Allows you to change the profiling attributes (on page 969) defined on all selected elements.
Cut (Ctrl + X (Command + X on OS X))
Removes the current selected content from the document and places it in the clipboard.

Copy (Ctrl + C (Command + C on OS X))
Places a copy of the current selected content in the clipboard.

Paste (Ctrl + V (Command + V on OS X))
Inserts the current clipboard content into the document at the cursor position.

Paste special submenu
This submenu includes the following special paste actions that are specific to the DITA framework:

Paste as content reference
Inserts a content reference (a DITA element with a conref attribute) to the DITA XML element from the clipboard. An entire DITA XML element with an ID attribute must be present in the clipboard when the action is invoked. The conref attribute will point to this ID value.

Paste as content key reference
Allows you to indirectly reference content using the conkeyref attribute. When the DITA content is processed, the key references are resolved using key definitions from DITA maps (on page 3281). To use this action, you must first do the following:

1. Make sure the DITA element that contains the copied content has an ID attribute assigned to it.
2. In the DITA Maps Manager view, make sure that the Root map combo box (on page 2995) points to the correct map that stores the keys.
3. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the DITA Maps Manager, select Edit Properties, and enter a value in the Keys field.

Paste as link
Looks for the first element with an ID value in the clipboard and inserts an xref that points to that element. If no elements with an ID value are found, a message will appear that informs you that to use this action, the clipboard contents must include at least one element with a declared ID.

Paste as link (keyref)
Inserts a link to the element that you want to reference. To use this action, you must first do the following:

1. Make sure the DITA element that contains the copied content has an ID attribute assigned to it.
2. In the DITA Maps Manager view, make sure that the Root map combo box (on page 2995) points to the correct map that stores the keys.
3. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the DITA Maps Manager, select Edit Properties, and enter a value in the Keys field.

**Insert submenu**

This submenu includes the following insert actions that are specific to the DITA framework:

- **Insert Table**
  
  Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a block element (on page 3280)) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

  **Note:** If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that Only lists, paragraphs, or inline content can be converted to tables.

- **Insert Image**
  
  Inserts an image reference (on page 1021) at the cursor position. Depending on the current location, an image-type element is inserted.

- **Insert Media Resource**
  
  Opens a Choose Media dialog box (on page 1055) that allows you to select the URL of a media object to be inserted into a document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted and rendered in Author mode so that it can be played directly from there.

- **Insert Equation**
Opens the XML Fragment Editor that allows you to insert and edit MathML notations (on page 1057).

**Insert Paragraph**

Inserts a new paragraph at current cursor position.

**Insert Section**

Inserts a new `section` element in the document, depending on the current context.

**Insert Topic**

Inserts a new `topic` element, depending on the current context. Topics are the basic units of DITA content and are usually organized around a single subject.

**Insert Entity**

Allows you to insert a predefined entity or character entity. Surrogate character entities (range #x10000 to #x10FFFF) are also accepted. Character entities can be entered in one of the following forms:

- `#<decimal value>` - e. g. #65
- `&#<decimal value>;` - e. g. &#65
- `#x<hexadecimal value>` - e. g. #x41
- `&#x<hexadecimal value>;` - e. g. &#x41

**Image Map Editor**

This action is available in the contextual menu when it is invoked on an image. This action applies an image map to the current image (if one does not already exist) and opens the Image Map Editor dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

**Table Actions**

The following table editing actions are available in the contextual menu when it is invoked on a table:

**Insert Rows**

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (Above or Below the current row).

**Delete Row(s)**
Deletes the table row located at cursor position or multiple rows in a selection.

**Insert Columns**

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (Above or Below the current column).

**Delete Column(s)***

Deletes the table column located at cursor position or multiple columns in a selection.

**Join Cells***

Joins the content of the selected cells (both horizontally and vertically).

**Split Cell***

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

**Sort***

Sorts cells or list items in a table.

**Table Properties***

Opens the *Table properties* dialog box that allows you to configure properties of a table (such as frame borders).

**Other Actions submenu***

This submenu gives you access to all the usual contextual menu actions.

**Link submenu***

The following link actions are available from this submenu:

**Cross Reference***

Opens the *Cross Reference (xref)* dialog box (on page 3164) that allows you to insert a link to a target DITA resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your *DITA map (on page 3281)* structure. Once the target resource has been selected, you can also target specific elements within that resource. For more information, see Linking in DITA Topics (on page 3163).

**File Reference***
Opens the **File Reference** dialog box ([on page 3164](#)) that allows you to insert a link to a target non-DITA file resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your **DITA map** structure. For more information, see [Linking in DITA Topics](#).

**Web Link**

Opens the **Web Link** dialog box ([on page 3164](#)) that allows you to insert a link to a target web-related resource at the current location within a document. The target resource can be a URL or a key that is already defined in your **DITA map** structure. For more information, see [Linking in DITA Topics](#).

**Related Link to Topic**

Opens the **Cross Reference (xref)** dialog box ([on page 3165](#)) that allows you to insert a link to a target DITA resource in a related links section at the bottom of the current document. The target resource can be the location of a file or a key that is already defined in your **DITA map** structure. Once the target resource has been selected, you can also target specific elements within that resource. If a related links section does not already exist, this action creates one. For more information, see [Linking in DITA Topics](#).

**Tip:** You can use the **Find Similar Topics** action that available in the **DITA** menu to quickly find related topics that can be added as related links. It opens the **Open/Find Resource** view and performs a search using text content from the `<title>`, `<shortdesc>`, `<keyword>`, and `<indexterm>` elements.

**Related Link to File**

Opens the **File Reference** dialog box ([on page 3165](#)) that allows you to insert a link to a target non-DITA file resource in a related links section at the bottom of the current document. The target resource can be the location of a file or a key that is already defined in your **DITA map** structure. If a related links section does not already exist, this action creates one. For more information, see [Linking in DITA Topics](#).

**Related Link to Web Page**

Opens the **Web Link** dialog box ([on page 3165](#)) that allows you to insert a link to a target web-related resource in a related links section at the bottom of the current document. The target resource can be a URL or a key that
is already defined in your DITA map structure. If a related links section does not already exist, this action creates one. For more information, see Linking in DITA Topics (on page 3163).

Sort

Available when invoked on a list, it opens a dialog box where you can configure a sorting operation for an entire list or a selection of list items.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the ID Options dialog box that are found in the current selection.

**Note:** The Generate IDs action does not overwrite existing ID values. It only affects elements that do not already have an id attribute.

Reuse submenu

This submenu includes the following actions regarding reusing content in DITA:

- **Reuse Content**
  
  This action provides a mechanism for reusing content fragments. It opens the Reuse Content dialog box (on page 3135) that allows you to insert several types of references to reusable content at the cursor position. The types of references that you can insert using this dialog box include content references (conref) (on page 3136), content key references (conkeyref) (on page 3137), or key references to metadata (keyref) (on page 3141).

- **Push Current Element**
  
  Opens the Push current element dialog box (on page 3144) that allows content from a source topic to be inserted into another topic without any special coding in the topic where the content will be re-used.

- **Edit Content Reference**
  
  This action is available for elements with a conref or conkeyref attribute. It opens the Edit Content Reference dialog box that allows you to edit the source location (or key) and source element of a content reference.
(or content key reference), and the reference details (conref / conkeyref
and conrefend attributes). For more information, see Reuse Content
Dialog Box (on page 3135).

Replace Reference with Content

Replaces the referenced fragment (conref or conkeyref) at the cursor
position with its content from it source. This action is useful if you
want to make changes to the content in the currently edited document
without changing the referenced fragment in its source location. If the
source content includes references to other topics/resources (hrefs),
the operation also resolves those references relative to the new location.
Attributes are preserved according to the following priority:

1. Attributes from the elements in the current document that reference
   other content are preserved except for attributes with a -dita-use-
   conref-target value.
2. Attributes from the referenced content are brought into the replaced
   elements in the current document except for id attributes.

Replace All References with Content

Replaces all referenced fragments (keyref, conref, or conkeyref) in the
current document with the content. Attributes are preserved according to
the following priority:

1. Attributes from the elements in the current document that reference
   other content are preserved except for attributes with a -dita-use-
   conref-target value.
2. Attributes from the referenced content are brought into the replaced
   elements in the current document except for id attributes.

For keyrefs inside xref or link elements, the keyref attribute is
changed to an href attribute, while the rest of the content for the keyref is
replaced with its source content.

If the source content includes references to other topics/resources (hrefs),
the operation also resolves those references relative to the new location.

Remove Content Reference

Removes the content reference (conref or conkeyref) inside the
element at the cursor position.

Create Reusable Component
Creates a reusable component from the selected fragment of text. For more information, see Creating a Reusable Content Component (on page 3147).

**Insert Reusable Component**

Inserts a reusable component at cursor location. For more information, see Inserting a Reusable Content Component (on page 3148).

**Search References (Ctrl + Shift + G)**

Finds the references to the `id` attribute value for the element at the current cursor position, in all the topics contained in the current DITA map (on page 3281) (opened in the [DITA Maps Manager view](on page 2990)). If no references are found for the current element, a dialog box will be displayed that offers you the option of searching for references to its ancestor elements.

**Figure 599. Search References to Ancestors Dialog Box**

![Search References to Ancestors Dialog Box](image)

**Tip:** If you are invoking the action on an image, see Searching for References to Images (on page 3065) for details about what will be reported.

**Show Key Definition**

Available for elements that have a `conkeyref` or `keyref` attribute set (or elements with an ancestor element that has a `conkeyref` or `keyref` attribute). It computes the key name and opens the DITA map (on page 3281) that contains the definition of the key with the element that defines that key selected.

**About Element submenu**

This submenu includes the following actions:

**Style Guide**

Opens the DITA Style Guide Best Practices for Authors in your browser and displays a topic that is relevant to the element at the cursor position. When editing DITA documents, this action is available in the contextual menu of the editing area (under the About Element sub-menu), in the DITA menu, and in some of the documentation tips that are displayed by the Content Completion Assistant (on page 3280).
Browse reference manual

Opens a reference to the documentation of the XML element closest to the cursor position in a web browser.

Go to Definition

Moves the cursor to the definition of the current element.

Select submenu

This submenu allows you to select the following:

Element

Selects the entire element at the current cursor position.

Content

Selects the entire content of the element at the current cursor position, excluding the start and end tag. Performing this action repeatedly will result in the selection of the content of the ancestor of the currently selected element content.

Parent

Selects the entire parent element at the current cursor position.

Text submenu

This submenu contains the following actions:

To Lower Case

Converts the selected content to lower case characters.

To Upper Case

Converts the selected content to upper case characters.

Capitalize Sentences

Converts to upper case the first character of every selected sentence.

Capitalize Words

Converts to upper case the first character of every selected word.

Count Words

Counts the number of words and characters (no spaces) in the entire document or in the selection for regular content and read-only content.

Note: The content marked as deleted with change tracking (on page 3288) is ignored when counting words.
Convert Hexadecimal Sequence to Character (**Ctrl + Shift + X (Command + Shift + X on OS X)**)

Converts a sequence of hexadecimal characters to the corresponding Unicode character *(on page 770)*. The action can be invoked if there is a selection containing a valid hexadecimal sequence or if the cursor is placed at the right side of a valid hexadecimal sequence. A valid hexadecimal sequence can be composed of 2 to 4 hexadecimal characters and may or may not be preceded by the **0x** or **0X** prefix. Examples of valid sequences and the characters they will be converted to:

- **0x0045** will be converted to **E**
- **0X0125** to **#**
- **265** to **#**
- **2190** to **#**

**Note:** For more information about finding the hexadecimal value of a character, see **Finding the Decimal, Hexadecimal, or Character Entity Equivalent (on page 779)**.

Refactoring submenu

Contains a series of actions designed to alter the XML structure of the document:

**Toggle Comment**

Encloses the currently selected text in an XML comment, or removes the comment if it is commented.

**Move Up (Alt + UpArrow)**

Moves the current node or selected nodes in front of the previous node.

**Move Down (Alt + DownArrow)**

Moves the current node or selected nodes after the subsequent node.

**Split Element (Alt + Shift + D (Ctrl + Alt + D on OS X))**

Splits the content of the closest element that contains the position of the cursor. Thus, if the cursor is positioned at the beginning or at the end of the element, the newly created sibling will be empty.

**Join Elements**

Joins two adjacent **block elements (on page 3280)** that have the same name. The action is available only when the cursor position is between the two adjacent block elements. Also, joining two block elements can be done
by pressing the **Delete** or **Backspace** keys and the cursor is positioned between the boundaries of these two elements.

**Surround with Tags (Ctrl + E (Command + E on OS X))**

Allows you to choose a tag to enclose a selected portion of content. If there is no selection, the start and end tags are inserted at the cursor position.

- If the **Position cursor between tags** option (on page 167) is selected in the **Content Completion** preferences page, the cursor is placed between the start and end tag.
- If the **Position cursor between tags** option (on page 167) is not selected in the **Content Completion** preferences page, the cursor is placed at the end of the start tag, in an insert-attribute position.

**Surround with '[tag]' (Ctrl + ForwardSlash (Command + ForwardSlash on OS X))**

Surround the selected content with the last tag used.

**Rename Element**

The element from the cursor position, and any elements with the same name, can be renamed according with the options from the **Rename** dialog box.

**Delete Element Tags**

Deletes the tags of the closest element that contains the position of the cursor. This operation is also executed if the start or end tags of an element are deleted by pressing the **Delete** or **Backspace** keys.

**Remove All Markup**

Removes all the XML markup inside the selected block of content and keeps only the text content.

**Remove Text**

Removes the text content of the selected block of content and keeps the markup intact with empty elements.

**DITA Refactoring Actions**

A variety of built-in XML refactoring operations that pertain to DITA documents with some of the information preconfigured based upon the current context.

**Change Topic ID to File Name**
Use this operation to change the ID of a topic to be the same as its file name.

**Convert CALS Tables to Simple Tables**

Use this operation to convert DITA CALS tables to simple tables. If you invoke this operation from a nested table (a table inside a table), only the nested table will be affected. If it is invoked on a parent table that contains nested tables, all of the contained tables will be converted.

**Convert conrefs to conkeyrefs**

Use this operation to convert conref attributes to conkeyref attributes.

**Convert Simple Tables to CALS Tables**

Use this operation to convert DITA simple tables to CALS tables. If you invoke this operation from a nested table (a table inside a table), only the nested table will be affected. If it is invoked on a parent table that contains nested tables, all of the contained tables will be converted.

**Convert to Concept**

Use this operation to convert a DITA topic (of any type) to a DITA Concept topic type (for example, Topic to Concept).

**Convert to General Task**

Use this operation to convert a DITA topic (of any type) to a DITA General Task topic type (for example, Task to General Task). A DITA General Task is a less restrictive alternative to the Strict Task information type.

**Convert to Reference**

Use this operation to convert a DITA topic (of any type) to a DITA Reference topic type (for example, Topic to Reference).

**Convert to Task**

Use this operation to convert a DITA topic (of any type) to a DITA Task topic type (for example, Topic to Task).

**Convert to Topic**

Use this operation to convert a DITA topic (of any type) to a DITA Topic (for example, Task to Topic).

**Convert to Troubleshooting**
Use this operation to convert a DITA topic (of any type) to a DITA Troubleshooting topic type (for example, Topic to Troubleshooting).

**Rename Key**

Available when invoked on a key, and can be used to quickly rename a key. It also updates all references to it. Note that it does not work on DITA 1.3 key scopes.

**Attributes Refactoring Actions**

Contains built-in XML refactoring operations that pertain to attributes with some of the information preconfigured based upon the current context.

**Add/Change attribute**

Allows you to change the value of an attribute or insert a new one.

**Convert attribute to element**

Allows you to change an attribute into an element.

**Delete attribute**

Allows you to remove one or more attributes.

**Rename attribute**

Allows you to rename an attribute.

**Replace in attribute value**

Allows you to search for a text fragment inside an attribute value and change the fragment to a new value.

**Comments Refactoring Actions**

Contains built-in XML refactoring operations that pertain to comments with some of the information preconfigured based upon the current context.

**Delete comments**

Allows you to delete comments found inside one or more elements.

**Elements Refactoring Actions**

Contains built-in XML refactoring operations that pertain to elements with some of the information preconfigured based upon the current context.

**Delete element**
Allows you to delete elements.

Delete element content
 Allows you to delete the content of elements.

Insert element
 Allows you to insert new elements.

Rename element
 Allows you to rename elements.

Unwrap element
 Allows you to remove the surrounding tags of elements, while keeping the content unchanged.

Wrap element
 Allows you to surround elements with element tags.

Wrap element content
 Allows you to surround the content of elements with element tags.

Fragments Refactoring Actions
 Contains built-in XML refactoring operations that pertain to XML fragments with some of the information preconfigured based upon the current context.

Insert XML fragment
 Allows you to insert an XML fragment.

Replace element content with XML fragment
 Allows you to replace the content of elements with an XML fragment.

Replace element with XML fragment
 Allows you to replace elements with an XML fragment.

Review submenu
 This submenu includes the following actions:

Track Changes
 Enables or disables the Track Changes (on page 3288) support for the current document.

Accept Change(s) and Move to Next
Accepts the *Tracked Change* (on page 3288) located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a deletion or insertion change, only the selected content is accepted.

**Accept All Changes**

Accepts all *Tracked Changes* (on page 3288) in the current document.

**Reject Change(s) and Move to Next**

Rejects the *Tracked Change* (on page 3288) located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a deletion or insertion change, only the selected content is rejected.

**Reject All Changes**

Rejects all *Tracked Changes* (on page 3288) in the current document.

**Comment Change**

Opens a dialog box that allows you to add a comment to an existing *Tracked Change* (on page 3288). The comment will appear in a callout and a tooltip when hovering over the change. If the action is selected on an existing commented change, the dialog box will allow you to edit the comment.

**Highlight**

Enables the highlighting tool that allows you to mark text in your document.

**Colors**

Allows you to select the color for highlighting text.

**Stop highlighting**

Use this action to deactivate the highlighting tool.

**Remove highlight(s)**

Use this action to remove highlighting from the document.

**Add Comment**

Inserts a comment at the cursor position. The comment appears in a callout box and a tooltip (when hovering over the change).

**Show/Edit Comment**

Opens a dialog box that displays the discussion thread and allows the current user to edit comments that do not have replies. If you are not the
author who inserted the original comment, the dialog box just displays the comment without the possibility of editing it.

_remove_comment

Remove Comment

Removes a selected comment. If you remove a comment that contains replies, all of the replies will also be removed.

manage_reviews

Manage Reviews

Opens the Review view (on page 964).

Folding submenu

This submenu includes the following actions:

_remove_comment_toggle_fold

Toggle Fold

Toggles the state of the current fold.

_remove_comment_collapse_other_folds

Collapse Other Folds (Ctrl + NumPad/ (Command + NumPad/ on OS X))

Folds all the elements except the current element.

_remove_comment_collapse_child_folds

Collapse Child Folds (Ctrl + NumPad. (Command + NumPad. on OS X))

Folds the elements indented with one level inside the current element.

_remove_comment_expand_child_folds

Expand Child Folds

Unfolds all child elements of the currently selected element.

_remove_comment_expand_all

Expand All (Ctrl + NumPad* (Command + NumPad* on OS X))

Unfolds all elements in the current document.

inspect_styles

Inspect Styles

Opens the CSS Inspector view (on page 439) that allows you to examine the CSS rules that match the currently selected element.

options

Options

Opens the Author mode preferences page (on page 131) where you can configure various options in regards to the Author editing mode.

DITA Drag/Drop (or Copy/Paste) Actions

Dragging a file from the Project view (on page 333) or DITA Maps Manager view (on page 2990) and dropping it into a DITA document that is edited in Author mode, creates a link to the dragged file (the xref DITA element with the href attribute) at the drop location. Copy and paste actions work the same.
You can also drag images or media files from your system explorer or the Project view (on page 333) and drop them into a DITA document (or copy and paste). This will insert the appropriate element at the drop or paste location (for example, dropping/pasting an image will insert the DITA image element with an href attribute).

Tip: For information about customizing Author mode actions for a particular framework (on page 3282) (document type), see the Configuring Actions, Menus, Toolbars, Content Completion for a Framework (on page 2323) section.

Related Information:

- Configuring Actions, Menus, Toolbars, Content Completion for a Framework (on page 2323)

DITA Map Document Type (Framework)

DITA maps (on page 3281) are documents that collect and organize references to DITA topics to indicate the relationships between the topics. They can be used as a container for topics used to transform a collection of content into a publication and they offer a sequence and structure to the topics. They can also serve as outlines or tables of contents for DITA deliverables and as build manifests for DITA projects. DITA maps allow scalable reuse of content across multiple contexts. Maps can reference topics or other maps, and can contain a variety of content types and metadata.

For much more detailed information, resources, and instructions, see the DITA Authoring (on page 2981) chapter.

File Definition

A file is considered to be a DITA map document when one of the following conditions are true:

- The root element name is one of the following: map, bookmap.
- The public ID of the document is -//OASIS//DTD DITA Map or -//OASIS//DTD DITA BookMap.
- The root element of the file has an attribute named class that contains the value map and a DITAArchVersion attribute from the http://dita.oasis-open.org/architecture/2005/namespace. This enhanced case of matching is only applied when the Enable DTD/XML Schema processing in document type detection option (on page 94) from the Document Type Association preferences page (on page 92) is selected.
Default Document Templates

There are a variety of default DITA map templates available when creating new documents from templates (on page 676) and they can be found in various folders inside: Framework Templates > DITA Map.

The default templates for DITA map documents are located in the \[OXYGEN_INSTALL_DIR]/frameworks/sita/templates/map folder.

Default Schema for Validation and Content Completion

Default schemas that are used if one is not detected in the DITA map document are stored in the various folders inside: \[DITA-OT-DIR]/dtd/ or \[DITA-OT-DIR]/schema/.

Default CSS

The default CSS files used for rendering DITA content in Author mode are stored in the various folders inside: \[OXYGEN_INSTALL_DIR]/frameworks/dita/css/.

By default, these default CSS files are merged with any that are specified in the document. For more information, see Configuring and Managing Multiple CSS Styles for a Framework (on page 2348).

Default XML Catalogs

The default XML Catalogs (on page 3289) for the DITA map document type are as follows:

- \[OXYGEN_INSTALL_DIR]/frameworks/dita/catalog.xml
- \[DITA-OT-DIR]/catalog-dita.xml

Transformation Scenarios

Oxygen XML Editor includes numerous built-in transformation scenarios that allow you to transform DITA maps to a variety of outputs, such as WebHelp, PDF, ODF, XHTML, EPUB, and CHM. All of them are listed in the DITA Map section in the Configure Transformation Scenario(s) dialog box (on page 1762).

For more information, see the DITA Map Transformation Scenarios (on page 1642) section.

Resources

- DITA Specifications
- DITA Style Guide Best Practices for Authors
DITA Map Author Mode Actions

A variety of actions are available in the DITA map (on page 3281) framework (on page 3282) that can be added to the DITA menu, the Author Custom Actions toolbar, the contextual menu, and the Content Completion Assistant (on page 3280).

DITA Map Toolbar and Menu Actions

When a DITA map is opened in Author mode, the following default actions are available on the DITA Map Author Custom Actions toolbar (by default, they are also available in the DITA menu and in various submenus of the contextual menu):

- **Insert New DITA Resource**
  
  Opens a New DITA file dialog box (on page 3050) where you can choose the type of DITA document to create and inserts a reference to it at the current position within the map.

- **Insert Topic Reference**
  
  Opens the Insert Reference dialog box (on page 3017) where you can configure a topic reference and inserts it at the current position within the map.

- **Reuse Content**

Related Information:

- Selecting a Root Map (on page 3007)
- DITA Authoring (on page 2981)
- Getting Started with DITA (on page 13)
- Editing XML Documents in Author Mode (on page 893)
- Editing XML Documents in Text Mode (on page 828)
Opens the **Reuse Content** dialog box *(on page 3135)* that allows you to insert and configure a content reference (`conref`), or a content key reference (`conkeyref`) at the cursor position.

**Insert Topic Heading**

Opens the **Insert Reference** dialog box *(on page 3017)* that allows you to insert a topic heading at the cursor position.

**Insert Topic Group**

Opens the **Insert Reference** dialog box *(on page 3017)* that allows you to insert a topic group at the cursor position.

**Insert Relationship Table**

Opens a dialog box that allows you to configure the relationship table to be inserted. The dialog box allows you to configure the number of rows and columns of the relationship table, if the header will be generated and if the title will be added.

**Relationship Table Properties**

Allows you to change the properties of rows in relationship tables.

**Insert Relationship Row**

Inserts a new table row with empty cells. The action is available when the cursor position is inside a table.

**Insert Relationship Column**

Inserts a new table column with empty cells after the current column. The action is available when the cursor position is inside a table.

**Delete Relationship Column**

Deletes the table column where the cursor is located.

**Delete Relationship Row**

Deletes the table row where the cursor is located.

**Move Up**

Moves the selected node up one position on its same level.

**Move Down**

Moves the selected node down one position on its same level.

**Promote** *(Alt + LeftArrow)*

Moves the selected node up one position to the level of its parent node.

**Demote** *(Alt + RightArrow)*
Moves the selected node down one level to the level of its child nodes.

**DITA Menu Actions**

The following additional actions can be found in the DITA menu when editing a *DITA map* in **Author** mode:

- **Refresh References**
  You can use this action to manually trigger a refresh and update of all referenced resources.

**Tags display mode Submenu**

- **Full Tags with Attributes**
  Displays full tag names with attributes for both *block* (on page 3280) and *inline elements* (on page 3283).

- **Full Tags**
  Displays full tag names without attributes for both *block* and *inline elements*.

- **Block Tags**
  Displays full tag names for *block elements* and simple tags without names for *inline elements*.

- **Inline Tags**
  Displays full tag names for *inline elements*, while *block elements* are not displayed.

- **Partial Tags**
  Displays simple tags without names for *inline elements*, while *block elements* are not displayed.

- **No Tags**
  No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

**Configure Tags Display Mode**

Use this option to go to the **Author preferences page** (on page 131) where you can configure the **Tags Display Mode** options.

**Profiling/Conditional Text Submenu**

- **Edit Profiling Attributes**
Allows you to configure the profiling attributes (on page 969) and their values.

**Show Profiling Colors and Styles**

Select this option to turn on conditional styling.

**Show Profiling Attributes**

Select this option to turn on conditional text markers. They are displayed at the end of conditional text blocks, as a list of attribute name and their currently set values.

**Show Excluded Content**

When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.

**List of all profiling condition sets that match the current document type**

You can click a listed condition set (on page 975) to activate it.

**Profiling Settings**

Opens the profiling options preferences page (on page 144), where you can manage profiling attributes and profiling conditions sets. You can also configure the profiling styles and colors options from the colors/styles preferences page (on page 146) and the attributes rendering preferences page (on page 148).

**ID Options**

Opens the ID Options dialog box that allows you to configure options for generating IDs in Author mode. The dialog box includes the following:

**ID Pattern**

The pattern for the ID values that will be generated. This text field can be customized using constant strings or any of the Oxygen XML Editor Editor Variables (on page 276).

**Element name or class value to generate ID for**

The elements for which ID values will be generated, specified using class attribute values. To customize the list, use the Add, Edit, or Remove buttons.

**Auto generate IDs for elements**

If selected, Oxygen XML Editor will automatically generate unique IDs for the elements listed in this dialog box when they are created in Author mode.
Remove IDs when copying content in the same document

When copying and pasting content in the same document, this option allows you to control whether or not pasted elements that are listed in this dialog box should retain their existing IDs. To retain the element IDs, deselect this option.

Note: This option does not have an effect on content that is cut and pasted.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the ID Options dialog box that are found in the current selection.

Note: The Generate IDs action does not overwrite existing ID values. It only affects elements that do not already have an id attribute.

DITA Map Contextual Menu Actions

In addition to many of the DITA Map toolbar actions (on page 1598) and the general Author mode contextual menu actions (on page 1065), the following DITA map framework-specific actions are also available in the contextual menu when editing in Author mode:

Add File to Review Task

This action can be used to add the current document to a task in the Content Fusion Tasks Manager view. Oxygen Content Fusion is a flexible, intuitive collaboration platform designed to adapt to any type of documentation review workflow. This functionality is available through a pre-installed connector add-on (on page 2679). To fully take advantage of all of the benefits and features of Content Fusion, your organization will need an Oxygen Content Fusion Enterprise Server. For more information, see the Oxygen Content Fusion website.

Edit Properties

Opens the Edit Properties dialog box that allows you to configure the properties of a selected node. For more details about this dialog box, see Edit Properties Dialog Box (on page 3027).
Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the ID Options dialog box that are found in the current selection.

Note: The Generate IDs action does not overwrite existing ID values. It only affects elements that do not already have an id attribute.

Search References

Finds the references to the href or keys attribute value of the topic/map reference element at the current cursor position, in all the topics from the current DITA map (opened in the DITA Maps Manager view (on page 2990)). The current topic/map reference element must have an href or keys attribute defined to complete the search.

Show Key Definition

Available for elements that have a conkeyref or keyref attribute set (or elements with an ancestor element that has a conkeyref or keyref attribute). It computes the key name and opens the DITA map (on page 3281) that contains the definition of the key with the element that defines that key selected.

DITA Map Drag/Drop Actions

Dragging a file from the Project view (on page 333) or DITA Maps Manager view (on page 2990) and dropping it into a DITA map document that is edited in Author mode creates a link to the dragged file (a topicref element, chapter, part, etc.) at the drop location.

Open Topic from DITA Map in Author Mode

When a DITA map is opened in Author mode, you can click the icon to the left of a topic to open that particular topic in the editor.

Tip: For information about customizing Author mode actions for a particular framework (on page 3282) (document type), see the Configuring Actions, Menus, Toolbars, Content Completion for a Framework (on page 2323) section.
XHTML Document Type (Framework)

The Extensible HyperText Markup Language (XHTML), is a markup language that has the same depth of expression as HTML, but also conforms to XML syntax.

**File Definition**

A file is considered to be an XHTML document when the root element name is `html`.

**Default Document Templates**

There are a variety of default XHTML templates available when creating new documents from templates (on page 676) and they can be found in: Framework Templates > XHTML.

The default templates for XHTML documents are located in the `/OXYGEN_INSTALL_DIR/frameworks/xhtml/templates/` folder.

**Default Schema for Validation and Content Completion**

Default schemas that are used if one is not detected in the XHTML file are stored in the following locations:

- XHTML 1.0 - `/OXYGEN_INSTALL_DIR/frameworks/xhtml/dtd/` or `/OXYGEN_INSTALL_DIR/frameworks/xhtml/nvdl/`.
- XHTML 1.1 - `/OXYGEN_INSTALL_DIR/frameworks/xhtml11/dtd/` or `/OXYGEN_INSTALL_DIR/frameworks/xhtml11/schema/`.
- XHTML 5 - `/OXYGEN_INSTALL_DIR/frameworks/xhtml/xhtml5 (epub3)/`.

**Default CSS**

The default CSS files used for rendering XHTML content in Author mode are stored in `/OXYGEN_INSTALL_DIR/frameworks/xhtml/css/`.

By default, these default CSS files are merged with any that are specified in the document. For more information, see Configuring and Managing Multiple CSS Styles for a Framework (on page 2348).
Default XML Catalogs

The default XML Catalogs (on page 3289) for the XHTML document type are as follows:

- \[OXYGEN_INSTALL_DIR\]/frameworks/xhtml/dtd/xhtmlcatalog.xml
- \[OXYGEN_INSTALL_DIR\]/frameworks/relaxng/catalog.xml
- \[OXYGEN_INSTALL_DIR\]/frameworks/nvdl/catalog.xml
- \[OXYGEN_INSTALL_DIR\]/frameworks/xhtml11/dtd/xhtmlcatalog.xml
- \[OXYGEN_INSTALL_DIR\]/frameworks/xhtml11/schema/xhtmlcatalog.xml
- \[OXYGEN_INSTALL_DIR\]/xhtml5 (epub3)/catalog-compat.xml

Transformation Scenarios

Oxygen XML Editor includes built-in transformation scenarios that allow you to transform XHTML documents to several types of DITA document types (topic, task, concept, reference). They can be found in the XHTML section in the Configure Transformation Scenario(s) dialog box (on page 1762).

- XHTML Specifications

XHTML Author Mode Actions

A variety of actions are available in the XHTML framework (on page 3282) that can be added to the XHTML menu, the Author Custom Actions toolbar, the contextual menu, and the Content Completion Assistant (on page 3280).
XHTML Toolbar Actions

The following default actions are readily available on the XHTML (Author Custom Actions) toolbar when editing in Author mode (by default, they are also available in the XHTML menu and some of them are in various submenus of the contextual menu):

- **Bold**
  Changes the style of the selected text to *bold* by surrounding it with `b` tag. You can use this action on multiple non-contiguous selections.

- **Italic**
  Changes the style of the selected text to *italic* by surrounding it with `i` tag. You can use this action on multiple non-contiguous selections.

- **Underline**
  Changes the style of the selected text to *underline* by surrounding it with `u` tag. You can use this action on multiple non-contiguous selections.

- **Link**
  Inserts an `a` element with an `href` attribute at the cursor position. You can type the URL of the reference you want to insert or use the browsing actions in the `Browse` drop-down menu.

- **Insert Image**
  Inserts a graphic object at the cursor position. This is done by inserting an `img` element regardless of the current context. The following graphical formats are supported: GIF, JPG, JPEG, BMP, PNG, SVG.

- **Insert Media Resource**
  Opens a Choose Media dialog box (on page 1055) that allows you to select the URL of a media object to be inserted into a document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted and rendered in Author mode so that it can be played directly from there.

- **Headings Drop-down Menu**
  A drop-down menu that includes actions for inserting `h1`, `h2`, `h3`, `h4`, `h5`, `h6` elements.

- **Insert Paragraph**
  Insert a new paragraph element at current cursor position.

- **Insert Equation**
Opens the XML Fragment Editor that allows you to insert and edit MathML notations (on page 1057).

Insert List Item

Inserts a list item in the current list type.

Insert Unordered List

Inserts an unordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an unordered list.

Insert Ordered List

Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

Insert a definition list at the cursor position

Inserts a definition list (\texttt{dl} element) with one list item (a \texttt{dt} child element and a \texttt{dd} child element). You can also use this action to convert selected paragraphs or other types of lists to a definition list.

Sort

Sorts cells or list items in a table.

Insert Table

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a block element (on page 3280)) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

Note: If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that Only lists, paragraphs, or inline content can be converted to tables.

Insert Row Below

Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

Insert Row Above

Inserts a new table row with empty cells above the current row. This action is available when the cursor is positioned inside a table.
**Insert Column After**

Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

**Insert Cell**

Inserts a new empty cell depending on the current context. If the cursor is positioned between two cells, Oxygen XML Editor a new cell at cursor position. If the cursor is inside a cell, the new cell is created after the current cell.

**Delete Column(s)**

Deletes the table column located at cursor position or multiple columns in a selection.

**Delete Row(s)**

Deletes the table row located at cursor position or multiple rows in a selection.

**Join Cells**

Joins the content of the selected cells (both horizontally and vertically).

**Split Cell**

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

**XHTML Menu Actions**

The following additional actions can be found in the XHTML menu when editing in Author mode (some of them are also available in the contextual menu):

**Table submenu**

In addition to the table actions available on the toolbar, the following actions are available in this submenu:

**Insert Rows**

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (Above or Below the current row).

**Insert Column Before**

Inserts a column before the current one.

**Insert Columns**
Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (Above or Below the current column).

Refresh References

You can use this action to manually trigger a refresh and update of all referenced resources.

Tags display mode Submenu

Full Tags with Attributes

Displays full tag names with attributes for both block (on page 3280) and inline elements (on page 3283).

Full Tags

Displays full tag names without attributes for both block and inline elements.

Block Tags

Displays full tag names for block elements and simple tags without names for inline elements.

Inline Tags

Displays full tag names for inline elements, while block elements are not displayed.

Partial Tags

Displays simple tags without names for inline elements, while block elements are not displayed.

No Tags

No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

Configure Tags Display Mode

Use this option to go to the Author preferences page (on page 131) where you can configure the Tags Display Mode options.

Profiling/Conditional Text Submenu

Edit Profiling Attributes

Allows you to configure the profiling attributes (on page 969) and their values.

Show Profiling Colors and Styles
Select this option to turn on conditional styling.

**Show Profiling Attributes**

Select this option to turn on conditional text markers. They are displayed at the end of conditional text blocks, as a list of attribute name and their currently set values.

**Show Excluded Content**

When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.

**List of all profiling condition sets that match the current document type**

You can click a listed condition set *(on page 975)* to activate it.

**Profiling Settings**

Opens the profiling options preferences page *(on page 144)*, where you can manage profiling attributes and profiling conditions sets. You can also configure the profiling styles and colors options from the colors/styles preferences page *(on page 146)* and the attributes rendering preferences page *(on page 148)*.

**XHTML Contextual Menu Actions**

In addition to many of the XHTML toolbar actions *(on page 1606)* and the **general Author mode contextual menu actions** *(on page 1065)*, the following XHTML framework-specific actions are also available in the contextual menu when editing in **Author mode**:

**Image Map Editor**

This action is available in the contextual menu when it is invoked on an image. This action applies an image map to the current image (if one does not already exist) and opens the Image Map Editor dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

**Table Actions**

The following table editing actions are available in the contextual menu when it is invoked on a table:

**Insert Rows**

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted *(Above or Below the current row)*.
Delete Row(s)

Deletes the table row located at cursor position or multiple rows in a selection.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (Above or Below the current column).

Delete Column(s)

Deletes the table column located at cursor position or multiple columns in a selection.

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

Sort

Sorts cells or list items in a table.

Table Properties

Opens the Table properties dialog box that allows you to configure properties of a table (such as frame borders).

Other Actions submenu

This submenu gives you access to all the usual contextual menu actions.

XHTML Drag/Drop (or Copy/Paste) Actions

Dragging a file from the Project view (on page 333) or DITA Maps Manager view (on page 2990) and dropping it into an XHTML document that is edited in Author mode, creates a link to the dragged file (the a element with the href attribute) at the drop location. Copy and paste actions work the same.

You can also drag images or media files from your system explorer or the Project view (on page 333) and drop them into an XHTML document (or copy and paste). This will insert the appropriate element at the drop or paste location (for example, dropping/pasting an image will insert the img element with the src attribute).
Tip: For information about customizing Author mode actions for a particular framework (on page 3282) (document type), see the Configuring Actions, Menus, Toolbars, Content Completion for a Framework (on page 2323) section.

Related Information:

- Configuring Actions, Menus, Toolbars, Content Completion for a Framework (on page 2323)

### TEI P5 Document Type (Framework)

The TEI (Text Encoding Initiative) document type is an international and interdisciplinary standard that enables libraries, museums, publishers, and individual scholars to represent a variety of literary and linguistic texts for online research, teaching, and preservation.

#### File Definition

A file is considered to be a TEI P5 document when one of the following conditions are true:

- The document namespace is http://www.tei-c.org/ns/1.0.
- The public ID of the document is -//TEI P5.

#### Default Document Templates

There are a variety of default TEI P5 templates available when creating new documents from templates (on page 676) and they can be found in: Framework Templates > TEI P5.

The default templates for TEI P5 documents are located in the \[OXYGEN_INSTALL_DIR\]/frameworks/tei/templates/TEI P5 folder.

#### Default Schema for Validation and Content Completion

The default schema that is used if one is not detected in the TEI P5 document is tei_all.rng and it is stored in \[OXYGEN_INSTALL_DIR\]/frameworks/tei/xml/tei/custom/schema/relaxng/.

#### Default CSS

The default CSS files used for rendering TEI content in Author mode are stored in \[OXYGEN_INSTALL_DIR\]/frameworks/tei/xml/tei/css/.
By default, these default CSS files are merged with any that are specified in the document. For more information, see Configuring and Managing Multiple CSS Styles for a Framework (on page 2348).

Default XML Catalogs

The default XML Catalogs (on page 3289) for the TEI P5 document type are as follows:

- `{OXYGEN_INSTALL_DIR}/frameworks/tei/xml/tei/schema/dtd/catalog.xml`
- `{OXYGEN_INSTALL_DIR}/frameworks/tei/xml/tei/custom/schema/dtd/catalog.xml`
- `{OXYGEN_INSTALL_DIR}/frameworks/tei/xml/tei/stylesheet/catalog.xml`

Transformation Scenarios

Oxygen XML Editor includes built-in transformation scenarios that allow you to transform TEI P5 documents to a variety of outputs, such as PDF, XHTML, EPUB, DOCX, and ODT. They can be found in the TEI P5 section in the Configure Transformation Scenario(s) dialog box (on page 1762).

TEI P5 Author Mode Actions

A variety of actions are available in the TEI P5 framework (on page 3282) that can be added to the TEI P5 menu, the Author Custom Actions toolbar, the contextual menu, and the Content Completion Assistant (on page 3280).
TEI P5 Toolbar Actions

The following default actions are readily available on the TEI P5 (Author Custom Actions) toolbar when editing in Author mode (by default, they are also available in the TEI P5 menu and some of them are in various submenus of the contextual menu):

**Bold**
Changes the style of the selected text to **bold** by surrounding it with `hi` tag and setting the `rend` attribute to `bold`. You can use this action on multiple non-contiguous selections.

**Italic**
Changes the style of the selected text to *italic* by surrounding it with `hi` tag and setting the `rend` attribute to `italic`. You can use this action on multiple non-contiguous selections.

**Underline**
Changes the style of the selected text to *underline* by surrounding it with `hi` tag and setting the `rend` attribute to `ul`. You can use this action on multiple non-contiguous selections.

**Insert Section**
Inserts a new section or subsection, depending on the current context. For example, if the current context is `div1`, then a `div2` is inserted. By default, this action also inserts a paragraph element as a child node.

**Insert Paragraph**
Insert a new paragraph element at current cursor position.

**Insert Image**
Inserts an image reference (on page 1021) at the cursor position. Depending on the current location, an image-type element is inserted.

**Insert List Item**
Inserts a list item in the current list type.

**Insert Ordered List**
Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

**Insert Itemized List**
Inserts an itemized list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an itemized list.

**Sort**

Sorts cells or list items in a table.

**Insert Table**

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a block element (on page 3280)) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

*Note:* If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that **Only lists, paragraphs, or inline content can be converted to tables.**

**Insert Row Below**

Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

**Insert Column After**

Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

**Insert Cell**

Inserts a new empty cell depending on the current context. If the cursor is positioned between two cells, Oxygen XML Editor a new cell at cursor position. If the cursor is inside a cell, the new cell is created after the current cell.

**Delete Column(s)**

Deletes the table column located at cursor position or multiple columns in a selection.

**Delete Row(s)**

Deletes the table row located at cursor position or multiple rows in a selection.

**Join Cells**

Joins the content of the selected cells (both horizontally and vertically).

**Split Cell**
Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

**TEI P5 Menu Actions**

The following additional actions can be found in the **TEI P5** menu when editing in **Author** mode (some of them are also available in the contextual menu):

**Table submenu**

In addition to the table actions available on the toolbar, the following actions are available in this submenu:

- **Insert Row Above**
  
  Inserts a new table row with empty cells above the current row. This action is available when the cursor is positioned inside a table.

- **Insert Rows**
  
  Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (**Above** or **Below** the current row).

- **Insert Column Before**
  
  Inserts a column before the current one.

- **Insert Columns**
  
  Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (**Above** or **Below** the current column).

**ID Options**

Opens the **ID Options** dialog box that allows you to configure options for generating IDs in **Author** mode. The dialog box includes the following:

- **ID Pattern**
  
  The pattern for the ID values that will be generated. This text field can be customized using constant strings or any of the Oxygen XML Editor Editor Variables (on page 276).

- **Element name or class value to generate ID for**
  
  The elements for which ID values will be generated, specified using class attribute values. To customize the list, use the **Add**, **Edit**, or **Remove** buttons.
Auto generate IDs for elements

If selected, Oxygen XML Editor will automatically generate unique IDs for the elements listed in this dialog box when they are created in Author mode.

Remove IDs when copying content in the same document

When copying and pasting content in the same document, this option allows you to control whether or not pasted elements that are listed in this dialog box should retain their existing IDs. To retain the element IDs, deselect this option.

Note: This option does not have an effect on content that is cut and pasted.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the ID Options dialog box that are found in the current selection.

Note: The Generate IDs action does not overwrite existing ID values. It only affects elements that do not already have an id attribute.

Refresh References

You can use this action to manually trigger a refresh and update of all referenced resources.

Tags display mode Submenu

Full Tags with Attributes

Displays full tag names with attributes for both block (on page 3280) and inline elements (on page 3283). Oxygen XML Editor

Full Tags

Displays full tag names without attributes for both block and inline elements.

Block Tags
Displays full tag names for block elements and simple tags without names for inline elements.

**Inline Tags**
Displays full tag names for inline elements, while block elements are not displayed.

**Partial Tags**
Displays simple tags without names for inline elements, while block elements are not displayed.

**No Tags**
No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

**Configure Tags Display Mode**
Use this option to go to the Author preferences page (on page 131) where you can configure the Tags Display Mode options.

**Profiling/Conditional Text Submenu**

**Edit Profiling Attributes**
Allows you to configure the profiling attributes (on page 969) and their values.

**Show Profiling Colors and Styles**
Select this option to turn on conditional styling.

**Show Profiling Attributes**
Select this option to turn on conditional text markers. They are displayed at the end of conditional text blocks, as a list of attribute name and their currently set values.

**Show Excluded Content**
When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.

**List of all profiling condition sets that match the current document type**
You can click a listed condition set (on page 975) to activate it.

**Profiling Settings**
Opens the profiling options preferences page (on page 144), where you can manage profiling attributes and profiling conditions sets. You can also
configure the profiling styles and colors options from the colors/styles preferences page (on page 146) and the attributes rendering preferences page (on page 148).

TEI Contextual Menu Actions

In addition to many of the TEI toolbar actions (on page 1614) and the general Author mode contextual menu actions (on page 1065), the following TEI framework-specific actions are also available in the contextual menu when editing in Author mode:

Image Map Editor

This action is available in the contextual menu when it is invoked on an image. This action applies an image map to the current image (if one does not already exist) and opens the Image Map Editor dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

Table Actions

The following table editing actions are available in the contextual menu when it is invoked on a table:

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (Above or Below the current row).

Delete Row(s)

Deletes the table row located at cursor position or multiple rows in a selection.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (Above or Below the current column).

Delete Column(s)

Deletes the table column located at cursor position or multiple columns in a selection.

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell
Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

Sort

Sorts cells or list items in a table.

Table Properties

Opens the Table properties dialog box that allows you to configure properties of a table (such as frame borders).

Other Actions submenu

This submenu gives you access to all the usual contextual menu actions.

TEI P5 Drag/Drop Actions

Dragging a file from the Project view (on page 333) or DITA Maps Manager view (on page 2990) and dropping it into a TEI P5 document that is edited in Author mode, creates a link to the dragged file (the ptr element with the target attribute) at the drop location. Dragging an image file from the default file system application (Windows Explorer on Windows or Finder on Mac OS X, for example) and dropping it into a TEI P5 document inserts a graphic element (the graphic element with the url attribute) at the drop location, similar to the Insert Image toolbar action.

Tip: For information about customizing Author mode actions for a particular framework (on page 3282) (document type), see the Configuring Actions, Menus, Toolbars, Content Completion for a Framework (on page 2323) section.

Related Information:

- Configuring Actions, Menus, Toolbars, Content Completion for a Framework (on page 2323)

Customization of TEI Frameworks Using the Latest Sources

The TEI P5 (on page 1612) framework (on page 3282) is available as a public project at the following SVN repository: https://github.com/TEIC/oxygen-tei. This project is the base for customizing a TEI framework.

To customize a TEI framework, follow this procedure:

1. Check out the project on a local computer from the SVN repository.
This action is done with an SVN client application that creates a working copy of the SVN repository on a local computer.

2. Customize the TEI framework in Oxygen XML Editor.

   a. Set the Oxygen XML Editor frameworks folder to the oxygen/frameworks subfolder of the folder of the SVN working copy.  
      
      Open the Preferences dialog box (Options > Preferences) (on page 79), go to Global, and set the path of the SVN working copy in the Use custom frameworks option.

   b. Open the Preferences dialog box (Options > Preferences) (on page 79), go to Document Type Association > Locations, and select Custom.

3. Build a JAR (on page 3283) file with the TEI framework.

   The SVN project includes a build.xml file that can be used for building a JAR file using the Ant tool. The command that should be used:

   ```
   ant -f build.xml
   ```

4. Distribute the JAR file to the users that need the customized TEI framework.

   The command from the above step creates a file tei.zip in the dist subfolder of the SVN project. Each user that needs the customized TEI framework will receive the tei.zip file and will unzip it in the frameworks folder of the Oxygen XML Editor install folder.

Customization of TEI Frameworks Using the Compiled Sources

The following procedure describes how to update to the latest stable version of TEI Schema and TEI XSL, already integrated in the TEI framework (on page 3282) for Oxygen XML Editor.

1. Go to https://code.google.com/p/oxygen-tei/;
2. Go to Downloads;
3. Download the latest uploaded .zip file;
4. Unpack the .zip file and copy its content in the Oxygen XML Editor frameworks folder.

TEI ODD Document Type (Framework)

The TEI ODD (Text Encoding Initiative - One Document Does it all) document type is a TEI XML-conformant specification format that allows you to create a custom TEI P5 schema in a literate programming fashion. A system of XSLT stylesheets called Roma was created by the TEI Consortium for manipulating the ODD files.
File Definition

A file is considered to be a TEI ODD document when the following conditions are true:

- The file extension is .odd.
- The document namespace is http://www.tei-c.org/ns/1.0.

Default Document Templates

There is a default TEI ODD document template available when creating new documents from templates (on page 676) and they can be found in: Framework Templates > TEI ODD.

The default template is located in the [OXYGEN_INSTALL_DIR]/frameworks/tei/templates/TEI ODD folder.

Default Schema for Validation and Content Completion

The default schema that is used if one is not detected in the TEI ODD document is tei_odds.rng and it is stored in [OXYGEN_INSTALL_DIR]/frameworks/tei/xml/tei/custom/schema/relaxng/.

Default CSS

The default CSS files used for rendering TEI ODD content in Author mode are stored in [OXYGEN_INSTALL_DIR]/frameworks/tei/xml/tei/css/.

By default, these default CSS files are merged with any that are specified in the document. For more information, see Configuring and Managing Multiple CSS Styles for a Framework (on page 2348).

Default XML Catalogs

The default XML Catalogs (on page 3289) for the TEI ODD document type are as follows:

- [OXYGEN_INSTALL_DIR]/frameworks/tei/xml/tei/custom/schema/catalog.xml
- [OXYGEN_INSTALL_DIR]/frameworks/tei/xml/tei/schema/catalog.xml

Transformation Scenarios

Oxygen XML Editor includes built-in transformation scenarios that allow you to transform TEI ODD documents to a variety of outputs, such as PDF, XHTML, EPUB, DOCX, ODT, RNG, DTD, and XML Schema. They can be found in the TEI ODD section in the Configure Transformation Scenario(s) dialog box (on page 1762).
Resources

- Oxygen Video Tutorial: Editing TEI Documents in Author Mode
- TEI: Getting Started with ODD

Related Information:

- Editing XML Documents in Author Mode (on page 893)
- Editing XML Documents in Text Mode (on page 828)

TEI ODD Author Mode Actions

A variety of actions are available in the TEI ODD framework (on page 3282) that can be added to the TEI ODD menu, the Author Custom Actions toolbar, the contextual menu, and the Content Completion Assistant (on page 3280).

TEI ODD Toolbar Actions

The following default actions are readily available on the TEI ODD (Author Custom Actions) toolbar when editing in Author mode (by default, they are also available in the TEI ODD menu and some of them are in various submenus of the contextual menu):

**Bold**

Changes the style of the selected text to `bold` by surrounding it with `hi` tag and setting the `rend` attribute to `bold`. You can use this action on multiple non-contiguous selections.

**Italic**

Changes the style of the selected text to `italic` by surrounding it with `hi` tag and setting the `rend` attribute to `italic`. You can use this action on multiple non-contiguous selections.

**Underline**

Changes the style of the selected text to `underline` by surrounding it with `hi` tag and setting the `rend` attribute to `ul`. You can use this action on multiple non-contiguous selections.

**Insert Section**
Inserts a new section or subsection, depending on the current context. For example, if the current context is `div1`, then a `div2` is inserted. By default, this action also inserts a paragraph element as a child node.

**Insert Paragraph**

Insert a new paragraph element at current cursor position.

**Insert Image**

Inserts an image reference (on page 1021) at the cursor position. Depending on the current location, an image-type element is inserted.

**Insert List Item**

Inserts a list item in the current list type.

**Insert Ordered List**

Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

**Insert Itemized List**

Inserts an itemized list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an itemized list.

**Insert Table**

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a block element (on page 3280)) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

**Note:** If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that Only lists, paragraphs, or inline content can be converted to tables.

**Insert Row Below**

Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

**Insert Column After**

Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.
Insert Cell

Inserts a new empty cell depending on the current context. If the cursor is positioned between two cells, Oxygen XML Editor a new cell at cursor position. If the cursor is inside a cell, the new cell is created after the current cell.

Delete Column(s)

Deletes the table column located at cursor position or multiple columns in a selection.

Delete Row(s)

Deletes the table row located at cursor position or multiple rows in a selection.

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

TEI ODD Menu Actions

The following additional actions can be found in the TEI ODD menu when editing in Author mode (some of them are also available in the contextual menu):

Table submenu

In addition to the table actions available on the toolbar, the following actions are available in this submenu:

Insert Row Above

Inserts a new table row with empty cells above the current row. This action is available when the cursor is positioned inside a table.

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (Above or Below the current row).

Insert Column Before

Inserts a column before the current one.

Insert Columns
Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (Above or Below the current column).

**ID Options**

Opens the **ID Options** dialog box that allows you to configure options for generating IDs in **Author** mode. The dialog box includes the following:

**ID Pattern**

The pattern for the ID values that will be generated. This text field can be customized using constant strings or any of the Oxygen XML Editor Editor Variables (on page 276).

**Element name or class value to generate ID for**

The elements for which ID values will be generated, specified using class attribute values. To customize the list, use the **Add, Edit, or Remove** buttons.

**Auto generate IDs for elements**

If selected, Oxygen XML Editor will automatically generate unique IDs for the elements listed in this dialog box when they are created in **Author** mode.

**Remove IDs when copying content in the same document**

When copying and pasting content in the same document, this option allows you to control whether or not pasted elements that are listed in this dialog box should retain their existing IDs. To retain the element IDs, deselect this option.

**Note:** This option does not have an effect on content that is cut and pasted.

**Generate IDs**

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the **ID Options** dialog box that are found in the current selection.
Note: The Generate IDs action does not overwrite existing ID values. It only affects elements that do not already have an id attribute.

Refresh References

You can use this action to manually trigger a refresh and update of all referenced resources.

Tags display mode Submenu

- Full Tags with Attributes
  Displays full tag names with attributes for both block (on page 3280) and inline elements (on page 3283). Oxygen XML Editor

- Full Tags
  Displays full tag names without attributes for both block and inline elements.

- Block Tags
  Displays full tag names for block elements and simple tags without names for inline elements.

- Inline Tags
  Displays full tag names for inline elements, while block elements are not displayed.

- Partial Tags
  Displays simple tags without names for inline elements, while block elements are not displayed.

- No Tags
  No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

Configure Tags Display Mode

Use this option to go to the Author preferences page (on page 131) where you can configure the Tags Display Mode options.

Profiling/Conditional Text Submenu

- Edit Profiling Attributes
  Allows you to configure the profiling attributes (on page 969) and their values.

- Show Profiling Colors and Styles
Select this option to turn on conditional styling.

**Show Profiling Attributes**

Select this option to turn on conditional text markers. They are displayed at the end of conditional text blocks, as a list of attribute name and their currently set values.

**Show Excluded Content**

When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.

**List of all profiling condition sets that match the current document type**

You can click a listed condition set *(on page 975)* to activate it.

**Profiling Settings**

Opens the profiling options preferences page *(on page 144)*, where you can manage profiling attributes and profiling conditions sets. You can also configure the profiling styles and colors options from the colors/styles preferences page *(on page 146)* and the attributes rendering preferences page *(on page 148)*.

**TEI Contextual Menu Actions**

In addition to many of the TEI toolbar actions *(on page 1623)* and the general Author mode contextual menu actions *(on page 1065)*, the following TEI framework-specific actions are also available in the contextual menu when editing in Author mode:

**Table Actions**

The following table editing actions are available in the contextual menu when it is invoked on a table:

**Insert Rows**

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted *(Above or Below the current row)*.

**Delete Row(s)**

Deletes the table row located at cursor position or multiple rows in a selection.

**Insert Columns**
Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (Above or Below the current column).

Delete Column(s)

Deletes the table column located at cursor position or multiple columns in a selection.

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

Sort

Sorts cells or list items in a table.

Table Properties

Opens the Table properties dialog box that allows you to configure properties of a table (such as frame borders).

Other Actions submenu

This submenu gives you access to all the usual contextual menu actions.

TEI ODD Drag/Drop Actions

Dragging a file from the Project view (on page 333) or DITA Maps Manager view (on page 2990) and dropping it into a TEI ODD document that is edited in Author mode, creates a link to the dragged file (the ptr element with the target attribute) at the drop location.

Tip: For information about customizing Author mode actions for a particular framework (on page 3282) (document type), see the Configuring Actions, Menus, Toolbars, Content Completion for a Framework (on page 2323) section.

Related Information:

- Configuring Actions, Menus, Toolbars, Content Completion for a Framework (on page 2323)
jTEI Document Type (Framework)

The jTEI (Journal of the Text Encoding Initiative) document type is a highly restrictive customization (only about 80 elements are included) of the TEI P5 framework.

File Definition

A file is considered to be a jTEI document when the root element is named TEI, it is in the namespace http://www.tei-c.org/ns/1.0, and the @rend attribute is set to "jTEI".

Default Document Templates

There is a default jTEI Article template available when creating new documents from templates (on page 676) and they can be found in: Framework Templates > TEI JTEI.

The default template is located in the [OXYGEN_INSTALL_DIR]/frameworks/tei/templates/TEI jTEI folder.

Default Schema for Validation and Content Completion

The default schema that is used if one is not detected is tei_jtei.rng and it is stored in [OXYGEN_INSTALL_DIR]/frameworks/tei/xml/tei/custom/schema/relaxng/.

Default CSS

The default CSS file (jtei.css) that is used for rendering jTEI in Author mode is stored in [OXYGEN_INSTALL_DIR]/frameworks/tei/xml/tei/css/.

By default, these default CSS files are merged with any that are specified in the document. For more information, see Configuring and Managing Multiple CSS Styles for a Framework (on page 2348).

Default XML Catalogs

The default XML Catalogs (on page 3289) for jTEI are as follows:

- [OXYGEN_INSTALL_DIR]/frameworks/tei/xml/tei/schema/dtd/catalog.xml
- [OXYGEN_INSTALL_DIR]/frameworks/tei/xml/tei/custom/schema/dtd/catalog.xml
- [OXYGEN_INSTALL_DIR]/frameworks/tei/xml/tei/stylesheet/catalog.xml
Transformation Scenarios

Oxygen XML Editor includes built-in transformation scenarios that allow you to transform jTEI documents to PDF and ODT. They can be found in the TEI JTEI section in the Configure Transformation Scenario(s) dialog box (on page 1762).

- Adding Tables in TEI Documents (on page 1016)

JATS Document Type (Framework)

The JATS (NISO Journal Article Tag Suite) document type is a technical standard that defines an XML format for scientific literature.

File Definition

A file is considered to be a JATS document when the PUBLIC ID of the document contains the string -//NLM//DTD.

Default Document Templates

There are some default JATS templates available when creating new documents from templates (on page 676) and they can be found in: Framework Templates > JATSKit - NISO JATS and NLM BITS

The default templates for JATS documents are located in the [OXYGEN_INSTALL_DIR]/frameworks/jats/templates/ folder.
Default Schema for Validation and Content Completion

Default schemas that are used if one is not detected in the JATS document are stored in

\[OXYGEN\_INSTALL\_DIR]/frameworks/jats/lib/schemas/.

Default CSS

The default CSS files used for rendering JATS content in Author mode are stored in

\[OXYGEN\_INSTALL\_DIR]/frameworks/jats/lib/author-css/.

By default, these default CSS files are merged with any that are specified in the document. For more information, see Configuring and Managing Multiple CSS Styles for a Framework (on page 2348).

Default XML Catalog

The default XML Catalog (on page 3289), jatskit-catalog.xml, is stored in

\[OXYGEN\_INSTALL\_DIR]/frameworks/jats/lib/schemas/.

Transformation Scenarios

Oxygen XML Editor includes built-in transformation scenarios that allow you to transform JATS documents to a variety of outputs, such as PDF, HTML, and EPUB. They can be found in the JATSKit section in the Configure Transformation Scenario(s) dialog box (on page 1762).

JATS Author Mode Actions

A variety of actions are available in the JATS framework (on page 3282) that can be added to the JATS menu, the Author Custom Actions toolbar, the contextual menu, and the Content Completion Assistant (on page 3280).

JATS Toolbar Actions

The following default actions are readily available on the JATS (Author Custom Actions) toolbar when editing in Author mode (by default, they are also available in the JATS menu and in various submenus of the contextual menu):

Paragraph Level Drop-Down Menu

- **Insert Paragraph**
  Insert a new paragraph element at current cursor position.

- **Insert Unordered List**
  Inserts an unordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an unordered list.

- **Insert Ordered List**
  Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

- **Boxed Text**
  Inserts or wraps content in a box with a shaded background.

- **Code**
  Inserts or wraps content in a code element.

- **Display Quote**
  Inserts or wraps content in a disp-quote element.

- **Figure**
  Inserts a fig element with a title (inside a caption element). This action opens a dialog box that allows you to enter the text for the title for the figure.

Graphic Figure
Inserts a `fig` element with a `title` (inside a `caption` element), and a `graphic` element. A dialog box is displayed that allows you to enter the title for the figure, followed by a dialog box that allows you to select the URL of the graphic to be inserted.

**Bold**

Surrounds the selected text with a `bold` tag. You can use this action on multiple non-contiguous selections.

**Italic**

Surrounds the selected text with an `italic` tag. You can use this action on multiple non-contiguous selections.

**Underline**

Surrounds the selected text with an `underline` tag. You can use this action on multiple non-contiguous selections.

**Monospace**

Inserts or wraps content with a `monospace` element.

**Insert Image**

Inserts an image reference (on page 1021) at the cursor position. Depending on the current location, an image-type element is inserted.

**Insert List Item**

Inserts a list item in the current list type.

**Insert MathML**

Opens the XML Fragment Editor that allows you to insert and edit MathML notations (on page 1057).

**Subscript**

Surrounds the selected text with a `subscript` tag, used for inserting a character (number, letter, or symbol) that will appear slightly below the baseline and slightly smaller than the rest of the text.

**Superscript**

Surrounds the selected text with a `superscript` tag, used for inserting a character (number, letter, or symbol) that will appear slightly above the baseline and slightly smaller than the rest of the text.
JATS Menu Actions

The following additional actions can be found in the JATS menu when editing in Author mode:

- **Refresh References**
  
  You can use this action to manually trigger a refresh and update of all referenced resources.

**Tags display mode Submenu**

- **Full Tags with Attributes**
  
  Displays full tag names with attributes for both block (on page 3280) and inline elements (on page 3283). Oxygen XML Editor

- **Full Tags**
  
  Displays full tag names without attributes for both block and inline elements.

- **Block Tags**
  
  Displays full tag names for block elements and simple tags without names for inline elements.

- **Inline Tags**
  
  Displays full tag names for inline elements, while block elements are not displayed.

- **Partial Tags**
  
  Displays simple tags without names for inline elements, while block elements are not displayed.

- **No Tags**
  
  No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

**Configure Tags Display Mode**

Use this option to go to the Author preferences page (on page 131) where you can configure the Tags Display Mode options.

**Profiling/Conditional Text Submenu**

**Edit Profiling Attributes**

Allows you to configure the profiling attributes (on page 969) and their values.
Show Profiling Colors and Styles
Select this option to turn on conditional styling.

Show Profiling Attributes
Select this option to turn on conditional text markers. They are displayed at the end of conditional text blocks, as a list of attribute name and their currently set values.

Show Excluded Content
When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.

List of all profiling condition sets that match the current document type
You can click a listed condition set (on page 975) to activate it.

Profiling Settings
Opens the profiling options preferences page (on page 144), where you can manage profiling attributes and profiling conditions sets. You can also configure the profiling styles and colors options from the colors/styles preferences page (on page 146) and the attributes rendering preferences page (on page 148).

JATS Drag/Drop Actions
Dragging a file from the Project view (on page 333) or DITA Maps Manager view (on page 2990) and dropping it into a JATS document that is edited in Author mode, creates a link to the dragged file (the ext-link element with the xlink:href attribute) at the drop location. Dragging an image file from the default file system application (Windows Explorer on Windows or Finder on Mac OS X, for example) and dropping it into a JATS document inserts an image element (the inline-graphic element with the xlink:href attribute) at the drop location, similar to the Insert Image toolbar action.

Tip: For information about customizing Author mode actions for a particular framework (on page 3282) (document type), see the Configuring Actions, Menus, Toolbars, Content Completion for a Framework (on page 2323) section.

Related Information:
- Configuring Actions, Menus, Toolbars, Content Completion for a Framework (on page 2323)
EPUB Document Type (Framework)

EPUB is an e-book file format that is a ZIP archive and can be downloaded and read on devices such as phones, tablets, computers, or e-readers. Oxygen XML Editor includes an Archive Browser view (on page 2191) that allows you to view the contents and structure of this type of file.

Three distinct frameworks (on page 3282) are supported for the EPUB document type:

- **NCX** - A declarative global navigation definition.
- **OCF** - The Open Container Format (OCF) defines a mechanism by which all components of an Open Publication Structure (OPS) can be combined into a single file system entity.
- **OPF** - The Open Packaging Format (OPF) defines the mechanism by which all components of a published work that conforms to the Open Publication Structure (OPS) standard (including metadata, reading order, and navigational information) are packaged in an OPS Publication.

Note: Oxygen XML Editor supports OPF 2.0, OPF 3.0, and OPF 3.1.

File Definition

A file is considered to be an EPUB document if it has a file extension of .epub.

Default Document Templates

There are a variety of default EPUB templates available when creating new documents from templates (on page 676) and they can be found the following folders in Framework Templates: NCX, OCF, OPF 2.0, OPF 3.0, and OPF 3.1.

- The default templates for the NCX document types are located in the `\[OXYGEN_INSTALL_DIR\]/frameworks/ncx/templates` folder.
- The default templates for the OCF document types are located in the `\[OXYGEN_INSTALL_DIR\]/frameworks/ocf/templates` folder.
- The default template for the OPF 2.0 document type is located in the `\[OXYGEN_INSTALL_DIR\]/frameworks/opf/templates/2.0` folder.
- The default template for the OPF 3.0 document type is located in the `\[OXYGEN_INSTALL_DIR\]/frameworks/opf/templates/3.0` folder.
- The default template for the OPF 3.1 document type is located in the `\[OXYGEN_INSTALL_DIR\]/frameworks/opf/templates/3.1` folder.

Default Schema

The default schema files for the various types of EPUB document types are located in the following directories:
• The default schema files for the **NCX** document types are located in the 
  \[OXYGEN_INSTALL_DIR\]/frameworks/ncx/schemas folder.
• The default schema files for the **OCF** document types are located in the 
  \[OXYGEN_INSTALL_DIR\]/frameworks/ocf/schemas folder.
• The default schema files for the **OPF 2.0** document type is located in the 
  \[OXYGEN_INSTALL_DIR\]/frameworks/opf/schemas/2.0 folder.
• The default schema files for the **OPF 3.0** document type is located in the 
  \[OXYGEN_INSTALL_DIR\]/frameworks/opf/schemas/3.0 folder.
• The default schema files for the **OPF 3.1** document type is located in the 
  \[OXYGEN_INSTALL_DIR\]/frameworks/opf/schemas/3.1 folder.

Related Information:

• Working with Archive Files (on page 2194)

### Other Supported Document Types

Along with the fully supported built-in frameworks (document types) (on page 1537), Oxygen XML Editor also provides limited support (including document templates) for editing a variety of other document types. All the specialized views, editors, actions, and options are dynamic according to the type of file that is opened or created. Other document types that are supported in Oxygen XML Editor include:

• **EPUB (NCX, OCF, OPF 2.0, 3.0, & 3.1) (on page 1636)** - A standard for e-book files.
• **OOXML (on page 2194)** - An XML-based file format for representing spreadsheets, charts, presentations, and word processing documents.
• **ODF (on page 2194)** - An free and open-source XML-based file format for electronic office documents, such as spreadsheets, charts, presentations, and word processing documents.
• **DocBook Targetset (on page 1572)** - For resolving cross-references when using olinks.
• **Ant Build Scripts (on page 1235)** - A tool for automating software build processes, written in Java and primarily intended for use with Java.
• **XSLT Stylesheets (on page 1183)** - A document type that provides a visual mode for editing XSLT stylesheets.
• **WSDL (on page 1354)** - Web Services Description Language is an XML language for describing the functionality offered by a web service.
• **Schematron (on page 1461)** - For making assertions about the presence or absence of patterns in XML documents. This document type applies to the ISO Schematron version.
• **Schematron Quick Fixes (SQF)** *(on page 1111)* - An extension of the ISO standard Schematron, allows developers to define **Quick Fixes** *(on page 3287)* for Schematron errors.

• **XProc** *(on page 1459)* - A document type for processing XProc script files.

• **XML Schema** *(on page 1249)* - Documents that provide support for editing annotations.

• **SVG** *(on page 1499)* - Scalable Vector Graphics is a language for describing two-dimensional graphics in XML.

• **MathML** *(on page 1057)* - Mathematical Markup Language (2.0 and 3.0) is an application of XML for describing mathematical notations.

• **XLIFF (1.2, 2.0, 2.1)** *(on page 1453)* - XML Localization Interchange File Format is a standard for passing data between tools during a localization process.

• **XQuery** *(on page 1337)* - The common query language for XML.

• **CSS** *(on page 1380)* - Cascading Style Sheets is a language used for describing the look and formatting of a document.

• **LESS** *(on page 1385)* - A dynamic style sheet language that can be compiled into CSS.

• **Relax NG Schema** *(on page 1388)* - A schema language that specifies a pattern for the structure and content of an XML document.

• **NVDL Schema** *(on page 1408)* - Namespace Validation Dispatching Language allows you to specify sections of XML documents to be validated against various schemas.

• **JSON** *(on page 1417)* - JavaScript Object Notation is a lightweight data-interchange format.

• **Markdown** *(on page 1507)* - A lightweight markup language with plain text formatting syntax that can be converted to HTML or DITA.

• **JavaScript** *(on page 1454)* - Programming language of HTML and the Web.

• **XMLSpec** - A markup language for W3C specifications and other technical reports.

• **DITAVAL** - DITA conditional processing profile to identify the values you want to conditionally process for a particular output, build, or other purpose.

• **Daisy** - A technical standard for digital audio books, periodicals, and computerized text. It is designed to be an audio substitute for print material.

• **EAD** - Encoded Archival Description is an XML standard for encoding archival finding aids.

• **KML** - Keyhole Markup Language is an XML notation for expressing geographic visualization in maps and browsers.

• **Maven Project & Settings** - Project or settings file for Maven build automation tool that is primarily used for Java projects.

• **Oasis XML Catalog** - An **XML Catalog** *(on page 3289)* document that describes a mapping between external entity references and locally-cached equivalents.

• **Other Non-XML Files** *(on page 706)* - Oxygen XML Editor also includes a simple text editor and a variety of helpful features for creating and editing non-XML files.
XML documents can be transformed into a variety of user-friendly output formats that can be viewed by end users. This process is known as a **transformation**.

Oxygen XML Editor includes numerous built-in transformation possibilities to publish XML content in various output formats (such as WebHelp, PDF, CHM, EPUB, JavaHelp, Eclipse Help, XHTML, etc.)

For transformations that are not included in your installed version of Oxygen XML Editor, simply install the tool chain required to perform the specific transformation and process the files in accordance with the processor instructions. A multitude of target formats are possible. The basic condition for a transformation to any format is that your source document is well-formed.

**Transformation Scenarios**

A transformation scenario is a set of complex operations and settings that gives you the possibility to obtain outputs of multiple types (XML, HTML, PDF, EPUB, etc.) from the same source of XML files and stylesheets.

**Note:** You need to use the appropriate stylesheet according to the source definition and the desired output. For example, if you want to transform into an HTML format using a DocBook stylesheet, your source XML document should conform with the DocBook DTD.

Executing a transformation scenario implies multiple actions, such as:

- Validating the input file.
- Obtaining intermediate output files (for example, formatting objects for the XML to PDF transformation).
- Using transformation engines to produce the output.

Before transforming an XML document in Oxygen XML Editor, you need to define a transformation scenario to apply to that document. A scenario is a set of values for various parameters that define a transformation. It is not related to a particular document, but rather to a document type. Oxygen XML Editor included preconfigured built-in transformation scenarios (on page 1641), but you can also create new transformation scenarios (on page 1674).

When creating new transformation scenarios, the types that are available include:
Scenarios that Apply to XML Files - This type of scenario contains the location of an XSLT stylesheet that is applied on the edited XML document, as well as other transformation parameters. For more information, see XML Transformation with XSLT (on page 1674) and XML Transformation with XQuery (on page 1690).

Scenarios that Apply to XSLT Files - This type of scenario contains the location of an XML document that the edited XSLT stylesheet is applied to, as well as other transform parameters. For more information, see XSLT Transformation (on page 1722).

Scenarios that Apply to XQuery Files - This type of scenario contains the location of an XML source, that the edited XQuery file is applied to, as well as other transform parameters. When the XML source is a native XML database, the XML source field of the scenario is empty because the XML data is read with XQuery-specific functions, such as document(). When the XML source is a local XML file, the URL of the file is specified in the XML input field of the scenario. For more information, see XQuery Transformation (on page 1749).

Scenarios that Apply to SQL Files - This type of scenario specifies a database connection for the database server that runs the SQL file that is associated with the scenario. The data processed by the SQL script is located in the database.

Scenarios that Apply to XProc Files - This type of scenario contains the location of an XProc script, as well as other transform parameters. For more information, see SQL Transformation (on page 1757).

DITA-OT Scenarios - This type of scenario provides the parameters for an Ant transformation that executes a DITA-OT build script. Oxygen XML Editor includes a built-in version of Ant and a built-in version of DITA-OT, although you can also set other versions in the scenario. For more information, see DITA OT Transformation (on page 1702).

ANT Scenarios - This type of scenario contains the location of an Ant build script, as well as other transform parameters. For more information, see Ant Transformation (on page 1718).

Note:

Status messages generated during the transformation process are displayed in the Information view (on page 822).

Built-in Transformation Scenarios

Oxygen XML Editor includes preconfigured built-in transformation scenarios that are used for common transformations. They can be found in the various sections in the Configure Transformation Scenario(s) dialog box (on page 1762) or Transformation Scenarios view (on page 1768). All the built-in document types (frameworks) (on page 3282) that are included in Oxygen XML Editor have various transformation scenarios in their specific sections, including the most popular frameworks, such as DITA, DocBook, TEI, XHTML, JATS, OOXML, and more.
To obtain the desired output, use one of the following actions from the toolbar or Transform submenu in the contextual menu of the Project view (on page 333):

- **Apply Transformation Scenario(s) (Ctrl + Shift + T (Command + Shift + T on OS X))** - If you have associated transformation scenarios for the current document, this action will simply apply the association (on page 1761) and begin the transformation process. If an association is not detected, this action will open the Configure Transformation Scenario(s) dialog box (on page 1762) where you can choose the scenarios you want to apply.

- **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))** - This action will open the Configure Transformation Scenario(s) dialog box (on page 1762) where you can choose the scenarios you want to apply.

**Note:**

- You can apply a transformation even if the current document is not associated with a transformation scenario.
- If the document contains an xml-stylesheet processing instruction that references an XSLT stylesheet (commonly used to display the document in web browsers), Oxygen XML Editor prompts you to associate the document with a built-in transformation scenario.
- The default transformation scenario is suggested based on the processing instruction from the edited document.

**Related Information:**

- Applying Associated Transformation Scenarios (on page 1761)
- Transformation Scenarios View (on page 1768)

**DITA Map Transformation Scenarios**

Built-in transformation scenarios allow you to transform DITA maps (on page 3281) to a variety of outputs, such as WebHelp, PDF, ODF, XHTML, EPUB, CHM, Kindle, and MS Word. Oxygen XML Editor also includes a special Run DITA-OT Integrator (on page 1665) that can be used to integrate a DITA-
OT plugin and a **DITA Map Metrics Report** transformation that generates a statistics report for your DITA map. All of them are listed in the **DITA Map** section in the **Configure Transformation Scenario(s)** dialog box (on page 1762).

A variety of transformations scenarios are available for **DITA maps** (on page 3281):

- **Built-in transformation scenarios** allow you to transform a **DITA map** to a variety of outputs, such as WebHelp, PDF, ODF, XHTML, EPUB, CHM, Kindle, and MS Word.

- **Run DITA-OT Integrator** (on page 1665) - Use this transformation scenario if you want to integrate a DITA-OT plugin (on page 3256). This scenario runs an Ant task that integrates all the plugins from the DITA-OT/plugins directory.

- **DITA Map Metrics Report** - Use this type of transformation scenario if you want to generate a **DITA map** statistics report. It contains information such as:
  - The number of processed maps and topics.
  - Content reuse percentage.
  - Number of elements, attributes, words, and characters used in the entire **DITA map** structure.
  - DITA conditional processing attributes used in the **DITA maps**.
  - Processing instructions.
  - External links.
  - All **@outputclass** attribute values gathered from the DITA project.

⚠️ **Important**: If you have cross references that point to content outside the scope of the DITA map, that referenced content will not be counted. For example, if you have links to topics that are not included in the DITA map hierarchy, the content in those topics is ignored when generating the statistics.

**DITA Map to WebHelp Responsive Transformation**

DITA content can be transformed into several types of WebHelp Responsive systems (with or without a feedback section). The **WebHelp Responsive layout and features** (on page 1858) are designed to adapt to any device and screen size to provide an optimal viewing and interaction experience. Oxygen
XML Editor also provides numerous possibilities for customizing the WebHelp Responsive output (on page 1935).

WebHelp Responsive Transformation Scenario

To publish a DITA map (on page 3281) as WebHelp Responsive output, follow these steps:

1. Select the Configure Transformation Scenario(s) action from the DITA Maps Manager (on page 2990) toolbar.
2. Select the DITA Map WebHelp Responsive scenario from the DITA Map section.
3. If you want to configure the transformation, click the Edit button.

**Step Result:** This opens an Edit scenario configuration dialog box that allows you to configure various options in the following tabs:

- **Templates Tab (on page 3199)** - This tab contains a set of built-in publishing templates (on page 1892) that you can use for the layout of your WebHelp system output. You can also create your own publishing templates or edit existing ones (on page 1935).
- **Parameters Tab (on page 3205)** - This tab includes numerous parameters that can be set to customize your WebHelp system output. See the Parameters section (on page 1645) below for details about the most commonly used parameters for WebHelp Responsive transformations.
- **Filters Tab (on page 3207)** - This tab allows you to filter certain content elements from the generated output.
- **Advanced Tab (on page 3208)** - This tab allows you to specify some advanced options for the transformation scenario.
- **Output Tab (on page 3210)** - This tab allows you to configure options that are related to the location where the output is generated.
4. Click **Apply associated** to process the transformation.

When the DITA Map WebHelp Responsive transformation is complete, the output is automatically opened in your default browser.

WebHelp Responsive with Feedback Transformation Scenario

To publish a DITA map (on page 3281) as a WebHelp Responsive with Feedback system, follow these steps:

1. Select the Configure Transformation Scenario(s) action from the DITA Maps Manager (on page 2990) toolbar.
2. Select the DITA Map WebHelp Responsive with Feedback scenario from the DITA Map section.
3. If you want to configure the transformation, click the Edit button.
Step Result: This opens an Edit scenario configuration dialog box that allows you to configure various options in the following tabs:

- Templates Tab (on page 3199) - This tab contains a set of built-in publishing templates (on page 1892) that you can use for the layout of your WebHelp system output. You can also create your own publishing templates or edit existing ones (on page 1935).
- Parameters Tab (on page 3205) - This tab includes numerous parameters that can be set to customize your WebHelp system output. See the Parameters section (on page 1645) below for details about the most commonly used parameters for WebHelp Responsive transformations.
- Filters Tab (on page 3207) - This tab allows you to filter certain content elements from the generated output.
- Advanced Tab (on page 3208) - This tab allows you to specify some advanced options for the transformation scenario.
- Output Tab (on page 3210) - This tab allows you to configure options that are related to the location where the output is generated.

4. Click Apply associated to begin the transformation.
5. Enter the documentation product ID (value for the webhelp.product.id parameter) and the documentation version (value for the webhelp.product.version parameter).

When the DITA Map WebHelp Responsive with Feedback transformation is complete, your default browser opens the installation.html file. This file contains information about the output location, system requirements, installation instructions, and deployment of the output. Follow the instructions to complete the system deployment (on page 1873).

Parameters for Customizing WebHelp Responsive Output

To customize a transformation scenario, you can edit various parameters, including the following most commonly used ones:

**default.language**

This parameter is used if the language is not detected in the DITA map. The default value is en-us.

**clean.output**

Deletes all files from the output folder before the transformation is performed (only no and yes values are valid and the default value is no).

**editlink.remote.ditamap.url**

Use this parameter in conjunction with editlink.web.author.url to add an Edit link next to the topic title in the WebHelp output. When a user clicks the link, the topic is opened in Oxygen XML Web Author where they can make changes that can be saved
to a file server. The value should be set as the custom URL of the *main DITA map*. For example, a GitHub custom URL might look like this: `https://getFileContent/ oxyengxml/userguide/master/UserGuide.ditamap`.

**editlink.web.author.url**

This parameter needs to be used in conjunction with `editlink.remote.ditamap.url` to add an *Edit* link next to the topic title in the WebHelp output. When a user clicks the link, the topic is opened in Oxygen XML Web Author where they can make changes that can be saved to a file server. The value should be set as the URL of the Web Author installation. For example: `https://www.oxygenxml.com/oxygen-xml-web-author/`.

**editlink.present.only.path.to.topic**

When this parameter is set to "true", the DITA topic path is displayed to the right of each topic title in the WebHelp Responsive output. Also, when this parameter is used, the `editlink.remote.ditamap.url` and `editlink.web.author.url` parameters are ignored.

**fix.external.refs.com.oxygenxml** (Only supported when the DITA OT transformation process is started from Oxygen XML Editor)

The DITA Open Toolkit usually has problems processing references that point to locations outside of the directory of the processed *DITA map*. This parameter is used to specify whether or not the application should try to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references. The fix has no impact on your edited DITA content. Allowed values: `true` or `false` (default).

**force.unique**

When set to `true` (default value), the transformation will be forced to create unique output files for each instance of a resource when a map contains multiple references to a single topic.

**use.stemming**

Controls whether or not you want to include stemming search algorithms into the published output (default setting is `false`).

**webhelp.custom.resources**

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

**webhelp.favicon**

The file path that points to an image to be used as a *favicon* in the WebHelp output.

**webhelp.reload.stylesheet**
Set this parameter to `true` if you have out of memory problems when generating WebHelp. It will increase processing time but decrease the memory footprint. The default value is `false`.

**webhelp.search.custom.excludes.file**

The path of the file that contains name patterns for HTML files that should not be indexed by the WebHelp search engine. Each exclude pattern must be on a new line. The patterns are considered to be relative to the output directory, and they accept wildcards such as ‘*’ (matches zero or more characters) or ‘?’ (matches one character). For more information about the patterns, see [https://ant.apache.org/manual/dirtasks.html#patterns](https://ant.apache.org/manual/dirtasks.html#patterns).

**webhelp.search.japanese.dictionary**

The file path of the dictionary that will be used by the *Kuromoji* morphological engine for indexing Japanese content in the WebHelp pages. The encoding for the dictionary must be UTF8.

**webhelp.search.enable.pagination**

Specifies whether or not search results will be displayed on multiple pages. Allowed values are `yes` or `no`.

**webhelp.search.page.numberOfItems**

Specifies the number of search results items displayed on each page. This parameter is only used when the `webhelp.search.enable.pagination` parameter is enabled.

**webhelp.search.ranking**

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the Search tab (default setting is `true`).

**webhelp.show.changes.and.comments**

When set to `yes`, user comments, replies to comments, and tracked changes are published in the WebHelp output. The default value is `no`.

**webhelp.sitemap.base.url**

Base URL for all the `loc` elements in the generated `sitemap.xml` file. The value of a `loc` element is computed as the relative file path from the `href` attribute of a `topicref` element from the DITA map, appended to this base URL value. The `loc` element is mandatory in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `sitemap.xml` file is not generated.

**webhelp.sitemap.change.frequency**

The value of the `changefreq` element in the generated `sitemap.xml` file. The `changefreq` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `changefreq` element is not added in `sitemap.xml`.
Allowed values: <empty string> (default), always, hourly, daily, weekly, monthly, yearly, never.

**webhelp.sitemap.priority**

The value of the priority element in the generated sitemap.xml file. It can be set to any fractional number between 0.0 (least important priority) and 1.0 (most important priority). For example, 0.3, 0.5, or 0.8. The priority element is optional in sitemap.xml. If you leave this parameter set to its default empty value, then the priority element is not added in sitemap.xml.

**Parameters Specific to WebHelp Responsive Output**

**webhelp.default.collection.type.sequence**

Specifies if the sequence value will be used by default when the collection-type attribute is not specified. This option is helpful if you want to have Next and Previous navigational buttons generated for all HTML pages. Allowed values are no (default) and yes.

**webhelp.enable.search.autocomplete**

Specifies if the Autocomplete feature is enabled in the WebHelp search text field. The default value is yes.

**webhelp.fragment.after.body**

In the generated output it displays a given XHTML fragment after the page body. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.logo_and_title**

In the generated output it displays a given XHTML fragment after the logo and title. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.main.page.search**

In the generated output it displays a given XHTML fragment after the search field. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.toc_or_tiles**

In the generated output it displays a given XHTML fragment after the table of contents or tiles in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.top_menu**
In the generated output it displays a given XHTML fragment after the top menu. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.body

In the generated output it displays a given XHTML fragment before the page body. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.logo_and_title

In the generated output it displays a given XHTML fragment before the logo and title. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.main.page.search

In the generated output it displays a given XHTML fragment before the search field. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.toc_or_tiles

In the generated output it displays a given XHTML fragment before the table of contents or tiles in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.top_menu

In the generated output it displays a given XHTML fragment before the top menu. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.footer

In the generated output it displays a given XHTML fragment as the page footer. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.head

In the generated output it inserts a given XHTML fragment in the <head> element. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.welcome

In the generated output it displays a given XHTML fragment as a welcome message (or title). The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.
webhelp.merge.nested.topics.related.links

Specifies if the related links from nested topics will be merged with the links in the parent topic. Thus the links will be moved from the topic content to the related links component and all of the links from the same group (for example, Related Tasks, Related References, Related Information) are merged into a single group. The default value is yes.

webhelp.search.stop.words.exclude

Specifies a list of words that will be excluded from the default list of stop words that are filtered out before the search processing. Use comma separators to specify more than one word (for example: if, for, is).

webhelp.show.breadcrumb

Specifies if the breadcrumb component will be presented in the output. The default value is yes.

webhelp.show.child.links

Specifies if child links will be generated in the output for all topics that have subtopics. The default value is no.

webhelp.show.indexterms.link

Specifies if an icon that links to the index will be presented in the output. The default value is yes.

webhelp.show.main.page.tiles

Specifies if the tiles component will be presented in the main page of the output. For a tree style layout, this parameter should be set to no.

webhelp.show.main.page.toc

Specifies if the table of contents will be presented in the main page of the output. The default value is yes.

webhelp.show.navigation.links

Specifies if navigation links will be presented in the output. The default value is yes.

webhelp.show.print.link

Specifies if a print link or icon will be presented within each topic in the output. The default value is yes.

webhelp.show.related.links

Specifies if the related links component will be presented in the WebHelp Responsive output. The default value is yes. The webhelp.merge.nested.topics.related.links parameter can be used in conjunction with this one to merge the related links from nested topics into the links in the parent topic.
**webhelp.show.publication.toc**

Specifies if a table of contents will be presented on the left side of each topic in the output. The default value is `yes`.

**webhelp.show.topic.toc**

Specifies if a topic table of contents will be presented on the right side of each topic in the output. This table of contents contains links to each `<section>` within the current topic that contains an `@id` attribute and the section corresponding to the current scroll position is highlighted. The default value is `yes`.

**webhelp.show.top.menu**

Specifies if a menu will be presented at the topic of the main page in the output. The default value is `yes`.

**webhelp.publication.toc.hide.chunked.topics**

Specifies if the table of contents will contain links for chunked topics. The default value is `yes`.

**webhelp.publication.toc.links**

Specifies which links will be included in the table of contents. The possible values are:

- **chapter** (default) - The TOC will include links for the current topic, its children, its siblings, and its direct ancestor (including the direct ancestor's siblings), and the parent chapter.
- **topic** - The TOC will only include links for the current topic and its direct children.
- **all** - The TOC will include all links.

**webhelp.publication.toc.tooltip.position**

By default, if a topic contains a `shortdesc` element, its content is displayed in a tooltip when the user hovers over its link in the table of contents. This parameter controls whether or not this tooltip is displayed and its position relative to the link. The possible values are:

- **left** (default)
- **right**
- **top**
- **bottom**
- **hidden** - The tooltip will not be displayed.

**webhelp.top.menu.depth**

Specifies the maximum depth level of the topics that will be included in the top menu. The default value is `3`. A value of `0` means that the menu has unlimited depth.
**webhelp.topic.collapsible.elements.initial.state**

Specifies the initial state of collapsible elements (tables with titles, nested topics with titles, sections with titles, index term groups). The possible values are `collapsed` or `expanded` (default value).

**Related Information:**

- Customizing the WebHelp Responsive Output *(on page 1935)*
- WebHelp Responsive Output Layout and Features *(on page 1858)*

**DITA Map to WebHelp Classic Transformation**

DITA content can be transformed into several types of WebHelp Classic systems (with or without a feedback section). The [WebHelp Classic layout and features (on page 1773)](onpage1773) are designed for desktop systems and include a familiar classical style. Oxygen XML Editor also provides numerous possibilities for customizing the [WebHelp Classic output (on page 1806)](onpage1806).

**WebHelp Classic Transformation Scenario**

To publish a [DITA map (on page 3281)](onpage3281) as a [WebHelp Classic](onpage1230) system, follow these steps:

1. Select the `Configure Transformation Scenario(s)` action from the [DITA Maps Manager (on page 2990)](onpage2990) toolbar.
2. Select the DITA Map WebHelp Classic scenario from the DITA Map section.
3. If you want to configure the transformation, click the Edit button.

**Step Result:** This opens an Edit scenario configuration dialog box that allows you to configure various options in the following tabs:

- [Skins Tab (on page 3197)](onpage3197) - This tab contains a set of built-in skins that you can use for the layout of your WebHelp system output.
- [Parameters Tab (on page 3205)](onpage3205) - This tab includes numerous parameters that can be set to customize your WebHelp system output. See the Parameters section *(on page 1654)* below for details about the most commonly used parameters for WebHelp Responsive transformations.
- [Filters Tab (on page 3207)](onpage3207) - This tab allows you to filter certain content elements from the generated output.
- [Advanced Tab (on page 3208)](onpage3208) - This tab allows you to specify some advanced options for the transformation scenario.
4. Click **Apply associated** to process the transformation.

When the **DITA Map WebHelp Classic** transformation is complete, the output is automatically opened in your default browser.

### WebHelp Classic with Feedback Transformation Scenario

To publish a **DITA map (on page 3281)** as a **WebHelp Classic with Feedback** system, follow these steps:

1. Select the **Configure Transformation Scenario(s)** action from the **DITA Maps Manager (on page 2990)** toolbar.
2. Select the **DITA Map WebHelp Classic with Feedback** scenario from the **DITA Map** section.
3. If you want to configure the transformation, click the **Edit** button.

**Step Result:** This opens an **Edit scenario** configuration dialog box that allows you to configure various options in the following tabs:

- **Skins Tab (on page 3197)** - This tab contains a set of built-in skins that you can use for the layout of your WebHelp system output.
- **Parameters Tab (on page 3205)** - This tab includes numerous parameters that can be set to customize your WebHelp system output. See the **Parameters section (on page 1654)** below for details about the most commonly used parameters for WebHelp Responsive transformations.
- **Filters Tab (on page 3207)** - This tab allows you to filter certain content elements from the generated output.
- **Advanced Tab (on page 3208)** - This tab allows you to specify some advanced options for the transformation scenario.
- **Output Tab (on page 3210)** - This tab allows you to configure options that are related to the location where the output is generated.

4. Click **Apply associated** to begin the transformation.

5. Enter the documentation product ID (value for the `webhelp.product.id` parameter) and the documentation version (value for the `webhelp.product.version` parameter).

When the **DITA Map WebHelp Classic with Feedback** transformation is complete, your default browser opens the **installation.html** file. This file contains information about the output location, system requirements, installation instructions, and deployment of the output. Follow the instructions to complete the system deployment (on page 1873).

For more information about the feedback-enabled WebHelp system, watch our video demonstration:
Parameters for Customizing WebHelp Classic Output

To customize a transformation scenario, you can edit various parameters, including the following most commonly used ones:

**default.language**

This parameter is used if the language is not detected in the DITA map. The default value is `en-us`.

**clean.output**

Deletes all files from the output folder before the transformation is performed (only `no` and `yes` values are valid and the default value is `no`).

**fix.external.refs.com.oxygenxml (Only supported when the DITA OT transformation process is started from Oxygen XML Editor)**

The DITA Open Toolkit usually has problems processing references that point to locations outside of the directory of the processed DITA map. This parameter is used to specify whether or not the application should try to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references. The fix has no impact on your edited DITA content. Allowed values: `true` or `false` (default).

**force.unique**

When set to `true` (default value), the transformation will be forced to create unique output files for each instance of a resource when a map contains multiple references to a single topic.

**use.stemming**

Controls whether or not you want to include stemming search algorithms into the published output (default setting is `false`).

**webhelp.body.script**

URL value that specifies the location of a well-formed XHTML file containing the custom script that will be copied in the `<body>` section of every WebHelp page.

**webhelp.copyright**

Adds a small copyright text that appears at the end of the Table of Contents pane.

**webhelp.custom.resources**

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

**webhelp.favicon**
The file path that points to an image to be used as a *favicon* in the WebHelp output.

**webhelp.footer.file**

Path to an XML file that includes the footer content for your WebHelp output pages. You can use this parameter to integrate social media features (such as widgets for Facebook™, Twitter™, Google Analytics, or Google+™). The file must be well-formed, each widget must be in separate div or span element, and the code for each script element is included in an XML comment (also, the start and end tags for the XML comment must be on a separate line). The following code exert is an example for adding a Facebook™ widget:

```xml
<div id="facebook">
  <div id="fb-root"/>
  <script>
    <!-- (function(d, s, id) { var js, fjs = d.getElementsByTagName(s)[0];
      if (d.getElementById(id)) return;
      js = d.createElement(s); js.id = id;
      js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
      fjs.parentNode.insertBefore(js, fjs); }
    (document, 'script', 'facebook-jssdk')); -->
  </script>
  <div data-share="true" data-show-faces="true" data-action="like"
    data-layout="standard" class="fb-like"/>
</div>
```

**webhelp.footer.include**

Specifies whether or not to include footer in each WebHelp page. Possible values: yes, no. If set to no, no footer is added to the WebHelp pages. If set to yes and the webhelp.footer.file parameter has a value, then the content of that file is used as footer. If the webhelp.footer.file has no value then a default Oxygen footer is inserted in each WebHelp page.

**webhelp.google.search.results**

A file path that specifies the location of a well-formed XHTML file containing the Google Custom Search Engine element gcse:searchresults-only. You can use all supported attributes for this element. It is recommend to set the linkTarget attribute to _frm for frameless (iframe) version of WebHelp or to _contentWin for the frameset version of WebHelp. The default value for this attribute is _blank and the search results will be loaded in a new window. If this parameter is not specified, the following code will be used:

```xml
<gcse:searchresults-only linkTarget="frm"></gcse:searchresults-only>
```

**webhelp.google.search.script**
A file path that specifies the location of a well-formed XHTML file containing the Custom Search Engine script from Google.

**webhelp.head.script**

URL value that specifies the location of a well-formed XHTML file containing the custom script that will be copied in the `<head>` section of every WebHelp page.

**webhelp.logo.image.target.url**

Specifies a target URL that is set on the logo image. When you click the logo image, you will be redirected to this address.

**webhelp.logo.image**

Specifies a path to an image displayed as a logo in the left side of the output header.

**webhelp.reload.stylesheet**

Set this parameter to `true` if you have out of memory problems when generating WebHelp. It will increase processing time but decrease the memory footprint. The default value is `false`.

**webhelp.search.custom.excludes.file**

The path of the file that contains name patterns for HTML files that should not be indexed by the WebHelp search engine. Each exclude pattern must be on a new line. The patterns are considered to be relative to the output directory, and they accept wildcards such as `*` (matches zero or more characters) or `?` (matches one character). For more information about the patterns, see [https://ant.apache.org/manual/dirtasks.html#patterns](https://ant.apache.org/manual/dirtasks.html#patterns).

**webhelp.search.japanese.dictionary**

The file path of the dictionary that will be used by the *Kuromoji* morphological engine for indexing Japanese content in the WebHelp pages. The encoding for the dictionary must be UTF8.

**webhelp.search.ranking**

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the *Search* tab (default setting is `true`).

**webhelp.show.changes.and.comments**

When set to `yes`, user comments, replies to comments, and tracked changes are published in the WebHelp output. The default value is `no`.

**webhelp.sitemap.base.url**

Base URL for all the `loc` elements in the generated `sitemap.xml` file. The value of a `loc` element is computed as the relative file path from the `href` attribute of a `topicref` element from the *DITA map*, appended to this base URL value. The `loc`
element is mandatory in sitemap.xml. If you leave this parameter set to its default empty value, then the sitemap.xml file is not generated.

**webhelp.sitemap.change.frequency**

The value of the changefreq element in the generated sitemap.xml file. The changefreq element is optional in sitemap.xml. If you leave this parameter set to its default empty value, then the changefreq element is not added in sitemap.xml. Allowed values: <empty string> (default), always, hourly, daily, weekly, monthly, yearly, never.

**webhelp.sitemap.priority**

The value of the priority element in the generated sitemap.xml file. It can be set to any fractional number between 0.0 (least important priority) and 1.0 (most important priority). For example, 0.3, 0.5, or 0.8. The priority element is optional in sitemap.xml. If you leave this parameter set to its default empty value, then the priority element is not added in sitemap.xml.

**DITA Map to PDF - based on HTML5 and CSS Transformation**

Oxygen XML Editor includes a built-in **DITA Map PDF - based on HTML5 & CSS** transformation scenario based on a **DITA-OT CSS-based PDF Publishing plugin** that converts DITA maps to PDF using a CSS-based processing engine and an HTML5 intermediate format. Oxygen XML Editor comes bundled with a built-in CSS-based PDF processing engine called **Oxygen PDF Chemistry**. Oxygen XML Editor also supports some third-party processors.

For those who are familiar with CSS, this makes it very easy to style and customize the PDF output of your DITA projects without having to work with xsl:fo customizations. This transformation also includes some built-in publishing templates that you can use for the layout of your PDF output and you can create your own templates or edit existing ones.

The following CSS-based PDF processors can be used:

- **Oxygen PDF Chemistry** - A built-in processor that is bundled with Oxygen XML Editor. For more information, see the **Oxygen PDF Chemistry User Guide**. This is the supported processor.
• **Prince Print with CSS** (not included in the Oxygen XML Editor installation kit) - A third-party component that needs to be purchased from [http://www.princexml.com](http://www.princexml.com).

• **Antenna House Formatter** (not included in the Oxygen XML Editor installation kit) - A third-party component that needs to be purchased from [http://www.antennahouse.com/antenna1/formatter/](http://www.antennahouse.com/antenna1/formatter/).

**How to Create the Transformation Scenario**

To create a **DITA Map PDF - based on HTML5 & CSS** transformation scenario, follow these steps:

1. Click the ✉️ Configure Transformation Scenario(s) button from the DITA Maps Manager (on page 2990) toolbar.
2. Select **DITA Map PDF - based on HTML5 & CSS**.
3. If you want to configure the transformation, click the **Edit** button.

**Step Result:** This opens an **Edit scenario** configuration dialog box that allows you to configure various options in the following tabs:

- **Templates Tab** (on page 3199) - This tab contains a set of built-in publishing templates that you can use for the layout of your WebHelp system output. You can also create your own publishing templates by saving one from the gallery and changing it.

- **CSS Processor** Tab - This is where you choose the processor type. You can select between Oxygen PDF Chemistry, Prince XML, or Antenna House.

- **Parameters Tab** (on page 3205) - This tab includes numerous parameters that can be set to customize your WebHelp system output.

- **Filters Tab** (on page 3207) - This tab allows you to filter certain content elements from the generated output.

- **Advanced Tab** (on page 3208) - This tab allows you to specify some advanced options for the transformation scenario.

- **Output Tab** (on page 3210) - This tab allows you to configure options that are related to the location where the output is generated.

4. In the **Parameters** tab, configure any of the following parameters (if applicable):

- **args.css** - Specifies a path to a custom CSS to be used in addition to those specified in the publishing template. The files must have URL syntax and be separated using semicolons. Also, the **dita.css.list** parameter must be left empty to use these files in addition to the selection in the **Styles** drop-down menu.

- **css.processor.path.chemistry** (if you are using the **Oxygen PDF Chemistry** processor) - Specifies the path to the **Oxygen PDF Chemistry** executable file that will be run to generate the PDF. If this parameter is not set, the transformation will use the processor specified in the **CSS-based Processors preferences page** (on page 220).
• **css.processor.path.prince** (if you are using the **Prince Print with CSS** processor) - Specifies the path to the Prince executable file that will be run to produce the PDF. If you installed Prince using its default settings, you can leave this blank.

• **css.processor.path.antenna-house** (if you are using the **Antenna House Formatter** processor) - Specifies the path to the Antenna House executable file that will be run to produce the PDF. If you installed Antenna House using its default settings, you can leave this blank.

• **show.changes.and.comments** - When set to **yes**, user comments, replies to comments, and tracked changes are published in the PDF output. The default value is **no**.

• **figure.title.placement** - Controls the position of the figure title relative to the image. Allowed values are "top" and "bottom", "top" is the default

5. Click **OK** and run the transformation scenario.

### Customizing the Output

For information about customizing the output, see **CSS-based DITA to PDF Customization** *(on page 2013)*.

**Related Information:**

- **Editing a Transformation Scenario** *(on page 1758)*

- **Configure Transformation Scenario(s) Dialog Box** *(on page 1762)*

- **Oxygen PDF Chemistry User Guide**

- **CSS-based DITA to PDF Customization** *(on page 2013)*

### DITA Map to PDF - based on DITA and CSS (WYSIWYG) (Deprecated)

⚠️ **Attention**: This transformation scenario was deprecated starting with version 21.0. If you have configured scenarios associated to your project based on this transformation scenario, you will still be able to use them, but for new transformations, it is recommended to use the **DITA Map PDF - based on HTML5 & CSS** transformation scenario *(on page 1657)* instead.

Oxygen XML Editor includes a built-in **DITA Map to PDF - based on DITA & CSS (WYSIWYG)** transformation scenario based on a **DITA-OT CSS-based PDF Publishing plugin** that convert DITA maps to PDF using a CSS-based processing engine. Oxygen XML Editor also comes bundled with a built-in CSS-based PDF processing engine called **Oxygen PDF Chemistry**. For those who are
familiar with CSS, this makes it very easy to style and customize the PDF output of your DITA projects without having to work with xsi:fo customizations. Oxygen XML Editor also supports some third-party processors.

The following processors are supported:

- **Oxygen PDF Chemistry** - A built-in processor that is bundled with Oxygen XML Editor. For more information, see the [Oxygen PDF Chemistry User Guide](#).

- **Prince XML** (not included in the Oxygen XML Editor installation kit) - A third-party component that needs to be purchased from [http://www.princexml.com](http://www.princexml.com).

- **Antenna House Formatter** (not included in the Oxygen XML Editor installation kit) - A third-party component that needs to be purchased from [http://www.antennahouse.com/antenna1/formatter/](http://www.antennahouse.com/antenna1/formatter/).

### DITA Map to PDF - based on DITA and CSS (WYSIWYG) Transformation Scenario

To create a DITA Map to PDF - based on DITA & CSS (WYSIWYG) transformation scenario, follow these steps:

1. Click the Configure Transformation Scenario(s) button from the DITA Maps Manager ([on page 2990](#)) toolbar.
2. Select DITA Map to PDF - based on DITA & CSS (WYSIWYG).
3. If you want to configure the transformation, click the Edit button.

**Step Result:** This opens an Edit scenario configuration dialog box that allows you to configure various options in the following tabs:

- **CSS Processor Tab** - This is where you choose the processor type. You can select between Oxygen PDF Chemistry, Prince XML, or Antenna House.

- **Parameters Tab** ([on page 3205](#)) - This tab includes numerous parameters that can be set to customize your WebHelp system output.

- **Filters Tab** ([on page 3207](#)) - This tab allows you to filter certain content elements from the generated output.

- **Advanced Tab** ([on page 3208](#)) - This tab allows you to specify some advanced options for the transformation scenario.

- **Output Tab** ([on page 3210](#)) - This tab allows you to configure options that are related to the location where the output is generated.

4. In the Parameters tab, configure any of the following parameters (if applicable):

- **args.css** - Specifies a path to a custom CSS ([on page 2041](#)) to be used in addition to those specified in the dita.css.list parameter OR in addition to the CSS that is currently selected in the Styles drop-down menu. The files must have URL syntax and be separated
using semicolons. Also, the `dita.css.list` parameter must be left empty to use these files in addition to the selection in the Styles drop-down menu.

- **dita.css.list** - Specifies a list of CSS URLs to be used by the PDF processor (instead of the default CSS files). The files must have URL syntax and be separated using semicolons. If the value is empty, the CSS associated with the current selection from the Styles drop-down menu is used.

- **css.processor.path.chemistry** (if you are using the Oxygen PDF Chemistry processor) - Specifies the path to the Oxygen PDF Chemistry executable file that will be run to generate the PDF. If this parameter is not set, the transformation will use the processor specified in the CSS-based Processors preferences page (on page 220).

- **css.processor.path.prince** (if you are using the Prince Print with CSS processor) - Specifies the path to the Prince executable file that will be run to produce the PDF. If you installed Prince using its default settings, you can leave this blank.

- **css.processor.path.antenna-house** (if you are using the Antenna House Formatter processor) - Specifies the path to the Antenna House executable file that will be run to produce the PDF. If you installed Antenna House using its default settings, you can leave this blank.

- **show.changes.and.comments** - When set to `yes`, user comments, replies to comments, and tracked changes are published in the PDF output. The default value is `no`.

- **figure.title.placement** - Controls the position of the figure title relative to the image. Allowed values are "top" and "bottom", "top" is the default

5. Click OK and run the transformation scenario.

### Customizing the Output

The **DITA-OT CSS-based PDF Publishing plugin** makes it very easy to style and customize the PDF output of your DITA projects without having to work with `xsl:fo` customizations. You can style the PDF output by simply using a custom CSS to change the styling and then re-running the transformation scenario until you get the desired result.

For more information about customizing the output, see: [CSS-based DITA to PDF Customization (on page 2013)](on page 2013).

### Changing the Style of an Element

To change the style of a particular element, you need to create an additional CSS file that will store the customization rules. Once you have created this file, you need to instruct the editor how to use this additional CSS. This can be done in two ways:

- Specify the path to your custom CSS using the `args.css` parameter:
  1. Edit a **DITA Map to PDF - based on DITA & CSS (WYSIWYG)** transformation scenario.
2. In the **Parameters** tab, specify the path to your custom CSS files in the `args.css` parameter.
3. Click **OK** and run the transformation scenario.

This method is appropriate if you just want to apply the styling customization to the output.

- Create an alternate CSS for the DITA document type:
  1. Follow the procedure for adding an alternate CSS file in [Customizing Author Mode Using CSS Files Associated with a Framework](on page 2346).
  2. Once you have configured your CSS as an additional layer, you can **select it from the Styles drop-down menu (on the toolbar)** (on page 2348).
  3. Run the **DITA Map to PDF - based on DITA & CSS (WYSIWYG)** transformation scenario and the customization rules from the additional CSS will be visible in the produced PDF.

This method allows you to have many customization CSS files and simply select the one that you need at any time for both the output and the rendering in **Author** mode.

**DITA Map to PDF - based on XSL-FO Transformation**

Oxygen XML Editor comes bundled with the DITA Open Toolkit that provides a mechanism for converting **DITA maps** (on page 3281) to PDF output.

**Creating a DITA Map to PDF - based on XSL-FO Transformation Scenario**

To create a **DITA Map to PDF - based on XSL-FO** transformation scenario, follow these steps:
1. Click the Configure Transformation Scenario(s) button from the DITA Maps Manager (on page 2990) toolbar.
2. Select DITA Map PDF - based on XSL-FO and click the Edit button (or use the Duplicate button if your framework (on page 3282) is read-only).
3. Use the various tabs to configure the transformation scenario. In the Parameters tab, you can use a variety of parameters to customize the output. For example, the following parameters are just a few of the most commonly used ones:
   - show.changes.and.comments - If set to yes, user comments, replies to comments, and tracked changes are published in the PDF output.
   - customization.dir - Specifies the path to a customization directory.
   - editlink.remote.ditamap.url - When this parameter is set to “true”, the DITA topic path is displayed to the right of each topic title in the PDF output.
4. Click OK and then the Apply Associated button to run the transformation scenario.

### DITA Map to MS Office Word Transformation

Oxygen XML Editor comes bundled with a transformation scenario that allows you to convert DITA maps (on page 3281) to Microsoft Office Word documents. It utilizes the DITA to Word plugin created by Jarno Elovirta. This plugin contains a Word document named Normal.docx (located in: \[OXYGEN_INSTALL_DIR\]/frameworks/dita/DITA-OT3.x/plugins/com.elovirta.ooxml/resources) that is used by the transformation scenario as a template to generate the final Word document.

Tip: You can make general modifications to the Normal.docx template file to alter the published output.

### Configuring the Transformation Scenario

To configure an DITA Map to MS Office Word transformation scenario, follow these steps:

1. Open the DITA map in the DITA Maps Manager (on page 2990).
2. Click the Configure Transformation Scenario(s) button from the DITA Maps Manager (on page 2990) toolbar.
3. Select DITA Map MS Office Word.
4. For advanced customizations, in the **Parameters** tab you can use any of the following parameters that are unique to this transformation scenario to specify paths to files that affect the output in various ways:

- **.dotx.file** - Specifies the path to a Word template file (.docx) that will be used in the transformation to generate the final Word document. Set this parameter if you want to use a different template file other than the **Normal.docx** file that is used by default.
- **.document.flat.xsl** - Specifies the path to a pre-process clean-up stylesheet.
- **.core.xsl** - Specifies the path to a core metadata stylesheet.
- **.custom.xsl** - Specifies the path to a custom metadata stylesheet.
- **.document.xsl** - Specifies the path to a main document stylesheet.
- **.comments.xsl** - Specifies the path to a comments stylesheet.
- **.numbering.xsl** - Specifies the path to a list and title numbering stylesheet.
- **.footnotes.xsl** - Specifies the path to a footnote stylesheet.
- **.document.xml.xsl** - Specifies the path to a document relations metadata stylesheet.
- **.inkscape.exec** - Specifies the path to an Inkscape (open-source vector graphics editor) executable file.

5. Click **OK** and run the transformation scenario.

**Result:** The result of the transformation will automatically be opened in your system's default word processing application (such as Microsoft Word).

**DITA Map to CHM (Compiled HTML Help) Transformation**

To perform a **Compiled HTML Help (CHM)** transformation, Oxygen XML Editor needs [Microsoft HTML Help Workshop](#) to be installed on your computer. Oxygen XML Editor automatically detects HTML Help Workshop and uses it.

**Note:** HTML Help Workshop might fail if the files used for transformation contain accents in their names, due to different encodings used when writing the .hhp and .hhc files. If the transformation fails to produce the CHM output but the .hhp (HTML Help Project) file is already generated, you can manually try to build the CHM output using HTML Help Workshop.
Changing the Output Encoding

Oxygen XML Editor uses the `htmlhelp.locale` parameter to correctly display specific characters of different languages in the output of the Compiled HTML Help (CHM) transformation. By default, the DITA Map CHM transformation scenario that comes bundled with Oxygen XML Editor has the `htmlhelp.locale` parameter set to `en-US`.

To customize this parameter, follow this procedure:

1. Use the `Configure Transformation Scenario(s)` (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu.
2. Select the DITA Map CHM transformation scenario and click the Edit button.
3. In the Parameter tab, search for the `htmlhelp.locale` parameter and change its value to the desired language tag.

**Note:** The format of the `htmlhelp.locale` parameter is `LL-CC`, where `LL` represents the language code (e.g., `en` for English) and `CC` represents the country code (e.g., `US` for the USA). The language codes are contained in the ISO 639-1 standard and the country codes are contained in the ISO 3166-1 standard. For further details about language tags, go to [http://www.rfc-editor.org/rfc/rfc5646.txt](http://www.rfc-editor.org/rfc/rfc5646.txt).

DITA Map to Kindle Transformation

Oxygen XML Editor requires KindleGen to generate Kindle output from DITA maps (on page 3281).

To install KindleGen for use by Oxygen XML Editor, follow these steps:

1. Go to [www.amazon.com/kindleformat/kindlegen](http://www.amazon.com/kindleformat/kindlegen) and download the zip file that matches your operating system.
2. Unzip the file on your local disk.
3. Start Oxygen XML Editor and open a DITA map in the DITA Maps Manager view (on page 2990).
4. Click the `Configure Transformation Scenario(s)` button.
5. Select the DITA Map Kindle transformation and press the Edit button to edit it.
6. Go to Parameters tab and set the `kindlegen.executable` parameter as the path to the KindleGen directory.
7. Accept the changes.

Run DITA OT Integrator Transformation

Oxygen XML Editor comes bundled with a transformation scenario designed to integrate DITA-OT plugins (on page 3285). These DITA-OT plugins are used for various customizations. It is called
Run DITA-OT Integrator and is found in the DITA Map section of the Configure Transformation Scenario(s) dialog box (on page 1762).

⚠️ Attention: The integration will be performed on the DITA-OT version specified in the DITA Open Toolkit section of the DITA preferences page (on page 225).

Running the Transformation Scenario

To integrate a DITA OT plugin, follow these steps:

1. If Oxygen XML Editor was installed in the default location, you may need to restart and run it as an administrator.
2. Select the Apply Transformation Scenario(s) or Configure Transformation Scenario(s) (on page 1762) action from the DITA Maps Manager toolbar (you could also use the same action on the main toolbar or open the Transformation Scenarios view (on page 1768)).
3. Select the Run DITA-OT Integrator transformation scenario. If the integrator is not visible, select the Show all scenarios action that is available in the Settings drop-down menu.
4. Apply the scenario (on page 1761).
5. Check the Results panel at the bottom of the application to make sure the build was successful.
6. Restart Oxygen XML Editor with your normal permissions.

Solving DITA Transformation Errors

If a DITA transformation results in errors or warnings, the information is displayed in the message panel at the bottom of the editor. The information includes the severity, description of the problem, the name of the resource, and the path of the resource.

To help prevent and solve DITA transformation problems, follow these steps:
1. Validate the DITA map (on page 3036) by using the Validate and Check for Completeness action that is available on the DITA Maps Manager (on page 2990) toolbar and in the DITA Maps menu.

2. If this action results in validation errors, solve them prior to executing the transformation. Also, you should pay attention to the warning messages because they may identify problems in the transformation.

3. Run the DITA transformation scenario (on page 1702).

4. If the transformation results in errors or warnings, they are displayed in the Results panel (on page 357) at the bottom of the editor. The following information is presented to help you troubleshoot the problems:
   - **Severity** - The first column displays the following icons that indicate the severity of the problem:
     - Informational - The transformation encountered a condition of which you should be aware.
     - Warning - The transformation encountered a problem that should be corrected.
     - Error - The transformation encountered a more severe problem, and the output is affected or cannot be generated.
   - **Info** - You can click the See More icon to open a web page that contains details about DITA-OT error messages.
   - **Description** - A description of the problem.
   - **Resource** - The name of the transformation resource.
   - **System ID** - The path of the transformation resource.

5. Use this information or other resources from the online DITA-OT community to solve the transformation problems before re-executing the transformation scenario.

6. If you need to contact the Oxygen technical support team, they will need you to send the entire transformation scenario execution log. To obtain it:
   a. Go to the Options > Preferences > DITA preferences page and set the Show console output option to Always.
   b. Execute the transformation scenario again. The console output messages are displayed in the DITA OT view.
   c. Copy the entire log, save it in a text file, then send it to the Oxygen technical support team.
   d. After your issue has been solved, go back to the Options > Preferences > DITA preferences page and set the Show console output option to When build fails.

Related Information:

- Troubleshooting DITA Transformation Problems (on page 3217)
DocBook Transformation Scenarios

Built-in transformation scenarios allow you to transform DocBook documents to a variety of outputs, such as WebHelp, PDF, HTML, HTML Chunk, XHTML, XHTML Chunk, and EPUB. Oxygen XML Editor also includes a DocBook 5.1 transformation scenario for Assembly documents. All of them are listed in the DocBook 4 and DocBook 5 sections in the Configure Transformation Scenario(s) dialog box (on page 1762).

Related Information:

- Editing a Transformation Scenario (on page 1758)

- Applying Associated Transformation Scenarios (on page 1761)

DocBook to WebHelp Classic Transformation

DocBook documents can be transformed into several types of WebHelp systems (with or without a feedback section). The WebHelp Classic layout and features (on page 1773) are designed for desktop systems and include a familiar classical style. Oxygen XML Editor also provides numerous possibilities for customizing the WebHelp Classic output (on page 1806).

WebHelp Classic Transformation Scenario

To publish a DocBook document as a WebHelp Classic system, follow these steps:

1. Click the Configure Transformation Scenario(s) action from the toolbar (or the Document > Transformation menu).
2. Select the DocBook WebHelp Classic scenario from the DocBook 4 or DocBook 5 section.
3. Click Apply associated.

When the DocBook WebHelp Classic transformation is complete, the output is automatically opened in your default browser.

WebHelp Classic with Feedback Transformation Scenario

To publish a DocBook document as a WebHelp Classic with Feedback system, follow these steps:

1. Click Configure Transformation Scenarios.
2. Select the **DocBook WebHelp Classic with Feedback** scenario from the **DocBook 4** or **DocBook 5** section.

3. Click **Apply associated**.

4. Enter the documentation product ID and the documentation version.

When the **DocBook WebHelp Classic with Feedback** transformation is complete, your default browser opens the **installation.html** file. This file contains information about the output location, system requirements, installation instructions, and deployment of the output. Follow the instructions to complete the system deployment. For more information, see **Deploying a Feedback-Enabled System (on page 1873)**.

For more information about the feedback-enabled WebHelp system, watch our video demonstration:

https://www.youtube.com/embed/eoQ2uxHvppE

**Customizing DocBook WebHelp Transformation Scenarios**

To customize a DocBook WebHelp transformation scenario, you can edit various parameters, including the following most commonly used ones:

- **default.language**
  
  This parameter is used if the language is not detected in the **DITA map**. The default value is **en-us**.

- **clean.output**
  
  Deletes all files from the output folder before the transformation is performed (only **no** and **yes** values are valid and the default value is **no**).

- **l10n.gentext.default.language**
  
  This parameter is used to identify the correct stemmer that differs from language to language. For example, for English the value of this parameter is **en** or for French it is **fr**, and so on.

- **use.stemming**
  
  Controls whether or not you want to include stemming search algorithms into the published output (default setting is **false**).

- **webhelp.copyright**
  
  Adds a small copyright text that appears at the end of the **Table of Contents** pane.

- **webhelp.custom.resources**
  
  The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.
webhelp.favicon

The file path that points to an image to be used as a favicon in the WebHelp output.

webhelp.footer.file

Path to an XML file that includes the footer content for your WebHelp output pages. You can use this parameter to integrate social media features (such as widgets for Facebook™, Twitter™, Google Analytics, or Google+™). The file must be well-formed, each widget must be in separate `div` or `span` element, and the code for each `script` element is included in an XML comment (also, the start and end tags for the XML comment must be on a separate line). The following code excerpt is an example for adding a Facebook™ widget:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<div id="facebook">
  <div id="fb-root"/>
  <script>
    //<![CDATA[
    (function(d, s, id) {
      var js, fjs = d.getElementsByTagName(s)[0];
      if (d.getElementById(id)) return;
      js = d.createElement(s); js.id = id;
      js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
      fjs.parentNode.insertBefore(js, fjs);
    }(document, 'script', 'facebook-jssdk'));
    //]]>

    <div data-share="true" data-show-faces="true" data-action="like"
      data-layout="standard" class="fb-like">
    </div>
  </script>
</div>
```

webhelp.footer.include

Specifies whether or not to include footer in each WebHelp page. Possible values: yes, no. If set to no, no footer is added to the WebHelp pages. If set to yes and the `webhelp.footer.file` parameter has a value, then the content of that file is used as footer. If the `webhelp.footer.file` has no value then a default Oxygen footer is inserted in each WebHelp page.

webhelp.logo.image.target.url

Specifies a target URL that is set on the logo image. When you click the logo image, you will be redirected to this address.

webhelp.logo.image

Specifies a path to an image displayed as a logo in the left side of the output header.

webhelp.product.id (available only for Feedback-enabled systems)
This parameter specifies a short name for the documentation target, or product (for example, mobile-phone-user-guide, hvac-installation-guide).

**Note:** You can deploy documentation for multiple products on the same server.

**Restriction:** The following characters are not allowed in the value of this parameter:

< > / \ ' ( ) { } = ; * % + &

**webhelp.product.version (available only for Feedback-enabled systems)**

Specifies the documentation version number (for example, 1.0, 2.5, etc.). New user comments are bound to this version.

**Note:** Multiple documentation versions can be deployed on the same server.

**Restriction:** The following characters are not allowed in the value of this parameter:

< > / \ ' ( ) { } = ; * % + &

**webhelp.search.ranking**

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the Search tab (default setting is `true`).

**webhelp.skin.css**

Path to a CSS file that sets the style theme in the WebHelp Classic output. It can be one of the built-in skin CSS from the OXYGEN_INSTALL_DIR\frameworks\docbook\xsl\com.oxygenxml.webhelp.classic\predefined-skins directory, or it can be a custom skin CSS generated with the Oxygen Skin Builder web application.

**Related Information:**

- DITA Map to WebHelp Classic Transformation *(on page 1652)*
- Customizing WebHelp Classic Output *(on page 1806)*

**DocBook to DITA Transformation**

Oxygen XML Editor includes a built-in transformation scenario that is designed to convert DocBook content to DITA. This transformation scenario is based upon a DITA Open Toolkit plugin that is available at sourceforge.net.
To convert a DocBook document to DITA, follow these steps:

1. Use one of the following two methods to begin the transformation process:
   • To apply the transformation scenario to a newly opened file, use the ☰️ *Apply Transformation Scenario(s) (Ctrl + Shift + T (Command + Shift + T on OS X))* action from the toolbar or the **Document > Transformation** menu.
   • To customize the transformation or change the scenario that is associated with the document, use the ⚙️ *Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))* action from the toolbar or the **Document > Transformation** menu.

2. Select the **DocBook to DITA** transformation scenario in the **DocBook 4** or **DocBook 5** section.
3. Click the **Apply associated** button to run the transformation.

   **Step Result:** The transformation will convert as many of the DocBook elements into equivalent DITA elements as it can recognize in its mapping process. For elements that cannot be mapped, the transformation will insert XML comments so that you can see which elements could not be converted.
4. Adjust the resulting DITA composite to suit your needs. You may have to remove comments, fix validation errors, adjust certain attributes, or split the content into individual topics.

**Related Information:**

- *Editing a Transformation Scenario (on page 1758)*
- *Configure Transformation Scenario(s) Dialog Box (on page 1762)*

**DocBook to PDF Transformation**

Oxygen XML Editor includes a built-in transformation scenario that is designed to convert DocBook content to PDF.

To convert a DocBook document to PDF, follow these steps:

1. Use one of the following two methods to begin the transformation process:
   • To apply the transformation scenario to a newly opened file, use the ☰️ *Apply Transformation Scenario(s) (Ctrl + Shift + T (Command + Shift + T on OS X))* action from the toolbar or the **Document > Transformation** menu.
   • To customize the transformation or change the scenario that is associated with the document, use the ⚙️ *Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))* action from the toolbar or the **Document > Transformation** menu.

2. Select the **DocBook PDF** transformation scenario in the **DocBook 4** or **DocBook 5** section.
3. Click the **Apply associated** button to run the transformation.

For information about customizing the PDF output for DocBook content, see *DocBook to PDF Output Customization* (on page 2180).

**Related Information:**

- Editing a Transformation Scenario (on page 1758)
- Configure Transformation Scenario(s) Dialog Box (on page 1762)
- DocBook to PDF Output Customization (on page 2180)

### DocBook to EPUB Transformation

Oxygen XML Editor includes a built-in transformation scenario that is designed to convert DocBook content to EPUB. The EPUB specification recommends the use of *OpenType* fonts (recognized by their `.otf` file extension) whenever possible. To use a specific font, follow these steps:

1. Declare it in your CSS file, as in the following example:

   ```
   @font-face {
     font-family: "MyFont";
     font-weight: bold;
     font-style: normal;
     src: url(fonts/MyFont.otf);
   }
   ```

2. In the CSS, specify where this font is used. To set it as default for `h1` elements, use the `font-family` rule, as in the following example:

   ```
   h1 {
     font-size: 20pt;
     margin-bottom: 20px;
     font-weight: bold;
     font-family: "MyFont";
     text-align: center;
   }
   ```

3. Open the **Configure Transformation Scenario(s) dialog box** (on page 1762), select the DocBook **EPUB** transformation scenario in the DocBook 4 or DocBook 5 section, and click **Edit**.
4. In the Parameters tab, set the `epub.embedded.fonts` parameter to `fonts/MyFont.otf`. If you need to provide more files, use commas to separate their file paths.

   **Note:** The `html.stylesheet` parameter allows you to include a custom CSS in the output EPUB.

5. Run the transformation scenario.

### DocBook PDF (Show Change Tracking and Comments)

Oxygen XML Editor includes a built-in transformation scenario that is designed to show tracked changes and comment in DocBook to PDF output.

To include comments and tracked changes (stored within your DocBook 5 documents) in the PDF output, follow these steps:

1. Click the **Configure Transformation Scenario(s)** button.
2. Select **DocBook PDF (Show Change Tracking and Comments)** in the DocBook 5 section.
3. If you need to configure the transformation, click the **Edit** (on page 1758) or **Duplicate** (on page 1760) button, make your changes to the scenario, and click **OK**.
4. Click the **Apply Associated** button to run the transformation scenario.

   **Result:** Comment threads and tracked changes will now appear in the PDF output. Details about each comment or change will be available in the footer section for each page.

### Creating New Transformation Scenarios

Defining a transformation scenario is the first step in the process of transforming a document. This section includes information on the types of new scenarios that are available in Oxygen XML Editor and how to create each type of transformation.

### XML Transformation with XSLT

This type of transformation specifies the transformation parameters and location of an XSLT stylesheet that is applied to the edited XML document. This scenario is useful when you develop an XML document and the XSLT document is in its final form.

To create an **XML transformation with XSLT** scenario, use one of the following methods:

- Use the **Configure Transformation Scenario(s)** (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the **Document > Transformation** menu. Then click the **New** button and select **XML transformation with XSLT**.
Go to Window > Show View and select Transformation Scenarios to display this view (on page 1768). Click the New Scenario drop-down menu button and select XML transformation with XSLT.

Both methods open the New Scenario dialog box.

The upper part of the dialog box allows you to specify the Name of the transformation scenario and the following Storage options:

- **Project Options (on page 3286)** - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- **Global Options (on page 3283)** - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

**XSLT Tab**

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The XSLT tab contains the following options:

**XML URL**

Specifies the source XML file. You can specify the path by using the text field, its history drop-down, the Insert Editor Variables (on page 276) button, or the browsing actions in the Browse drop-down list. You can also use the Open in editor button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, then the file is used directly from its remote location.

**Note:** If the transformer engine is Saxon 9.x and a custom URI resolver is configured in the advanced Saxon preferences page (on page 204), the XML input of the transformation is passed to that URI resolver. If the transformer engine is one of the built-in XSLT 2.0 / 3.0 engines and the name of an initial template (on page 1676) is specified in the scenario, the XML URL field can be empty. The XML URL field can also be empty if you use external XSLT processors (on page 1689). Otherwise, a value is mandatory in this field.

**XSL URL**
Specifies the source XSL file that the transformation will use. You can specify the path by using the text field, its history drop-down, the Insert Editor Variables button, or the browsing actions in the Browse drop-down list. You can also use the Open in editor button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, the file is used directly from its remote location.

**Use "xml-stylesheet" declaration**

If selected, the scenario applies the stylesheet specified explicitly in the XML document with the xml-stylesheet processing instruction. By default, this option is deselected and the transformation applies the XSLT stylesheet that is specified in the XSL URL field.

**Transformer**

This drop-down menu presents all the transformation engines available to Oxygen XML Editor for performing a transformation. These include the built-in engines and the external engines defined in the Custom Engines preferences page (on page 215). The engine you choose is used as the default transformation engine. Also, if an XSLT or XQuery document does not have an associated validation scenario, this transformation engine is used in the validation process (if it provides validation support).

**Advanced options**

Allows you to configure the advanced options of the Saxon HE/PE/EE engine (on page 1679) for the current transformation scenario. To configure the same options globally, go to the Saxon-HE/PE/EE preferences page (on page 201). For the current transformation scenario, these Advanced options override the options configured in that preferences page.

**Parameters**

Opens a Configure parameters dialog box (on page 1677) that allows you to configure the XSLT parameters used in the current transformation. In this dialog box, you can also configure the parameters for additional XSLT stylesheets (on page 1676). If the XSLT transformation engine is custom-defined, you can not use this dialog box to configure the parameters sent to the custom engine. Instead, you can copy all parameters from the dialog box using contextual menu actions and edit the custom XSLT engine to include the necessary parameters in the command line that starts the transformation process.

**Extensions**

Opens a dialog box for configuring the XSLT extension JARS or classes (on page 1678) that define extension Java functions or extension XSLT elements used in the transformation.

**Additional XSLT stylesheets**
Opens a dialog box for adding XSLT stylesheets (on page 1678) that are applied on the main stylesheet specified in the XSL URL field. This is useful when a chain of XSLT stylesheets must be applied to the input XML document.

**XSLT Parameters**

The global parameters of the XSLT stylesheet used in a transformation scenario can be configured by using the Parameters button in the XSLT tab of a new or edited transformation scenario dialog box.

The resulting dialog box includes a table that displays all the parameters of the current XSLT stylesheet, all imported and included stylesheets, and all additional stylesheets (on page 1678), along with their descriptions and current values. You can also add, edit, and remove parameters, and you can use the Filter text box to search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

If the XPath column is selected, the parameter value is evaluated as an XPath expression before starting the XSLT transformation.

**Example:**

For example, you can use expressions such as:

```xml
doc('test.xml')//entry
//person[@atr='val']
```

**Note:**

1. The `doc` function solves the argument relative to the XSL stylesheet location. You can use full paths or editor variables (on page 276) (such as `$(cfdu)` [current file directory]) to specify other locations: `doc('$(cfdu)/test.xml')/*`
2. You cannot use XSLT Functions. Only XPath functions are allowed.

Below the table, the following actions are available for managing the parameters:

**New**

Opens the Add Parameter dialog box that allows you to add a new parameter to the list. An editor variable (on page 276) can be inserted in the text box using the Insert Editor Variables button. If the Evaluate as XPath option is selected, the parameter will be evaluated as an XPath expression.

**Edit**

Opens the Edit Parameter dialog box that allows you to edit the selected parameter. An editor variable (on page 276) can be inserted in the text box using the Insert Editor Variables button.
Variables button. If the **Evaluate as XPath** option is selected, the parameter will be evaluated as an XPath expression.

**Unset**

Resets the selected parameter to its default value. Available only for edited parameters with set values.

**Delete**

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

The bottom panel presents the following:

- The default value of the parameter selected in the table.
- A description of the parameter, if available.
- The system ID of the stylesheet that declares it.

### Related Information:

- Editor Variables *(on page 276)*

### XSLT Extensions

The **Extensions** button opens a dialog box that allows you to specify the [JARS *(on page 3283)*] and classes that contain extension functions called from the XSLT file of the current transformation scenario. You can use the **Add**, **Edit**, and **Remove** buttons to configure the extensions.

⚠ **Tip:** You can specify the path to the resources using wildcards (for example, `${oxygenHome}/lib/*.jar`).

An extension function called from the XSLT file of the current transformation scenario will be searched, in the specified extensions, in the order displayed in this dialog box. To change the order of the items, select the item to be moved and press the ↑ Move up or ↓ Move down buttons.

### Additional XSLT Stylesheets

Use the **Additional XSLT Stylesheets** button in the XSLT tab to display a list of additional XSLT stylesheets to be used in the transformation and you can add files to the list or edit existing entries. The following actions are available:

**Add**
Adds a stylesheet in the Additional XSLT stylesheets list using a file browser dialog box. You can type an editor variable (on page 276) in the file name field of the browser dialog box. The name of the stylesheet will be added in the list after the current selection.

Remove

Deletes the selected stylesheet from the Additional XSLT stylesheets list.

Open

Opens the selected stylesheet in a separate view.

Up

Moves the selected stylesheet up in the list.

Down

Moves the selected stylesheet down in the list.

Advanced Saxon HE/PE/EE XSLT Transformation Options

The XSLT transformation scenario allows you to configure advanced options that are specific for the Saxon HE (Home Edition), PE (Professional Edition), and EE (Enterprise Edition) engines. They are the same options as those in the Saxon HE/PE/EE preferences page (on page 201) but they are configured as a specific set of transformation options for each transformation scenario, while the values set in the preferences page apply as global options. The advanced options configured in a transformation scenario override the global options (on page 3283) defined in the preferences page.

Saxon-HE/PE/EE Options

The advanced options for Saxon 9.8.0.12 Home Edition (HE), Professional Edition (PE), and Enterprise Edition (EE) are as follows:

Mode ("-im")

A Saxon-specific option that sets the initial mode for the transformation. If this value is also specified in a configuration file (on page 1679), the value in this option takes precedence.

Template ("-it")

A Saxon-specific option that sets the name of the initial XSLT template to be executed. If this value is also specified in a configuration file (on page 1679), the value in this option takes precedence.

Use a configuration file ("-config")

Select this option if you want to use a Saxon 9.8.0.12 configuration file that will be executed for the XSLT transformation and validation processes. You can specify the
path to the configuration file by entering it in the URL field, or by using the Insert Editor Variables button, or using the browsing actions in the Browse drop-down list.

**Debugger trace into XPath expressions (applies to debugging sessions)**

Instructs the XSLT Debugger (on page 2309) to step into XPath expressions.

**Enable Optimizations ("-opt")**

This option is selected by default, which means that optimization is enabled. If not selected, the optimization is suppressed, which is helpful when reducing the compiling time is important, optimization conflicts with debugging, or optimization causes extension functions with side-effects to behave unpredictably.

**Line numbering ("-l")**

Line numbers where errors occur are included in the output messages.

**Expand attributes defaults ("-expand")**

Specifies whether or not the attributes defined in the associated DTD or XML Schema are expanded in the output of the transformation you are executing.

**DTD validation of the source ("-dtd")**

Specifies whether or not the source document will be validated against their associated DTD. You can choose from the following:

- **On** - Requests DTD validation of the source file and of any files read using the document() function.
- **Off** - (default setting) Suppresses DTD validation.
- **Recover** - Performs DTD validation but treats the errors as non-fatal.

**Note:** Any external DTD is likely to be read even if not used for validation, since DTDs can contain definitions of entities.

**Recoverable errors ("-warnings")**

Specifies how dynamic errors are handled. The following options can be selected:

- **Recover silently ("silent")** - Continues processing without reporting the error.
- **Recover with warnings ("recover")** - Issues a warning but continues processing.
- **Signal the error and do not attempt recovery ("fatal")** - Issues an error and stops processing.

**Strip whitespaces ("-strip")**

Specifies how the strip whitespaces operation is handled. You can choose one of the following values:
• **All ("all")** - Strips all whitespace text nodes from source documents before any further processing, regardless of any `xml:space` attributes in the source document.

• **Ignore ("ignorable")** - Strips all ignorable whitespace text nodes from source documents before any further processing, regardless of any `xml:space` attributes in the source document. Whitespace text nodes are ignorable if they appear in elements defined in the DTD or schema as having element-only content.

• **None ("none")** - Strips no whitespace before further processing.

### Saxon-PE/EE Options

The following advanced options are specific for Saxon 9.8.0.12 Professional Edition (PE) and Enterprise Edition (EE) only:

**Register Saxon-JS extension functions and instructions**

Registers the Saxon-CE extension functions and instructions when compiling a stylesheet using the Saxon 9.8.0.12 processors.

**Note:** Saxon-CE, being JavaScript-based, was designed to run inside a web browser. This means that you will use Oxygen XML Editor only for developing the Saxon-CE stylesheet, leaving the execution part to a web browser. See more details about executing such a stylesheet on Saxonica’s website.

**Allow calls on extension functions ("-ext")**

If selected, the stylesheet is allowed to call external Java functions. This does not affect calls on integrated extension functions, including Saxon and EXSLT extension functions. This option is useful when loading an untrusted stylesheet (such as from a remote site using `http://[URL]`). It ensures that the stylesheet cannot call arbitrary Java methods and thus gain privileged access to resources on your machine.

**Enable assertions ("-ea")**

In XSLT 3.0, you can use the `xsl:assert` element to make assertions in the form of XPath expressions, causing a dynamic error if the assertion turns out to be false. If this option is selected, XSLT 3.0 `xsl:assert` instructions are enabled. If it is not selected (default), the assertions are ignored.

### Saxon-EE Options

The advanced options that are specific for Saxon 9.8.0.12 Enterprise Edition (EE) are as follows:

**XML Schema version**

Use this option to change the default XML Schema version for this transformation. To change the default XML Schema version globally, open the Preferences dialog box.
(Options > Preferences) (on page 79) and go to XML > XML Parser > XML Schema and use the Default XML Schema version option (on page 193).

Validation of the source file ("-val")

Requests schema-based validation of the source file and of any files read using document() or similar functions. It can have the following values:

- **Schema validation ("strict")** - This mode requires an XML Schema and allows for parsing the source documents with strict schema-validation enabled.
- **Lax schema validation ("lax")** - If an XML Schema is provided, this mode allows for parsing the source documents with schema-validation enabled but the validation will not fail if, for example, element declarations are not found.
- **Disable schema validation** - This specifies that the source documents should be parsed with schema-validation disabled.

Validation errors in the result tree treated as warnings ("-outval")

Normally, if validation of result documents is requested, a validation error is fatal. Selecting this option causes such validation failures to be treated as warnings.

Write comments for non-fatal validation errors of the result document

The validation messages for non-fatal errors are written (wherever possible) as a comment in the result document itself.

Enable streaming mode

Selecting this option will allow an XSLT to run in streaming mode. It is not selected by default.

Other Options

**Initializer class**

Equivalent to the -init Saxon command-line argument. The value is the name of a user-supplied class that implements the net.sf.saxon.lib.Initializer interface. This initializer is called during the initialization process, and may be used to set any options required on the configuration programmatically. It is particularly useful for tasks such as registering extension functions, collations, or external object models, especially in Saxon-HE where the option cannot be set via a configuration file. Saxon only calls the initializer when running from the command line, but the same code may be invoked to perform initialization when running user application code.
Using Saxon Integrated Extension Functions

Saxon, the transformation and validation engine used by Oxygen XML Editor, can be customized by adding custom functions (called Integrated Extension Functions) that can be called from XPath.

To define such a function, follow these steps:

1. Create a file with a Java class that extends net.sf.saxon.lib.ExtensionFunctionDefinition. Here is an example:

```java
private static class ShiftLeft extends ExtensionFunctionDefinition {
    @Override
    public StructuredQName getFunctionQName() {
        return new StructuredQName("eg", "http://example.com/saxon-extension", "shift-left");
    }
}

@override
public SequenceType[] getArgumentTypes() {
    return new SequenceType[] {SequenceType.SINGLE_INTEGER, SequenceType.SINGLE_INTEGER};
}

@Override
public SequenceType getResultType(SequenceType[] suppliedArgumentTypes) {
    return SequenceType.SINGLE_INTEGER;
}

@Override
public ExtensionFunctionCall makeCallExpression() {
    return new ExtensionFunctionCall() {
        public SequenceIterator call(SequenceIterator[] arguments, XPathContext context) throws XPathException {
            long v0 = ((IntegerValue)arguments[0].next()).longValue();
            long v1 = ((IntegerValue)arguments[1].next()).longValue();
            long result = v0<<v1;
            return Value.asIterator(Int64Value.makeIntegerValue(result));
        }
    };
}
```
2. Compile the class and add it to a JAR file.

3. Add a file called net.sf.saxon.lib.ExtensionFunctionDefinition that contains the fully qualified name of the Java class in the META-INF/services/ folder of the JAR file.

**Note:** To add more function definitions in the same JAR file, you need to add their fully qualified names on different lines.

To enable Oxygen XML Editor to pick up your custom function definition, the JAR file should be added to the classpath of the transformer. Here are some possibilities:

- If you develop a framework, you just need to link the JAR file in the Classpath tab (on page 99).
- In a validation scenario (on page 1094), you can use the Extensions button to open a dialog box where you can add libraries.
- In a transformation scenario, you can use the Extensions button in the XSLT tab (on page 1676) to open a dialog box where you can add libraries.
- You can also create a plugin that contributes such a JAR file in the classpath (on page 2580).

**FO Processor Tab (XSLT Transformations)**

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The FO Processor tab contains the following options:

**Perform FO Processing**

Specifies whether or not an FO processor is applied (either the built-in Apache FOP engine or an external engine defined in Preferences) during the transformation.

**Input**

Choose between the following options to specify which input file to use:

- **XSLT result as input** - The FO processor is applied to the result of the XSLT transformation that is defined in the XSLT tab.
- **XML URL as input** - The FO processor is applied to the input XML file.

**Method**

The output format of the FO processing. The available options depend on the selected processor type.
Processor

Specifies the FO processor to be used for the transformation. It can be the built-in Apache FOP processor or an external processor (on page 216).

Output Tab (XSLT Transformations)

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The Output tab contains the following options:

Prompt for file

At the end of the transformation, a file browser dialog box is displayed for specifying the path and name of the file that stores the transformation result.

Save As

The path of the file where the result of the transformation is stored. You can specify the path by using the text field, the Insert Editor Variables (on page 276) button, or the Browse button.

Open in Browser/System Application

If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the file type of the result (for example, in Windows PDF files are often opened in Acrobat Reader).

Note: To set the web browser that is used for displaying HTML/XHTML pages, go to Options > Preferences > Global, and set it in the Default Internet browser field.

- **Output file** - When Open in Browser/System Application is selected, you can use this button to automatically open the default output file at the end of the transformation.
- **Other location** - When Open in Browser/System Application is selected, you can use this option to open the file specified in this field at the end of the transformation.
  
  You can specify the path by using the text field, the Insert Editor Variables (on page 276) button, or the Browse button.

Open in editor

When this option is selected, at the end of the transformation, the default output file is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor, or if it is an XSL-FO file it is opened with the built-in FO editor).
Show in results view as

You can choose to view the results in one of the following:

- **XML** - If this is selected, Oxygen XML Editor displays the transformation result in an XML viewer panel at the bottom of the application window with syntax highlighting (on page 178).

- **SVG** - If this is selected, Oxygen XML Editor displays the transformation result in an integrated SVG viewer in the Results panel (on page 1502) at the bottom of the application window and renders the result as an SVG image.

- **XHTML** - This option is only available if **Open in Browser/System Application** is not selected. If selected, Oxygen XML Editor displays the transformation result in a built-in XHTML browser panel at the bottom of the application window.

⚠️ **Important:** When transforming very large documents, you should be aware that selecting this option may result in very long processing times. This drawback is due to the built-in Java XHTML browser implementation. To avoid delays for large documents, if you want to see the XHTML result of the transformation, you should use an external browser by selecting the **Open in Browser/System Application** option instead.

- **Image URLs are relative to** - If **Show in results view as XHTML** is selected, this option specifies the path used to resolve image paths contained in the transformation result. You can specify the path by using the text field, the ⌘ Insert Editor Variables (on page 276) button, or the ⚪ Browse button.

⚠️ **Attention:** If your input XSLT contains `<xsl:result-document>` elements, then the secondary results will be saved to the specified URLs while the principal result is specified in this Output tab. For more information, see: https://www.w3.org/TR/xslt-30/#element-result-document.

Configuring an XSLT Processor for Generating Output

This section explains how to configure an XSLT processor and extensions for such a processor in Oxygen XML Editor.

**Supported XSLT Processors**

Oxygen XML Editor includes the following XSLT processors:

- **Xalan 2.7.2** - Xalan-Java is an XSLT processor for transforming XML documents into HTML, text, or other XML document types. It implements XSL Transformations (XSLT) Version 1.0 and XML Path Language (XPath) Version 1.0.
• **Saxon 6.5.5** - Saxon 6.5.5 is an XSLT processor that implements the Version 1.0 XSLT and XPath with a number of powerful extensions. This version of Saxon also includes many of the new features that were first defined in the XSLT 1.1 working draft, but for conformance and portability reasons these are not available if the stylesheet header specifies `version="1.0"`.

• **Saxon 9.8.0.12 Home Edition (HE), Professional Edition (PE)** - Saxon-HE/PE implements the basic conformance level for XSLT 2.0 / 3.0 and XQuery 1.0. The term *basic XSLT 2.0 / 3.0 processor* is defined in the draft XSLT 2.0 / 3.0 specifications. It is a conformance level that requires support for all features of the language other than those that involve schema processing. The HE product remains open source, but removes some of the more advanced features that are present in Saxon-PE.

• **Saxon 9.8.0.12 Enterprise Edition (EE)** - Saxon EE is the schema-aware edition of Saxon and it is one of the built-in processors included in Oxygen XML Editor. Saxon EE includes an XML Schema processor, and schema-aware XSLT, XQuery, and XPath processors.

The validation in schema aware transformations is done according to the XML Schema 1.0 or 1.1. This can be configured in Preferences (on page 192).

**Note:** Oxygen XML Editor implements a Saxon framework that allows you to create Saxon configuration files. Two templates are available: Saxon collection catalog and Saxon configuration. Both of these templates support content completion, element annotation, and attribute annotation.

**Note:** Saxon can use the *ICU-J localization library* (`saxon9-icu.jar`) to add support for sorting and date/number formatting in a wide variety of languages. This library is not included in the Oxygen XML Editor installation kit. However, Saxon will use the default collation and localization support available in the currently used JRE. To enable this capability, follow these steps:

2. Unpack the downloaded archive.
3. Create a new XSLT transformation scenario (or edit an existing one). In the XSLT tab, click the Extensions button to open the list of additional libraries used by the transformation process.
4. Click Add and browse to the folder where you unpacked the downloaded archive and choose the `saxon9-icu.jar` file.

Note that the `saxon9-icu.jar` should NOT be added to the application library folder because it will conflict with another version of the ICU-J library that comes bundled with Oxygen XML Editor.

• **Saxon-CE (Client Edition)** is Saxonica's implementation of XSLT 2.0 for use on web browsers.

Oxygen XML Editor provides support for editing stylesheets that contain Saxon-CE extension functions and instructions. This support improves the validation, content completion, and syntax highlighting.
**Note:** Saxon-CE, being JavaScript-based, was designed to run inside a web browser. This means that you will use Oxygen XML Editor only for developing the Saxon-CE stylesheet, leaving the execution part to a web browser. See more details about executing such a stylesheet on Saxonica’s website.

**Note:** A specific template, named Saxon-CE stylesheet, is available in the New document wizard (on page 676).

- **Xsltproc (libxslt)** - Libxslt is the XSLT library developed for the Gnome project. Libxslt is based on libxml2, the XML C library developed for the Gnome project. It also implements most of the EXSLT set of processor-portable extensions, functions, and some of Saxon's evaluate and expression extensions.

Oxygen XML Editor uses Libxslt through its command-line tool (Xsltproc). Depending on your operating system, you must download the Libxslt libraries on your machine from http://xmlsoft.org/XSLT/downloads.html and place them in a local folder. Then you need to update the PATH environmental variable to contain the parent folder where the xsltproc executable is located.

**Tip:** As an example, a Windows installation of the Xsltproc engine would follow these steps:

2. Unzip all of them into the same folder of your choice.
3. Edit the PATH environment variable and add the bin folder for all four archives:

   ![Edit environment variable](image)

4. Restart Oxygen XML Editor.

**Result:** You can now use the xsltproc processor as an XSLT engine in the XSLT transformation scenario.

**Note:** The Xsltproc processor can be configured from the XSLTPROC options page (on page 204).

**CAUTION:** There is a known problem where file paths that contain spaces are not handled correctly in the LIBXML processor. For example, the built-in XML Catalog (on page 3289) files
of the built-in document types (DocBook, TEI, DITA, etc.) are not handled properly by LIBXML if Oxygen XML Editor is installed in the default location on Windows (C:\Program Files). This is because the built-in XML catalog files are stored in the \OXYGEN_INSTALL_DIR\frameworks subdirectory of the installation directory, and in this case it contains a space character.

• **MSXML 4.0** - MSXML 4.0 is available only on Windows platforms. It can be used for transformation (on page 1674) and validation of XSLT stylesheets (on page 1186).

Oxygen XML Editor uses the Microsoft XML parser through its command-line tool `msxsl.exe`.

Since `msxsl.exe` is only a wrapper, Microsoft Core XML Services (MSXML) must be installed on the computer. Otherwise, you will get a corresponding warning. You can get the latest Microsoft XML parser from Microsoft web-site.

• **MSXML .NET** - MSXML .NET is available only on Windows platforms. It can be used for transformation (on page 1674) and validation of XSLT stylesheets (on page 1186).

Oxygen XML Editor performs XSLT transformations and validations using the .NET Framework XSLT implementation (`System.Xml.Xsl.XslTransform` class) through the `nxslt` command-line utility. The `nxslt` version included in Oxygen XML Editor is 1.6.

You should have the .NET Framework version 1.0 already installed on your system. Otherwise, you will get the following warning: MSXML.NET requires .NET Framework version 1.0 to be installed. Exit code: 128.

You can get the .NET Framework version 1.0 from the Microsoft website.

• **.NET 1.0** - A transformer based on the `System.Xml` 1.0 library available in the .NET 1.0 and .NET 1.1 frameworks from Microsoft (http://msdn.microsoft.com/xml/). It is available only on Windows.

You should have the .NET Framework version 1.0 or 1.1 already installed on your system. Otherwise, you will get the following warning: MSXML.NET requires .NET Framework version 1.0 to be installed. Exit code: 128.

You can get the .NET Framework version 1.0 from the Microsoft website.

• **.NET 2.0** - A transformer based on the `System.Xml` 2.0 library available in the .NET 2.0 Framework from Microsoft. It is available only on Windows.

You should have the .NET Framework version 2.0 already installed on your system. Otherwise, you will get the following warning: MSXML.NET requires .NET Framework version 2.0 to be installed. Exit code: 128.

You can get the .NET Framework version 2.0 from the Microsoft website.

For information about configuring the XSLT preferences, see the XSLT options (on page 200) section.
Configuring Custom XSLT Processors

Oxygen XML Editor allows you to configure custom processors to be used for running XSLT and XQuery transformations.

To add a new custom processor, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to XML > XSLT-FO-XQuery > Custom Engines.
2. Click the New button at the bottom of the dialog box.
3. Configure the parameters for the custom engine (on page 215).
4. Click OK.

Note: You can not use these custom engines in the Debugger perspective (on page 2290).

The output messages of a custom processor are displayed in an output view at the bottom of the application window. If an output message follows the format of an Oxygen XML Editor linked message (on page 1091), clicking it highlights the location of the message in an editor panel containing the file referenced in the message.

Related Information:

- Custom Engines Preferences (on page 215)

Configuring the XSLT Processor Extensions Paths

The Xalan and Saxon processors support the use of extension elements and extension functions. Unlike a literal result element, which the stylesheet simply transfers to the result tree, an extension element performs an action. The extension is usually used because the XSLT stylesheet fails in providing adequate functions for accomplishing a more complex task.

For more information about how to use extensions, see the following links:

- Saxon 6.5.5 - http://saxon.sourceforge.net/saxon6.5.5/extensions.html

To set an XSLT processor extension (a directory or a jar file), use the Extensions button (on page 1676) in the Edit scenario dialog box.
XML Transformation with XQuery

This type of transformation specifies the transform parameters and location of an XQuery file that is applied to the edited XML document.

Use the **XML transformation with XQuery** scenario to apply a transformation in which an XQuery file queries an XML file for the output results.

To create an **XML transformation with XQuery** scenario, use one of the following methods:

- Use the **Configure Transformation Scenario(s)** (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the **Document > Transformation** menu. Then click the **New** button and select **XML transformation with XQuery**.
- Go to **Window > Show View** and select **Transformation Scenarios** to display this view (on page 1768). Click the **+ New Scenario** drop-down menu button and select **XML transformation with XQuery**.

Both methods open the **New Scenario** dialog box.

The upper part of the dialog box allows you to specify the **Name** of the transformation scenario and the following **Storage** options:

- **Project Options** (on page 3286) - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- **Global Options** (on page 3283) - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

**XQuery Tab**

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **XQuery** tab contains the following options:

**XML URL**

Specifies the source XML file. You can specify the path by using the text field, its history drop-down, the **Insert Editor Variables** (on page 276) button, or the browsing actions in the **Browse** drop-down list. You can also use the **Open in editor** button to open
the specified file in the editor panel. This URL is resolved through the catalog resolver.
If the catalog does not have a mapping for the URL, then the file is used directly from its
remote location.

**Note:** If the transformer engine is Saxon 9.x and a custom URI resolver is configured in the
advanced Saxon preferences page (on page 204), the XML input of the transformation is passed to
that URI resolver.

XQuery URL

Specifies the source XQuery file to be used for the transformation. You can specify the
path by using the text field, its history drop-down, the 🔄 Insert Editor Variables (on page
276) button, or the browsing actions in the 🕵️‍♂️ Browse drop-down list. You can also
use the 🖨️ Open in editor button to open the specified file in the editor panel. This URL
is resolved through the catalog resolver. If the catalog does not have a mapping for the
URL, the file is used directly from its remote location.

Transformer

This drop-down menu presents all the transformation engines available to Oxygen
XML Editor for performing a transformation. These include the built-in engines and the
external engines defined in the Custom Engines preferences page (on page 215). The
engine you choose is used as the default transformation engine. Also, if an XSLT or
XQuery document does not have an associated validation scenario, this transformation
engine is used in the validation process (if it provides validation support).

⌥ Advanced options

Allows you to configure the advanced options of the Saxon HE/PE/EE engine (on
page 1694) for the current transformation scenario. To configure the same options
globally, go to the Saxon-HE/PE/EE preferences page (on page 201). For the current
transformation scenario, these Advanced options override the options configured in that
preferences page.

Parameters

Opens the Configure parameters dialog box (on page 1693) for configuring the
XQuery parameters. You can use the buttons in this dialog box to add, edit, or remove
parameters. If the XQuery transformation engine is custom-defined, you cannot use
this dialog box to set parameters. Instead, you can copy all parameters from the dialog
box using contextual menu actions and edit the custom XQuery engine to include the
necessary parameters in the command line that starts the transformation process.

Extensions
Opens a dialog box for configuring the XQuery extension JARS or classes (on page 1694) that define extension Java functions or extension XSLT elements used in the transformation.

XQuery Parameters

The global parameters of the XQuery file used in a transformation scenario can be configured by using the Parameters button in the XQuery tab.

The resulting dialog box includes a table that displays all the parameters of the current XQuery file, along with their descriptions and current values. You can also add, edit, and remove parameters, and use the Filter text box to search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

If the XPath column is selected, the parameter value is evaluated as an XPath expression before starting the XQuery transformation.

Example:

For example, you can use expressions such as:

```
doc('test.xml')//entry
//person[@atr='val']
```

**Note:**

1. The doc function solves the argument relative to the XQuery file location. You can use full paths or editor variables (on page 276) (such as $cfdu [current file directory]) to specify other locations: `doc($cfdu/test.xml')/*`
2. Only XPath functions are allowed.

Below the table, the following actions are available for managing the parameters:

**New**

Opens the Add Parameter dialog box that allows you to add a new parameter to the list. An editor variable (on page 276) can be inserted in the text box using the Insert Editor Variables button. If the Evaluate as XPath option is selected, the parameter will be evaluated as an XPath expression.

**Edit**

Opens the Edit Parameter dialog box that allows you to edit the selected parameter. An editor variable (on page 276) can be inserted in the text box using the Insert Editor Variables button.
Variables button. If the Evaluate as XPath option is selected, the parameter will be evaluated as an XPath expression.

Unset

Resets the selected parameter to its default value. Available only for edited parameters with set values.

Delete

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

The bottom panel presents the following:

- The default value of the parameter selected in the table.
- A description of the parameter, if available.
- The system ID of the stylesheet that declares it.

Related Information:

- Editor Variables (on page 276)

XQuery Extensions

The Extensions button is used to specify the JAR (on page 3283) and classes that contain extension functions called from the XQuery file of the current transformation scenario. You can use the Add, Edit, and Remove buttons to configure the extensions.

An extension function called from the XQuery file of the current transformation scenario will be searched, in the specified extensions, in the order displayed in this dialog box. To change the order of the items, select the item to be moved and press the ↑ Move up or ↓ Move down buttons.

Advanced Saxon HE/PE/EE XQuery Transformation Options

The XQuery transformation scenario allows you to configure advanced options that are specific for the Saxon HE (Home Edition), PE (Professional Edition), and EE (Enterprise Edition) engines. They are the same options as those in the Saxon HE/PE/EE preferences page (on page 209) but they are configured as a specific set of transformation options for each transformation scenario, while the values set in the preferences page apply as global options. The advanced options configured in a transformation scenario override the global options (on page 3283) defined in the preferences page.
Saxon-HE/PE/EE Options

The advanced options for Saxon 9.8.0.12 Home Edition (HE), Professional Edition (PE), and Enterprise Edition (EE) are as follows:

Use a configuration file ("-config")

Sets a Saxon 9.8.0.12 configuration file that is used for XQuery transformation and validation scenarios.

Enable Optimizations ("-opt")

This option is selected by default, which means that optimization is enabled. If not selected, the optimization is suppressed, which is helpful when reducing the compiling time is important, optimization conflicts with debugging, or optimization causes extension functions with side-effects to behave unpredictably.

Use linked tree model ("-tree:linked")

This option activates the linked tree model.

Recoverable errors ("-warnings")

Specifies how dynamic errors are handled. The following options can be selected:

- Recover silently ("silent") - Continues processing without reporting the error.
- Recover with warnings ("recover") - Issues a warning but continues processing.
- Signal the error and do not attempt recovery ("fatal") - Issues an error and stops processing.

Strip whitespaces ("-strip")

Specifies how the strip whitespaces operation is handled. You can choose one of the following values:

- All ("all") - Strips all whitespace text nodes from source documents before any further processing, regardless of any xml:space attributes in the source document.
- Ignore ("ignorable") - Strips all ignorable whitespace text nodes from source documents before any further processing, regardless of any xml:space attributes in the source document. Whitespace text nodes are ignorable if they appear in elements defined in the DTD or schema as having element-only content.
- None ("none") - Strips no whitespace before further processing.

Saxon-PE/EE Options

The following advanced options are specific for Saxon 9.8.0.12 Professional Edition (PE) and Enterprise Edition (EE) only:
Allow calls on extension functions ("-ext")

If selected, calls on external functions are allowed. Selecting this option is recommended in an environment where untrusted stylesheets may be executed. It also disables user-defined extension elements and the writing of multiple output files, both of which carry similar security risks.

Saxon-EE Options

The advanced options that are specific for Saxon 9.8.0.12 Enterprise Edition (EE) are as follows:

Validation of the source file ("-val")

Requests schema-based validation of the source file and of any files read using document() or similar functions. It can have the following values:

- Schema validation ("strict") - This mode requires an XML Schema and allows for parsing the source documents with strict schema-validation enabled.
- Lax schema validation ("lax") - If an XML Schema is provided, this mode allows for parsing the source documents with schema-validation enabled but the validation will not fail if, for example, element declarations are not found.
- Disable schema validation - This specifies that the source documents should be parsed with schema-validation disabled.

Validation errors in the result tree treated as warnings ("-outval")

Normally, if validation of result documents is requested, a validation error is fatal. Selecting this option causes such validation failures to be treated as warnings.

Write comments for non-fatal validation errors of the result document

The validation messages for non-fatal errors are written (wherever possible) as a comment in the result document itself.

Enable XQuery update ("-update:(on|off)")

This option controls whether or not XQuery update syntax is accepted. The default value is off.

Backup files updated by XQuery ("-backup:(on|off)")

If selected, backup versions for any XML files updated with an XQuery Update are generated. This option is available when the Enable XQuery update option is selected.
Other Options

Initializer class

Equivalent to the --init Saxon command-line argument. The value is the name of a user-supplied class that implements the net.sf.saxon.lib.Initializer interface. This initializer is called during the initialization process, and may be used to set any options required on the configuration programmatically. It is particularly useful for tasks such as registering extension functions, collations, or external object models, especially in Saxon-HE where the option cannot be set via a configuration file. Saxon only calls the initializer when running from the command line, but the same code may be invoked to perform initialization when running user application code.

FO Processor Tab (XQuery Transformations)

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The FO Processor tab contains the following options:

Perform FO Processing

Specifies whether or not an FO processor is applied (either the built-in Apache FOP engine or an external engine defined in Preferences) during the transformation.

Input

Choose between the following options to specify which input file to use:

- **XQuery result as input** - The FO processor is applied to the result of the XQuery transformation that is defined in the XQuery tab.
- **XML URL as input** - The FO processor is applied to the input XML file.

Method

The output format of the FO processing. The available options depend on the selected processor type.

Processor

Specifies the FO processor to be used for the transformation. It can be the built-in Apache FOP processor or an external processor (on page 216).
Output Tab (XQuery Transformations)

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Output** tab contains the following options:

**Present as a sequence**

Selecting this option will reduce the time necessary to fetch the full results, as it will only fetch the first chunk of the results.

**Prompt for file**

At the end of the transformation, a file browser dialog box is displayed for specifying the path and name of the file that stores the transformation result.

**Save As**

The path of the file where the result of the transformation is stored. You can specify the path by using the text field, the ![Insert Editor Variables](on page 276) button, or the ![Browse](button).

**Open in Browser/System Application**

If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the file type of the result (for example, in Windows PDF files are often opened in Acrobat Reader).

**Note:** To set the web browser that is used for displaying HTML/XHTML pages, go to **Options > Preferences > Global**, and set it in the **Default Internet browser** field.

- **Output file** - When **Open in Browser/System Application** is selected, you can use this button to automatically open the default output file at the end of the transformation.
- **Other location** - When **Open in Browser/System Application** is selected, you can use this option to open the file specified in this field at the end of the transformation. You can specify the path by using the text field, the ![Insert Editor Variables](on page 276) button, or the ![Browse](button).

**Open in editor**

When this is option is selected, at the end of the transformation, the default output file is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor, or if it is an XSL-FO file it is opened with the built-in FO editor).
Show in results view as

You can choose to view the results in one of the following:

- **XML** - If this is selected, Oxygen XML Editor displays the transformation result in an XML viewer panel at the bottom of the application window with syntax highlighting (on page 178).

- **SVG** - If this is selected, Oxygen XML Editor displays the transformation result in an integrated SVG viewer in the Results panel (on page 1502) at the bottom of the application window and renders the result as an SVG image.

- **XHTML** - This option is only available if Open in Browser/System Application is not selected. If selected, Oxygen XML Editor displays the transformation result in a built-in XHTML browser panel at the bottom of the application window.

⚠️ Important: When transforming very large documents, you should be aware that selecting this option may result in very long processing times. This drawback is due to the built-in Java XHTML browser implementation. To avoid delays for large documents, if you want to see the XHTML result of the transformation, you should use an external browser by selecting the Open in Browser/System Application option instead.

- **Image URLs are relative to** - If Show in results view as XHTML is selected, this option specifies the path used to resolve image paths contained in the transformation result. You can specify the path by using the text field, the Insert Editor Variables (on page 276) button, or the Browse button.

XML to PDF Transformation with CSS

This type of transformation uses the Oxygen PDF Chemistry processing engine to obtain PDF output by applying CSS styling to the edited XML document. This scenario is useful for those who are familiar with CSS and want to obtain PDF output as its final form.

To create an XML to PDF transformation with CSS scenario, use one of the following methods:

- Use the Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu. Then click the New button and select XML to PDF transformation with CSS.

- Go to Window > Show View and select Transformation Scenarios to display this view (on page 1768). Click the New Scenario drop-down menu button and select XML to PDF transformation with CSS.

Both methods open the New Scenario dialog box.
The upper part of the dialog box allows you to specify the **Name** of the transformation scenario and the following **Storage** options:

- **Project Options** *(on page 3286)* - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- **Global Options** *(on page 3283)* - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

For more information about the **Oxygen PDF Chemistry** processing engine and numerous tips for customizing the output, see the **Oxygen Chemistry User Guide**.

**CSS Tab (XML to PDF Transformation with CSS)**

When you create a new transformation scenario *(on page 1674)* or edit an existing one *(on page 1758)*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **CSS** tab contains the following options:

**XML URL**

Specifies the source XML file. You can specify the path by using the text field, its history drop-down, the **Insert Editor Variables** *(on page 276)* button, or the browsing actions in the **Browse** drop-down list. You can also use the **Open in editor** button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, then the file is used directly from its remote location.

**CSS URL**

Optionally, you can use this option to specify the location of a custom CSS file to be applied to the transformation. If this option is left blank, only the CSS referenced directly from the document will be applied. You can specify the path by using the text field, its history drop-down, the **Insert Editor Variables** *(on page 276)* button, or the browsing actions in the **Browse** drop-down list. You can also use the **Open in editor** button to open the specified file in the editor panel.

**Apply CSS stylesheets set in the current framework**
If selected, CSS stylesheets that are specified in the framework (in the Document Type configuration CSS subtab (on page 101)) are applied to the transformation in addition to any CSS referenced directly in the document or specified in the CSS URL field (on page 1700).

**Note:** If CSS files are specified in multiple ways, the transformation applies the CSS in the following order (from lowest priority to highest):

- CSS files that are specified in the framework (in the Document Type configuration CSS subtab (on page 101)).
- CSS files referenced directly in the document.
- CSS files specified in the CSS URL field (on page 1700).

**Processor options link**

Opens the CSS-based Processors preferences page (on page 220) where you can configure some options for generating PDF output.

**Output Tab (XML to PDF Transformation with CSS)**

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Output tab** contains the following options:

**Output File section**

**Save As**

The path of the file where the result of the transformation is stored. You can specify the path by using the text field, the Insert Editor Variables (on page 276) button, or the Browse button.

**Open in Browser/System Application**

If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the PDF file type (for example, in Windows PDF files are often opened in Acrobat Reader).

**Debugging section**

**Dump the intermediate annotated XML**

Select this option to include (dump) the intermediate, annotated XML file in the same location as the output file. This can be used for debugging purposes.
Dump the FO file

Select this option to include (dump) the FO file (before it is converted to PDF) in the same location as the output file. This can be used for debugging purposes.

Console options link

Opens the CSS-based Processors preferences page (on page 220) where you can configure some options for generating PDF output.

DITA OT Transformation

This type of transformation specifies the parameters for an Ant transformation that executes a DITA-OT build script. Oxygen XML Editor includes a built-in version of Ant and a built-in version of DITA-OT, but other versions can be set in the scenario.

To create a DITA OT Transformation scenario, use one of the following methods:

- Use the Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the DITA Maps Manager toolbar, main toolbar, or the Document > Transformation menu. Then click the New button and select DITA OT Transformation.
- Go to Window > Show View and select Transformation Scenarios to display this view (on page 1768). Click the New Scenario drop-down menu button and select DITA OT Transformation.

Both methods open the DITA Transformation Type dialog box that presents the list of possible outputs.

Figure 600. DITA Transformation Type Dialog Box
Select the desired type of output and click **OK**. This opens the **New Scenario** dialog box.

The upper part of the dialog box allows you to specify the **Name** of the transformation scenario and the following **Storage** options:

- **Project Options** *(on page 3286)* - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- **Global Options** *(on page 3283)* - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation. Some of these tabs are only available for certain output types (for example, a **Skins** tab is only available for **WebHelp Classic** and **WebHelp Classic with Feedback** output types, a **Templates** tab is available only for **WebHelp Responsive** and **WebHelp Responsive with Feedback**, and a **FO Processor** tab is available for PDF output).

**Skins Tab (DITA OT Transformations)**

When you create a new transformation scenario *(on page 1674)* or edit an existing one *(on page 1758)*, a configuration dialog box allows you to customize the transformation with various options in several tabs.
The **Skins** tab is available for DITA OT transformations with WebHelp Classic or WebHelp Classic with Feedback output types and it provides a set of built-in skins that you can use as a base for your WebHelp system output.

A **skin** is a collection of CSS properties that can alter the look of the output by changing colors, font types, borders, margins, and paddings. This allows you to rapidly adapt the look and feel of your output.

Figure 601. Skins Tab

The **Skins** tab includes the following sections:

- **Built-in Skins**
  
  This sections presents the built-in skins that are included in Oxygen XML Editor. The built-in skins cover a wide range of chromatic themes, ranging from a very light one to a high-contrast variant. To see how the skin looks when applied on a sample documentation project that is stored on the Oxygen XML Editor website, press the **Online preview** link.

- **Custom Skins**

  You can use this section to customize the look of the output.

  **CSS File**

  You can set this field to point to a custom CSS stylesheet or customized skin. A custom CSS file will overwrite a skin selection.
**Note:** The output can also be styled by setting the `args.css` parameter in the **Parameters tab**. The properties taken from the stylesheet referenced in this parameter take precedence over the properties declared in the **Skins tab**.

Create custom skin

Use this link to open the **WebHelp Skin Builder** (on page 1806) tool.

**Templates Tab (DITA OT Transformations)**

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Templates** tab is available for DITA OT transformations with **WebHelp Responsive**, **WebHelp Responsive with Feedback**, or **PDF - based on HTML5 & CSS** output types and it provides a set of built-in publishing templates (on page 1892). You can use one of them to publish your documentation or as a starting point for a new publishing template.

**Figure 602. Templates Tab**

**Filtering and Previewing Templates**

You can click on the tags at the top of the pane to filter the templates and narrow your search. Each built-in template also includes an **Online preview** icon in the bottom-right corner that opens
a webpage in your default browser providing a sample of how the main page will look when that particular template is used to generate the output.

**Built-in Templates Locations**

Oxygen XML Editor scans the following locations to find the built-in templates to display in the dialog box:

- **WebHelp Responsive Templates** - All built-in WebHelp Responsive publishing templates are stored in the following directory: `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/templates`.
- **PDF - based on HTML5 & CSS** - All built-in PDF publishing templates are stored in the following directories:
  - `DITA-OT-DIR/plugins/com.oxygenxml.pdf.css/templates`
  - `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/templates`

**Custom Templates Locations**

Oxygen XML Editor scans the locations specified in the [DITA > Publishing preferences page](on page 228) to find custom templates to display in the dialog box. You can access that preferences page directly from the Template tab by clicking on the Configure Publishing Templates Gallery link.

**Selecting Custom Templates**

Once you are finished configuring your template, you can click the Choose Custom Publishing Template link to select your template. You can also add your custom templates (on page 1938) to the list of templates displayed in the Templates tab. To do this, store them in a directory, then click the Configure Publishing Templates Gallery link to open the [DITA > Publishing preferences page](on page 228) where you can add that directory to the list. All the templates contained in your template directory will be displayed in the preview pane along with all the built-in templates.

**Save Template As Button**

You can use the Save template as button (at the bottom-left of the transformation dialog box) to export the currently selected template into a new template package that can be used as a starting point to create your own custom template (on page 2029). Clicking this button will open a template package configuration dialog box (on page 1707) that contains some options and displays the parameters that will be exported to your template package.
Template Errors

When the **Templates** tab is opened, all templates (built-in and custom) are loaded and validated. Specifically, certain elements in the template descriptor file are checked for validity. If errors are encountered that prevents the template from loading, the following message will be displayed toward the bottom of the dialog box:

![Some templates could not be loaded. More details](image)

If you click the **More details** link, a window will open with more information about the encountered error. For example, it might offer a hint for which element is missing from the expected descriptor file structure.

Also, if a template could be loaded, but certain elements could not be found in the descriptor file, a warning icon (⚠️) will be displayed on the template's image (in the **Templates** tab of the transformation dialog box). For example, this happens if a valid preview-image element cannot be found.

Sharing Publishing Template

To share a publishing template with others, following these steps:

1. Copy your template in a new folder.
2. Go to **Options > Preferences > DITA > Publishing (on page 228)** and add that new folder to the list.
3. Switch the option as the bottom of that preferences page to **Project Options**.
4. Share your project file (.xpr).

For more information about customizing publishing templates, watch our video demonstration:

- [Publishing Template Package Contents for WebHelp Responsive Customizations (on page 1895)]()
Template Package Configuration Dialog Box

The **Save template as** button (at the bottom-left of the transformation dialog box for **WebHelp Responsive** or **PDF - based on HTML5 & CSS** transformations) can be used to export the currently selected template into a new template package that can be used as a starting point to **create your own custom template** *(on page 2029)*. The result will be a ZIP archive that contains a template descriptor file and other resources (such as CSS files) that were attached to the selected template.

Clicking the **Save template as** button opens a template package configuration dialog box contains the following options and components:

**Name**

Required field used to specify the name for the new template. This will become the text value of the `<name>` element in the template descriptor file. This information is displayed as the name of the template in the transformation scenario dialog box.

**Description**

Optional field used to specify a template description. This will become the text value of the `<description>` element in the template descriptor file. This information is displayed when the user hovers over the template in the transformation scenario dialog box.

**Parameter Table**

This table displays the parameters that will be exported. Only relevant parameters are exported. The parameters and their values will be inserted in the `<parameters>` section of the template descriptor file. If any of the parameter values point to a file path that references a template resource (such as CSS files, custom HTML fragments, images), those resources will automatically be copied to the new template package and their references will be changed accordingly.

**Note:** Additional resources that are referenced in CSS files or other resources will not be copied to the new template package, so you will need to copy them manually and update their references in the template descriptor file.

**Include WebHelp Customization**

The same publishing template package can contain both a WebHelp Responsive and PDF customization and you can use the same template in both types of transformations (**DITA Map WebHelp Responsive** *(on page 1643)* or **DITA Map to PDF - based on HTML5 & CSS** *(on page 1657)*). This option specifies that the custom template will include a WebHelp Responsive customization.

**Include HTML Page Layout Files**

For **WebHelp Responsive** customizations, select this option if you want to copy the default **HTML Page Layout Files** *(on page 1909)* into your
template package. They are helpful if you want to change the structure of
the generated HTML pages.

**Include PDF Customization**

The same publishing template package can contain both a WebHelp Responsive and
PDF customization and you can use the same template in both types of transformations
(See [DITA Map WebHelp Responsive](on page 1643) or [DITA Map to PDF - based on
HTML5 & CSS](on page 1657)). This option specifies that the custom template will
include a PDF customization.

**Save as**

Use this field to specify the name and path of the ZIP file where the template will be
saved.

FO Processor Tab (DITA OT Transformations)

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The FO Processor tab is available for DITA OT transformations with a PDF output type.

This tab allows you to select an FO Processor to be used for the transformation.

Figure 604. FO Processor Configuration Tab

You can choose one of the following processors:

**Apache FOP**

The default processor that comes bundled with Oxygen XML Editor.

**XEP**

The RenderX XEP processor. If XEP is already installed, Oxygen XML Editor displays the detected installation path under the drop-down menu. XEP is considered installed if it was detected in one of the following sources:

- XEP was configured as an external FO Processor in the FO Processors option page (on page 216).
- The system property `com.oxygenxml.xep.location` was set to point to the XEP executable file for the platform (for example: `xep.bat` on Windows).
- XEP was installed in the `DITA-OT-DIR/plugins/org.dita.pdf2/lib` directory of the Oxygen XML Editor installation directory.

**Antenna House**
The Antenna House (AH Formatter) processor. If Antenna House is already installed, Oxygen XML Editor displays the detected installation path under the drop-down menu. Antenna House is considered installed if it was detected in one of the following sources:

- Environment variable set by Antenna House installation (the newest installation version will be used).
- Antenna House was added as an external FO Processor in the Oxygen XML Editor preferences pages.

To further customize the PDF output obtained from the Antenna House processor, follow these steps:

1. **Edit** the transformation scenario.
2. Open the **Parameters tab** *(on page 3205)*.
3. Add the `env.AXF_OPT` parameter and point to the Antenna House configuration file.

**Related Information:**

- [FO Processors Preferences *(on page 216)*](#)
- [XSL-FO (Apache FOP) Processor for Generating PDF Output *(on page 1738)*](#)

**Parameters Tab (DITA OT Transformations)**

When you **create a new transformation scenario** *(on page 1674)* or **edit an existing one** *(on page 1758)*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Parameters** tab allows you to configure the parameters sent to the DITA-OT build file.

The table in this tab displays all the parameters that the DITA-OT documentation specifies as available for each chosen type of transformation (for example, XHTML or PDF), along with their description and current values. You can find more information about each parameter in the **DITA OT Documentation**.

You can also add, edit, and remove parameters, and you can use the text box to filter or search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

Depending on the type of a parameter, its value can be one of the following:

- A simple text field for simple parameter values.
- A combo box with some predefined values.
A file chooser and an editor variable (on page 276) selector to simplify setting a file path as the value of a parameter.

**Note:** To input parameter values at runtime, use the ask editor variable (on page 277) in the Value column.

Below the table, the following actions are available for managing parameters:

**New**

Opens the Add Parameter dialog box that allows you to add a new parameter to the list. You can specify the Value of the parameter by using the Insert Editor Variables (on page 276) button or the Browse button.

**Unset**

Resets the selected parameter to its default value. Available only for edited parameters with set values.

**Edit**

Opens the Edit Parameter dialog box that allows you to change the value of the selected parameter or its description.

**Delete**

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

### Parameters Contributed by an Oxygen Publishing Template

Transformation parameters that are defined in an Oxygen Publishing Template (on page 2021) descriptor file are displayed in italics. After creating a publishing template (on page 2029) and adding it to the templates gallery (on page 1938), when you select the template in the Templates tab (on page 3199), the Parameters tab will automatically be updated to include the parameters defined in the template descriptor file.

**Related Information:**

- DITA Open Toolkit Documentation
Feedback Tab (DITA OT Transformations)

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

⚠️ Attention: This tab is for a feature that has not yet been implemented. To check the progress of the feature, see https://feedback.oxygenxml.com/.

The Feedback tab is available for the WebHelp Responsive transformation type and can be used to connect the published WebHelp Responsive output to an Oxygen Feedback server to provide a comment section in the output where users can offer feedback and ask questions.

When you configure the Oxygen Feedback server, you will retrieve an HTML fragment during site creation procedure. Click the Edit button at the bottom-right of this tab to open a dialog box where you will paste the HTML fragment (using keyboard shortcut keys or contextual menu actions).

Filters Tab (DITA Transformations)

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The Filters tab allows you to add filters to remove certain content elements from the generated output.

Figure 605. Edit Filters Tab
You can choose one of the following options to define filters:

**Use DITAVAL file**

If you already have a DITAVAL file associated with the DITA map (on page 3281), you can specify the file to be used when filtering content. You can specify the path by using the text field, its history drop-down, the Insert Editor Variables (on page 276) button, or the browsing actions in the Browse drop-down list. You can find out more about constructing a DITAVAL file in the DITA Documentation.

⚠️ **Attention:** If a filter file is specified in the args.filter parameter (in the Parameters tab (on page 3205)), that file takes precedence over a DITAVAL file specified here.

**Use profiling condition set**

Sets the profiling condition set (on page 3234) that will be applied to your transformation.

**Exclude from output all elements with any of the following attributes**

By using the New, Edit, or Delete buttons at the bottom of the pane, you can configure a list of attributes (name and value) to exclude all elements that contain any of these attributes from the output.

**Advanced Tab (DITA OT Transformations)**

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The Advanced tab allows you to specify advanced options for the transformation scenario.

Figure 606. Advanced Settings Tab
You can specify the following parameters:

**Custom build file**

If you use a custom DITA-OT build file, you can specify the path to the customized build file. If empty, the `build.xml` file from the `dita.dir` parameter that is configured in the **Parameters** tab (on page 3205) is used. You can specify the path by using the text field, the **Insert Editor Variables** (on page 276) button, or the **Browse** button.

**Build target**

Optionally, you can specify a build target for the build file. If no target is specified, the default `init` target is used.

**Additional arguments**

You can specify additional command-line arguments to be passed to the transformation (such as `-verbose`).

**Ant Home**

You can choose between the default or custom Ant installation to run the transformation. The default path can be configured in the **Ant preferences page** (on page 221).

**Java Home**
You can choose between the default or custom Java installation to run the transformation. The default path is the Java installation that is used by Oxygen XML Editor.

![Note:](image) It may be possible that the used Java version is incompatible with the DITA Open Toolkit engine. For example, DITA-OT 2.0 and newer requires Java 1.7 or newer. Thus, if you encounter related errors running the transformation, consider installing a Java VM that is supported by the DITA OT publishing engine and using it in the Java Home text field.

**JVM Arguments**

This parameter allows you to set specific parameters for the Java Virtual Machine used by Ant. For example, if it is set to `-Xmx384m`, the transformation process is allowed to use 384 megabytes of memory. When performing a large transformation, you may want to increase the memory allocated to the Java Virtual Machine. This will help avoid Out of Memory error messages (OutOfMemoryError).

**Libraries**

By default, Oxygen XML Editor adds libraries (as high priority) that are not transformation-dependent and also patches for certain DITA Open Toolkit bugs. You can use this button to specify additional libraries (JAR files or additional class paths) to be used by the transformer.

![Tip:](image) You can specify the path to the additional libraries using wildcards (for example, `${oxygenHome}/lib/*.jar`).

**Output Tab (DITA OT Transformations)**

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Output** tab allows you to configure options that are related to the location where the output is generated.

Figure 607. Output Settings Tab
You can specify the following parameters:

**Base directory**

All the relative paths that appear as values in parameters are considered relative to the base directory. The default value is the directory where the transformed map is located. You can specify the path by using the text field, the Insert Editor Variables button, or the Browse button.

**Temporary files directory**

This directory is used to store pre-processed temporary files until the final output is obtained. You can specify the path by using the text field, the Insert Editor Variables button, or the Browse button.

**Output directory**

The folder where the content of the final output is stored. You can specify the path by using the text field, the Insert Editor Variables button, or the Browse button.

**Note:** If the DITA map or topic is opened from a remote location or a ZIP file, the parameters must specify absolute paths.

**Open in Browser/System Application**
If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the file type of the result (for example, in Windows PDF files are often opened in Acrobat Reader).

**Note:** To set the web browser that is used for displaying HTML/XHTML pages, go to Options > Preferences > Global, and set it in the Default Internet browser field.

- **Output file** - When Open in Browser/System Application is selected, you can use this button to automatically open the default output file at the end of the transformation.
- **Other location** - When Open in Browser/System Application is selected, you can use this option to open the file specified in this field at the end of the transformation. You can specify the path by using the text field, the ![Insert Editor Variables](on page 276) button, or the ![Browse](button).

**Open in editor**

When this option is selected, at the end of the transformation, the default output file is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor, or if it is an XSL-FO file it is opened with the built-in FO editor).

At the bottom of the pane there is a link to the Console options (on page 228) preferences page that contains options to control the display of the console output received from the publishing engine.

**Ant Transformation**

This type of transformation allows you to configure the options and parameters of an Ant build script.

An Ant transformation scenario is usually associated with an Ant build script. Oxygen XML Editor runs an Ant transformation scenario as an external process that executes the Ant build script with the built-in Ant distribution (Apache Ant (on page 3279) version 1.9.8) that is included with the application, or optionally with a custom Ant distribution configured in the scenario.

**Tip:** Certain Ant tasks require additional JAR libraries (for example, Ant mail tasks). The additional libraries can be added by editing the Ant transformation scenario, and in the Output tab, click the Libraries button (on page 1719) in the bottom right corner. This opens a dialog box where you can add JAR libraries. For a list of library dependencies, see [https://ant.apache.org/manual/install.html#librarydependencies](https://ant.apache.org/manual/install.html#librarydependencies).

To create an Ant transformation scenario, use one of the following methods:
• Use the Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu. Then click the New button and select ANT transformation.

• Go to Window > Show View and select Transformation Scenarios to display this view (on page 1768). Click the New Scenario drop-down menu button and select ANT transformation.

Both methods open the transformation configuration dialog box.

The upper part of the dialog box allows you to specify the Name of the transformation scenario and the following Storage options:

• Project Options (on page 3286) - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.

• Global Options (on page 3283) - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

Related Information:

• Transforming Ant Build Files (on page 1237)

Options Tab (Ant Transformations)

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The Options tab allows you to specify the following options:

Working directory

The path of the current directory of the Ant external process. You can specify the path by using the text field, the Insert Editor Variables (on page 276) button, or the Browse button.

Build file
The Ant script file that is the input of the Ant external process. You can specify the path by using the text field, the ✉ Insert Editor Variables (on page 276) button, or the 🗂 Browse button.

**Build target**

Optionally, you can specify a build target for the Ant script file. If no target is specified, the Ant target that is specified as the default in the Ant script file is used.

**Additional arguments**

You can specify additional command-line arguments to be passed to the transformation (such as `-verbose`).

**Ant Home**

You can choose between the default or custom Ant installation to run the transformation. The default path can be configured in the Ant preferences page (on page 221).

**Java Home**

You can choose between the default or custom Java installation to run the transformation. The default path is the Java installation that is used by Oxygen XML Editor.

**JVM Arguments**

This parameter allows you to set specific parameters for the Java Virtual Machine used by Ant. For example, if it is set to `-Xmx384m`, the transformation process is allowed to use 384 megabytes of memory. When performing a large transformation, you may want to increase the memory allocated to the Java Virtual Machine. This will help avoid Out of Memory error messages (OutOfMemoryError).

**Libraries**

By default, Oxygen XML Editor adds libraries (as high priority) that are not transformation-dependent and also patches for certain DITA Open Toolkit bugs. You can use this button to specify additional libraries (JAR (on page 3283) files or additional class paths) to be used by the transformer.

**Tip:** You can specify the path to the additional libraries using wildcards (for example, `${oxygenHome}/lib/*.*.jar`).

**Parameters Tab (Ant Transformations)**

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.
The **Parameters** tab allows you to configure the parameters that are accessible as Ant properties in the Ant build script.

The table displays all the parameters that are available in the Ant build script, along with their description and current values. You can also add, edit, and remove parameters, and use the **Filter** text box to search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

Depending on the type of a parameter, its value can be one of the following:

- A simple text field for simple parameter values.
- A combo box with some predefined values.
- A file chooser and an **editor variable** *(on page 276)* selector to simplify setting a file path as the value of a parameter.

**Note:** To input parameter values at runtime, use the **ask editor variable** *(on page 277)* in the **Value** column.

Below the table, the following actions are available for managing parameters:

**New**

Opens the **Add Parameter** dialog box that allows you to add a new parameter to the list. You can specify the **Value** of the parameter by using the **Insert Editor Variables** *(on page 276)* button or the **Browse** button.

**Edit**

Opens the **Edit Parameter** dialog box that allows you to change the value of the selected parameter or its description.

**Delete**

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

These parameters are also available for the built-in validation processor and the **Content Completion Assistant** *(on page 3280)*.

**Related Information:**

- Content Completion in Ant Build Files *(on page 1238)*
Output Tab (Ant Transformations)

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Output** tab contains the following options:

- **Open**
  Allows you to specify the file to open automatically when the transformation is finished. This is usually the output file of the Ant process. You can specify the path by using the text field, the [Insert Editor Variables](on page 276) button, or the [Browse](on page 1722) button.

  - **In System Application** - The file specified in the **Open** text box is opened in the system application that is set in the operating system as the default application for that type of file (for example, in Windows PDF files are often opened in Acrobat Reader).
  - **In Editor** - The file specified in the **Open** text box is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor).

- **Show console output**
  Allows you to specify when to display the console output log in the message panel at the bottom of the editor. The following options are available:

  - **When build fails** - Displays the console output log only if the build fails.
  - **Always** - Displays the console output log, regardless of whether or not the build fails.

XSLT Transformation

This type of transformation specifies the parameters and location of an XML document that the edited XSLT stylesheet is applied on. This scenario is useful when you develop an XSLT document and the XML document is in its final form.

To create an **XSLT transformation** scenario, use one of the following methods:

- **Use the [Configure Transformation Scenario(s)](on page 1722) (or [Command + Shift + C](on page 1722) on OS X) action from the toolbar or the **Document > Transformation** menu. Then click the **New** button and select **XSLT transformation**.
- **Go to** **Window > Show View** and select [Transformation Scenarios](on page 1768) to display this view (on page 1768). Click the [New Scenario](on page 1722) drop-down menu button and select **XSLT transformation**.
Both methods open the **New Scenario** dialog box.

The upper part of the dialog box allows you to specify the **Name** of the transformation scenario and the following **Storage** options:

- **Project Options** *(on page 3286)* - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- **Global Options** *(on page 3283)* - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

**XSLT Tab**

When you create a new transformation scenario *(on page 1674)* or edit an existing one *(on page 1758)*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **XSLT** tab contains the following options:

**XML URL**

Specifies the source XML file. You can specify the path by using the text field, its history drop-down, the **Insert Editor Variables** *(on page 276)* button, or the browsing actions in the **Browse** drop-down list. You can also use the **Open in editor** button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, then the file is used directly from its remote location.

**Note:** If the transformer engine is Saxon 9.x and a custom URI resolver is configured in the advanced Saxon preferences page *(on page 204)*, the XML input of the transformation is passed to that URI resolver. If the transformer engine is one of the built-in XSLT 2.0 / 3.0 engines and the name of an initial template *(on page 1676)* is specified in the scenario, the **XML URL** field can be empty. The **XML URL** field can also be empty if you use external XSLT processors *(on page 1689)*. Otherwise, a value is mandatory in this field.

**XSL URL**

Specifies the source XSL file that the transformation will use. You can specify the path by using the text field, its history drop-down, the **Insert Editor Variables** *(on page 276)* button, or the browsing actions in the **Browse** drop-down list. You can also
use the **Open in editor** button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, the file is used directly from its remote location.

**Use "xml-stylesheet" declaration**

If selected, the scenario applies the stylesheet specified explicitly in the XML document with the `xml-stylesheet` processing instruction. By default, this option is deselected and the transformation applies the XSLT stylesheet that is specified in the **XSL URL** field.

**Transformer**

This drop-down menu presents all the transformation engines available to Oxygen XML Editor for performing a transformation. These include the built-in engines and the external engines defined in the Custom Engines preferences page *(on page 215)*. The engine you choose is used as the default transformation engine. Also, if an XSLT or XQuery document does not have an associated validation scenario, this transformation engine is used in the validation process (if it provides validation support).

**Advanced options**

Allows you to configure the advanced options of the Saxon HE/PE/EE engine *(on page 1679)* for the current transformation scenario. To configure the same options globally, go to the Saxon-HE/PE/EE preferences page *(on page 201)*. For the current transformation scenario, these **Advanced options** override the options configured in that preferences page.

**Parameters**

Opens a **Configure parameters** dialog box *(on page 1677)* that allows you to configure the XSLT parameters used in the current transformation. In this dialog box, you can also configure the parameters for additional XSLT stylesheets *(on page 1676)*. If the XSLT transformation engine is custom-defined, you cannot use this dialog box to configure the parameters sent to the custom engine. Instead, you can copy all parameters from the dialog box using contextual menu actions and edit the custom XSLT engine to include the necessary parameters in the command line that starts the transformation process.

**Extensions**

Opens a dialog box for configuring the XSLT extension JARS or classes *(on page 1678)* that define extension Java functions or extension XSLT elements used in the transformation.

**Additional XSLT stylesheets**
Opens a dialog box for adding XSLT stylesheets (on page 1678) that are applied on the main stylesheet specified in the XSL URL field. This is useful when a chain of XSLT stylesheets must be applied to the input XML document.

XSLT Parameters

The global parameters of the XSLT stylesheet used in a transformation scenario can be configured by using the Parameters button in the XSLT tab of a new or edited transformation scenario dialog box.

The resulting dialog box includes a table that displays all the parameters of the current XSLT stylesheet, all imported and included stylesheets, and all additional stylesheets (on page 1678), along with their descriptions and current values. You can also add, edit, and remove parameters, and you can use the Filter text box to search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

If the XPath column is selected, the parameter value is evaluated as an XPath expression before starting the XSLT transformation.

Example:

For example, you can use expressions such as:

```xml
<doc('test.xml')//entry
//person[@atr='val']
```

Note:

1. The `doc` function solves the argument relative to the XSL stylesheet location. You can use full paths or editor variables (on page 276) (such as `${cfdu} [current file directory]`) to specify other locations: `doc('${cfdu}/test.xml')//*`.
2. You cannot use XSLT Functions. Only XPath functions are allowed.

Below the table, the following actions are available for managing the parameters:

New

Opens the Add Parameter dialog box that allows you to add a new parameter to the list. An editor variable (on page 276) can be inserted in the text box using the Insert Editor Variables button. If the Evaluate as XPath option is selected, the parameter will be evaluated as an XPath expression.

Edit

Opens the Edit Parameter dialog box that allows you to edit the selected parameter. An editor variable (on page 276) can be inserted in the text box using the Insert Editor Variables button.
Variables button. If the Evaluate as XPath option is selected, the parameter will be evaluated as an XPath expression.

Unset

Resets the selected parameter to its default value. Available only for edited parameters with set values.

Delete

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

The bottom panel presents the following:

• The default value of the parameter selected in the table.
• A description of the parameter, if available.
• The system ID of the stylesheet that declares it.

Related Information:

• Editor Variables (on page 276)

XSLT Extensions

The Extensions button opens a dialog box that allows you to specify the JARS (on page 3283) and classes that contain extension functions called from the XSLT file of the current transformation scenario. You can use the Add, Edit, and Remove buttons to configure the extensions.

Tip: You can specify the path to the resources using wildcards (for example, ${oxygenHome}/lib/*.jar).

An extension function called from the XSLT file of the current transformation scenario will be searched, in the specified extensions, in the order displayed in this dialog box. To change the order of the items, select the item to be moved and press the Move up or Move down buttons.

Additional XSLT Stylesheets

Use the Additional XSLT Stylesheets button in the XSLT tab to display a list of additional XSLT stylesheets to be used in the transformation and you can add files to the list or edit existing entries.

The following actions are available:

Add
Adds a stylesheet in the **Additional XSLT stylesheets** list using a file browser dialog box. You can type an editor variable ([on page 276](#)) in the file name field of the browser dialog box. The name of the stylesheet will be added in the list after the current selection.

### Remove

Deletes the selected stylesheet from the **Additional XSLT stylesheets** list.

### Open

Opens the selected stylesheet in a separate view.

### Up

Moves the selected stylesheet up in the list.

### Down

Moves the selected stylesheet down in the list.

---

**Advanced Saxon HE/PE/EE XSLT Transformation Options**

The XSLT transformation scenario allows you to configure advanced options that are specific for the Saxon HE (Home Edition), PE (Professional Edition), and EE (Enterprise Edition) engines. They are the same options as those in the **Saxon HE/PE/EE preferences page ([on page 201](#))** but they are configured as a specific set of transformation options for each transformation scenario, while the values set in the preferences page apply as global options. The advanced options configured in a transformation scenario override the **global options ([on page 3283](#))** defined in the preferences page.

**Saxon-HE/PE/EE Options**

The advanced options for Saxon 9.8.0.12 Home Edition (HE), Professional Edition (PE), and Enterprise Edition (EE) are as follows:

#### Mode ("-im")

A Saxon-specific option that sets the initial mode for the transformation. If this value is also specified in a [configuration file ([on page 1679](#))](#), the value in this option takes precedence.

#### Template ("-it")

A Saxon-specific option that sets the name of the initial XSLT template to be executed. If this value is also specified in a [configuration file ([on page 1679](#))](#), the value in this option takes precedence.

#### Use a configuration file ("-config")

Select this option if you want to use a Saxon 9.8.0.12 configuration file that will be executed for the XSLT transformation and validation processes. You can specify the
PATH to the configuration file by entering it in the URL field, or by using the Insert Editor Variables button, or using the browsing actions in the Browse drop-down list.

Debugger trace into XPath expressions (applies to debugging sessions)

Instructs the XSLT Debugger (on page 2309) to step into XPath expressions.

Enable Optimizations ("-opt")

This option is selected by default, which means that optimization is enabled. If not selected, the optimization is suppressed, which is helpful when reducing the compiling time is important, optimization conflicts with debugging, or optimization causes extension functions with side-effects to behave unpredictably.

Line numbering ("-l")

Line numbers where errors occur are included in the output messages.

Expand attributes defaults ("-expand")

Specifies whether or not the attributes defined in the associated DTD or XML Schema are expanded in the output of the transformation you are executing.

DTD validation of the source ("-dtd")

Specifies whether or not the source document will be validated against their associated DTD. You can choose from the following:

- **On** - Requests DTD validation of the source file and of any files read using the document() function.
- **Off** - (default setting) Suppresses DTD validation.
- **Recover** - Performs DTD validation but treats the errors as non-fatal.

Note: Any external DTD is likely to be read even if not used for validation, since DTDs can contain definitions of entities.

Recoverable errors ("-warnings")

Specifies how dynamic errors are handled. The following options can be selected:

- **Recover silently** ("silent") - Continues processing without reporting the error.
- **Recover with warnings** ("recover") - Issues a warning but continues processing.
- **Signal the error and do not attempt recovery** ("fatal") - Issues an error and stops processing.

Strip whitespaces ("-strip")

Specifies how the strip whitespaces operation is handled. You can choose one of the following values:
• **All** ("all") - Strips all whitespace text nodes from source documents before any further processing, regardless of any \texttt{xml:space} attributes in the source document.

• **Ignore** ("ignorable") - Strips all ignorable whitespace text nodes from source documents before any further processing, regardless of any \texttt{xml:space} attributes in the source document. Whitespace text nodes are ignorable if they appear in elements defined in the DTD or schema as having element-only content.

• **None** ("none") - Strips no whitespace before further processing.

### Saxon-PE/EE Options

The following advanced options are specific for Saxon 9.8.0.12 Professional Edition (PE) and Enterprise Edition (EE) only:

#### Register Saxon-JS extension functions and instructions

Registers the Saxon-CE extension functions and instructions when compiling a stylesheet using the Saxon 9.8.0.12 processors.

**Note:** Saxon-CE, being JavaScript-based, was designed to run inside a web browser. This means that you will use Oxygen XML Editor only for developing the Saxon-CE stylesheet, leaving the execution part to a web browser. See more details about executing such a stylesheet on Saxonica's website.

#### Allow calls on extension functions ("-ext")

If selected, the stylesheet is allowed to call external Java functions. This does not affect calls on integrated extension functions, including Saxon and EXSLT extension functions. This option is useful when loading an untrusted stylesheet (such as from a remote site using \texttt{http://[URL]}). It ensures that the stylesheet cannot call arbitrary Java methods and thus gain privileged access to resources on your machine.

#### Enable assertions ("-ea")

In XSLT 3.0, you can use the \texttt{xsl:assert} element to make assertions in the form of XPath expressions, causing a dynamic error if the assertion turns out to be false. If this option is selected, XSLT 3.0 \texttt{xsl:assert} instructions are enabled. If it is not selected (default), the assertions are ignored.

### Saxon-EE Options

The advanced options that are specific for Saxon 9.8.0.12 Enterprise Edition (EE) are as follows:

#### XML Schema version

Use this option to change the default XML Schema version for this transformation. To change the default XML Schema version globally, open the Preferences dialog box.
(Options > Preferences) (on page 79) and go to XML > XML Parser > XML Schema and use the Default XML Schema version option (on page 193).

Validation of the source file ("-val")

Requests schema-based validation of the source file and of any files read using `document()` or similar functions. It can have the following values:

- **Schema validation ("strict")** - This mode requires an XML Schema and allows for parsing the source documents with strict schema-validation enabled.

- **Lax schema validation ("lax")** - If an XML Schema is provided, this mode allows for parsing the source documents with schema-validation enabled but the validation will not fail if, for example, element declarations are not found.

- **Disable schema validation** - This specifies that the source documents should be parsed with schema-validation disabled.

Validation errors in the result tree treated as warnings ("-outval")

Normally, if validation of result documents is requested, a validation error is fatal. Selecting this option causes such validation failures to be treated as warnings.

Write comments for non-fatal validation errors of the result document

The validation messages for non-fatal errors are written (wherever possible) as a comment in the result document itself.

Enable streaming mode

Selecting this option will allow an XSLT to run in streaming mode. It is not selected by default.

Other Options

Initializer class

Equivalent to the `-init` Saxon command-line argument. The value is the name of a user-supplied class that implements the `net.sf.saxon.lib.Initializer` interface. This initializer is called during the initialization process, and may be used to set any options required on the configuration programmatically. It is particularly useful for tasks such as registering extension functions, collations, or external object models, especially in Saxon-HE where the option cannot be set via a configuration file. Saxon only calls the initializer when running from the command line, but the same code may be invoked to perform initialization when running user application code.
Using Saxon Integrated Extension Functions

Saxon, the transformation and validation engine used by Oxygen XML Editor, can be customized by adding custom functions (called Integrated Extension Functions) that can be called from XPath.

To define such a function, follow these steps:

1. Create a file with a Java class that extends net.sf.saxon.lib.ExtensionFunctionDefinition. Here is an example:

```java
private static class ShiftLeft extends ExtensionFunctionDefinition {
    @Override
    public StructuredQName getFunctionQName() {
        return new StructuredQName("eg", "http://example.com/saxon-extension", "shift-left");
    }

    @Override
    public SequenceType[] getArgumentTypes() {
        return new SequenceType[] {SequenceType.SINGLE_INTEGER, SequenceType.SINGLE_INTEGER};
    }

    @Override
    public SequenceType getResultType(SequenceType[] suppliedArgumentTypes) {
        return SequenceType.SINGLE_INTEGER;
    }

    @Override
    public ExtensionFunctionCall makeCallExpression() {
        return new ExtensionFunctionCall() {
            public SequenceIterator call(SequenceIterator[] arguments, XPathContext context)
                throws XPathException {
                long v0 = ((IntegerValue)arguments[0].next()).longValue();
                long v1 = ((IntegerValue)arguments[1].next()).longValue();
                long result = v0<<v1;
                return Value.asIterator(Int64Value.makeIntegerValue(result));
            }
        }
    }
}
```
2. Compile the class and add it to a JAR file.
3. Add a file called `net.sf.saxon.lib.ExtensionFunctionDefinition` that contains the fully qualified name of the Java class in the `META-INF/services/` folder of the JAR file.

**Note:** To add more function definitions in the same JAR file, you need to add their fully qualified names on different lines.

To enable Oxygen XML Editor to pick up your custom function definition, the JAR file should be added to the classpath of the transformer. Here are some possibilities:

- If you develop a framework, you just need to link the JAR file in the **Classpath** tab (on page 99).
- In a validation scenario (on page 1094), you can use the **Extensions** button to open a dialog box where you can add libraries.
- In a transformation scenario, you can use the **Extensions** button in the **XSLT** tab (on page 1676) to open a dialog box where you can add libraries.
- You can also create a plugin that contributes such a JAR file in the classpath (on page 2580).

**FO Processor Tab (XSLT Transformations)**

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **FO Processor** tab contains the following options:

**Perform FO Processing**

Specifies whether or not an FO processor is applied (either the built-in Apache FOP engine or an external engine defined in **Preferences**) during the transformation.

**Input**

Choose between the following options to specify which input file to use:

- **XSLT result as input** - The FO processor is applied to the result of the XSLT transformation that is defined in the **XSLT** tab.
- **XML URL as input** - The FO processor is applied to the input XML file.

**Method**

The output format of the FO processing. The available options depend on the selected processor type.
**Processor**

Specifies the FO processor to be used for the transformation. It can be the built-in Apache FOP processor or an external processor (on page 216).

**Output Tab (XSLT Transformations)**

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Output** tab contains the following options:

**Prompt for file**

At the end of the transformation, a file browser dialog box is displayed for specifying the path and name of the file that stores the transformation result.

**Save As**

The path of the file where the result of the transformation is stored. You can specify the path by using the text field, the ✉️ Insert Editor Variables (on page 276) button, or the ✰ Browse button.

**Open in Browser/System Application**

If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the file type of the result (for example, in Windows PDF files are often opened in Acrobat Reader).

ᆡ Note: To set the web browser that is used for displaying HTML/XHTML pages, go to Options > Preferences > Global, and set it in the Default Internet browser field.

- **Output file** - When Open in Browser/System Application is selected, you can use this button to automatically open the default output file at the end of the transformation.
- **Other location** - When Open in Browser/System Application is selected, you can use this option to open the file specified in this field at the end of the transformation.

You can specify the path by using the text field, the ✉️ Insert Editor Variables (on page 276) button, or the ✰ Browse button.

**Open in editor**

When this is option is selected, at the end of the transformation, the default output file is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor, or if it is an XSL-FO file it is opened with the built-in FO editor).
Show in results view as

You can choose to view the results in one of the following:

- **XML** - If this is selected, Oxygen XML Editor displays the transformation result in an XML viewer panel at the bottom of the application window with syntax highlighting ([on page 178](#)).

- **SVG** - If this is selected, Oxygen XML Editor displays the transformation result in an integrated SVG viewer in the Results panel ([on page 1502](#)) at the bottom of the application window and renders the result as an SVG image.

- **XHTML** - This option is only available if Open in Browser/System Application is not selected. If selected, Oxygen XML Editor displays the transformation result in a built-in XHTML browser panel at the bottom of the application window.

⚠️ **Important:** When transforming very large documents, you should be aware that selecting this option may result in very long processing times. This drawback is due to the built-in Java XHTML browser implementation. To avoid delays for large documents, if you want to see the XHTML result of the transformation, you should use an external browser by selecting the Open in Browser/System Application option instead.

- **Image URLs are relative to** - If Show in results view as XHTML is selected, this option specifies the path used to resolve image paths contained in the transformation result. You can specify the path by using the text field, the ![Insert Editor Variables](#) button, or the ![Browse](#) button.

⚠️ **Attention:** If your input XSLT contains `<xsl:result-document>` elements, then the secondary results will be saved to the specified URIs while the principal result is specified in this Output tab. For more information, see: [https://www.w3.org/TR/xslt-30/#element-result-document](https://www.w3.org/TR/xslt-30/#element-result-document).

Configuring an XSLT Processor for Generating Output

This section explains how to configure an XSLT processor and extensions for such a processor in Oxygen XML Editor.

Supported XSLT Processors

Oxygen XML Editor includes the following XSLT processors:

- **Xalan 2.7.2** - Xalan-Java is an XSLT processor for transforming XML documents into HTML, text, or other XML document types. It implements XSL Transformations (XSLT) Version 1.0 and XML Path Language (XPath) Version 1.0.
• **Saxon 6.5.5** - **Saxon 6.5.5** is an XSLT processor that implements the Version 1.0 XSLT and XPath with a number of powerful extensions. This version of Saxon also includes many of the new features that were first defined in the XSLT 1.1 working draft, but for conformance and portability reasons these are not available if the stylesheet header specifies `version="1.0"`.

• **Saxon 9.8.0.12 Home Edition (HE), Professional Edition (PE)** - **Saxon-HE/PE** implements the basic conformance level for XSLT 2.0 / 3.0 and XQuery 1.0. The term *basic XSLT 2.0 / 3.0 processor* is defined in the draft XSLT 2.0 / 3.0 specifications. It is a conformance level that requires support for all features of the language other than those that involve schema processing. The HE product remains open source, but removes some of the more advanced features that are present in Saxon-PE.

• **Saxon 9.8.0.12 Enterprise Edition (EE)** - **Saxon EE** is the schema-aware edition of Saxon and it is one of the built-in processors included in Oxygen XML Editor. Saxon EE includes an XML Schema processor, and schema-aware XSLT, XQuery, and XPath processors.

The validation in schema aware transformations is done according to the XML Schema 1.0 or 1.1. This can be configured in Preferences (on page 192).

**Note:** Oxygen XML Editor implements a Saxon framework that allows you to create Saxon configuration files. Two templates are available: Saxon collection catalog and Saxon configuration. Both of these templates support content completion, element annotation, and attribute annotation.

**Note:** Saxon can use the *ICU-J localization library* (`saxon9-icu.jar`) to add support for sorting and date/number formatting in a wide variety of languages. This library is not included in the Oxygen XML Editor installation kit. However, Saxon will use the default collation and localization support available in the currently used JRE. To enable this capability, follow these steps:

2. Unpack the downloaded archive.
3. Create a new XSLT transformation scenario (or edit an existing one). In the XSLT tab, click the Extensions button to open the list of additional libraries used by the transformation process.
4. Click Add and browse to the folder where you unpacked the downloaded archive and choose the `saxon9-icu.jar` file.

Note that the `saxon9-icu.jar` should NOT be added to the application library folder because it will conflict with another version of the ICU-J library that comes bundled with Oxygen XML Editor.

• **Saxon-CE (Client Edition)** is Saxicona's implementation of XSLT 2.0 for use on web browsers. Oxygen XML Editor provides support for editing stylesheets that contain Saxon-CE extension functions and instructions. This support improves the validation, content completion, and syntax highlighting.
Note: Saxon-CE, being JavaScript-based, was designed to run inside a web browser. This means that you will use Oxygen XML Editor only for developing the Saxon-CE stylesheet, leaving the execution part to a web browser. See more details about executing such a stylesheet on Saxonica’s website.

Note: A specific template, named Saxon-CE stylesheet, is available in the New document wizard (on page 676).

- Xsltproc (libxslt) - Libxslt is the XSLT C library developed for the Gnome project. Libxslt is based on libxml2, the XML C library developed for the Gnome project. It also implements most of the EXSLT set of processor-portable extensions, functions, and some of Saxon’s evaluate and expression extensions.

Oxygen XML Editor uses Libxslt through its command-line tool (Xsltproc). Depending on your operating system, you must download the Libxslt libraries on your machine from http://xmlsoft.org/XSLT/downloads.html and place them in a local folder. Then you need to update the PATH environmental variable to contain the parent folder where the xsltproc executable is located.

Tip: As an example, a Windows installation of the Xsltproc engine would follow these steps:

2. Unzip all of them into the same folder of your choice.
3. Edit the PATH environment variable and add the bin folder for all four archives:

   ![Edit environment variable](image)

   C:\Users\Desktop\abc\libxslt-1.1.26\win32\bin
   C:\Users\Desktop\abc\libxml2-2.7.8\win32\bin
   C:\Users\Desktop\abc\iconv-1.9.2\win32\bin
   C:\Users\Desktop\abc\zlib-1.2.5\bin

4. Restart Oxygen XML Editor.

Result: You can now use the xsltproc processor as an XSLT engine in the XSLT transformation scenario.

Note: The Xsltproc processor can be configured from the XSLTPROC options page (on page 204).

CAUTION: There is a known problem where file paths that contain spaces are not handled correctly in the LIBXML processor. For example, the built-in XML Catalog (on page 3289) files
of the built-in document types (DocBook, TEI, DITA, etc.) are not handled properly by LIBXML if
Oxygen XML Editor is installed in the default location on Windows (C:\Program Files). This is
because the built-in XML catalog files are stored in the \OXYGEN_INSTALL_DIR\frameworks
subdirectory of the installation directory, and in this case it contains a space character.

- **MSXML 4.0** - MSXML 4.0 is available only on Windows platforms. It can be used for
  transformation (on page 1674) and validation of XSLT stylesheets (on page 1186).

Oxygen XML Editor uses the Microsoft XML parser through its command-line tool **msxsl.exe**.

Since **msxsl.exe** is only a wrapper, Microsoft Core XML Services (MSXML) must be installed on
the computer. Otherwise, you will get a corresponding warning. You can get the latest Microsoft
XML parser from Microsoft web-site.

- **MSXML .NET** - MSXML .NET is available only on Windows platforms. It can be used for
  transformation (on page 1674) and validation of XSLT stylesheets (on page 1186).

Oxygen XML Editor performs XSLT transformations and validations using the .NET Framework
XSLT implementation (System.Xml.Xsl.XsltTransform class) through the **nxslt** command-line
utility. The nxslt version included in Oxygen XML Editor is 1.6.

You should have the .NET Framework version 1.0 already installed on your system. Otherwise,
you will get the following warning: **MSXML.NET requires .NET Framework version 1.0 to be
installed. Exit code: 128**.

You can get the .NET Framework version 1.0 from the Microsoft website.

- **.NET 1.0** - A transformer based on the System.Xml 1.0 library available in the .NET 1.0 and .NET
  1.1 frameworks from Microsoft (http://msdn.microsoft.com/xml/). It is available only on
  Windows.

You should have the .NET Framework version 1.0 or 1.1 already installed on your system.
Otherwise, you will get the following warning: **MSXML.NET requires .NET Framework version 1.0
to be installed. Exit code: 128**.

You can get the .NET Framework version 1.0 from the Microsoft website.

- **.NET 2.0** - A transformer based on the System.Xml 2.0 library available in the .NET 2.0
  Framework from Microsoft. It is available only on Windows.

You should have the .NET Framework version 2.0 already installed on your system. Otherwise,
you will get the following warning: **MSXML.NET requires .NET Framework version 2.0 to be
installed. Exit code: 128**.

You can get the .NET Framework version 2.0 from the Microsoft website.

For information about configuring the XSLT preferences, see the XSLT options (on page 200) section.
### Configuring Custom XSLT Processors

Oxygen XML Editor allows you to configure custom processors to be used for running XSLT and XQuery transformations.

To add a new custom processor, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) and go to XML > XSLT-FO-XQuery > Custom Engines.
2. Click the New button at the bottom of the dialog box.
3. Configure the parameters for the custom engine.
4. Click OK.

**Note:** You cannot use these custom engines in the Debugger perspective.

The output messages of a custom processor are displayed in an output view at the bottom of the application window. If an output message follows the format of an Oxygen XML Editor linked message, clicking it highlights the location of the message in an editor panel containing the file referenced in the message.

#### Related Information:

- Custom Engines Preferences (on page 215)

### Configuring the XSLT Processor Extensions Paths

The Xalan and Saxon processors support the use of extension elements and extension functions. Unlike a literal result element, which the stylesheet simply transfers to the result tree, an extension element performs an action. The extension is usually used because the XSLT stylesheet fails in providing adequate functions for accomplishing a more complex task.

For more information about how to use extensions, see the following links:

- Saxon 6.5.5 - http://saxon.sourceforge.net/saxon6.5.5/extensions.html

To set an XSLT processor extension (a directory or a jar file), use the Extensions button (on page 1676) in the Edit scenario dialog box.
XSL-FO (Apache FOP) Processor for Generating PDF Output

The Oxygen XML Editor installation package is distributed with the Apache FOP that is a Formatting Objects processor for transforming your XML documents to PDF. FOP is a print and output independent formatter driven by XSL Formatting Objects. FOP is implemented as a Java application that reads a formatting object tree and renders the resulting pages to a specified output.

To see the version of the built-in XSL-FO processor for your installation, go to Help > About > Libraries and search for Apache FOP.

Other FO processors can be configured in the FO Processors preferences page (on page 216).

Add a Font to the Built-in FO Processor - Simple Version

If the font that must be set to Apache FOP is one of the fonts that are installed in the operating system you should follow the next steps for creating and setting a FOP configuration file that looks for the font that it needs in the system fonts. It is a simplified version of the procedure for setting a custom font in Apache FOP (on page 1740).

1. Register the font in FOP configuration. (This is not necessary for DITA PDF transformations, skip to the next step)
   a. Create a FOP configuration file that specifies that FOP should look for fonts in the installed fonts of the operating system.

   ```xml
   <fop version="1.0">
     <renderers>
       <renderer mime="application/pdf">
         <fonts>
           <auto-detect/>
         </fonts>
       </renderer>
     </renderers>
   </fop>
   ```
   b. Open the Preferences dialog box (Options > Preferences) (on page 79), go to XML > XSLT/FO/XQuery > FO Processors, and enter the path of the FOP configuration file in the Configuration file text field.

2. Set the font on the document content.
   This is done usually with XSLT stylesheet parameters and depends on the document type processed by the stylesheet.
• For DocBook documents you can start with the built-in scenario called DocBook PDF, edit the XSLT parameters (on page 1674) and set the font name (for example, Arial Unicode MS) to the parameters body.font.family and title.font.family.

• For TEI documents you can start with the built-in scenario called TEI PDF, edit the XSLT parameters (on page 1674) and set the font name (for example, Arial Unicode MS) to the parameters bodyFont and sansFont.

• For DITA transformations to PDF using DITA-OT you should modify the following two files:
  * DITA-OT-DIR/plugins/org.dita.pdf2/cfg/fo/font-mappings.xml - The font-face element included in each element physical-font having the attribute char-set="default" must contain the name of the font (for example, Arial Unicode MS)
  * DITA-OT-DIR/plugins/org.dita.pdf2.fop/fop/conf/fop.xconf - An element auto-detect must be inserted in the element fonts, which is inside the element renderer that has the attribute mime="application/pdf":

```
<renderer mime="application/pdf">
  ...
  <fonts>
    <auto-detect/>
  </fonts>
  ...
</renderer>
```

Add a Font to the Built-in FO Processor - Advanced Version

If an XML document is transformed to PDF using the built-in Apache FOP processor but it contains some Unicode characters that cannot be rendered by the default PDF fonts, then a special font that is capable to render these characters must be configured and embedded in the PDF result.

⚠️ Important: On Windows, fonts are located into the C:\Windows\Fonts directory. On Mac, they are placed in /Library/Fonts. To install a new font on your system, it is enough to copy it in the Fonts directory. If a special font is installed in the operating system, there is a simple way of telling FOP to look for it. See the simplified procedure for adding a font to FOP (on page 1739).

1. Locate the font.

   First, find out the name of a font that has the glyphs for the special characters you used. One font that covers most characters, including Japanese, Cyrillic, and Greek, is Arial Unicode MS.

2. Register the font in the FOP configuration.
Note: DITA PDF transformations have their own fop.xconf (DITA-OT-DIR/plugins/org.dita.pdf2.fop/fop/conf/fop.xconf). If the font is not installed in the system, it needs to be referenced in the fop.xconf.

a. For information about registering the font in the FOP Configuration, see: https://xmlgraphics.apache.org/fop/2.3/fonts.html.

b. Open the Preferences dialog box (Options > Preferences) (on page 79), go to XML > XSLT/FO/XQuery > FO Processors, and enter the path of the FOP configuration file in the Configuration file text field.

3. Set the font on the document content.
   This is usually done with XSLT stylesheet parameters and depends on the document type processed by the stylesheet.

   **DocBook Example:** For DocBook documents, you can start with the built-in scenario called DocBook PDF, edit the XSLT parameters (on page 1674), and set the font name (for example, Arialuni) to the parameters body.font.family and title.font.family.

   **TEI Example:** For TEI documents, you can start with the built-in scenario called TEI PDF, edit the XSLT parameters (on page 1674), and set the font name (for example, Arialuni) to the parameters bodyFont and sansFont.

   **DITA Example:** For DITA to PDF transformations using DITA-OT modify the following two files:

   - DITA-OT-DIR/plugins/org.dita.pdf2/cfg/fo/font-mappings.xml - The font-face element included in each element physical-font having the attribute charset="default" must contain the name of the font.
   - DITA-OT-DIR/plugins/org.dita.pdf2/fop/conf/fop.xconf - An element font must be inserted in the element fonts, which is inside the element renderer that has the attribute mime="application/pdf".

   For more information, see: https://xmlgraphics.apache.org/fop/2.1/fonts.html.

Adding Libraries to the Built-in FO Processor (XML with XSLT and FO)

Starting with Oxygen XML Editor version 20.0, both hyphenation and PDF image support are enabled by default in the built-in Apache FO processor. For older version of Oxygen XML Editor, use the following procedures to enable such support.

**Adding Hyphenation Support for XML with XSLT Transformation Scenarios**

If you want to add newer hyphenation libraries or you are using an older version of Oxygen XML Editor, follow this procedure:
1. Create a folder called fop in the \{OXYGEN_INSTALL_DIR\}/lib folder.
2. Download the compiled JAR (on page 3283) from OFFO.
3. Copy the fop-hyph.jar file into the \{OXYGEN_INSTALL_DIR\}/lib/fop folder.
4. Restart Oxygen XML Editor.

Adding Support for PDF Images

To add support for PDF images in an older version of Oxygen XML Editor, follow these steps:

1. Create a folder called fop in the \{OXYGEN_INSTALL_DIR\}/lib folder.
2. Download the fop-pdf-images JAR libraries.
3. Copy the libraries into the \{OXYGEN_INSTALL_DIR\}/lib/fop folder.
4. Restart Oxygen XML Editor.

How to Enable Debugging for FO Processor Transformations

If you encounter errors when running PDF transformations that use an FO processor, it is possible to enable debugging/logging to help you identify the problem. To enable debugging/logging for FO processing, follow this procedure:

1. Locate and edit the following configuration file: \{OXYGEN_INSTALL_DIR\}/tools/config/log4j.xml.

   Note: You need write access to this folder, so if you do not have administrator permissions, you may first need to copy the file to another location where you have write access.
2. Edit the priority element (inside the root element) and change its value to debug.
3. Save the file in the original location.
4. Restart Oxygen XML Editor and re-run the transformation.

   Tip: It is recommended that you use a small input file when trying to reproduce the problem, to make it easier to analyze the data in the log.
5. Once you are finished with the debugging session, remember to edit the log4j.xml file and change the priority element back to its original value. Otherwise, performance could be affected.

XProc Transformation

This type of transformation specifies the parameters and location of an XProc script.

A sequence of transformations described by an XProc script can be executed with an XProc transformation scenario. To create an XProc transformation scenario, use one of the following methods:
• Use the Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu. Then click the New button and select XProc transformation.

• Go to Window > Show View and select Transformation Scenarios to display this view (on page 1768). Click the • New Scenario drop-down menu button and select XProc transformation.

Both methods open the New Scenario dialog box.

The upper part of the dialog box allows you to specify the Name of the transformation scenario and the following Storage options:

• Project Options (on page 3286) - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.

• Global Options (on page 3283) - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

Related Information:

• Integrating an External XProc Engine (on page 1747)

• Editing XProc Scripts (on page 1459)

XProc Tab

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The XProc tab contains the following options:

XProc URL

Specify the source XSL file to be used by the transformation. You can specify the path by using the text field, its history drop-down, the Insert Editor Variables (on page 276) button, or the browsing actions in the Browse drop-down list. This URL is resolved
through the catalog resolver. If the catalog does not have a mapping for the URL, the file is used directly from its remote location.

**Processor**

Allows you to select the XProc engine to be used for the transformation. You can select the *Add-on for Calabash XProc engine* or a custom engine that is configured in the **XProc Preferences** page (on page 198).

**Inputs Tab (XProc Transformations)**

When you *create a new transformation scenario* (on page 1674) or *edit an existing one* (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Inputs** tab contains a list with the ports that the XProc script uses to read input data. Use the **Filter** text box to search for a specific term in the entire ports collection.

Each input port has an assigned name in the XProc script. The XProc engine reads data from the URL specified in the **URL** column.

The following actions are available for managing the input ports:

**New**

Opens an **Edit** dialog box that allows you to add a new port and its URL. The *built-in editor variables* (on page 276) and *custom editor variables* (on page 284) can be used to specify the URL.

**Edit**

Opens an **Edit** dialog box that allows you to modify the selected port and its URL. The *built-in editor variables* (on page 276) and *custom editor variables* (on page 284) can be used to specify the URL.

**Delete**

Removes the selected port from the list. It is available only for new ports that have been added to the list.

**Parameters Tab (XProc Transformations)**

When you *create a new transformation scenario* (on page 1674) or *edit an existing one* (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Parameters** tab presents a list of ports and parameters collected from the XProc script. The tab is divided into three sections:
**List of Ports**

In this section, you can use the **New** and **Delete** buttons to add or remove ports.

**List of Parameters**

This section presents a list of parameters for each port and includes columns for the parameter name, namespace URI, and its value. Use the **Filter** text box to search for a specific term in the entire parameters collection. You can use the **New** and **Delete** buttons to add or remove parameters. You can edit the value of each cell in this table by double-clicking the cell. You can also sort the parameters by clicking the column headers.

**Editor Variable Information**

The built-in editor variables (on page 276) and custom editor variables (on page 284) can be used for specifying the URI. The message pane at the bottom of the dialog box provides more information about the editor variables that can be used.

**Outputs Tab (XProc Transformations)**

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Outputs** tab displays a list of output ports (along with the URL) collected from the XProc script. Use the **Filter** text box to search for a specific term in the entire ports collection. You can also sort the columns by clicking the column headers.

The following actions are available for managing the output ports:

**New**

Opens an **Edit** dialog box that allows you to add a new output port and its URL. An editor variable (on page 276) can be inserted for the URL by using the ✱. **Insert Editor Variables** button. There is also a **Show in transformation results view** option that allows you to select whether or not the results will be displayed in the output **Results view** (on page 357).

**Edit**

Opens an **Edit** dialog box that allows you to edit an existing output port and its URL. An editor variable (on page 276) can be inserted for the URL by using the ✱. **Insert Editor Variables** button. There is also a **Show in transformation results view** option that allows you to select whether or not the results will be displayed in the output **Results view** (on page 357).

**Delete**
Removes the selected output port from the list. It is available only for new ports that have been added to the list.

Additional options that are available at the bottom of this tab include:

**Open in Editor**

If this option is selected, the XProc transformation result is automatically opened in an editor panel.

**Open in Browser/System Application**

If this option is selected, you can specify a file to be opened at the end of the XProc transformation in the browser or system application that is associated with the file type. You can specify the path by using the text field, its history drop-down, the *Insert Editor Variables (on page 276)* button, or the browsing actions in the *Browse* drop-down list.

**Results**

The result of the XProc transformation can be displayed as a sequence in an output view with two sections:

- A list with the output ports on the left side.
- The content that correspond to the selected output port on the right side.

Figure 608. XProc Transformation Results View

---

**Options Tab (XProc Transformations)**

When you create a new transformation scenario *(on page 1674)* or edit an existing one *(on page 1758)*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Options** tab displays a list of the options collected from the XProc script. The tab is divided into two sections:

**List of Options**
This section presents a list of options and includes columns for the option name, namespace URI, and its value. Use the Filter text box to search for a specific term in the entire options collection. You can use the New and Delete buttons to add or remove options. You can edit the value of each cell in this table by double-clicking the cell. You can also sort the parameters by clicking the column headers. The names of edited options are displayed in bold.

**Editor Variable Information**

The built-in editor variables *(on page 276)* and custom editor variables *(on page 284)* can be used for specifying the URI. This section provides more information about the editor variables that can be used.

**Calabash XProc Processor for Generating PDF Output**

To generate PDF output from your XProc pipeline (when using the Calabash XProc processor), follow these steps:

1. Open the \([OXYGEN_INSTALL_DIR]/lib/xproc/calabash/engine.xml\) file.
2. Uncomment the \(<\text{system-property name}="com.xmlcalabash.fo-processor" value="com.xmlcalabash.util.FoXEP"/>\) system property.
3. Uncomment the \(<\text{system-property name}="com.renderx.xep.CONFIG" file="../tools/xep/xep.xml"/>\) system property. Edit the file attribute to point to the configuration file that is usually located in the XEP installation folder.
4. Uncomment the references to the XEP libraries. Edit them to point to the matching library names from the XEP installation directory.
5. Restart Oxygen XML Editor.

**Integrating an External XProc Engine**

Oxygen XML Editor includes a bundled version of the Calabash XProc engine that can be used for XProc transformations and validation, but you can also integrate other external XProc engines. When you edit an XProc transformation scenario, there is a Processor drop-down menu where you can select the XProc engine to be used for the transformation.

If you do not need the external XProc engine to be used for automatic validation or pass parameters/ports and it is not Java-based, you can simply add the external engine by using the XProc preferences page *(on page 198)*. Otherwise, if the external engine is Java-based, or it has validation support, or it has the ability to receive parameters or ports passed from the transformation, you need to integrate it using the plugin extension procedure below.

For example, there is a public project on GitHub that is an implementation for integrating Morgana XProc with Oxygen XML Editor: [https://github.com/xml-project/support-for-xmleditor](https://github.com/xml-project/support-for-xmleditor). Also, the
Javadoc documentation of the XProc API is available for download from the application website as a zip file: `xprocAPI.zip`.

To create an XProc integration project, follow these steps:

1. Move the `oxygen.jar` file from `{OXYGEN_INSTALL_DIR}/lib` to the `lib` folder of your project.
2. Implement the `ro.sync.xml.transformer.xproc.api.XProcTransformerInterface` interface.
3. Create a [Java archive (JAR) (on page 3283)](#) from the classes you created.
4. Create an `engine.xml` file according to the `engine.dtd` file. The attributes of the `engine` element are as follows:
   - **name** - The name of the XProc engine.
   - **description** - A short description of the XProc engine.
   - **class** - The complete name of the class that implements `ro.sync.xml.transformer.xproc.api.XProcTransformerInterface`.
   - **version** - The version of the integration.
   - **engineVersion** - The version of the integrated engine.
   - **vendor** - The name of the vendor / implementer.
   - **supportsValidation** - true if the engine supports validation (otherwise, false).

   The `engine` element has only one child, `runtime`. The `runtime` element contains several `library` elements with the `name` attribute containing the relative or absolute location of the libraries necessary to run this integration.

5. Create a new folder (for example, named `MyXprocEngine`) and place the `engine.xml` and all the libraries necessary to run the new integration in that folder.
6. Place that new folder (e.g. `MyXprocEngine`) inside a new plugin folder. This new plugin folder should also contain a `plugin.xml` file that points to the new engine folder (e.g. `MyXprocEngine`).

   The `plugin.xml` file would look like this (it is based on the `AdditionalXProcEngine` extension (on page 2591)):

```
<plugin
   id="morgana.xproc.addon"
   name="Contribute Morgana XProc"
   description="Contribute Morgana XProc"
   version="1.0"
   vendor="Syncro Soft"
   class="ro.sync.exml.plugin.Plugin"
   classLoaderType="preferReferencedResources">
```

<extension type="AdditionalXProcEngine" path="MyXprocEngine/"></extension>

- Creating an XProc Transformation Scenario (on page 1742)
- Additional XProc Engine Plugin Extension (on page 2591)

XQuery Transformation

This type of transformation specifies the parameters and location of an XML source that the edited XQuery file is applied on.

**Note:** When the XML source is a native XML database, the source field of the scenario is empty because the XML data is read with XQuery-specific functions, such as `document()` . When the XML source is a local XML file, the URL of the file is specified in the input field of the scenario.

To create an XQuery transformation scenario, use one of the following methods:

- Use the Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu. Then click the New button and select XQuery transformation.
- Go to Window > Show View and select Transformation Scenarios to display this view (on page 1768). Click the New Scenario drop-down menu button and select XQuery transformation.

Both methods open the New Scenario dialog box.

The upper part of the dialog box allows you to specify the Name of the transformation scenario and the following Storage options:

- **Project Options (on page 3286)** - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.

- **Global Options (on page 3283)** - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.
The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

**XQuery Tab**

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **XQuery** tab contains the following options:

**XML URL**

Specifies the source XML file. You can specify the path by using the text field, its history drop-down, the Insert Editor Variables (on page 276) button, or the browsing actions in the Browse drop-down list. You can also use the Open in editor button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, then the file is used directly from its remote location.

**Note:** If the transformer engine is Saxon 9.x and a custom URI resolver is configured in the advanced Saxon preferences page (on page 204), the XML input of the transformation is passed to that URI resolver.

**XQuery URL**

Specifies the source XQuery file to be used for the transformation. You can specify the path by using the text field, its history drop-down, the Insert Editor Variables (on page 276) button, or the browsing actions in the Browse drop-down list. You can also use the Open in editor button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, the file is used directly from its remote location.

**Transformer**

This drop-down menu presents all the transformation engines available to Oxygen XML Editor for performing a transformation. These include the built-in engines and the external engines defined in the Custom Engines preferences page (on page 215). The engine you choose is used as the default transformation engine. Also, if an XSLT or XQuery document does not have an associated validation scenario, this transformation engine is used in the validation process (if it provides validation support).

**Advanced options**

Allows you to configure the advanced options of the Saxon HE/PE/EE engine (on page 1694) for the current transformation scenario. To configure the same options
globally, go to the Saxon-HE/PE/EE preferences page (on page 201). For the current transformation scenario, these **Advanced options** override the options configured in that preferences page.

**Parameters**

Opens the **Configure parameters** dialog box (on page 1693) for configuring the XQuery parameters. You can use the buttons in this dialog box to add, edit, or remove parameters. If the XQuery transformation engine is custom-defined, you can not use this dialog box to set parameters. Instead, you can copy all parameters from the dialog box using contextual menu actions and edit the custom XQuery engine to include the necessary parameters in the command line that starts the transformation process.

**Extensions**

Opens a dialog box for configuring the XQuery extension JARS or classes (on page 1694) that define extension Java functions or extension XSLT elements used in the transformation.

**XQuery Parameters**

The global parameters of the XQuery file used in a transformation scenario can be configured by using the **Parameters** button in the **XQuery** tab.

The resulting dialog box includes a table that displays all the parameters of the current XQuery file, along with their descriptions and current values. You can also add, edit, and remove parameters, and use the **Filter** text box to search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

If the **XPath** column is selected, the parameter value is evaluated as an XPath expression before starting the XQuery transformation.

**Example:**

For example, you can use expressions such as:

```xml
(doc('test.xml')//entry
 //person[@atr='val']
```

**Note:**

1. The **doc** function solves the argument relative to the XQuery file location. You can use full paths or **editor variables** (on page 276) (such as **$cfdu** [current file directory]) to specify other locations: `doc('${cfdu}/test.xml')//*`
2. Only XPath functions are allowed.
Below the table, the following actions are available for managing the parameters:

**New**

Opens the **Add Parameter** dialog box that allows you to add a new parameter to the list. An *editor variable (on page 276)* can be inserted in the text box using the ▶️ **Insert Editor Variables** button. If the Evaluate as XPath option is selected, the parameter will be evaluated as an XPath expression.

**Edit**

Opens the **Edit Parameter** dialog box that allows you to edit the selected parameter. An *editor variable (on page 276)* can be inserted in the text box using the ▶️ **Insert Editor Variables** button. If the Evaluate as XPath option is selected, the parameter will be evaluated as an XPath expression.

**Unset**

Resets the selected parameter to its default value. Available only for edited parameters with set values.

**Delete**

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

The bottom panel presents the following:

- The default value of the parameter selected in the table.
- A description of the parameter, if available.
- The system ID of the stylesheet that declares it.

Related Information:

- Editor Variables (on page 276)

**XQuery Extensions**

The **Extensions** button is used to specify the JAR (on page 3283) and classes that contain extension functions called from the XQuery file of the current transformation scenario. You can use the **Add**, **Edit**, and **Remove** buttons to configure the extensions.

An extension function called from the XQuery file of the current transformation scenario will be searched, in the specified extensions, in the order displayed in this dialog box. To change the order of the items, select the item to be moved and press the ▲ **Move up** or ▼ **Move down** buttons.
Advanced Saxon HE/PE/EE XQuery Transformation Options

The XQuery transformation scenario allows you to configure advanced options that are specific for the Saxon HE (Home Edition), PE (Professional Edition), and EE (Enterprise Edition) engines. They are the same options as those in the Saxon HE/PE/EE preferences page (on page 209) but they are configured as a specific set of transformation options for each transformation scenario, while the values set in the preferences page apply as global options. The advanced options configured in a transformation scenario override the global options (on page 3283) defined in the preferences page.

Saxon-HE/PE/EE Options

The advanced options for Saxon 9.8.0.12 Home Edition (HE), Professional Edition (PE), and Enterprise Edition (EE) are as follows:

**Use a configuration file (“-config”)**
Sets a Saxon 9.8.0.12 configuration file that is used for XQuery transformation and validation scenarios.

**Enable Optimizations (“-opt”)**
This option is selected by default, which means that optimization is enabled. If not selected, the optimization is suppressed, which is helpful when reducing the compiling time is important, optimization conflicts with debugging, or optimization causes extension functions with side-effects to behave unpredictably.

**Use linked tree model (“-tree:linked”)**
This option activates the linked tree model.

**Recoverable errors (“-warnings”)**
Specifies how dynamic errors are handled. The following options can be selected:

- **Recover silently (“silent”)** - Continues processing without reporting the error.
- **Recover with warnings (“recover”)** - Issues a warning but continues processing.
- **Signal the error and do not attempt recovery (“fatal”)** - Issues an error and stops processing.

**Strip whitespaces (“-strip”)**
Specifies how the strip whitespaces operation is handled. You can choose one of the following values:

- **All (“all”)** - Strips all whitespace text nodes from source documents before any further processing, regardless of any xml:space attributes in the source document.
- **Ignore** (*ignorable*) - Strips all *ignorable* whitespace text nodes from source documents before any further processing, regardless of any xml:space attributes in the source document. Whitespace text nodes are ignorable if they appear in elements defined in the DTD or schema as having element-only content.

- **None** (*none*) - Strips no whitespace before further processing.

### Saxon-PE/EE Options

The following advanced options are specific for Saxon 9.8.0.12 Professional Edition (PE) and Enterprise Edition (EE) only:

**Allow calls on extension functions** (*-ext*)

If selected, calls on external functions are allowed. Selecting this option is recommended in an environment where untrusted stylesheets may be executed. It also disables user-defined extension elements and the writing of multiple output files, both of which carry similar security risks.

### Saxon-EE Options

The advanced options that are specific for Saxon 9.8.0.12 Enterprise Edition (EE) are as follows:

**Validation of the source file** (*-val*)

Requests schema-based validation of the source file and of any files read using `document()` or similar functions. It can have the following values:

- **Schema validation** (*strict*) - This mode requires an XML Schema and allows for parsing the source documents with strict schema-validation enabled.

- **Lax schema validation** (*lax*) - If an XML Schema is provided, this mode allows for parsing the source documents with schema-validation enabled but the validation will not fail if, for example, element declarations are not found.

- **Disable schema validation** - This specifies that the source documents should be parsed with schema-validation disabled.

**Validation errors in the result tree treated as warnings** (*-outval*)

Normally, if validation of result documents is requested, a validation error is fatal. Selecting this option causes such validation failures to be treated as warnings.

**Write comments for non-fatal validation errors of the result document**

The validation messages for non-fatal errors are written (wherever possible) as a comment in the result document itself.

**Enable XQuery update** (*-update:(on|off)*)
This option controls whether or not XQuery update syntax is accepted. The default value is off.

**Backup files updated by XQuery (~-backup:(on|off))**

If selected, backup versions for any XML files updated with an XQuery Update are generated. This option is available when the Enable XQuery update option is selected.

**Other Options**

**Initializer class**

Equivalent to the `-init` Saxon command-line argument. The value is the name of a user-supplied class that implements the `net.sf.saxon.lib.Initializer` interface. This initializer is called during the initialization process, and may be used to set any options required on the configuration programmatically. It is particularly useful for tasks such as registering extension functions, collations, or external object models, especially in Saxon-HE where the option cannot be set via a configuration file. Saxon only calls the initializer when running from the command line, but the same code may be invoked to perform initialization when running user application code.

**FO Processor Tab (XQuery Transformations)**

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **FO Processor** tab contains the following options:

**Perform FO Processing**

Specifies whether or not an FO processor is applied (either the built-in Apache FOP engine or an external engine defined in Preferences) during the transformation.

**Input**

Choose between the following options to specify which input file to use:

- **XQuery result as input** - The FO processor is applied to the result of the XQuery transformation that is defined in the XQuery tab.
- **XML URL as input** - The FO processor is applied to the input XML file.

**Method**

The output format of the FO processing. The available options depend on the selected processor type.
Processor

Specifies the FO processor to be used for the transformation. It can be the built-in Apache FOP processor or an external processor (on page 216).

Output Tab (XQuery Transformations)

When you create a new transformation scenario (on page 1674) or edit an existing one (on page 1758), a configuration dialog box allows you to customize the transformation with various options in several tabs.

The Output tab contains the following options:

**Present as a sequence**

Selecting this option will reduce the time necessary to fetch the full results, as it will only fetch the first chunk of the results.

**Prompt for file**

At the end of the transformation, a file browser dialog box is displayed for specifying the path and name of the file that stores the transformation result.

**Save As**

The path of the file where the result of the transformation is stored. You can specify the path by using the text field, the Insert Editor Variables (on page 276) button, or the Browse button.

**Open in Browser/System Application**

If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the file type of the result (for example, in Windows PDF files are often opened in Acrobat Reader).

**Note:** To set the web browser that is used for displaying HTML/XHTML pages, go to Options > Preferences > Global, and set it in the Default Internet browser field.

- **Output file** - When Open in Browser/System Application is selected, you can use this button to automatically open the default output file at the end of the transformation.

- **Other location** - When Open in Browser/System Application is selected, you can use this option to open the file specified in this field at the end of the transformation.

You can specify the path by using the text field, the Insert Editor Variables (on page 276) button, or the Browse button.

**Open in editor**
When this option is selected, at the end of the transformation, the default output file is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor, or if it is an XSL-FO file it is opened with the built-in FO editor).

**Show in results view as**

You can choose to view the results in one of the following:

- **XML** - If this is selected, Oxygen XML Editor displays the transformation result in an XML viewer panel at the bottom of the application window with syntax highlighting *(on page 178)*.
- **SVG** - If this is selected, Oxygen XML Editor displays the transformation result in an integrated SVG viewer in the Results panel *(on page 1502)* at the bottom of the application window and renders the result as an SVG image.
- **XHTML** - This option is only available if Open in Browser/System Application is not selected. If selected, Oxygen XML Editor displays the transformation result in a built-in XHTML browser panel at the bottom of the application window.

⚠️ **Important:** When transforming very large documents, you should be aware that selecting this option may result in very long processing times. This drawback is due to the built-in Java XHTML browser implementation. To avoid delays for large documents, if you want to see the XHTML result of the transformation, you should use an external browser by selecting the Open in Browser/System Application option instead.

- **Image URLs are relative to** - If Show in results view as XHTML is selected, this option specifies the path used to resolve image paths contained in the transformation result. You can specify the path by using the text field, the Insert Editor Variables *(on page 276)* button, or the Browse button.

**SQL Transformation**

This type of transformation specifies a database connection for the database server that runs the SQL file associated with the scenario. The data processed by the SQL script is located in the database.

To create an SQL transformation scenario, use one of the following methods:

- Use the Configure Transformation Scenario(s) *(Ctrl + Shift + C (Command + Shift + C on OS X))* action from the toolbar or the Document > Transformation menu. Then click the New button and select SQL transformation.
- Go to Window > Show View and select Transformation Scenarios to display this view *(on page 1768)*. Click the New Scenario drop-down menu button and select SQL transformation.
Both methods open the **New Scenario** dialog box. This dialog box allows you to configure the following options that control the transformation:

**Name**

The unique name of the SQL transformation scenario.

**Storage**

Allows you to select one of the following storage options:

- **Project Options (on page 3286)** - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- **Global Options (on page 3283)** - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

**SQL URL**

Allows you to specify the URL of the SQL script. You can specify the path by using the text field, its history drop-down, the • Insert Editor Variables (on page 276) button, or the browsing actions in the • Browse drop-down list. You can also use the • Open in editor button to open the specified file in the editor panel.

**Connection**

Allows you to select a connection from a drop-down list. To configure a connection, use the • Advanced options button to open the Data Source preferences page (on page 229).

**Parameters**

Allows you to add or configure parameters for the transformation.

### Editing a Transformation Scenario

Editing a transformation scenario is useful if you need to configure some of its parameters.

**Note:** Since transformation scenarios that are associated with built-in frameworks (on page 3282) are read-only, to edit one of these scenarios you will need to duplicate it and edit the duplicated scenario (on page 1760).

To configure an existing transformation scenario, follow these steps:

1. Select the • Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu.
Step Result: The **Configure Transformation Scenario(s)** dialog box *(on page 1762)* is opened.

2. Select the particular transformation scenario and click the **Edit** button at the bottom of the dialog box or from the contextual menu.

Tip: You could also select the scenario and the **Edit** button in the **Transformation Scenarios view** *(on page 1768)* to achieve the same result.

Result: This will open an **Edit scenario** configuration dialog box that allows you to configure various options in several tabs, depending on the type of transformation scenario that was selected.

Transformation Types

The **Configure Transformation Scenario(s)** dialog box *(on page 1762)* contains a **Type** column that shows you the transformation type for each of the listed scenarios. Each type of transformation contains includes some tabs with various configuration options.

The following is a list of the transformation types and their particular tabs (click the name of each tab below to see details about all the options that are available):

- **DITA OT** - This type of transformation includes configurable options in the following tabs:
  - **Skins Tab** *(on page 3197)* (Available for **WebHelp Classic** and **WebHelp Classic with Feedback**)
  - **Templates Tab** *(on page 3199)* (Available for **WebHelp Responsive** and **WebHelp Responsive with Feedback**)
  - **FO Processor Tab** *(on page 3203)* (Available for PDF output)
  - **Parameters Tab** *(on page 3205)*
  - **Filters Tab** *(on page 3207)*
  - **Advanced Tab** *(on page 3208)*
  - **Output Tab** *(on page 3210)*
• **ANT** - This type of transformation includes configurable options in the following tabs:
  ◦ Options Tab (on page 1719)
  ◦ Parameters Tab (on page 1720)
  ◦ Output Tab (on page 1721)

• **XSLT** - This type of transformation includes configurable options in the following tabs:
  ◦ XSLT Tab (on page 1675)
  ◦ FO Processor Tab (on page 1684)
  ◦ Output Tab (on page 1685)

• **XProc** - This type of transformation includes configurable options in the following tabs:
  ◦ XProc Tab (on page 1743)
  ◦ Inputs Tab (on page 1744)
  ◦ Parameters Tab (on page 1744)
  ◦ Outputs Tab (on page 1745)
  ◦ Options Tab (on page 1746)

• **XQuery** - This type of transformation includes configurable options in the following tabs:
  ◦ XQuery Tab (on page 1691)
  ◦ FO Processor Tab (on page 1697)
  ◦ Output Tab (on page 1697)

Related Information:

• Creating New Transformation Scenarios (on page 1674)

• Duplicating a Transformation Scenario (on page 1760)

• Configure Transformation Scenario(s) Dialog Box (on page 1762)

• Applying Associated Transformation Scenarios (on page 1761)

Duplicating a Transformation Scenario

Duplicating a transformation scenario is useful for creating a scenario that is similar to an existing one or to edit a built-in transformation scenario.

To configure an existing transformation scenario, follow these steps:

1. Select the **Configure Transformation Scenario(s)** (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu.
Step Result: The Configure Transformation Scenario(s) dialog box (on page 1762) is opened.

2. Select the particular transformation scenario and click the Duplicate button at the bottom of the dialog box or from the contextual menu.

Tip: You could also select the scenario and the Duplicate button in the Transformation Scenarios view (on page 1768) to achieve the same result.

Result: This will open an Edit scenario configuration dialog box that allows you to configure various options in several tabs, depending on the type of transformation scenario that was selected. For information about all the specific options in the various tabs, see the Transformation Types section (on page 1759).

Related Information:

- Creating New Transformation Scenarios (on page 1674)
- Editing a Transformation Scenario (on page 1758)

Applying Associated Transformation Scenarios

If you have associated transformation scenarios for the current document (in the Configure Transformation Scenario(s) dialog box (on page 1762) or Transformation Scenarios view (on page 1768)), Oxygen XML Editor included an Apply Transformation Scenario(s) action that allows you to quickly apply the associated transformation scenarios on the current document. Note that if an association is not detected, this action will open the Configure Transformation Scenario(s) dialog box (on page 1762) where you can choose the scenarios you want to apply.

The Apply Transformation Scenario(s) action can be initiated from any of the following methods:

- Use the Ctrl + Shift + T (Command + Shift + T on OS X) keyboard shortcut.
- Click the Apply Transformation Scenario(s) button on the main toolbar.
- Click the Apply Transformation Scenario(s) button on the toolbar in the Transformation Scenarios view (on page 1768).
- Right-click a file in the Project view (on page 333) and select Transform > Apply Transformation Scenario(s).
- Use the Apply Associated button in the Configure Transformation Scenario(s) dialog box (on page 1762).

Related Information:
Configure Transformation Scenario(s) Dialog Box

You can use the Configure Transformation Scenario(s) dialog box for editing existing transformation scenarios (on page 1758) or creating new ones (on page 1674).

To open this dialog box, use the Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu.

Figure 610. Configure Transformation Scenario(s) Dialog Box

Top Section

The top section of the dialog box contains a filter that allows you to search through the scenarios list and the Settings button allows you to configure the following options:
Show all scenarios

Select this option to display all the available scenarios, regardless of the document they are associated with.

Show only the scenarios available for the editor

Select this option to only display the scenarios that Oxygen XML Editor can apply for the current document type.

Show associated scenarios

Select this option to only display the scenarios associated with the document you are editing.

ี้ Import scenarios

This option opens the Import scenarios dialog box that allows you to select the scenarios file that contains the scenarios you want to import. If one of the scenarios you import is identical to an existing scenario, Oxygen XML Editor ignores it. If a conflict appears (an imported scenario has the same name as an existing one), you can choose between two options:

- Keep or replace the existing scenario.
- Keep both scenarios.

Note: When you keep both scenarios, Oxygen XML Editor adds imported to the name of the imported scenario.

Export selected scenarios

Use this option to export selected scenarios individually. Oxygen XML Editor creates a scenarios file that contains the scenarios that you export. This is useful if you want to share scenarios with others or export them to another computer.

Middle Section

The middle section of the dialog box displays the scenarios that you can apply to the current document. You can view both the scenarios associated with the current document type and the scenarios defined at project level (on page 3286). The following columns are used to display the transformation scenarios:

- Association - The checkboxes in this column mark whether or not a transformation scenario is associated with the current document.
- Scenario - This column presents the names of the transformation scenarios.
• **Type** - If the **Show Type** contextual menu option is selected, this column displays the type of the transformation scenario. For further details about the types of transformation scenarios that are available in Oxygen XML Editor, see the **Transformation Types section (on page 1759)**.

• **Storage** - If the **Show Storage** contextual menu option is selected, this column displays where a transformation scenario is stored.

To sort each column you can left-click its header. The contextual menu of each header also includes the following actions:

**Show Type**

Use this option to display the transformation type of each scenario.

**Show Storage**

Use this option to display the storage location of the scenarios.

**Group by Association**

Select this option to group the scenarios depending on whether or not they are associated with the current document.

**Group by Type**

Select this option to group the scenarios by their type.

**Group by Storage**

Select this option to group the scenarios by their storage location.

**Ungroup all**

Select this option to ungroup all the scenarios.

**Reset Layout**

Select this option to restore the default settings of the layout.

Each transformation scenario listed in the middle section of the dialog box also includes the following contextual menu actions:

**Edit**

This button opens the **Edit Scenario configuration dialog box (on page 1758)** that allows you to configure the options of the transformations scenario.

**Duplicate**

Use this button to create a **duplicate transformation scenario (on page 1760)**.

**Remove**

Use this button to remove custom transformation scenarios.

**Change storage**
Allows you to change the storage location of a transformation scenario to Project Options (on page 3286) or Global Options (on page 3283). You are also able to keep the original storage location and make a copy of the selected scenario in the new storage location.

Import scenarios

This option opens the Import scenarios dialog box that allows you to select the scenarios file that contains the scenarios you want to import. If one of the scenarios you import is identical to an existing scenario, Oxygen XML Editor ignores it. If a conflict appears (an imported scenario has the same name as an existing one), you can choose between two options:

- Keep or replace the existing scenario.
- Keep both scenarios.

Note: When you keep both scenarios, Oxygen XML Editor adds imported to the name of the imported scenario.

Export selected scenarios

Use this option to export selected scenarios individually. Oxygen XML Editor creates a scenarios file that contains the scenarios that you export. This is useful if you want to share scenarios with others or export them to another computer.

Bottom Section

The bottom section of the dialog box contains the following actions and information:

Association follows selection

Select this checkbox to automatically associate selected transformation scenarios with the current document. This option can also be used for multiple selections.

Note: When this option is selected, the Association column is hidden.

New

This button allows you to create a new transformation scenario (on page 1674).

Edit

This button opens the Edit Scenario dialog box that allows you to configure the options of the transformations scenario. For information about all the specific options in the various tabs, see the Transformation Types section (on page 1759).

Note: If you try to edit a transformation scenario associated with a defined document type, Oxygen XML Editor displays a warning message to inform you that this
is not possible and gives you the option to create a duplicate transformation scenario (on page 1760) to edit instead.

**Duplicate**

Use this button to create a duplicate transformation scenario (on page 1760).

**Remove**

Use this button to remove transformation scenarios.

**Note:** Removing scenarios associated with a defined document type is not allowed.

**Associated scenarios section**

Displays the scenarios that are associated with the current document. Selecting a checkbox in the **Association** column (on page 1763) in the list of scenarios will add that scenario to this section. To remove a scenario from being associated with the current document, simply click the remove icon (✖) to the right of the scenario name.

**Save and close**

Saves the current configuration and closes the dialog box.

**Apply associated**

Use this button to apply the associated scenarios and run the transformation on the current document.

**Cancel**

Cancels any changes made in the dialog box and reverts to the previously saved association.

Your selections in the **Configure Transformation Scenarios(s)** dialog box are persistent so the configured associations for the current document will be remembered after the dialog box is closed.

**Related Information:**

- Editing a Transformation Scenario (on page 1758)
- Duplicating a Transformation Scenario (on page 1760)
- Applying Associated Transformation Scenarios (on page 1761)
- Creating New Transformation Scenarios (on page 1674)
Batch Transformations

A transformation action can be applied on a batch of selected files from the contextual menu of the Project view without having to open the files involved in the transformation. You can apply the same scenario to a batch of files or multiple scenarios to a single file or batch of files.

1. (Optional, but recommended) Organize the files you want to transform in logical folders.
   a. Create a logical folder in the Project view by using the New > Logical Folder action from the contextual menu of the root file.
   b. Add files you want to transform to the logical folder by using the Add Files or Add Edited File actions from the contextual menu of the logical folder.

   Note: You can skip this step if the files are already in a dedicated folder that does not include any additional files or folders. You can also manually select the individual files in the Project view each time you want to transform them, but this can be tedious.

2. Select the files you want to transform (or the newly created logical folder) and from the contextual menu, select Transform > Configure Transformation Scenario(s) to choose one or more transformation scenarios to be applied on all the files in the logical folder.

3. Use Oxygen XML Editor editor variables to specify the input and output files. This ensures that each file from the selected set of resources is processed and that the output is not overwritten by the subsequent processing.
   a. Edit the transformation scenario to make sure the appropriate editor variable is assigned for the input file. For example, for a DocBook PDF transformation, make sure the XML URL input box is set to the ${currentFileURL} editor variable. For a DITA PDF transformation, make sure the args.input parameter is set to the ${cf} editor variable.
   b. Edit the transformation scenario to make sure the appropriate editor variable is assigned for the output file. For example, for an XML transformation with XSLT, switch to the Output tab and set the path of the output file using a construct of editor variables, such as ${cfd}/${cfn}.html.

4. Now that logical folder has been associated with one or more transformation scenarios, whenever you want to apply the same batch transformation you can select Transform > Transform with from the contextual menu and the same previously associated scenario(s) will be applied.
5. If you want a different type of transformation to be applied to each file inside the logical folder, associate individual scenarios for each file and select **Transform > Apply Transformation Scenario(s)** from the contextual menu of the logical folder.

Related Information:

- Editor Variables (on page 276)

Sharing Transformation Scenarios

The transformation scenarios and their settings can be shared with other users by saving them at **project level (on page 3286)** or by exporting them to a specialized scenarios file (on page 276) that can then be imported. When you create a new transformation scenario or edit an existing one, there is a **Storage** option to control whether the scenarios are stored in **Project Options (on page 3286)** or **Global Options (on page 3283)**.

Selecting **Project Options (on page 3286)** stores the scenario in the project file and can be shared with other users that have access to the project. If your project is saved on a source versioning system (CVS, SVN, Source Safe, etc.) then your team will have access to the scenarios that you define. When you create a scenario at the project level, the URLs from the scenario become relative to the project URL.

Selecting **Global Options (on page 3283)** stores the scenario in the global options that are stored in the user home directory.

You can also change the storage options on existing transformation scenarios by using the **Change storage action (on page 1762)** from the contextual menu of the list of scenarios.

Related Information:

- Sharing Application Settings (on page 266)

Transformation Scenarios View

You can manage the transformation scenarios by using the **Transformation Scenarios** view. To open this view, select **Window > Show View > Transformation Scenarios**.
Oxygen XML Editor supports multiple scenarios association. To associate multiple scenarios with a document, select the checkboxes in front of each scenario. You can also associate multiple scenarios with a document from the Configure Transformation Scenario(s) dialog box (on page 1762).

The Transformation Scenarios view presents both global and project-level (on page 3286) scenarios. By default, Oxygen XML Editor presents the items in the following order:

1. Scenarios that match the current framework (on page 3282).
2. Scenarios that match the current project.
3. Scenarios that match other frameworks.

Toolbar/Contextual Menu Actions and Options

The following actions and options are available on the toolbar or in the contextual menu:

- **Apply selected scenarios**
  
  Select this option to run the current transformation scenario.

- **Debug selected scenario**
Select this option to switch to the **Debugger perspective** *(on page 3285)* and initialize it with the parameters from the scenario (the XML, XSLT, or XQuery input, the transformation engine, the XSLT parameters).

**New**

This drop-down menu contains a list of the **scenarios that you can create** *(on page 1674)*. Oxygen XML Editor determines the most appropriate scenarios for the current type of file and displays them at the beginning of the list, followed by the rest of the scenarios.

**Duplicate**

Adds a new scenario to the list that is a duplicate of the current scenario. It is useful for creating a scenario that is similar to an existing one.

**Edit**

Opens the dialog box that allows you to configure various options in several tabs, depending on the type of transformation scenario that was selected. For information about all the specific options in the various tabs, see the **Transformation Types section** *(on page 1759)*.

**Remove**

Removes the current scenario from the list. This action is also available by using the **Delete** key.

**Change storage**

Use this option to change the storage location of the selected scenario. You are also able to keep the original storage location and make a copy of the selected scenario in the target storage location.

**Import scenarios**

This option opens the **Import scenarios** dialog box that allows you to select the **scenarios** file that contains the scenarios you want to import. If one of the scenarios you import is identical to an existing scenario, Oxygen XML Editor ignores it. If a conflict appears (an imported scenario has the same name as an existing one), you can choose between two options:

- Keep or replace the existing scenario.
- Keep both scenarios.

**Note:** When you keep both scenarios, Oxygen XML Editor adds **imported** to the name of the imported scenario.

**Export selected scenarios**
Use this option to export transformation and validation scenarios individually. Oxygen XML Editor creates a scenarios file that contains the scenarios that you export.

### Settings

This drop-down menu allows you to configure the following options (many of these options are also available if you right-click the name of a column):

#### Show all scenarios

Select this option to display all the available scenarios, regardless of the document they are associated with.

#### Show only the scenarios available for the editor

Select this option to only display the scenarios that Oxygen XML Editor can apply for the current document type.

#### Show associated scenarios

Select this option to only display the scenarios associated with the document you are editing.

### Change storage

Use this option to change the storage location of the selected scenario to Project Options (on page 3286) or Global Options (on page 3283). You are also able to keep the original storage location and make a copy of the selected scenario in the new storage location.

### Import scenarios

This option opens the Import scenarios dialog box that allows you to select the scenarios file that contains the scenarios you want to import. If one of the scenarios you import is identical to an existing scenario, Oxygen XML Editor ignores it. If a conflict appears (an imported scenario has the same name as an existing one), you can choose between two options:

- Keep or replace the existing scenario.
- Keep both scenarios.

Note: When you keep both scenarios, Oxygen XML Editor adds imported to the name of the imported scenario.

### Export selected scenarios

Use this option to export selected scenarios individually. Oxygen XML Editor creates a scenarios file that contains the scenarios that you
export. This is useful if you want to share scenarios with others or export them to another computer.

**Show Type**

Use this option to display the transformation type of each scenario.

**Show Storage**

Use this option to display the storage location of the scenarios.

**Group by Association**

Select this option to group the scenarios depending on whether or not they are associated with the current document.

**Group by Type**

Select this option to group the scenarios by their type.

**Group by Storage**

Select this option to group the scenarios by their storage location.

**Ungroup all**

Select this option to ungroup all the scenarios.

**Reset Layout**

Select this option to restore the default settings of the layout.

Your selections in the **Transformation Scenarios** view are persistent so the configured associations for the current document will be remembered whenever the document is opened.

**Related Information:**

**WebHelp Output Customization**

**Oxygen XML WebHelp** provides the ability to generate two different types of output, **WebHelp Responsive** and **WebHelp Classic**. Both types include a feedback-enabled variant and each has its own set of options and features. The **WebHelp Responsive** variants are available for DITA documents while the **WebHelp Classic** variants are available for both DITA and DocBook.

### WebHelp Classic Output

The **WebHelp Classic** variant is designed for desktop systems when feedback from users is not necessary and it is available for DocBook and DITA document types. The **WebHelp Classic with Feedback** variant also includes a feedback system that allows your users to make comments and allows you to manage and reply to them. This section contains information about configuring a WebHelp Classic system and customizing the output.

This type of WebHelp system can be generated by using one of the following transformation scenarios:

- DITA Map WebHelp Classic transformation scenario *(on page 1652)*
- DITA Map WebHelp Classic with Feedback transformation scenario *(on page 1653)*
- DocBook WebHelp Classic transformation scenario *(on page 1668)*
- DocBook WebHelp Classic with Feedback transformation scenario *(on page 1668)*

### WebHelp Classic Output Layout and Features

#### Layout of the WebHelp Classic System Interface

The layout of the **WebHelp Classic** system is comprised of the following components:

- **Left Pane or Frame**
This section on the left side of the help system includes the following tabs:

**Content**

A typical table of contents style presentation of your content. You can use the [Expand all]/[Collapse all] buttons to expand or collapse all the topics presented in the Table of Contents.

*Note:* You can enhance the appearance of items in the *Table of Contents*. See the *Customizing WebHelp Classic Output chapter* (on page 1806) for more details.

**Index**

Presents the index terms for your content. If your content does not contain any `indexterm` elements, this tab is not generated.

**Search Results**

This tab is generated when the *Search* field is used. It presents the search results in the form of links to topics where the search terms are found, along with a rating scheme for each result. For more details, see the *Search Feature section* (on page 1777).

**Upper Pane or Frame**

The upper section of the help system includes the following features:

**Search Field**

Use this feature to perform searches in your content. When you enter search terms in this field, the results are displayed in the **Search Results** tab in the left section of the help system, along with a rating scheme for each result. For more details, see the *Search Feature section* (on page 1777).

**Frames Option**

Click on this option to display the output rendered in HTML frames.

**Print Option**

Opens a dialog box with various printing options and a print preview.

**Navigation Links**

You can navigate through the content of your output using the navigation links or arrows in the upper-right part of the page. These arrows allow you to move to the ‹ Parent topic, ‹ Previous topic, or ․ Next topic. Links to the parent topics of the currently opened topic are also presented at
the top of the page. For DITA output, these navigation links are controlled by the `collection-type` attribute. For example, if you set `collection-type="sequence"` on a parent topic reference, navigation links will be generated in the output for that topic and all of its child topics.

**Tip:** To hide the **Parent**, **Next**, and **Previous** links, you can edit the transformation scenario and set the value of the `args.hide.parent.link` parameter to `yes`.

**Main Pane or Frame**

The content of the help pages are rendered and displayed in this main section.

**Figure 612. WebHelp Classic Output**

![WebHelp Classic Output](image)

**WebHelp Classic with Feedback Enabled**

The **WebHelp Classic with Feedback** variant also contains a **Comments** section at the bottom of each topic. This section is where you can interact with users through a comment system. For information about deploying a feedback-enabled system, see [Deploying a Feedback-Enabled System](on page 1873).
Figure 613. WebHelp Classic with Feedback Comments Section

To add a new comment, click the Add New Comment button, or click Reply to add a comment to an existing thread. You can click on the Log in button on the right side of this bar to be authenticated as a user and your user name will be included in any comments that you add. If you do not have a user name, you can click on the Sign Up button to create a new user.

After you log in, your name and user name are displayed in the Comments bar, along with the Log off and Edit buttons. Click the Edit button to open the User Profile dialog box where you can customize the following options:

- **Your Name** - You can use this field to edit the initial name that you used to create your user profile.
- **Your email address** - You can use this field to edit the initial email address that you used to create your profile.
- You can choose to receive an email in the following situations:
  - When a comment is left on a page that you commented on.
  - When a comment is left on any topic in the WebHelp Classic system.
  - When a reply is left to one of my comments.
- **New Password** - Allows you to enter a new password for your user account.
Note: The Current Password field from the top of the User Profile is mandatory if you want to save the changes you make.

If you are an administrator, you can manage user information and comments. For more information, see Managing Users and Comments in a Feedback-Enabled System (on page 1877).

WebHelp Classic Search Engine

Search Rules

Rules that are applied during a search include:

- You can use quotes to perform an exact search for multiple word phrases (for example, "grow flowers" will only return results if both words are found consecutively and exactly as they are typed in the search field). This type of search is known as a phrase search.
- Boolean Search is supported using the following operators: and, or, not. When there are two adjacent search terms without an operator, or is used as the default search operator (for example, grow flowers is the same as grow or flowers).
- The space character separates keywords (an expression such as grow flowers counts as two separate keywords: grow and flowers).
- \texttt{indexterm} and \texttt{keywords} DITA elements are an effective way to increase the ranking of a page (for example, content inside a \texttt{keywords} element weighs more than an \texttt{H1 HTML} element).
- Words composed by merging two or more words with colon (""), minus (""), underline (""), or dot ("") characters count as a single word.
- Your search terms should contain two or more characters (note that stop words will be ignored). This rule does not apply to CJK (Chinese, Japanese, Korean) languages.
- When searching for multi-word phrases in CJK (Chinese, Japanese, Korean) languages that often have multiple words appear in strings without a space separator, you need to add a space to separate the words. Otherwise WebHelp will not find results. For example, Chinese uses a specialized character for space separators, but the current WebHelp implementation cannot detect such specialized characters, so to search for #### (it translates as "before you begin" or "before start"), you have to enter ## ## (notice the space between the second and third symbols) in the search field.

5-Star Rating Mechanism and Sorting

The Search feature is also enhanced with a rating mechanism that computes scores for every result that matches the search criteria. These scores are then translated into a 5-star rating scheme and the stars are displayed to the right of each result. The search results are sorted depending on the following:

- Search entries that satisfy the phrase search criterion are presented first.
• The number of keywords found in a single page (the higher the number, the better).
• The context (for example, a word found in a title, scores better than a word found in unformatted text). The search ranking order, sorted by relevance is as follows:
  ◦ The search term is included in a meta keyword.
  ◦ The search term is in the title of the page.
  ◦ The search term is in bold text in a paragraph.
  ◦ The search term is in normal text in a paragraph.

Excluded Terms

To improve performance, the Search feature excludes certain stop words. For example, the English version of the stop words includes: a, an, and, are, as, at, be, but, by, for, if, in, into, is, it, no, not, of, on, or, such, that, the, their, then, there, these, they, this, to, was, will, with.

WebHelp Classic Search Results Tab

When you enter search terms in the Search field at the top of the help system, the results are displayed in the Search Results tab in the left section. When you click on a result in the Search Results tab, that result is displayed in the main pane with the search terms highlighted. If you press Enter with the Search field empty, the highlights are removed.

Figure 614. WebHelp Classic Search Results Tab
Missing Terms

If you enter multiple search terms (other than stop words), for any result that the search engine found at least one term but not one or more of the other terms, the Missing terms will be listed below each result.

Tag Element Scoring Values

HTML tag elements are also assigned a scoring value and these values are evaluated for the search results. For information about editing these values, see How to Change Element Scoring in Search Results (on page 1825).

Browser Compatibility

This output format is compatible with the most recent versions of the following common browsers:

• Edge
• Internet Explorer (IE 10 or newer)
Important: Due to some security restrictions in certain browsers (Google Chrome and Internet Explorer), WebHelp Classic pages loaded from the local system (through URLs of the file:///... format) may not work properly. It is recommended that you load WebHelp Classic pages in Google Chrome or Internet Explorer only from a web server (with a URL such as http://your.server.com/webhelp/index.html or http://localhost/web_pages/index.html).

Warning: Due to some restrictions in web browsers regarding JavaScript code, the frameless version (index.html start page) of the WebHelp Classic system should only be loaded from a web server (with a URL such as http://your.server.com/webhelp/index.html or http://localhost/web_pages/index.html). When loading WebHelp Classic pages from the local file system, the frameset version (index_frames.html start page) of the WebHelp Classic system should be used instead (file:///...).

Deploying a Feedback-Enabled System

System Requirements

The feedback-enabled WebHelp system requires a standard server deployment. You can request this from your server administrator and it requires the following system components:

- A Web server (such as Apache Web Server)
- A MySQL or MariaDB database server
- A database admin tool (such as phpMyAdmin)
- PHP Version 5.1.6 or later

The WebHelp system supports most of the recent versions of the following browsers: Chrome, Firefox, Edge, Internet Explorer, Safari, Opera.

Create WebHelp with Feedback Database

The WebHelp with Feedback system needs a database to store user details and the actual feedback, and a user added to it with all privileges. After this is created, you should have the following information:

- Database name
- Username
Exactly how you create the database and user depends on your web host and your particular needs.

**Example:**

The following procedure uses *phpMyAdmin* to create a MySQL database for the feedback system and a MySQL user with privileges for that database. The feedback system uses these credentials to connect to the database.

**Using *phpMyAdmin* to create a database:**

1. Access the *phpMyAdmin* instance running on your server.
2. Click *Databases* (in the right frame) and then create a *database*. You can give it any name you want (for example *comments*).
3. Create a user with connection privileges for this database.
4. Under *localhost*, in the right frame, click *Privileges* and then at the bottom of the page click the *reload the privileges* link.

**Deploying the WebHelp with Feedback Output**

If you have a web server configured with PHP and MySQL, you can deploy the *WebHelp with Feedback* output by following these steps:

1. Connect to your server using an FTP client.
2. Locate the home directory (from now on, referred to as *DOCUMENT_ROOT*) of your server.
3. Copy the transformation output folder into the *DOCUMENT_ROOT* folder.
4. Rename it to something relevant (for example, *myProductWebHelp*).
5. Open the output folder (for example, `http://[YOUR_SERVER]/myProductWebHelp/`). You are redirected to the installation wizard. Proceed with the installation as follows:
   a. Verify that the prerequisites are met.
   b. Press *Start Installation*.
   c. Configure the *Deployment Settings* section. Default values are provided, but you should adjust them as needed.

   **Tip:** You can change some of the options later. The installation creates a *config.php* file in `[/OXYGEN_WEBHELP_INSTALL_DIR]/feedback/resources/php/config/config.php` where all your configuration options are stored.

   d. Configure the *MySql Database Connection Settings* section. Use the information (database name, username, password) from the *Create WebHelp with Feedback Database* section (on page 1874) to fill-in the appropriate text boxes.
**Warning:** Selecting the **Create new database structure** option will overwrite any existing data in the selected database, if it already exists. Therefore, it is useful the first time you install the **WebHelp with Feedback** system, but you do not want to select this option on subsequent deployments.

e. If you are using a domain (such as *OpenLDAP* or *Active Directory*) to manage users in your organization, select the **Enable LDAP Authentication** option. This will allow you to configure the LDAP server, which will provide information and credentials for users who will access the WebHelp system. Also, this will allow you to choose which of the domain users will have administrator privileges.

f. If the **Create new database structure** option is selected, the **Create WebHelp Administrator Account** section becomes available. Here you can set the administrator account data. The administrator is able to moderate new posts and manage WebHelp users.

The same database can be used to store comments for multiple **WebHelp with Feedback** deployments. If a topic is available in multiple deployments and there are comments associated with it, you can choose to display the comments in all deployments that share the database. To do this, select the **Display comments from other products** option. In the **Display comments from** section, a list with the deployments sharing the same database is displayed. Select the deployments allowed to share common feedback.

**Note:** You can restrict the displayed comments of a product depending on its version. If you have two products that use the same database and you restrict one of them to display comments starting from a certain version, the comments of the other product are also displayed from the specified version onwards.

g. Press **Next Step**.

h. Remove the installation folder from your web server.

**Important:** When you publish subsequent iterations of your **WebHelp with Feedback** system, you will not upload the `/install` folder in the output, as you only need it uploaded the first time you create the installation. On subsequent uploads, you will just upload the other output files.

i. In your Web browser, go to your **WebHelp with Feedback** system main page.

**Testing Your WebHelp with Feedback System**

To test your system, create a user and post a comment. Check to see if the notification emails are delivered to your email inbox.

**Note:** To read debug messages generated by the system:

1. Enable **JavaScript** logging by doing one of the following:
Open the `log.js` file, locate the `var log= new Log(Level.NONE);` line, and change the logging level to: `Level.INFO`, `Level.DEBUG`, `Level.WARN`, or `Level.ERROR`.

2. Inspect the PHP and Apache server log files.

### Documentation Product ID and Version

When you run a **WebHelp with Feedback** transformation scenario, by default you are prompted for a documentation product ID and version number. This is needed when multiple WebHelp systems are deployed on the same server. Think of your WebHelp output as a *product*. If you have three different WebHelp outputs, you have three different *products* (each with their own unique documentation product ID). This identifier is included in a configuration file so that comments are tied to a particular output (product ID and version number).

**Note:** The **WebHelp with Feedback** installation includes a configuration option (Display comments from other products) that allows you to choose to have comments visible in other specified *products*.

### Refreshing the Content of a Feedback-Enabled System

It is common to update the content of an existing installation of a **WebHelp with Feedback** system on a regular basis. In this case, reinstalling the whole system is not a viable option since it might result in the loss of the comments associated with your topics. Also, reconfiguring the system every time you want to refresh it may be time consuming.

Fortunately, you can refresh just the content without losing the comments or the initial system configuration. To do so, follow these steps:

1. Execute the transformation scenario that produces the **WebHelp with Feedback** output directory.
2. Go to the output directory (specified in the **Output** tab of the transformation scenario), locate the `feedback/resources/php/config/config.php` file, and delete it.
3. Locate the `feedback/install` directory and delete it.
4. Copy the remaining structure of the output folder and paste it into your **WebHelp with Feedback** system installation directory, overwriting the existing content.
Managing Users and Comments in a Feedback-Enabled System

When you installed the WebHelp with Feedback system the first time (assuming the Create new database structure option (on page 1875) was selected), you should have been prompted to create an administrator account (or a user named administrator was created by default). As an administrator, you have access to manage comments posted in your feedback-enabled WebHelp system. You can also manage the user information (such as role, status, or notification options).

To manage comments and user information, follow these steps:

1. At the bottom of each specific topic there is a Comments navigation bar and on the right side there is a Log in button. Click this button and log in with your administrator credentials. This gives you access to an Admin Panel button.
2. Click the Admin Panel button to display an administration page.

Figure 615. Administrative Page

3. Use this page to manage the following options:

   **Delete Orphaned Comments**
   
   Allows you to delete comments that are no longer associated with a topic in your WebHelp system.

   **Delete Pending Users**
   
   Allows you to delete user accounts that you do not wish to activate.

   **View All Posts**
   
   Allows you to view all the comments that are associated with topics in your WebHelp system.

   **Export Comments**
   
   Allows you to export all posts associated with topics in your WebHelp system into an XML file.

   **Set Version**
   
   Use this action to display comments starting with a particular version.
Manage User Information

To edit the details for a user, click on the corresponding row. This opens a window that allows you to customize the following information associated with the user:

**Name**

The full name of the user.

**Level**

Use this field to modify the privilege level (role) for the selected user. You can choose from the following:
- **User** - Regular user, able to post comments and receive e-mail notifications.
- **Moderator** - In addition to the regular User rights, this type of user has access to the Admin Panel where a moderator can view, delete, export comments, and set the version of the feedback-enabled WebHelp system.
- **Admin** - Full administrative privileges. Can manage WebHelp-specific settings, users, and their comments.

**Company**

The name of the organization associated with the user.

**E-Mail**

The contact email address for the user. This is also the address where the WebHelp system sends notifications.

**WebHelp Notification**

When selected, the user receives notifications when comments are posted anywhere in your feedback-enabled WebHelp system.

**Reply Notification**

When selected, the user receives notifications when comments are posted as a reply to one of their comments.

**Page Notification**

When selected, the user receives notifications when comments are posted on a topic where they previously posted a comment.

**Date**

The date the user registered is displayed.

**Status**
Use this drop-down list to change the status of the user. You can choose from the following:

- **Created** - The user is created but does not yet have any rights for the feedback-enabled WebHelp system.
- **Validated** - The user is able to use the feedback-enabled WebHelp system.
- **Suspended** - The user has no rights for the feedback-enabled WebHelp system.

⚠️ **Warning:** The key used for identifying the page a comment is attached to is the relative file path to the output page. Since the output file and folder names mirror the source, any change to the file name (or its folder) in the source will affect the comments associated with that WebHelp page. If you change the file name or path, the comment history for that topic will become orphaned (a change to the topic ID does not affect the comment history).

### Context-Sensitive WebHelp Classic System

Context-sensitive help systems assist users by providing specific informational topics for certain components of a user interface, such as a button or window. This mechanism works based on mappings between a unique ID defined in the topic and a corresponding HTML page.

### Generating Context-Sensitive Help

When WebHelp Classic output is generated, the transformation process produces an XML mapping file called `context-help-map.xml` and copies it in the output folder of the transformation. This XML file maps an ID to a corresponding HTML page through an `appContext` element, as in the following example:

```xml
<map productID="oxy-webhelp" productVersion="1.1">
  <appContext helpID="myapp-functionid1" path="tasks/app-help1.html"/>
  <appContext helpID="myapp-functionid2" path="tasks/app-help1.html"/>
  ...
</map>
```

The possible attributes are as follows:

- **helpID**
  
  A Unique ID provided by a topic from two possible sources (`resourceid` element or the `id` attribute that is set on the topic root element):

  ```xml
  resourceid
  ```
The `resourceid` element is mapped into the `appContext` element and can be specified in either the `topicref` within a DITA map or in a prolog within a DITA topic. The `resourceid` element accepts the following attributes:

- **appname** - A name for the external application that references the topic. If this attribute is not specified, its value is considered to be empty ("").
- **appid** - An ID used by an application to identify the topic.
- **id** - Specifies a value that is used by a specific application to identify the topic, but this attribute is ignored if an `appid` attribute is used. Also, starting with DITA 1.3, the `id` attribute was deprecated in favor of the `appid` attribute.

**Note:** Multiple `appid` values can be associated with a single `appname` value (and multiple `appname` values can be associated with a single `appid` value), but the values for both attributes work in combination to specify a specific ID for a specific application, and therefore each combination of values for the `appid` and `appname` attributes should be unique within the context of a single root map (on page 3287). For example, suppose that you need two different functions of an application to both open the same WebHelp page.

**Example: resourceid Specified in a DITA Map**

The `resourceid` element can be specified in a `topicmeta` element within a `topicref`.

```xml
<map title="App Help">  
   <topicref href="app-help1.dita" type="task">  
      <topicmeta>  
         <resourceid appname="myapp" appid="functionid1"/>  
         <resourceid appname="myapp" appid="functionid2"/>  
      </topicmeta>  
   </topicref>  
</map>
```

**Example: resourceid Specified in a DITA Topic**

The `resourceid` element can be specified in a `prolog` element within a DITA topic.

```xml
<task id="app-help1">  
```
For more information about the `resourceid` element, see DITA Specifications: `<resourceid>`.

**id**

If a `resourceid` element is not declared in the DITA map or DITA topic (as described above), the `id` attribute that is set on the topic root element is mapped into the `appContext` element.

⚠️ **Important:** You should ensure that these defined IDs are unique in the context of the entire DITA project. If the IDs are not unique, the transformation scenario will display warning messages in the transformation console output and the help system will not work properly.

**path**

The path to a corresponding WebHelp page. This path is relative to the location of the `context-help-map.xml` mapping file.

**productID** *(Applicable only if you are using the WebHelp Classic with Feedback transformation scenario)*

The ID of the product for your documentation project.

**productVersion** *(Applicable only if you are using the WebHelp Classic with Feedback transformation scenario)*

The version of the product for your documentation project.

There are two ways of implementing context-sensitive help in your system:

- The XML mapping file can be loaded by a PHP script on the server side. The script receives the `contextId` value and will look it up in the XML file.
- Invoke one of the WebHelp system files `index.html` or `index_frames.html` and pass the `contextId` parameter with a specific value. The WebHelp system will automatically open the help page associated with the value of the `contextId` parameter.

**Note:** The `contextId` parameter is not case-sensitive.
The following example will open a frameless version of the WebHelp system showing the page associated with the ID dialog1ID:

```
index.html?contextId=dialog1ID
```

The following example will open a frameset version of the WebHelp system showing the page associated with the ID view1ID:

```
index_frames.html?contextId=view1ID
```

Tip: You can use an anchor (on page 3279) in the contextId parameter to jump to a specific section in a document. For example, contextId=topicID#anchor.

Context-Sensitive Queries

You can use the URL field in your browser to search for topics in a context-sensitive WebHelp system with the assistance of the following parameters:

- **contextId** - The WebHelp JavaScript engine will look for this value in the context-help-map.xml mapping file and load the corresponding help page.

  Note: You can use an anchor (on page 3279) in the contextId parameter to jump to a specific section in a document. For example, contextId=topicID#anchor.

- **appname** - You can use this parameter in conjunction with contextId to search for this value in the corresponding appname attribute value (on page 1787) in the mapping file.

```
http://localhost/webhelp/index.html?contextId=topicID&appname=myApplication
```

Generating WebHelp Classic Output for DITA

The publishing process can be initiated from a transformation scenario within Oxygen XML Editor/Author, from a command line outside Oxygen XML Editor/Author, or from an integration server.

Running from Oxygen XML Editor/Author

To publish DITA content to WebHelp Classic output from a transformation scenario inside Oxygen XML Editor/Author, use one of the following procedures, depending on whether or not you want a feedback section in your output.

**WebHelp Classic Output**

To publish a DITA map (on page 3281) as a WebHelp Classic system, follow these steps:
1. Select the Configure Transformation Scenario(s) action from the DITA Maps Manager toolbar.

2. Select the DITA Map WebHelp Classic scenario from the DITA Map section.

3. If you want to configure the transformation, click the Edit button.

**Step Result:** This opens an Edit scenario configuration dialog box that allows you to configure various options in the following tabs:

- **Templates Tab** - This tab contains a set of built-in skins that you can use for the layout of your WebHelp system output.
- **Parameters Tab** - This tab includes numerous transformation parameters that can be set to customize your WebHelp system output.
- **Filters Tab** - This tab allows you to filter certain content elements from the generated output.
- **Advanced Tab** - This tab allows you to specify some advanced options for the transformation scenario.
- **Output Tab** - This tab allows you to configure options that are related to the location where the output is generated.

4. Click Apply associated to process the transformation.

When the DITA Map WebHelp Classic transformation is complete, the output is automatically opened in your default browser.

To further customize this transformation, you can edit various parameters, including the following most commonly used ones:

### WebHelp Classic with Feedback Output

To publish a DITA map (on page 3281) as a WebHelp Classic with Feedback system, follow these steps:

1. Select the Configure Transformation Scenario(s) action from the DITA Maps Manager toolbar.

2. Select the DITA Map WebHelp Classic with Feedback scenario from the DITA Map section.

3. If you want to configure the transformation, click the Edit button.

**Step Result:** This opens an Edit scenario configuration dialog box that allows you to configure various options in the following tabs:

- **Templates Tab** - This tab contains a set of built-in skins that you can use for the layout of your WebHelp system output.
- **Parameters Tab** - This tab includes numerous transformation parameters that can be set to customize your WebHelp system output.
- **Filters Tab** - This tab allows you to filter certain content elements from the generated output.
- **Advanced Tab** - This tab allows you to specify some advanced options for the transformation scenario.
• **Output Tab** - This tab allows you to configure options that are related to the location where the output is generated.

4. Click **Apply associated** to begin the transformation.

5. Enter the documentation product ID (value for the `webhelp.product.id` parameter) and the documentation version (value for the `webhelp.product.version` parameter).

When the DITA Map WebHelp Classic with Feedback transformation is complete, your default browser opens the `installation.html` file. This file contains information about the output location, system requirements, installation instructions, and deployment of the output. Follow the instructions to complete the system deployment *(on page 1873)*.

For more information about the feedback-enabled WebHelp system, watch our video demonstration:

[https://www.youtube.com/embed/eoQ2uxHvppE](https://www.youtube.com/embed/eoQ2uxHvppE)

### Running from Command Line

To publish to the WebHelp Classic output from a command line outside of Oxygen XML Editor/Author, you can use the *dita* startup script that comes bundled with *DITA Open Toolkit* distribution.

**Required Arguments for the *dita* Command Startup Script:**

```
DITA-OT-DIR (on page 3282)\bin\[executable] -i [path_to_input.ditamap] -f [transformation_type]
```

**executable**

**Windows** - The *dita.bat* script located in: *DITA-OT-DIR* *(on page 3282)\bin\*.

**Linux/Mac OS X** - The *dita* script file located in: *DITA-OT-DIR* *(on page 3282)*/bin/*.

**-i / -input**

Specifies the master file for your DITA documentation project. Typically this is a DITA map.

**-f / -format**

Specifies the transformation type. The **Oxygen XML WebHelp Plugin** contributes the following transformation types for DITA:

*webhelp* - The transformation that produces WebHelp Classic output for desktop.

*webhelp-feedback* - The transformation that produces feedback-enabled WebHelp Classic with Feedback for desktop.

**Additional Options or Parameters:**
You can also use DITA-OT options to modify the command behavior or additional configuration parameters that are contributed by the Oxygen XML WebHelp Plugin (on page 1792).

DITA-OT-DIR (on page 3282)\bin\[executable] -i [path_to_input.ditamap] -f [transformation_type] [option] -D[parameter=value]

Command Line Examples:

- **Windows**: dita.bat -i c:\mySample.ditamap -f webhelp-responsive -o c:\output - Dwebhelp.logo.image=C:\images\myLogo.jpg
- **Linux/Mac OS X**: dita -i /mySample.ditamap -f webhelp-responsive -o /output - Dwebhelp.logo.image=/images/myLogo.jpg

Additional WebHelp Parameters for DITA

You can append the following parameters to the command line that runs the transformation:

- **-Dwebhelp.copyright** *(not available for WebHelp Responsive systems)*
  Adds a small copyright text that appears at the end of the Table of Contents pane.

- **-Dwebhelp.custom.resources**
  The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

- **-Dwebhelp.favicon**
  The file path that points to an image to be used as a favicon in the WebHelp output.

- **-Dwebhelp.footer.file** *(not available for WebHelp Responsive systems)*
  Path to an XML file that includes the footer content for your WebHelp output pages. You can use this parameter to integrate social media features (such as widgets for Facebook™, Twitter™, Google Analytics, or Google+™). The file must be well-formed, each widget must be in separate div or span element, and the code for each script element is included in an XML comment (also, the start and end tags for the XML comment must be on a separate line). The following code exert is an example for adding a Facebook™ widget:

```html
<div id="facebook">
  <div id="fb-root"></div>
  <script>
    <!-- (function(d, s, id) { var js, fjs = d.getElementsByTagName(s)[0];
      if (d.getElementById(id)) return;
      js = d.createElement(s); js.id = id;
      js.src = "//connect.facebook.net/en_US/sdk.jsxfbml=1&version=v2.0";
  
```
-Dwebhelp.footer.include (not available for WebHelp Responsive systems)

Specifies whether or not to include footer in each WebHelp page. Possible values:
  yes, no. If set to no, no footer is added to the WebHelp pages. If set to yes and the webhelp.footer.file parameter has a value, then the content of that file is used as footer. If the webhelp.footer.file has no value then a default Oxygen footer is inserted in each WebHelp page.

-Dwebhelp.google.search.results

A file path that specifies the location of a well-formed XHTML file containing the Google Custom Search Engine element gcse:searchresults-only. You can use all supported attributes for this element. It is recommend to set the linkTarget attribute to frm for frameless (iframe) version of WebHelp or to contentWin for the frameset version of WebHelp. The default value for this attribute is _blank and the search results will be loaded in a new window. If this parameter is not specified, the following code will be used
<gcse:searchresults-only linkTarget="frm"></gcse:searchresults-only>

-Dwebhelp.google.search.script

A file path that specifies the location of a well-formed XHTML file containing the Custom Search Engine script from Google.

-Dwebhelp.logo.image.target.url

Specifies a target URL that is set on the logo image. When you click the logo image, you will be redirected to this address.

-Dwebhelp.logo.image

Specifies a path to an image displayed as a logo in the left side of the output header.

-Dwebhelp.product.id (available only for Feedback-enabled systems)

This parameter specifies a short name for the documentation target, or product (for example, mobile-phone-user-guide, hvac-installation-guide).

Note: You can deploy documentation for multiple products on the same server.

Restriction: The following characters are not allowed in the value of this parameter:
< > / \ ' ( ) { } = ; * % + & .
-Dwebhelp.product.version (available only for Feedback-enabled systems)

Specifies the documentation version number (for example, 1.0, 2.5, etc.). New user
comments are bound to this version.

Note: Multiple documentation versions can be deployed on the same server.

Restriction: The following characters are not allowed in the value of this parameter:

< > / \ ' () { } = ; * % + & .

-Dwebhelp.search.japanese.dictionary

The file path of the dictionary that will be used by the Kuromoji morphological engine for
indexing Japanese content in the WebHelp pages. The encoding for the dictionary must
be UTF8.

-Dwebhelp.search.ranking

If this parameter is set to false then the 5-star rating mechanism is no longer included
in the search results that are displayed on the Search tab (default setting is true).

-Dwebhelp.show.changes.and.comments

When set to yes, user comments, replies to comments, and tracked changes are
published in the WebHelp output. The default value is no.

-Dwebhelp.sitemap.base.url

Base URL for all the loc elements in the generated sitemap.xml file. The value
of a loc element is computed as the relative file path from the href attribute of a
topicref element from the DITA map, appended to this base URL value. The loc
element is mandatory in sitemap.xml. If you leave this parameter set to its default
empty value, then the sitemap.xml file is not generated.

-Dwebhelp.sitemap.change.frequency

The value of the changefreq element in the generated sitemap.xml file. The
changefreq element is optional in sitemap.xml. If you leave this parameter set to
its default empty value, then the changefreq element is not added in sitemap.xml.

Allowed values: <empty string> (default), always, hourly, daily, weekly, monthly,
yearly, never.

-Dwebhelp.sitemap.priority

The value of the priority element in the generated sitemap.xml file. It can be
set to any fractional number between 0.0 (least important priority) and 1.0 (most
important priority). For example, 0.3, 0.5, or 0.8. The priority element is optional
in sitemap.xml. If you leave this parameter set to its default empty value, then the
priority element is not added in sitemap.xml.
-Dwebhelp.skin.css (available only for WebHelp Classic and WebHelp Classic with Feedback systems)

Path to a CSS file that sets the style theme in the WebHelp Classic output. It can be one of the built-in skin CSS from the DITA-OT-DIR/com.oxygenxml.webhelp.classic/predefined-skins directory, or it can be a custom skin CSS generated with the Oxygen Skin Builder web application.

Parameters Specific to WebHelp Responsive Output (available only for WebHelp Responsive and WebHelp Responsive with Feedback systems)

-Dbwebhelp.default.collection.type.sequence

Specifies if the sequence value will be used by default when the collection-type attribute is not specified. This option is helpful if you want to have Next and Previous navigational buttons generated for all HTML pages. Allowed values are no (default) and yes.

-Dbwebhelp.enable.search.autocomplete

Specifies if the Autocomplete feature is enabled in the WebHelp search text field. The default value is yes.

-Dbwebhelp.fragment.after.body

In the generated output it displays a given XHTML fragment after the page body. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

-Dbwebhelp.fragment.after.logo_and_title

In the generated output it displays a given XHTML fragment after the logo and title. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

-Dbwebhelp.fragment.after.main.page.search

In the generated output it displays a given XHTML fragment after the search field. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

-Dbwebhelp.fragment.after.toc_or_tiles

In the generated output it displays a given XHTML fragment after the table of contents or tiles in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

-Dbwebhelp.fragment.after.top_menu
In the generated output it displays a given XHTML fragment after the top menu. The value of the parameter can be either a *well-formed* XHTML fragment or a path to a file that contains a *well-formed* XHTML fragment.

- **webhelp.fragment.before.body**

  In the generated output it displays a given XHTML fragment before the page body. The value of the parameter can be either a *well-formed* XHTML fragment or a path to a file that contains a *well-formed* XHTML fragment.

- **webhelp.fragment.before.logo_and_title**

  In the generated output it displays a given XHTML fragment before the logo and title. The value of the parameter can be either a *well-formed* XHTML fragment or a path to a file that contains a *well-formed* XHTML fragment.

- **webhelp.fragment.before.main.page.search**

  In the generated output it displays a given XHTML fragment before the search field. The value of the parameter can be either a *well-formed* XHTML fragment or a path to a file that contains a *well-formed* XHTML fragment.

- **webhelp.fragment.before.toc_or_tiles**

  In the generated output it displays a given XHTML fragment before the table of contents or tiles in the main page. The value of the parameter can be either a *well-formed* XHTML fragment or a path to a file that contains a *well-formed* XHTML fragment.

- **webhelp.fragment.before.top_menu**

  In the generated output it displays a given XHTML fragment before the top menu. The value of the parameter can be either a *well-formed* XHTML fragment or a path to a file that contains a *well-formed* XHTML fragment.

- **webhelp.fragment.footer**

  In the generated output it displays a given XHTML fragment as the page footer. The value of the parameter can be either a *well-formed* XHTML fragment or a path to a file that contains a *well-formed* XHTML fragment.

- **webhelp.fragment.head**

  In the generated output it inserts a given XHTML fragment in the `<head>` element. The value of the parameter can be either a *well-formed* XHTML fragment or a path to a file that contains a *well-formed* XHTML fragment.

- **webhelp.fragment.welcome**

  In the generated output it displays a given XHTML fragment as a welcome message (or title). The value of the parameter can be either a *well-formed* XHTML fragment or a path to a file that contains a *well-formed* XHTML fragment.
-Dwebhelp.merge.nested.topics.related.links

  Specifies if the related links from nested topics will be merged with the links in the parent topic. Thus the links will be moved from the topic content to the related links component and all of the links from the same group (for example, Related Tasks, Related References, Related Information) are merged into a single group. The default value is yes.

-Dwebhelp.search.enable.pagination

  Specifies whether or not search results will be displayed on multiple pages. Allowed values are yes or no.

-Dwebhelp.search.page.numberOfItems

  Specifies the number of search results items displayed on each page. This parameter is only used when the webhelp.search.enable.pagination parameter is enabled.

-Dwebhelp.search.stop.words.exclude

  Specifies a list of words that will be excluded from the default list of stop words that are filtered out before the search processing. Use comma separators to specify more than one word (for example: if,for,is).

-Dwebhelp.show.breadcrumb

  Specifies if the breadcrumb component will be presented in the output. The default value is yes.

-Dwebhelp.show.child.links

  Specifies if child links will be generated in the output for all topics that have subtopics. The default value is no.

-Dwebhelp.show.indexterms.link

  Specifies if an icon that links to the index will be presented in the output. The default value is yes.

-Dwebhelp.show.main.page.tiles

  Specifies if the tiles component will be presented in the main page of the output. For a tree style layout, this parameter should be set to no.

-Dwebhelp.show.main.page.toc

  Specifies if the table of contents will be presented in the main page of the output. The default value is yes.

-Dwebhelp.show.navigation.links

  Specifies if navigation links will be presented in the output. The default value is yes.
Specifies if a print link or icon will be presented within each topic in the output. The default value is `yes`.

-Dwebhelp.show.publication.toc

Specifies if a table of contents will be presented on the left side of each topic in the output. The default value is `yes`.

-Dwebhelp.show.topic.toc

Specifies if a topic table of contents will be presented on the right side of each topic in the output. This table of contents contains links to each `<section>` within the current topic that contains an `@id` attribute and the section corresponding to the current scroll position is highlighted. The default value is `yes`.

-Dwebhelp.show.top.menu

Specifies if a menu will be presented at the topic of the main page in the output. The default value is `yes`.

-Dwebhelp.publication.toc.hide.chunked.topics

Specifies if the table of contents will contain links for chunked topics. The default value is `yes`.

-Dwebhelp.publication.toc.links

Specifies which links will be included in the table of contents. The possible values are:

- **chapter** (default) - The TOC will include links for the current topic, its children, its siblings, and its direct ancestor (including the direct ancestor’s siblings), and the parent chapter.
- **topic** - The TOC will only include links for the current topic and its direct children.
- **all** - The TOC will include all links.

-Dwebhelp.publication.toc.tooltip.position

By default, if a topic contains a `shortdesc` element, its content is displayed in a tooltip when the user hovers over its link in the table of contents. This parameter controls whether or not this tooltip is displayed and its position relative to the link. The possible values are:

- **left** (default)
- **right**
- **top**
- **bottom**
- **hidden** - The tooltip will not be displayed.

-Dwebhelp.top.menu.depth
Specifies the maximum depth level of the topics that will be included in the top menu. The default value is 3. A value of 0 means that the menu has unlimited depth.

-Dwebhelp.topic.collapsible.elements.initial.state

Specifies the initial state of collapsible elements (tables with titles, nested topics with titles, sections with titles, index term groups). The possible values are collapsed or expanded (default value).

**Note:** Note that the `fix.external.refs.com.oxygenxml` parameter is not supported. This parameter is normally used to specify whether or not the application tries to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references.

**Further Customization**

If you need to further customize the transformation process, you can append other DITA-OT parameters as well. Any parameter that you want to append must follow the `-D` model of the above parameters. For example, to append the `args.csspath` parameter, use:

```
-Dargs.csspath=[CSS_FILE_PATH]
```

where `[CSS_FILE_PATH]` is the location of the directory that contains the CSS file.

**Related Information:**

- Setting DITA-OT Parameters

**Running from an Integration Server**

Oxygen XML Editor can be processed from an automatic publishing system, such as *Jenkins* or *Travis*.

**Automating DITA to WebHelp Output with Jenkins**

To integrate WebHelp output with the Jenkins continuous integration tool, follow these steps:

1. Create a Maven project to incorporate the DITA-OT that already integrates Oxygen XML Editor.
2. Go to the root of your Maven project and edit the `pom.xml` file to include the following fragment:

```xml
<properties>
  <oxygen-webhelp>${basedir}/tools/plugins/com.oxygenxml.webhelp.responsive</oxygen-webhelp>
</properties>
```
3. Go to the Jenkins top page and create a new Jenkins job. Configure this job to suit your particular requirements, such as the build frequency and location of the Maven project.

Automating DITA to WebHelp Output with Travis CI

This topic assumes you have a DITA project hosted on a GitHub public or private repository.

The goal of this tutorial is to help you set up a Travis continuous integration job that automatically publishes your DITA project to GitHub pages after every commit. The published website will contain a feedback link on each page that would allow a contributor to easily suggest changes to the documentation by creating a pull request on GitHub with just a few clicks.

Enable the Travis CI Build

1. Sign in to Travis CI with your GitHub account, accepting the GitHub access permissions confirmation.
2. Once you are signed in, and you have synchronized your GitHub repositories, go to your profile page and enable Travis CI for the repository you want to build.

Configure the Travis CI Build in your GitHub Project

1. Checkout your GitHub project locally.
2. Copy the .travis folder from here to the root directory of your project.
3. In the root of your GitHub project, add a file called `.travis.yml` with the following content:

```yaml
language: dita
install:
  - echo "Installed"
script:
  - sh .travis/publish.sh
after_success:
  - sh .travis/deploy.sh
env:
  global:
    - DITAMAP=/path/to/your/ditamap/file
    - DITAVAL=/path/to/your/ditaval/file
    - ANT_OPTS=-Xmx1024M

Note: Replace `/path/to/your/ditamap/file` and `/path/to/your/ditaval/file` with the appropriate paths to your DITA map and ditaval files.

4. Create a GitHub personal access token by following this procedure.

5. Define an environment variable in the repository settings that has the name `GH_TOKEN` and the value equal with the GitHub personal access token created earlier.

### Register Your License Key

1. Edit your `.gitignore` file (or create it if it does not already exist) and add the following line:

   ```
   licenseKey.txt
   ```

2. Copy your WebHelp license to the root of your GitHub project in a file called `licenseKey.txt`.

   **Important:** The `licenseKey.txt` file should not be committed to GitHub as it contains a license key that is issued only to you.

3. Encrypt the license key file and add it to the `.travis.yml` configuration file. This way only the Travis CI server will be able to decrypt it during the build process.

### Commit to GitHub

1. Commit the following files and folders and push the commit to GitHub:

   ```
   git add .gitignore licenseKey.txt.enc .travis.yml .travis/
   git commit -m "Set up the Travis CI publishing system"
   git push
   ```
2. Create a gh-pages branch in your GitHub project where the WebHelp output will be published. You can follow the procedure here.

Generating WebHelp Classic Output for DocBook

The publishing process can be initiated from a transformation scenario within Oxygen XML Editor/Author or from a command line outside Oxygen XML Editor/Author.

Running from Oxygen XML Editor/Author

To publish DocBook content to WebHelp Classic output from a transformation scenario inside Oxygen XML Editor/Author, use one of the following procedures, depending on whether or not you want a feedback section in your output.

**WebHelp Classic Output**

To publish a DocBook document as a WebHelp Classic system, follow these steps:

1. Click the Configure Transformation Scenario(s) action from the toolbar (or the Document > Transformation menu).
2. Select the DocBook WebHelp Classic scenario from the DocBook 4 or DocBook 5 section.
3. Click Apply associated.

   When the DocBook WebHelp Classic transformation is complete, the output is automatically opened in your default browser.

**WebHelp Classic with Feedback Output**

To publish a DocBook document as a WebHelp Classic with Feedback system, follow these steps:

1. Click Configure Transformation Scenarios.
2. Select the DocBook WebHelp Classic with Feedback scenario from the DocBook 4 or DocBook 5 section.
3. Click Apply associated.
4. Enter the documentation product ID and the documentation version.

   When the DocBook WebHelp Classic with Feedback transformation is complete, your default browser opens the installation.html file. This file contains information about the output location, system requirements, installation instructions, and deployment of the output. Follow the instructions to complete the system deployment. For more information, see Deploying a Feedback-Enabled System (on page 1873).
For more information about the feedback-enabled WebHelp system, watch our video demonstration:

https://www.youtube.com/embed/eoQ2uxHypPE

Running from Command Line

PREREQUISITES: Before you begin, the WebHelp DocBook distribution must be integrated into a DocBook XSL installation.

To run a DocBook to WebHelp transformation outside of Oxygen XML Editor/Author, use the following script file:

- Windows - \[DocBook XSL directory]\com.oxygenxml.webhelp.classic\docbook.bat
- Linux/Mac OS X - \[DocBook XSL directory]/com.oxygenxml.webhelp.classic/docbook.sh

Before running the script to generate output, you must customize it to specify various paths and transformation type. To do this, open the script file and edit the following variables:

- JVM_INSTALL_DIR - Specifies the path to the Java Virtual Machine installation directory on your disk.
- ANT_INSTALL_DIR - Specifies the path to the installation directory of Ant.
- SAXON_6_DIR - Specifies the path to the installation directory of Saxon 6.5.5.
- SAXON_9_DIR - Specifies the path to the installation directory of Saxon 9.1.0.8.
- DOCBOOK_XSL_DIR - Specifies the path to the installation directory of the DocBook XSL distribution.
- TRANSTYPE - Specifies the type of the transformation you want to apply. The Oxygen XML WebHelp Plugin contributes the following transformation types for DocBook:
  - webhelp - The transformation that produces WebHelp Classic output for desktop.
  - webhelp-feedback - The transformation that produces feedback-enabled WebHelp Classic with Feedback for desktop.
- INPUT_DIR - Specifies the path to the input directory, containing the input XML file.
- XML_INPUT_FILE - Specifies the name of the input XML file.
- OUTPUT_DIR - Specifies the path to the output directory where the transformation output is generated.
- DOCBOOK_XSL_DIR_URL - Specifies the path to the directory of the DocBook XSL distribution in URL format.

You can also add additional configuration parameters that are contributed by the Oxygen XML WebHelp Plugin (on page 1804).
Additional WebHelp Parameters for DocBook

You can use various parameters in the command line to customize the transformation. Some of the most commonly used parameters include:

-Ddefault.language

This parameter is used if the language is not detected in the DITA map. The default value is en-us.

-Dclean.output

Deletes all files from the output folder before the transformation is performed (only no and yes values are valid and the default value is no).

-Dl10n.gentext.default.language

This parameter is used to identify the correct stemmer that differs from language to language. For example, for English the value of this parameter is en or for French it is fr, and so on.

-Duse.stemming

Controls whether or not you want to include stemming search algorithms into the published output (default setting is false).

-Dwebhelp.copyright

Adds a small copyright text that appears at the end of the Table of Contents pane.

-Dwebhelp.custom.resources

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

-Dwebhelp.favicon

The file path that points to an image to be used as a favicon in the WebHelp output.

-Dwebhelp.footer.file

Path to an XML file that includes the footer content for your WebHelp output pages. You can use this parameter to integrate social media features (such as widgets for Facebook™, Twitter™, Google Analytics, or Google+™). The file must be well-formed, each widget must be in separate div or span element, and the code for each script element is included in an XML comment (also, the start and end tags for the XML comment must be on a separate line). The following code exert is an example for adding a Facebook™ widget:

```xml
<div id="facebook">
  <div id="fb-root"/>
</div>
```
-Dwebhelp.footer.include

Specifies whether or not to include footer in each WebHelp page. Possible values:

- yes, no. If set to no, no footer is added to the WebHelp pages. If set to yes and the webhelp.footer.file parameter has a value, then the content of that file is used as footer. If the webhelp.footer.file has no value then a default Oxygen footer is inserted in each WebHelp page.

-Dwebhelp.logo.image.target.url

Specifies a target URL that is set on the logo image. When you click the logo image, you will be redirected to this address.

-Dwebhelp.logo.image

Specifies a path to an image displayed as a logo in the left side of the output header.

-Dwebhelp.product.id (available only for Feedback-enabled systems)

This parameter specifies a short name for the documentation target, or product (for example, mobile-phone-user-guide, hvac-installation-guide).

Note: You can deploy documentation for multiple products on the same server.

Restriction: The following characters are not allowed in the value of this parameter:
< > / \ ' ( ) { } = ; * % + & .

-Dwebhelp.product.version (available only for Feedback-enabled systems)

Specifies the documentation version number (for example, 1.0, 2.5, etc.). New user comments are bound to this version.

Note: Multiple documentation versions can be deployed on the same server.

Restriction: The following characters are not allowed in the value of this parameter:
< > / \ ' ( ) { } = ; * % + & .
If this parameter is set to \texttt{false} then the 5-star rating mechanism is no longer included in the search results that are displayed on the \texttt{Search} tab (default setting is \texttt{true}).

\texttt{-Dwebhelp.skin.css}

Path to a CSS file that sets the style theme in the WebHelp Classic output. It can be one of the built-in skin CSS from the \texttt{OXYGEN\_INSTALL\_DIR/frameworks/docbook/xsl/com.oxygenxml.webhelp.classic/predefined-skins} directory, or it can be a custom skin CSS generated with the \texttt{Oxygen Skin Builder} web application.

If you need to further customize your transformation, other DocBook XSL parameters can be appended. Any parameter that you want to append must follow the \texttt{-D} model of the above parameters. For example, you can append the \texttt{html.stylesheet} parameter in the following form:

\begin{verbatim}
-Dhtml.stylesheet=/path/to/directory/of/stylesheet.css
\end{verbatim}

Customizing WebHelp Classic Output

\textbf{Oxygen XML WebHelp} provides support for customizing the \textbf{WebHelp Classic} output to suit your specific needs. The \textbf{WebHelp Classic} type of output is designed for desktop systems and features a familiar \textit{tri-pane} layout. You can use this system to publish DITA and DocBook document types. The \textbf{WebHelp Classic with Feedback} variant allows your users to add comments to your output.

To change the overall appearance of the \textbf{WebHelp Classic} output, you can use the visual \textbf{WebHelp Skin Builder tool (on page 1806)}, which does not require knowledge of CSS language. If you are familiar with CSS and coding, you can style your WebHelp output through your own custom stylesheets. You can also customize your output by modifying option and parameters in the transformation scenario.

This section includes topics that explain various ways to customize your WebHelp system output, such as how to improve the appearance of the Table of Contents, add logo images in the title area, integrate with social media, add custom headers and footers, and much more.

\textbf{Changing the Layout and Styles}

This section contains some topics that explain how to customize the layout and style of your WebHelp Classic output using custom CSS, inserting custom HTML content, and more.

\textbf{WebHelp Skin Builder}

The \textbf{WebHelp Skin Builder} is a simple, easy-to-use tool, specially designed to assist users to visually customize the look and feel of the WebHelp output. It is implemented as an online tool hosted
on the Oxygen XML website and allows you to experiment with various styles and colors over a documentation sample.

To be able to use the Skin Builder, you need:

- An Internet connection and unrestricted access to Oxygen XML website.
- A late version web browser.

To start the Skin Builder, do one of the following:

- For DocBook or DITA WebHelp systems, use a web browser to go to [https://www.oxygenxml.com/webhelp-skin-builder](https://www.oxygenxml.com/webhelp-skin-builder).
- For DITA WebHelp systems, you can click the Online preview link in the Skins tab (on page 3197) of a DITA OT transformation scenario. In the upper section of the preview, click the Select Skin button, then choose Customize Skin.

### Skin Builder Layout

The left side panel of the Skin Builder is divided into 3 sections:

- **Actions** - Contains the following two buttons:
  - Import - Opens an Import CSS dialog box that allows you to load a CSS stylesheet and apply it over the documentation sample.
  - Export - Saves all properties as a CSS file.
- **Settings** - Includes a Highlight selection option that helps you identify the areas affected by a particular element customization.
  - When hovering an item in the customizable elements menu, the affected sample area is highlighted with a dotted blue border.
  - When an item in the customizable elements menu is selected, the affected sample area is highlighted with a solid red border.
- **Customize** - Provides a series of customizable elements organized under four main categories:
  - Header
  - TOC Area
  - Vertical Splitter
  - Content

For each customizable element, you can alter properties such as background color or font face. Any alteration made in the customizable elements menu is applied in real time over the sample area.
Creating a Customization Skin

1. You can start with one of the built-in skins or a CSS stylesheet applied over the sample using the **Import** button.
2. Use the elements in the **Customize** section to set properties that modify the look of the skin. By default, all customizable elements display a single property, but you can make more visible by clicking the **Add** button and choosing from the available properties.

   **Note:** If you want to revert a particular property to its initial value, press the **Reset** button.
3. When you are happy with the skin customizations you have made, press the **Export** button. All settings will be saved in a CSS file.

Applying a Custom Skin to a DITA Map to WebHelp Classic Transformation Scenario

1. Start Oxygen XML Editor.
2. Load the **DITA map (on page 3281)** you want to produce as a WebHelp output.
3. Edit a **DITA Map to WebHelp** transformation scenario. Set the previously exported CSS file in the **Custom** section of the **Skins** tab.
4. Run the transformation to obtain the WebHelp output.

Apply a Customization Skin to a DocBook to WebHelp Classic Transformation Scenario

1. Start Oxygen XML Editor.
2. Load the DocBook file you want to produce as a WebHelp output.
3. In the **Parameters** tab, set the **webhelp.skin.css** parameter to point to the previously exported CSS.
4. To customize the logo, use the following parameters: **webhelp.logo.image** and **webhelp.logo.image.target.url**.
5. Run the transformation to obtain the WebHelp output.

For more information about using the WebHelp Skin Builder, watch our video demonstration:

[https://www.youtube.com/embed/32PGX--PQx0](https://www.youtube.com/embed/32PGX--PQx0)

Related Information:
How to Use CSS Styling to Customize WebHelp Output

The most common way to customize the look and style of your WebHelp output is to use custom CSS styling. This method can be used to make small, simple styling changes or more advanced, precise changes. To implement the styling in your WebHelp output, you simply need to create the custom CSS file and reference it in your transformation scenario or script. This custom file will be the final CSS to be applied so its content will override the styles in the other pre-existing CSS files.

Using the CSS Inspector to Identify Content for Custom CSS File

You can use your browser's CSS inspector to identify the pertinent code in the current CSS files and you can even make changes directly in the CSS inspector to test the results so that you know exactly what content to use in your custom CSS file.

In most popular browsers (such as Chrome, Firefox, and Edge), you can access the CSS inspector by using F12 or by selecting Inspect Element (or simply Inspect) from the contextual menu.

Tip: When using Safari on Mac OS X, you must first enable the Develop menu by going to the Advanced settings and selecting Show Develop menu in menu bar. Then you can select Show Web Inspector from the Develop menu or click Command + Option + I.

Referencing the Custom CSS Using Oxygen XML Editor/Author

To use a custom CSS to style WebHelp output and use a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Create your custom CSS file.
2. Edit the WebHelp transformation scenario and open the Parameters tab.
   • For a DITA transformation, set the args.css parameter to the path of your custom CSS file. Also, set the args.copycss parameter to yes to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
   • For a DocBook transformation, set the html.stylesheet parameter to the path of your custom CSS file.
3. Run the WebHelp transformation scenario to generate the output.

Referencing the Custom CSS Using a Script Outside of Oxygen XML Editor/Author

Important: Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:
• You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).

• The Oxygen XML WebHelp Plugin must be installed and integrated for the DITA Open Toolkit or a DocBook XSL Distribution.

To use a custom CSS to style WebHelp output and use a script outside of Oxygen XML Editor/Author (on page 1789), follow this procedure:

1. Create your custom CSS file.
2. Reference your custom CSS file:
   • For DITA transformations, use the args.css parameter in your transformation script and set its value to the path of your custom CSS file. Also, set the args.copycss parameter to yes to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
   • For DocBook transformations, use the html.stylesheet parameter in your transformation script and set its value to the path of your custom CSS file.
3. Execute the transformation script.

For example, a DITA script might look like this:

• Windows:
  
dita.bat -i c:\mySample.ditamap -f webhelp -Dargs.css=c:\myFile.css -Dargs.copycss=yes

• Mac OS X/ Linux:
  
dita -i /mySample.ditamap -f webhelp -Dargs.css=/myFile.css -Dargs.copycss=yes

How to Add Custom HTML Content in WebHelp Classic Output

You can add custom HTML content in the WebHelp Classic output by inserting it in a well-formed XML file that will be referenced in the transformation. This content may include references to additional JavaScript, CSS, and other types of resources, or such resources can be inserted inline within the HTML content that is inserted in the XML file.

Using Oxygen XML Editor/Author

To include custom HTML content in the WebHelp Classic output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Insert the HTML content in a well-formed XML file considering the following notes:
• **Well-Formedness** - If the file is not a *Well-formed XML document* (on page 1079) (or fragments are not well-formed), the transformation will fail.

A common use case is if you want to include several `script` or `link` elements. In this case, the XML fragment has multiple root elements and to make it well-formed, you can wrap it in an `html` element. This element tag will be filtered out and only its children will be copied to the output documents. Similarly, you can wrap your content in `head`, `body`, `html/head`, or `html/body` elements.

• **Referencing Resources in the XML File** - You can include references to local resources (such as JavaScript or CSS files) by using the built-in `${oxygen-webhelp-output-dir}` macro to specify their paths relative to the output directory:

```html
<html>
<script type="text/javascript" src="${oxygen-webhelp-output-dir}/js/test.js"></script>
<link rel="stylesheet" type="text/css" href="${oxygen-webhelp-output-dir}/css/test.css" />
</html>
```

To copy the referenced resources to the output directory, follow the procedure in: *How to Copy Additional Resources to Output Directory* (on page 1823).

• **Inline JavaScript or CSS Content**:

JavaScript:

```html
<script type="text/javascript">
/* Include JavaScript code here. */

function myFunction() {
    return true;
}
</script>
```

CSS:

```html
<style>
/* Include CSS style rules here. */

* {
    color:red
}
</style>
```
Note: If you have special characters (for example, ``, ``, `<`) that break the well-formedness of the XML fragment, it is important to place this content inside an XML comment:

```xml
<script type="text/javascript">
<!--
/* Include JavaScript code here. */

function myFunction() {
    return true;
}
-->
</script>
```

2. Edit the WebHelp Classic transformation scenario.
3. Go to the Parameters tab.
4. Edit the value of the `webhelp.head.script` parameter and set it to reference the URL of the XML file created in step 1. Your additional content will be included at the end of the `head` element of your output document.

Note: If you want to include the content in the `body` element, use the `webhelp.body.script` parameter instead.

5. Click OK to save the changes and run the transformation scenario.

Using a Script Outside of Oxygen XML Editor/Author

⚠️ Important: Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated for the DITA Open Toolkit or a DocBook XSL Distribution.

To include custom HTML content in the WebHelp Classic output using a script outside of Oxygen XML Editor/Author (on page 1789), follow this procedure:

1. Insert the HTML content in a well-formed XML file considering the following notes:
   - Well-Formedness - If the file is not a Well-formed XML document (on page 1079) (or fragments are not well-formed), the transformation will fail.

     A common use case is if you want to include several `script` or `link` elements. In this case, the XML fragment has multiple root elements and to make it well-formed, you can wrap it in
an `html` element. This element tag will be filtered out and only its children will be copied to the output documents. Similarly, you can wrap your content in `head, body, html/head, or html/body` elements.

- **Referencing Resources in the XML File** - You can include references to local resources (such as JavaScript or CSS files) by using the built-in `${oxygen-webhelp-output-dir}` macro to specify their paths relative to the output directory:

```xml
<html>
  <script type="text/javascript" src="${oxygen-webhelp-output-dir}/js/test.js"></script>
  <link rel="stylesheet" type="text/css" href="${oxygen-webhelp-output-dir}/css/test.css" />
</html>
```

To copy the referenced resources to the output directory, follow the procedure in: How to Copy Additional Resources to Output Directory (on page 1823).

- **Inline JavaScript or CSS Content**:

  **JavaScript**:

  ```xml
  <script type="text/javascript">
  /* Include JavaScript code here. */
  
  function myFunction() {
      return true;
  }
  </script>
  ```

  **CSS**:

  ```xml
  <style>
  /* Include CSS style rules here. */
  
  *{
      color:red
  }
  </style>
  ```

  **Note**: If you have special characters (for example, `&`, `<`) that break the well-formedness of the XML fragment, it is important to place this content inside an XML comment:

  ```xml
  <script type="text/javascript">
  <!--
  ```
2. Use the `webhelp.head.script` parameter in your transformation script and set its value to reference the URL of the XML file created in step 1. Your additional content will be included at the end of the `head` element of your output document.

**Note:** If you want to include the content in the `body` element, use the `webhelp.body.script` parameter instead.

3. Execute the transformation script.

For example, a DITA script might look like this:

- **Windows:**

  ```bash
dita.bat -i c:\mySample.ditamap -f webhelp -Dwebhelp.head.script=c:\myFile.xml
  ```

- **Mac OS X/ Linux:**

  ```bash
dita -i /mySample.ditamap -f webhelp -Dwebhelp.head.script=/myFile.xml
  ```

**Related Information:**

- [How to Copy Additional Resources to Output Directory](on page 1823)

**How to Change Number Styles for Ordered Lists**

Ordered lists (`ol`) are usually numbered in XHTML output using numerals. If you want to change the numbering to alphabetical, follow these steps:

1. Define a custom `outputclass` value and set it as an attribute of the ordered list, as in the following example:

   ```xml
   <ol outputclass="number-alpha">
     <li>A</li>
     <li>B</li>
     <li>C</li>
   </ol>
   ```
2. Add the following code snippet in a custom CSS file:

```css
ol.number-alpha{
    list-style-type:lower-alpha;
}
```

3. Edit the WebHelp transformation scenario and open the **Parameters** tab.
   a. For a DITA transformation, set the `args.css` parameter to the path of your custom CSS file. Also, set the `args.copycss` parameter to `yes` to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
   b. For a DocBook transformation, set the `html.stylesheet` parameter to the path of your custom CSS file.

4. Run the transformation scenario.

**How to Change the Icons in a WebHelp Classic Table of Contents**

You can change the icons that appear in a WebHelp Classic table of contents by assigning new image files in a custom CSS file. By default, these icons are defined with the following CSS codes (the first example is the icon that appears for a collapsed menu and the second for an expanded menu):

```css
.hasSubMenuClosed{
    background: url('../img/book_closed16.png') no-repeat;
    padding-left: 16px;
    cursor: pointer;
}

.hasSubMenuOpened{
    background: url('../img/book_opened16.png') no-repeat;
    padding-left: 16px;
    cursor: pointer;
}
```

**Using Oxygen XML Editor/Author**

To assign other icons and use a transformation scenario from within **Oxygen XML Editor/Author**, follow this procedure:

1. Create a custom CSS file that assigns your desired icons to the `.hasSubMenuClosed` and `.hasSubMenuOpened` properties.
2. It is recommended that you store the image files in the same directory as the default icons.
   - For DITA transformations: \DITA-OT-DIR\plugins\com.oxygenxml.webhelp.classic \oxygen-webhelp\resources\img\. 
   - For DocBook transformations: \[OXYGEN_INSTALL_DIR]\frameworks\docbook\xsl \com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\img\. 

3. Edit the WebHelp transformation scenario and open the Parameters tab.
   - For a DITA transformation, set the args.css parameter to the path of your custom CSS file.
     Also, set the args.copycss parameter to yes to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
   - For a DocBook transformation, set the html.stylesheet parameter to the path of your custom CSS file.

4. Run the WebHelp transformation scenario to generate the output.

Using a Script Outside of Oxygen XML Editor/Author

⚠️ Important: Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

   - You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
   - The Oxygen XML WebHelp Plugin must be installed and integrated for the DITA Open Toolkit or a DocBook XSL Distribution.

To assign other icons and use a script outside of Oxygen XML Editor/Author (on page 1789), follow this procedure:

1. Create a custom CSS file that assigns your desired icons to the .hasSubMenuClosed and .hasSubMenuOpened properties.

```css
.hasSubMenuClosed{
    background: url('TOC-my-closed-button.png') no-repeat;
}

.hasSubMenuOpened{
    background: url('TOC-my-opened-button.png') no-repeat;
}
```
2. It is recommended that you store the image files in the same directory as the default icons.
   - For DITA transformations: `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\img\`
   - For DocBook transformations: `[DocBook XSL directory]\com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\img\`

3. Reference your custom CSS file:
   - For DITA transformations, use the `args.css` parameter in your transformation script and set its value to the path of your custom CSS file. Also, set the `args.copycss` parameter to `yes` to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
   - For DocBook transformations, use the `html.stylesheet` parameter in your transformation script and set its value to the path of your custom CSS file.

4. Execute the transformation script.

   For example, a DITA script might look like this:
   
   - **Windows:**
     ```shell
dita.bat -i c:\mySample.ditamap -f webhelp -Dargs.css=c:\myFile.css -Dargs.copycss=yes
     ```
   - **Mac OS X/ Linux:**
     ```shell
dita -i /mySample.ditamap -f webhelp -Dargs.css=/myFile.css -Dargs.copycss=yes
     ```

**How to Customize the Appearance of Selected Items in the Table of Contents**

The appearance of selected items in the table of contents of WebHelp Classic output can be enhanced.

For example, to highlight the background of the selected item, follow these steps:

1. Locate the `toc.css` file in the following directory:
   - a. For DITA transformations: `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\css`
   - b. For DocBook transformations: `[DocBook XSL directory]\com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\css`

2. Edit that CSS file, find the `menuItemSelected` class, and change the value of the `background` property.

3. Run the transformation.
Note: You can also overwrite the same value from your own custom CSS and then specify the path to your CSS in the transformation scenario by doing one of the following:

- For DITA transformations, use the `args.css` parameter and set its value to the path of your custom CSS file. Also, set the `args.copycss` parameter to `yes` to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
- For DocBook transformations, use the `html.stylesheet` parameter and set its value to the path of your custom CSS file.

How to Generate or Hide Navigation Links in WebHelp Classic Output

The WebHelp Classic output can contain navigation links (Previous / Next / Parent topic arrows) that can be used to navigate to the previous, next, or parent topic.

How to Generate Navigation Links in WebHelp Classic Output

The navigation links are controlled by the `collection-type` attribute. For example, if you set `collection-type="sequence"` on a parent topic reference in your DITA map, navigation links will be generated in the output for all of its child topics (from children to parent, and from child to previous sibling and next sibling).

```xml
<map id="example_map" title="Example Map">
  <topicref href="../topics/ParentTopic.dita" collection-type="sequence">
    <topicref href="../topics/Childtopic.dita"/>
  </topicref>
</map>
```

How to Hide All Navigation Links in WebHelp Classic Output

To hide all navigation links, use the `args.hide.parent.link` parameter in the transformation and set its value to `no`.

Adding Graphics and Media Resources

This section contains topics that explain how to add media resources to the published WebHelp Classic output or to the output directory.

How to Add a Favicon in WebHelp Systems

You can add a custom favicon to your WebHelp output by simply using a parameter in the transformation scenario to point to your favicon image. This is available for DITA and DocBook WebHelp output using WebHelp Classic or WebHelp Classic with Feedback transformations.
Using Oxygen XML Editor/Author

To add a favicon to your WebHelp output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Edit the WebHelp transformation scenario and open the Parameters tab.
2. Locate the webhelp.favicon parameter and enter the file path that points to the image that will be use as the favicon.
3. Run the transformation scenario.

Result: Browsers that provide favicon support will display the favicon (typically in the browser's address bar, in the list of bookmarks, and in the history).

Using a Script Outside of Oxygen XML Editor/Author

⚠️ Important: Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated for the DITA Open Toolkit or a DocBook XSL Distribution.

To add a favicon to your WebHelp output using a script outside of Oxygen XML Editor/Author, follow this procedure:

1. Specify the file path that points to the image that will be use as the favicon using the webhelp.favicon parameter.
2. Execute the transformation script.

Result: Browsers that provide favicon support will display the favicon (typically in the browser's address bar, in the list of bookmarks, and in the history).

For example:

- Windows:
  
  dita.bat -i c:\mySample.ditamap -f webhelp -Dwebhelp.favicon=c:\myFavicon.jpg

- Mac OS X/ Linux:
  
  dita -i /mySample.ditamap -f webhelp -Dwebhelp.favicon=/myFavicon.jpg
How to Add a Logo Image in the Title Area

You can customize WebHelp Classic output to include a logo in the title area. It will be displayed before the publication title. You can also specify a URL that can be used to send users to a specific website when they click the logo image.

This customization can be done using a transformation scenario from within Oxygen XML Editor/Author or using a command-line script outside of Oxygen XML Editor/Author.

Using Oxygen XML Editor/Author

To add a logo in the title area of your WebHelp output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Edit a WebHelp Classic transformation scenario, then open the Parameters tab.
2. Specify the path to your logo in the webhelp.logo.image parameter.
3. If you also want to add a link to your website when you click the logo image, set the URL in the webhelp.logo.image.target.url parameter.
4. Run the transformation scenario.

Using a Script Outside of Oxygen XML Editor/Author

⚠️ Important: Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated for the DITA Open Toolkit or a DocBook XSL Distribution.

To add a logo in the title area of your WebHelp output using a script outside of Oxygen XML Editor/Author, follow this procedure:

1. Specify the path to your logo using the webhelp.logo.image parameter.
2. If you also want to add a link to your website when you click the logo image, set the URL using the webhelp.logo.image.target.url parameter.
3. Execute the transformation script.

For example:

- Windows:
How to Add Video and Audio Objects in DITA WebHelp Classic

You can insert references to video and audio media resources (such as videos, audio clips, or embedded HTML frames) in your DITA topics and then publish them to WebHelp output. The media objects can be played directly in all HTML5-based outputs, including WebHelp systems.

To add media objects in the WebHelp output generated from DITA documents, follow the procedures below.

Adding Videos to DITA WebHelp Output

1. Edit the DITA topic and insert a reference to the video through one of the following methods:
   • Use the [Insert Media Object] toolbar action (on page 3066).
   • Drag (or copy) the video file from your system explorer or the Project view (on page 333) and drop (or paste) it into your document.
   • Manually add an object element, as in one of the following examples:

   ```xml
   <object outputclass="video" type="video/mp4" data="MyVideo.mp4"/>
   ```

   or, instead of the data attribute, you can specify the video using a parameter like this:

   ```xml
   <object outputclass="video">
   <param name="src" value="videos/MyVideo.mp4"/>
   </object>
   ```

2. Apply a DITA to WebHelp transformation to obtain the output.

   Result: The transformation converts the object element to an HTML5 video element.

   ```xml
   <video controls="controls"><source type="video/mp4" src="MyVideo.mp4"></source></video>
   ```

Adding Audio Clips to DITA WebHelp Output

1. Edit the DITA topic and insert a reference to the audio clip through one of the following methods:
   • Use the [Insert Media Object] toolbar action (on page 3066).
• Drag (or copy) the audio file from your system explorer or the Project view (on page 333) and drop (or paste) it into your document.

• Manually add an object element, as in one of the following examples:

```xml
<object outputclass="audio" type="audio/mpeg" data="MyClip.mp3"/>
```

or, instead of the data attribute, you can specify the video using a parameter like this:

```xml
<object outputclass="audio">
  <param name="src" value="audio/MyClip.mp3"/>
</object>
```

2. Apply a DITA to WebHelp transformation to obtain the output.

**Result:** The transformation converts the object element to an HTML5 audio element.

```html
<audio controls="controls"> <source type="audio/mpeg" src="MyClip.mp3"></source> </audio>
```

### Adding Embedded HTML Frames (such as YouTube videos) to DITA WebHelp Output

1. Edit the DITA topic and insert a reference to the embedded object by using the Insert Media Object toolbar action (on page 3066) or by manually adding an object element, as in one of the following examples:

```xml
<object outputclass="iframe" data="https://www.youtube.com/embed/m_vv2s5Trn4"/>
```

or, instead of the data attribute, you can specify the object using a parameter like this:

```xml
<object outputclass="iframe">
  <param name="src" value="http://www.youtube.com/embed/m_vv2s5Trn4"/>
</object>
```

2. If you want the video to be allowed to play in full screen mode once the document is converted to XHTML output, also add an allowfullscreen parameter and set its value to true:

```xml
<object outputclass="iframe" data="https://www.youtube.com/embed/m_vv2s5Trn4"/>
  <param name="allowfullscreen" value="true"/>
</object>
```

**Tip:** If you copy the embed code from the source and paste it into the Insert Media dialog box (see the specific instructions: here (on page 3068)), the allowfullscreen parameter will automatically be added and all you have to do is set the value to true.

3. Apply a DITA to WebHelp transformation to obtain the output.

**Result:** The transformation converts the object element to an HTML5 iframe element.
For more information, see the following video demonstration:

https://www.youtube.com/embed/llX11gS4WaU

Related Information:

- Adding Video, Audio, and Embedded HTML Resources in DITA Topics (on page 3066)

How to Add Videos in DocBook WebHelp Classic Output

You can insert references to videos in your DocBook topics and then publish them to WebHelp Classic output. The videos can be played directly in all HTML5-based outputs, including WebHelp systems.

To add videos in the WebHelp Classic output generated from DocBook documents, follow these steps:

1. Edit the DocBook document and reference the video using an `<mediaobject>` element, as in the following example:

   ```xml
   <mediaobject>
     <videoobject>
       <videodata fileref="http://www.youtube.com/watch/v/VideoName"/>
     </videoobject>
   </mediaobject>
   ``

2. Apply a WebHelp or WebHelp with Feedback transformation scenario to obtain the output.

How to Copy Additional Resources to Output Directory

You can copy additional resources (such as JavaScript, CSS or other resources) to the output directory of a WebHelp system by using the `webhelp.custom.resources` parameter.

Using Oxygen XML Editor/Author

To copy additional resources to the output directory using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Place all your resources in the same directory.
2. Edit the WebHelp transformation scenario, then open the Parameters tab.
3. Edit the value for the `webhelp.custom.resources` parameter and set it to the absolute path of the directory in step 1.
4. Click **OK** to save the changes to the transformation scenario.
5. Run the transformation scenario.

**Result:** All files from the new directory will be copied to the root of the WebHelp output directory.

**Using a Script Outside of Oxygen XML Editor/Author**

⚠️ **Important:** Running WebHelp transformations from a script outside of **Oxygen XML Editor/Author** requires an additional license and some additional setup:

- You must have a valid license for the **Oxygen XML WebHelp Plugin** ([https://www.oxygenxml.com/buy_webhelp.html](https://www.oxygenxml.com/buy_webhelp.html)).
- The **Oxygen XML WebHelp Plugin** must be installed and integrated for the DITA Open Toolkit or a DocBook XSL Distribution.

To copy additional resources to the output directory using a script outside of **Oxygen XML Editor/Author** ([on page 1789](on page 1789)), follow this procedure:

1. Place all your resources in the same directory.
2. Specify the absolute path to that directory using the `webhelp.custom.resources` parameter.
3. Execute the transformation script.

**Result:** All files from the new directory will be copied to the root of the WebHelp output directory.

For example:

- **Windows:**
  
  ```
  dita.bat -i c:\mySample.ditamap -f webhelp-responsive -Dwebhelp.custom.resources=c:\resources
  ```

- **Mac OS X/ Linux:**
  
  ```
  dita -i /mySample.ditamap -f webhelp-responsive -Dwebhelp.custom.resources=/resources
  ```

**How to Publish MathML Formulas when Generating WebHelp from a Command Line**

The DITA-OT distribution that comes bundled with **Oxygen** includes some additional pre-installed DITA-OT plugins that add support for properly displaying MathML formulas in the WebHelp output. However, if you are generating your WebHelp output from a command line, MathML formulas will not be displayed properly unless you install these plugins manually.
These plugins can be downloaded and installed from DITA 1.3 Support for Open Toolkit (https://github.com/dita-community/dita13-dita-ot-1.x-support). This plugin package adds DITA 1.3 support, including MathML.

**How to Add Support for MathML when Generating WebHelp from a Command Line**

1. Download and unzip the **DITA 1.3 Support for Open Toolkit 1.x distribution package**. It includes 4 DITA-OT plugins.
2. Copy the four plugin directories to your `DITA-OT-DIR/plugins` directory.
3. In the home directory of your DITA-OT installation, run the `ant -f integrator.xml` command.

**Searching the Output**

This section contains topics that explain how to customize some of the search features in WebHelp Classic output.

**How to Change Element Scoring in Search Results**

The WebHelp **Search** feature is enhanced with a rating mechanism that computes scores for every page that matches the search criteria. HTML tag elements are assigned a scoring value and these values are evaluated for the search results. The WebHelp directory includes a properties file that defines the scoring values for tag elements and this file can be edited to customize the values according to your needs.

To edit the scoring values of HTML tag element for enhancing WebHelp search results, follow these steps:

1. Edit the scoring properties file for DITA or DocBook WebHelp systems. The properties file includes instructions and examples to help you with your customization.
   a. For DITA WebHelp Classic systems, edit the following file: `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.classic\indexer\scoring.properties`.
   b. For DocBook WebHelp system, edit the following file: `[DocBook XSL directory]\com.oxygenxml.webhelp.classic\indexer\scoring.properties`.

The values that can be edited in the `scoring.properties` file:

<table>
<thead>
<tr>
<th>Tag</th>
<th>Score</th>
</tr>
</thead>
<tbody>
<tr>
<td>h1</td>
<td>10</td>
</tr>
<tr>
<td>h2</td>
<td>9</td>
</tr>
<tr>
<td>h3</td>
<td>8</td>
</tr>
<tr>
<td>h4</td>
<td>7</td>
</tr>
<tr>
<td>h5</td>
<td>6</td>
</tr>
<tr>
<td>h6</td>
<td>5</td>
</tr>
<tr>
<td>b</td>
<td>5</td>
</tr>
</tbody>
</table>
2. Save your changes to the file.

3. Re-run your WebHelp transformation.

How to Exclude Certain DITA Topics from Search Results

There are several ways to exclude certain DITA resources from your WebHelp system's search results. This is useful if you have topics in your DITA map (on page 3281) structure that you do not want to be included in search results for your WebHelp system. The first method involves setting a parameter in the WebHelp transformation scenario and the second involves setting an attribute for each DITA topic reference that you want to exclude.

Transformation Parameter Method

To exclude DITA topics from WebHelp search results using a transformation parameter, follow these steps:

1. Create a simple text file that will contain your excluded file patterns. Each pattern must be on a new line. The patterns are considered to be relative to the output directory and they accept wildcards such as * (matches zero or more characters) or ? (matches one character). For more information about the patterns, see https://ant.apache.org/manual/dirtasks.html#patterns.

   **Example:** Suppose that in your project, you want to exclude all files located in the resources directory and all files located in the topics directory that have a .bak file extension. You could create a simple text file (for example, named exclude.properties), and add the following lines:

   ```
   resources/*
   topics/* .bak
   ```

2. Edit the WebHelp transformation scenario and open the Parameters tab.
3. Set the `webhelp.search.custom.excludes.file` parameter to specify the path to the file that contains the excluded file patterns (for example, `exclude.properties` in step 1).
4. Run the transformation scenario.

**Search Attribute Method**

The WebHelp Search engine does not index DITA topics that have the `@search` attribute set to `no`.

To exclude DITA topics from WebHelp search results using this attribute, follow these steps:

1. Edit the DITA map and for any `topicref` that you want to exclude from search results, set the `search` attribute to `no`. For example:
   ```xml
   <topicref href="../topics/internal-topic1.dita" search="no"/>
   ```
2. Save your changes to the DITA map.
3. Run your WebHelp system transformation scenario.

**How to Optimize Search Results in WebHelp Classic**

A DITA Map WebHelp transformation scenario can be configured to produce a `sitemap.xml` file that is used by search engines to aid crawling and indexing mechanisms. A `sitemap` lists all pages of a WebHelp system and allows webmasters to provide additional information about each page, such as the date it was last updated, change frequency, and importance of each page in relation to other pages in your WebHelp deployment.

The structure of the `sitemap.xml` file looks like this:

```xml
<urlset xmlns="http://www.sitemaps.org/schemas/sitemap/0.9">
  <url>
    <loc>http://www.example.com/topics/introduction.html</loc>
    <lastmod>2014-10-24</lastmod>
    <changefreq>weekly</changefreq>
    <priority>0.5</priority>
  </url>
  <url>
    <loc>http://www.example.com/topics/care.html#care</loc>
    <lastmod>2014-10-24</lastmod>
    <changefreq>weekly</changefreq>
    <priority>0.5</priority>
  </url>
  . . .
</urlset>
```
Each page has an `<url>` element structure containing additional information, such as:

- **loc** - the URL of the page. This URL must begin with the protocol (such as http), if required by your web server. It is constructed from the value of the `webhelp.sitemap.base.url` parameter from the transformation scenario and the relative path to the page (collected from the `href` attribute of a `topicref` element in the DITA map).

  **Note:** The value must have fewer than 2,048 characters.

- **lastmod** (optional) - the date when the page was last modified. The date format is `YYYY-MM-DD`.

- **changefreq** (optional) - indicates how frequently the page is likely to change. This value provides general information to assist search engines, but may not correlate exactly to how often they crawl the page. Valid values are: always, hourly, daily, weekly, monthly, yearly, and never. The first time the `sitemap.xml` file is generated, the value is set based upon the value of the `webhelp.sitemap.change.frequency` parameter in the DITA WebHelp transformation scenario. You can change the value in each `url` element by editing the `sitemap.xml` file.

  **Note:** The value `always` should be used to describe documents that change each time they are accessed. The value `never` should be used to describe archived URLs.

- **priority** (optional) - the priority of this page relative to other pages on your site. Valid values range from 0.0 to 1.0. This value does not affect how your pages are compared to pages on other sites. It only lets the search engines know which pages you deem most important for the crawlers. The first time the `sitemap.xml` file is generated, the value is set based upon the value of the `webhelp.sitemap.priority` parameter in the DITA WebHelp transformation scenario. You can change the value in each `url` element by editing the `sitemap.xml` file.

Creating and Editing the `sitemap.xml` File

Follow these steps to produce a `sitemap.xml` file for your WebHelp system, which can then be edited to fine-tune search engine optimization:

1. **Edit** the transformation scenario you currently use for obtaining your WebHelp output. This opens the `Edit DITA Scenario` dialog box.
2. Open the **Parameters** tab and set a value for the following parameters:
   - **webhelp.sitemap.base.url** - the URL of the location where your WebHelp system is deployed
     
     **Note:** This parameter is required for Oxygen XML Editor to generate the `sitemap.xml` file.
   - **webhelp.sitemap.change.frequency** - how frequently the WebHelp pages are likely to change (accepted values are: always, hourly, daily, weekly, monthly, yearly, and never)
   - **webhelp.sitemap.priority** - the priority of each page (value ranging from 0.0 to 1.0)
3. Run the transformation scenario.
4. Look for the `sitemap.xml` file in the transformation's output folder. Edit the file to fine-tune the parameters of each page, according to your needs.

**How to Index Japanese Content in WebHelp Classic**

To optimize the indexing of Japanese content in WebHelp pages, the Lucene Kuromoji Japanese analyzer can be used. This analyzer is included in the Oxygen XML Editor/Author installation kit.

**Using Oxygen XML Editor/Author**

To activate the Japanese indexing in your WebHelp output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Set the language for your content to Japanese (depending on your framework):
   - **DITA**: Edit a DITA to WebHelp transformation scenario and in the Parameters tab, set the value of the `default.language` parameter to `ja-jp`.
     
     **Note**: Alternatively, you could set the `xml:lang` attribute on the root of the DITA map (on page 3281) and the referenced topics to `ja-jp`. Another alternative for DITA output is to use the `webhelp.search.japanese.dictionary` parameter to specify a path to a Japanese dictionary that will be used by the Kuromoji morphological engine (note that the encoding for the dictionary must be UTF8).
   - **DocBook**: Edit a DocBook to WebHelp transformation scenario and in the Parameters tab, set the value of the `l10n.gentext.default.language` parameter to `ja`.

2. Run the WebHelp transformation scenario to generate the output.

**Using a Script Outside of Oxygen XML Editor/Author**

**Important**: Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated for the DITA Open Toolkit or a DocBook XSL Distribution.

To activate the Japanese indexing in your WebHelp output using a script outside of Oxygen XML Editor/Author, follow this procedure:

1. Set the language for your content to Japanese (depending on your framework):
   - **DITA**: Use the `args.default.language` parameter in your transformation script and set its value to `ja-jp`.
Note: Alternatively, you could set the `xml:lang` attribute on the root of the DITA map (on page 3281) and the referenced topics to `ja-jp`. Another alternative for DITA output is to use the `webhelp.search.japanese.dictionary` parameter to specify a path to a Japanese dictionary that will be used by the Kuromoji morphological engine (note that the encoding for the dictionary must be UTF8).

- **DocBook:** Use the `l10n.gentext.default.language` parameter in your transformation script and set its value to `ja`.

2. Execute the transformation script.

For example, a DITA script might look like this:

- **Windows:**
  
  dita.bat -i c:\mySample.ditamap -f webhelp -Dargs.default.language=ja-jp

- **Mac OS X/ Linux:**
  
  dita -i /mySample.ditamap -f webhelp -Dargs.default.language=ja-jp

---

**Related Information:**

- **How to Localize the Interface of DITA Map to WebHelp Classic Output (on page 1832)**

- **How to Localize the Interface of DocBook to WebHelp Classic Output (on page 1835)**

---

**Localization in WebHelp Classic Output**

This section contains topics that explain the localization support for DITA or DocBook WebHelp Classic transformations.

**How to Localize Email Notifications of WebHelp Classic with Feedback Output**

The feedback-enabled WebHelp systems use emails to notify users when comments are posted. These emails are based on templates stored in the WebHelp directory. The default messages are in English, French, German, and Japanese. These messages are copied into the WebHelp system deployment directory during the execution of the corresponding transformation scenario.

**Using Oxygen XML Editor/Author**

To change the language of the emails for WebHelp Classic with Feedback output using a transformation scenario from within **Oxygen XML Editor/Author**, follow this procedure:
1. Create the following directory, depending on your framework:
   - **DITA**: `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\php\templates\[Language code]` (where the *Language code* is the 2-digit code, such as *nl* for Dutch)
   - **DocBook**: `[DocBook XSL directory]\com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\php\templates\[Language code]` (where the *Language code* is the 2-digit code, such as *nl* for Dutch)

2. Copy all English template files from the following directory (depending on your framework) and paste them into the directory you just created.
   - **DITA**: `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\php\templates\en`
   - **DocBook**: `[DocBook XSL directory]\com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\php\templates\en`

3. Edit the HTML files from the following directory (depending on your framework) and translate the content into your language.
   - **DITA**: `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\php\templates\[Language code]` (where the *Language code* is the 2-digit code, such as *nl* for Dutch)
   - **DocBook**: `[DocBook XSL directory]\com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\php\templates\[Language code]` (where the *Language code* is the 2-digit code, such as *nl* for Dutch)

4. Edit a WebHelp Classic with Feedback transformation scenario and open the Parameters tab.
5. In the Parameters tab, look for the default.language parameter and set its value to the appropriate language code (for example, *nl* for Dutch).

   **Note:** If you set the parameter to a value such as LanguageCode-CountryCode (for example, *en-us*), the transformation scenario will only use the language code.

6. Run the transformation scenario.

### Using a Script Outside of Oxygen XML Editor/Author

**Important:** Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated for the DITA Open Toolkit or a DocBook XSL Distribution.

To change the language of the emails for WebHelp Classic with Feedback output using a script outside of Oxygen XML Editor/Author (on page 1789), follow this procedure:
1. Create the following directory, depending on your framework:
   - **DITA**: `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\php\templates\[Language code]` (where the *Language code* is the 2-digit code, such as `nl` for Dutch)
   - **DocBook**: `[DocBook XSL directory]\com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\php\templates\[Language code]` (where the *Language code* is the 2-digit code, such as `nl` for Dutch)

2. Copy all English template files from the following directory (depending on your framework) and paste them into the directory you just created:
   - **DITA**: `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\php\templates\en`
   - **DocBook**: `[DocBook XSL directory]\com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\php\templates\en`

3. Edit the HTML files from the following directory (depending on your framework) and translate the content into your language:
   - **DITA**: `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\php\templates\[Language code]` (where the *Language code* is the 2-digit code, such as `nl` for Dutch)
   - **DocBook**: `[DocBook XSL directory]\com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\php\templates\[Language code]` (where the *Language code* is the 2-digit code, such as `nl` for Dutch)

4. Use the `args.default.language` parameter in your transformation script and set its value to the appropriate language code (for example, `nl` for Dutch).

   **Note:** If you set the parameter to a value such as `LanguageCode-CountryCode` (for example, `en-us`), the transformation scenario will only use the language code.

5. Execute the transformation script.

   For example, a DITA to WebHelp Classic with Feedback script might look like this:

   - **Windows**:
     ```
     dita.bat -i c:\mySample.ditamap -f webhelp-feedback -Dargs.default.language=nl
     ```
   - **Mac OS X/ Linux**:
     ```
     dita -i /mySample.ditamap -f webhelp-feedback -Dargs.default.language=nl
     ```

   **How to Localize the Interface of DITA Map to WebHelp Classic Output**

   Static labels used in the WebHelp output are stored in translation files that have the `strings-lang1-lang2.xml` name format, where `lang1` and `lang2` are ISO language codes. For example, the US English labels are kept in the `strings-en-us.xml` file.
These translation files are collected from two locations:

- **DITA-OT-DIR/xsl/common folder** - DITA-OT's default translations (generated text for note, fig, and table elements).
- **DITA-OT-DIR/plugins/com.oxygenxml.webhelp.classic/oxygen-webhelp/resources/localization folder** - These translations are contributed by the WebHelp plugin and extend the default ones provided by DITA-OT. The labels defined in this folder take precedence over the DITA-OT defaults.

There are two major reasons you may want to use modify the translation files: to modify the existing strings or to translate to a new language.

**Modifying the Existing Strings**

To modify the generated text for WebHelp transformations, you need to create a DITA-OT extension plugin that uses the `dita.xsl.messages` extension point. The following procedure is for changing English labels, but you can adapt it for any language:

1. Create a `com.oxygenxml.webhelp.localization` plugin directory inside the DITA-OT-DIR/plugins/ location.
2. Create a plugin.xml file inside that `com.oxygenxml.webhelp.localization` directory with the following content:

```xml
<plugin id="com.oxygenxml.webhelp.localization">
  <require plugin="com.oxygenxml.webhelp.classic"/>
  <require plugin="com.oxygenxml.webhelp.responsive"/>
  <feature extension="dita.xsl.strings" file="webhelp-extension-strings.xml"/>
</plugin>
```

3. Create a webhelp-extension-strings.xml file with the following content:

```xml
<langlist>
  <lang xml:lang="en" filename="strings-en-us.xml"/>
  <lang xml:lang="en-us" filename="strings-en-us.xml"/>
</langlist>
```

4. Copy the strings you want to change from the translation files (on page 1833) to the strings-en-us.xml file. Make sure you leave the name attribute unchanged because this is the key used to look up the string. A sample content might be:

```xml
<strings xml:lang="en-US">
  <str name="Figure">Fig</str>
  <str name="Draft comment">ADDRESS THIS DRAFT COMMENT</str>
</strings>
```
5. Use the Run DITA-OT Integrator transformation scenario (on page 1665) found in the DITA Map section in the Configure Transformation Scenario(s) dialog box (on page 1762).

Adding a New Language

To add a new language for WebHelp transformations, you need to create a DITA-OT extension plugin that uses the `dita.xsl.messages` extension point. The following sample procedure is for adding translation files for the Polish language, but you can adapt it for any language:

1. Create a `com.oxygenxml.webhelp.localization` plugin directory inside the `DITA-OT-DIR/plugins/` location.
2. Create a `plugin.xml` file inside that `com.oxygenxml.webhelp.localization` directory with the following content:

   ```xml
   <plugin id="com.oxygenxml.webhelp.localization">
     <require plugin="com.oxygenxml.webhelp.classic"/>
     <require plugin="com.oxygenxml.webhelp.responsive"/>
     <feature extension="dita.xsl.strings" file="webhelp-extension-strings.xml"/>
   </plugin>
   ```

3. Create a `webhelp-extension-strings.xml` file with the following content:

   ```xml
   <langlist>
     <lang xml:lang="pl" filename="strings-pl-pl.xml"/>
     <lang xml:lang="pl-PL" filename="strings-pl-pl.xml"/>
   </langlist>
   ```

5. In the `strings-pl-pl.xml` file, change the `@xml:lang` attribute on the root element that conforms with the new language.

   ```xml
   <strings xml:lang="pl-PL">
     ...
   </strings>
   ```

6. Translate the content of each `<str>` element (make sure to leave the `name` attribute unchanged).

   ```xml
   <strings xml:lang="pl-PL">
     ...
   </strings>
   ```
7. Copy the common DITA-OT strings defined in the DITA-OT-DIR/xsl/common/strings-en-us.xml file. It defines a set generated text available for HTML based transformations (such as note, fig, and table elements). Translate the content of each <str> element.

Result:

```xml
<strings xml:lang="pl-PL">
  ...
  <str name="webhelp.content" js="true" php="false">Polish translation for "Content".</str>
  <str name="webhelp.search" js="true" php="false">Polish translation for "Search"</str>
  ...
</strings>
```

8. Use the Run DITA-OT Integrator transformation scenario (on page 1665) found in the DITA Map section in the Configure Transformation Scenario(s) dialog box (on page 1762).

How to Localize the Interface of DocBook to WebHelp Classic Output

Static labels that are used in the WebHelp output are kept in translation files in the [DocBook XSL directory]/com.oxygenxml.webhelp.classic/oxygen-webhelp/resources/localization folder. Translation files have the strings-lang1-lang2.xml name format, where lang1 and lang2 are ISO language codes. For example, the US English text is kept in the strings-en-us.xml file.

To localize the interface of the WebHelp output for DocBook transformations, follow these steps:
1. Look for the strings-[lang1]-[lang2].xml file in [DocBook XSL directory]/com.oxygenxml.webhelp.classic/oxygen-webhelp/resources/localization directory (for example, the Canadian French file would be: strings-fr-ca.xml). If it does not exist, create one starting from the strings-en-us.xml file.

2. Translate all the labels from the above language file. Labels are stored in XML elements that have the following format: `<str name="Label name">Caption</str>`.

3. Make sure that the new XML file that you created in the previous two steps is listed in the file [DocBook XSL directory]/com.oxygenxml.webhelp.classic/oxygen-webhelp/resources/localization/strings.xml. For example, a Canadian French file would be listed as: `<lang xml:lang="fr-ca" filename="strings-fr-ca.xml"/>`.

4. Edit any of the DocBook to WebHelp transformation scenarios (with or without feedback) and set the l10n.gentext.default.language parameter to the code of the language you want to localize (for example, fr-ca for Canadian French).

5. Run the transformation scenario to produce the WebHelp output.

How to Activate Support for Right-to-Left (RTL) Languages

To activate support for RTL (right-to-left) languages in WebHelp output, edit the DITA map (on page 3281) and set the xml:lang attribute on its root element (map). The corresponding attribute value can be set for following RTL languages:

- ar-eg - Arabic
- he-il - Hebrew
- ur-pk - Urdu

Integrating Social Media and Google Tools in the WebHelp Classic Output

Oxygen XML Editor includes support for integrating some of the most popular social media sites in WebHelp output.

How to Add a Facebook Like Button in WebHelp Classic Output

It is possible to integrate Facebook™ into your WebHelp Classic output and the widget will appear in the footer sections of your WebHelp page.
Using Oxygen XML Editor/Author

To add a Facebook Like widget to your WebHelp output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Go to the Facebook Developers website.
2. Fill-in the displayed form, then click the Get Code button.
3. Copy the two code snippets and paste them into a `<div>` element inside an XML file called `facebook-widget.xml`. Make sure you follow these rules:
   - The file must be well-formed.
   - The code for each `<script>` element must be included in an XML comment.
   - The start and end tags for the XML comment must be on a separate line.

   The content of the XML file should look like this:

   ```xml
   <div id="facebook">
     <div id="fb-root"/>
     <script>
       <!--
       (function(d, s, id) {
         var js, fjs = d.getElementsByTagName(s)[0];
         if (d.getElementById(id)) return;
         js = d.createElement(s); js.id = id;
         js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
         fjs.parentNode.insertBefore(js, fjs);
       })(document, 'script', 'facebook-jssdk');
       -->
     </script>
     <div class="fb-like" data-layout="standard" data-action="like"
      data-show-faces="true" data-share="true"/>
   </div>
   ```

4. In Oxygen XML Editor/Author, click the Configure Transformation Scenario(s) action from the toolbar (or the Document > Transformation menu).
5. Select an existing WebHelp Classic transformation scenario (depending on your needs, it may be with or without feedback) and click the Duplicate button to open the Edit Scenario dialog box.
6. Switch to the Parameters tab and edit the `webhelp.footer.file` parameter to reference the `facebook-widget.xml` file that you created earlier.
7. Click Ok and run the transformation scenario.
Using a Script Outside of Oxygen XML Editor/Author

⚠️ Important: Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated for the DITA Open Toolkit or a DocBook XSL Distribution.

To add a Facebook Like widget to your WebHelp output using a script outside of Oxygen XML Editor/Author (on page 1789), follow this procedure:

1. Go to the Facebook Developers website.
2. Fill-in the displayed form, then click the Get Code button.
3. Copy the two code snippets and paste them into a `<div>` element inside an XML file called `facebook-widget.xml`. Make sure you follow these rules:
   - The file must be well-formed.
   - The code for each `<script>` element must be included in an XML comment.
   - The start and end tags for the XML comment must be on a separate line.

   The content of the XML file should look like this:

   ```xml
   <div id="facebook">
       <div id="fb-root"/>
       <script>
           <!--
               (function(d, s, id) {
                   var js, fjs = d.getElementsByTagName(s)[0];
                   if (d.getElementById(id)) return;
                   js = d.createElement(s); js.id = id;
                   js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
                   fjs.parentNode.insertBefore(js, fjs);
               })(document, 'script', 'facebook-jssdk');
           -->
       </script>
       <div class="fb-like" data-layout="standard" data-action="like"
           data-show-faces="true" data-share="true"/>
   </div>
   ```

4. Use the webhelp.footer.file parameter in your transformation script and set its value to reference the `facebook-widget.xml` file that you created earlier.
5. Execute the transformation script.

For example:

- **Windows:**

  ```
  dita.bat -i c:\mySample.ditamap -f webhelp -Dwebhelp.footer.file=c:\facebook-widget.xml
  ```

- **Mac OS X/ Linux:**

  ```
  dita -i /mySample.ditamap -f webhelp -Dwebhelp.footer.file=/facebook-widget.xml
  ```

---

**How to Add a Google+ Button in WebHelp Classic Output**

It is possible to integrate Google into your WebHelp Classic output and the widget will appear in the footer section of your WebHelp page.

**Using Oxygen XML Editor/Author**

To add a Google+ widget to your WebHelp Classic output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Go to the Google Developers website.
2. Fill-in the displayed form. The preview area on the right side displays the code and a preview of the widget.
3. Copy the code snippet displayed in the preview area and paste it into a `div` element inside an XML file called `google-plus-button.xml`. Make sure that the content of the file is well-formed. The content of the XML file should look like this:

   ```
   <div id="google-plus">
       <!-- Place this tag in your head or just before your close body tag. -->
       <script src="https://apis.google.com/js/platform.js" async defer"></script>
       <!-- Place this tag where you want the +1 button to render. -->
       <div class="g-plusone" data-annotation="inline" data-width="300"></div>
   </div>
   ```

4. In Oxygen XML Editor/Author, click the Configure Transformation Scenario(s) action from the toolbar (or the Document > Transformation menu).
5. Select an existing WebHelp Responsive transformation scenario (depending on your needs, it may be with or without feedback) and click the Duplicate button to open the Edit Scenario dialog box.
6. Switch to the Parameters tab and edit the `webhelp.footer.file` parameter to reference the `google-plus-button.xml` file that you created earlier.
7. Click Ok and run the transformation scenario.

Using a Script Outside of Oxygen XML Editor/Author

⚠️ Important: Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated for the DITA Open Toolkit or a DocBook XSL Distribution.

To add a Google+ widget to your WebHelp Classic output using a script outside of Oxygen XML Editor/Author (on page 1789), follow this procedure:

1. Go to the Google Developers website.
2. Fill-in the displayed form. The preview area on the right side displays the code and a preview of the widget.
3. Copy the code snippet displayed in the preview area and paste it into a div element inside an XML file called google-plus-button.xml. Make sure that the content of the file is well-formed. The content of the XML file should look like this:

   <div id="google-plus">
     <!-- Place this tag in your head or just before your close body tag. -->
     <script src="https://apis.google.com/js/platform.js" async defer></script>
     <!-- Place this tag where you want the +1 button to render. -->
     <div class="g-plusone" data-annotation="inline" data-width="300"></div>
   </div>

4. Use the webhelp.footer.file parameter in your transformation script and set its value to reference the google-plus-button.xml file that you created earlier.
5. Execute the transformation script.

For example:

- Windows:
  
  dita.bat -i c:\mySample.ditamap -f webhelp -Dwebhelp.footer.file=c:\google-plus-button.xml

- Mac OS X/ Linux:
  
  dita -i /mySample.ditamap -f webhelp -Dwebhelp.footer.file=/google-plus-button.xml
How to Add Tweet Button in WebHelp Classic Output

It is possible to integrate Twitter into your WebHelp Classic output and the widget will appear in the footer section of your WebHelp page.

Using Oxygen XML Editor/Author

To add a Twitter Tweet widget to your WebHelp Classic output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Go to the Tweet button generator page.
2. Fill-in the displayed form. The Preview and code area displays the code that you will need.
3. Copy the code snippet displayed in the Preview and code area and paste it into a div element inside an XML file called tweet-button.xml. Make sure you follow these rules:
   - The file must be well-formed.
   - The code for each script element must be included in an XML comment.
   - The start and end tags for the XML comment must be on a separate line.

The content of the XML file should look like this:

```xml
<div id='twitter'>
  <a href='https://twitter.com/share' class='twitter-share-button'>Tweet</a>
  <script>
    !function(d, s, id) {
      var js, fjs = d.getElementsByTagName(s)[0], p = /^http:/.test(d.location) ? 'http' : 'https';
      if (! d.getElementById(id)) {
        js = d.createElement(s);
        js.id = id;
        js.src = p + '//platform.twitter.com/widgets.js';
        fjs.parentNode.insertBefore(js, fjs);
      }
    }
    {document,
      'script', 'twitter-wjs'};
  </script>
</div>
```

4. In Oxygen XML Editor/Author, click the Configure Transformation Scenario(s) action from the toolbar (or the Document > Transformation menu).
5. Select an existing WebHelp Responsive transformation scenario (depending on your needs, it may be with or without feedback) and click the **Duplicate** button to open the **Edit Scenario** dialog box.

6. Switch to the **Parameters** tab and edit the `webhelp.footer.file` parameter to reference the `tweet-button.xml` file that you created earlier.

7. Click **Ok** and run the transformation scenario.

---

**Using a Script Outside of Oxygen XML Editor/Author**

⚠️ **Important:** Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the [Oxygen XML WebHelp Plugin](https://www.oxygenxml.com/buy_webhelp.html).
- The [Oxygen XML WebHelp Plugin](https://www.oxygenxml.com/buy_webhelp.html) must be installed and integrated for the DITA Open Toolkit or a DocBook XSL Distribution.

To add a Twitter Tweet widget to your WebHelp Classic output using a script outside of Oxygen XML Editor/Author (on page 1789), follow this procedure:

1. Go to the Tweet button generator page.
2. Fill-in the displayed form. The **Preview and code** area displays the code that you will need.
3. Copy the code snippet displayed in the **Preview and code** area and paste it into a `div` element inside an XML file called `tweet-button.xml`. Make sure you follow these rules:
   - The file must be well-formed.
   - The code for each `script` element must be included in an XML comment.
   - The start and end tags for the XML comment must be on a separate line.

The content of the XML file should look like this:

```xml
<div id="twitter">
  <a href="https://twitter.com/share" class="twitter-share-button">Tweet</a>
  <script>
    <!--
    !function (d, s, id) {
      var js, fjs = d.getElementsByTagName(s)[0], p = /^http/.test(d.location) ? 'http': 'https';
      if (! d.getElementById(id)) {
        js = d.createElement(s);
        js.id = id;
        js.src = p + '://platform.twitter.com/widgets.js';
    ```
4. Use the `webhelp.footer.file` parameter in your transformation script and set its value to reference the `tweet-button.xml` file that you created earlier.

5. Execute the transformation script.

For example:

- **Windows:**

  ```bash
dita.bat -i c:\mySample.ditamap -f webhelp -Dwebhelp.footer.file=c:\tweet-button.xml
  ```

- **Mac OS X/ Linux:**

  ```bash
dita -i /mySample.ditamap -f webhelp -Dwebhelp.footer.file=/tweet-button.xml
  ```

---

**How to Integrate Google Analytics in WebHelp Classic Output**

You can use Google Analytics to track and report site data for your WebHelp Classic output.

**Using Oxygen XML Editor/Author**

To integrate Google Analytics into your WebHelp Classic output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Create a new Google Analytics account (if you do not already have one) and log on.
2. Choose the Analytics solution that best fits the needs of your website.
3. Follow the on-screen instructions to obtain a Tracking Code that contains your Tracking ID. A Tracking Code looks like this:

```html
<script>
(function(i,s,o,r,a,m){i['GoogleAnalyticsObject']=r;i[r]=i[r]||function(){
  (i[r].q=i[r].q||[]).push(arguments)},i[r].l=1*new Date();a=s.createElement(o),
m=s.getElementsByTagName(o)[0];a.async=1;a.src=g;m.parentNode.insertBefore(a,m)
 })(window,document,'script','//www.google-analytics.com/analytics.js','ga');

ga('create', 'UA-XXXXXXXX-X', 'auto');
</script>
```
4. Save the Tracking Code (obtained in the previous step) in a new XML file called `googleAnalytics.xml`. Note that the file should only contain the tracking code.

5. In Oxygen XML Editor/Author, click the Configure Transformation Scenario(s) action from the toolbar (or the Document > Transformation menu).

6. Select an existing WebHelp Responsive transformation scenario (depending on your needs, it may be with or without feedback) and click the Duplicate button to open the Edit Scenario dialog box.

7. Switch to the Parameters tab and edit the `webhelp.footer.file` parameter to reference the `googleAnalytics.html` file that you created earlier.

8. Click Ok and run the transformation scenario.

Using a Script Outside of Oxygen XML Editor/Author

⚠️ **Important:** Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated for the DITA Open Toolkit or a DocBook XSL Distribution.

To integrate Google Analytics into your WebHelp Classic output using a script outside of Oxygen XML Editor/Author (on page 1789), follow this procedure:

1. Create a new Google Analytics account (if you do not already have one) and log on.
2. Choose the Analytics solution that best fits the needs of your website.
3. Follow the on-screen instructions to obtain a Tracking Code that contains your Tracking ID. A Tracking Code looks like this:

```html
<script>
(function(i,s,o,g,r,a,m){i['GoogleAnalyticsObject']=r;i[r]=i[r]||function()
(i[r].q=i[r].q||[]).push(arguments)},i[r].l=1*new Date();a=s.createElement(o), m=s.getElementsByTagName(o)[0];a.async=1;a.src=g;m.parentNode.insertBefore(a,m)
)(window,document,'script','//www.google-analytics.com/analytics.js','ga');

ga('create', 'UA-XXXXXXXX-X', 'auto');
ga('send', 'pageview');
</script>
```
4. Save the Tracking Code (obtained in the previous step) in a new XML file called `googleAnalytics.xml`. Note that the file should only contain the tracking code.

5. Use the `webhelp.footer.file` parameter in your transformation script and set its value to reference the `googleAnalytics.html` file that you created earlier.

6. Execute the transformation script.

For example:

- **Windows:**
  
  `dita.bat -i c:\mySample.ditamap -f webhelp -Dwebhelp.footer.file=c:\googleAnalytics.xml`

- **Mac OS X/ Linux:**
  
  `dita -i /mySample.ditamap -f webhelp -Dwebhelp.footer.file=/googleAnalytics.xml`

### How to Integrate Google Search in WebHelp Classic Output

It is possible to integrate the *Google Search Engine* into your *WebHelp Classic* output and you can specify where you want the results to appear in your WebHelp page.

### Using Oxygen XML Editor/Author

To integrate the *Google Search Engine* into your WebHelp Responsive output using a transformation scenario from within *Oxygen XML Editor/Author*, follow this procedure:

1. Go to the *Google Custom Search Engine page* using your Google account.
2. Select the *Create a custom search engine* button.
3. Follow the on-screen instructions to create a search engine for your site. At the end of this process you should obtain a code snippet that looks like this:

```html
<script>
(function() {
    var cx = '000888210889775888983:8mn4x_mf-yg';
    var gcse = document.createElement('script');
    gcse.type = 'text/javascript';
    gcse.async = true;
    var s = document.getElementsByTagName('script')[0];
    s.parentNode.insertBefore(gcse, s);
});
</script>
```
4. Save the script into a well-formed HTML file called `googlecse.html`.

5. In **Oxygen XML Editor/Author**, click the Configure Transformation Scenario(s) action from the toolbar (or the Document > Transformation menu).

6. Select an existing WebHelp Responsive transformation scenario (depending on your needs, it may be with or without feedback) and click the **Duplicate** button to open the **Edit Scenario** dialog box.

7. Switch to the **Parameters** tab and edit the `webhelp.google.search.script` parameter to reference the `googlecse.html` file that you created earlier.

8. You can also use the `webhelp.google.search.results` parameter to choose where to display the search results.
   a. Create an HTML file with the following content:
      ```html
      <div class="gcse-searchresults-only" data-autoSearchOnLoad="true" data-queryParameterName="searchQuery"></div>
      ```
      (you must use the HTML5 version for the GCSE). For more information about other supported attributes, see [Google Custom Search: Supported Attributes](#).
   b. Set the value of the `webhelp.google.search.results` parameter to the file path of the file you just created. If this parameter is not specified, the following code is used:
      ```html
      <div class="gcse-searchresults-only" data-autoSearchOnLoad="true" data-queryParameterName="searchQuery"></div>.
      ```

9. Click **Ok** and run the transformation scenario.

---

**Using a Script Outside of Oxygen XML Editor/Author**

⚠️ **Important**: Running WebHelp transformations from a script outside of **Oxygen XML Editor/Author** requires an additional license and some additional setup:

- You must have a valid license for the **Oxygen XML WebHelp Plugin** ([https://www.oxygenxml.com/buy_webhelp.html](https://www.oxygenxml.com/buy_webhelp.html)).
- The **Oxygen XML WebHelp Plugin** must be installed and integrated for the DITA Open Toolkit or a DocBook XSL Distribution.

To integrate the **Google Search Engine** into your WebHelp Classic output using a script outside of **Oxygen XML Editor/Author (on page 1789)**, follow this procedure:

1. Go to the **Google Custom Search Engine page** using your Google account.
2. Select the **Create a custom search engine** button.
3. Follow the on-screen instructions to create a search engine for your site. At the end of this process you should obtain a code snippet that looks like this:
function() {
    var cx = '00088821089775889983:8mn4x_mf-yg';
    var gcse = document.createElement('script');
    gcse.type = 'text/javascript';
    gcse.async = true;
    var s = document.getElementsByTagName('script')[0];
    s.parentNode.insertBefore(gcse, s);
})();
</script>

4. Save the script into a well-formed HTML file called googlecse.html.

5. Use the webhelp.google.search.script parameter in your transformation script and set its value to reference the googlecse.html file that you created earlier.

6. You can also use the webhelp.google.search.results parameter to choose where to display the search results.
   a. Create an HTML file with the following content: `<div class="gcse-searchresults-only" data-autoSearchOnLoad="true" data-queryParameterName="searchQuery"></div>` (you must use the HTML5 version for the GCSE). For more information about other supported attributes, see Google Custom Search: Supported Attributes.
   b. Set the value of the webhelp.google.search.results parameter to the file path of the file you just created. If this parameter is not specified, the following code is used: `<div class="gcse-searchresults-only" data-autoSearchOnLoad="true" data-queryParameterName="searchQuery"></div>`.

7. Execute the transformation script.

For example:

- **Windows:**
  
  dita.bat -i c:\mySample.ditamap -f webhelp -Dwebhelp.google.search.script=c:\googlecse.html -Dwebhelp.google.search.results=c:\myFile.html

- **Mac OS X/ Linux:**
  
  dita -i /mySample.ditamap -f webhelp -Dwebhelp.google.search.script=/googlecse.html -Dwebhelp.google.search.results=/myFile.html
Overriding XSLT Processing Step of DITA WebHelp Classic Transformations

Since WebHelp output is primarily obtained by running XSLT transformations over the DITA input files (through the DITA Map WebHelp Classic transformation scenarios), one customization method would be to override the default XSLT templates that are used by the WebHelp transformations.

There are two methods available to override the XSLT stylesheets implied by the WebHelp transformation.

• The first method is to use one of the WebHelp XSLT-import extension points (on page 1848) that allow you to import an XSLT stylesheet so that it becomes part of the normal build. This method uses the same mechanism as the DITA-OT XSLT-import extension points. Note that this method will affect all the outputs generated with the WebHelp system.

• The second method implies that you will create a DITA-OT extension plugin (on page 1850) with a custom transtype and use an Ant build file to define the transformation process. The main difference from the first customization method is that you will not affect all WebHelp transformations. Only the transformations that use the declared plugin transtype will be affected.

WebHelp Classic XSLT-Import and XSLT-Parameter Extension Points

The WebHelp XSLT-Import extension points allows you to extend the XSLT stylesheets associated with some of the WebHelp transformation steps. The DITA-OT plug-in installer adds an XSLT import statement in the default WebHelp XSLT so that the XSLT stylesheet referenced by the extension point becomes part of the normal build.

Example:

```xml
<plugin id="com.oxygenxml.webhelp.classic.extension">
  <feature extension="com.oxygenxml.webhelp.classic.xsl.dita2webhelp"
    file="xsl/fixup.xsl"/>
</plugin>
```

⚠️ Attention: The customizations you make by using this extension point will affect all WebHelp transformations. If you want to have a customization that is only available for a certain transformation, use the Overriding a WebHelp XSLT Stylesheet from an Ant Build File (on page 1850) method.

XSLT-Import Extension Points

The following extension points are available:

  com.oxygenxml.webhelp.classic.xsl.dita2webhelp
Extension point to override the XSLT stylesheet (dita2webhelpImpl.xsl) that produces an HTML file for each DITA topic. The path to this stylesheet is: DITA-OT-DIR\plugins\com.oxygenxml.webhelp.classic\xsl\dita\desktop\dita2webhelpImpl.xsl

com.oxygenxml.webhelp.classic.xsl.createMainFiles

Extension point to override the XSLT stylesheet (createMainFilesImpl.xsl) that produces the WebHelp main HTML page (index.html). The path to this stylesheet is: DITA-OT-DIR\plugins\com.oxygenxml.webhelp.classic\xsl\dita\desktop\createMainFilesImpl.xsl

com.oxygenxml.webhelp.classic.xsl.createTocXML

Extension point to override the XSLT stylesheet (tocDita.xsl) that produces the toc.xml file. This file contains information extracted from the DITA map (on page 3281) and it is mainly used to construct the WebHelp Table of Contents and navigational links. The path to this stylesheet is: DITA-OT-DIR\plugins\com.oxygenxml.webhelp.classic\xsl\dita\tocDita.xsl.

XSLT-Parameter Extension Points

If your customization stylesheet declares one or more XSLT parameters and you want to control their values from the transformation scenario, you can use one of the following XSLT parameter extension points:

com.oxygenxml.webhelp.classic.xsl.dita2webhelp.param

Use this extension point to pass parameters to the stylesheet specified using the com.oxygenxml.webhelp.classic.xsl.dita2webhelp extension point (on page 1848).

com.oxygenxml.webhelp.classic.xsl.createMainFiles.param

Use this extension point to pass parameters to the stylesheet specified using the com.oxygenxml.webhelp.classic.xsl.createMainFiles extension point (on page 1849).

com.oxygenxml.webhelp.classic.xsl.createTocXML.param

Use this extension point to pass parameters to the stylesheet specified using the com.oxygenxml.webhelp.classic.xsl.createTocXML extension point (on page 1849).

Related Information:

• [DITA-OT] XSLT-Import Extension Points
How to Override a WebHelp Classic XSLT Stylesheet from Ant Build File

To create a WebHelp XSLT customization that is only available for a certain DITA OT transformation, the extension plugin should declare a custom transtype. The WebHelp XSLT stylesheets can be overridden from an ANT file provided by the DITA-OT extension plugin. From the Ant target associated with the plugin, you will specify a custom XSLT stylesheet that imports the original WebHelp stylesheet and add some customization templates.

The following procedure explains how to create a DITA-OT extension plugin that uses this extension method:

1. In the `DITA-OT-DIR\plugins\` folder, create a folder for this plugin (for example, `com.oxygenxml.webhelp.classic.custom`).
2. Create a `plugin.xml` file (in the folder you created in step 1) that specifies a new DITA-OT transtype and the build file associated with the plugin. For example:

   ```xml
   <plugin id="com.oxygenxml.webhelp.classic.custom">
     <feature extension="dita.conductor.target.relative" file="integrator.xml"/>
     <transtype name="webhelp-classic-custom" extends="webhelp"
               desc="WebHelp Classic Customization"/>
   </plugin>
   ```

3. Create the `integrator.xml` file that will import the actual plugin Ant build file.

   ```xml
   <project basedir="." name="Webhelp Classic Customization">
     <import file="build.xml"/>
   </project>
   ```

4. Create the `build.xml` file that overrides the value of properties associated with the XSLT stylesheets used to produce HTML files (on page 1852). The following Ant properties can be overridden to specify your customization stylesheets:

   ```xml
   <property name="args.wh.classic.topic.xsl" value="com.oxygenxml.webhelp.classic.custom.webhelp-classic-custom.xsl"/>
   Specify this property if you want to customize the XSLT stylesheet used to produce an HTML file for each topic (on page 1852).
   ```

   ```xml
   <property name="args.wh.classic.create.main.files.xsl" value="com.oxygenxml.webhelp.classic.custom.webhelp-classic-custom.xsl"/>
   Specify this property if you want to customize the XSLT stylesheet used to produce the main HTML files (on page 1852).
   ```
Specify this property if you want to customize the XSLT stylesheet used to produce the toc.xml file (on page 1853). The toc.xml file contains information extracted from DITA map and it is mainly used to create the WebHelp TOC.

For example, to customize a WebHelp Classic transformation type, the build file should look like:

```xml
<project basedir="." name="Webhelp Classic Customization">
  <target name="dita2webhelp-classic-custom">
    <!--
    Override this property if you want to customize the XSLT stylesheet used to produce an HTML file for each topic
    -->
    <property name="args.wh.classic.topic.xsl" value="${dita.plugin.com.oxygenxml.webhelp.classic.custom.dir}/xsl/dita2webhelpCustom.xsl"/>
    <!--
    Override this property if you want to customize the XSLT stylesheet used to produce the main HTML file.
    -->
    <property name="args.wh.classic.create.main.files.xsl" value="${dita.plugin.com.oxygenxml.webhelp.classic.custom.dir}/xsl/createMainFilesCustom.xsl"/>
    <!--
    Override this property if you want to customize the XSLT stylesheet used to produce the toc.xml file.
    -->
    <property name="args.wh.classic.createTocXML.xsl" value="${dita.plugin.com.oxygenxml.webhelp.classic.custom.dir}/xsl/createTocXMLCustom.xsl"/>
    <!--
    You need to delegate the build target:
    * dita2webhelp - for WebHelp Classic
    -->
    <antcall target="dita2webhelp"/>
  </target>
</project>
```

5. Create an xsl directory in the plugin customization directory (that you created in step 1) to store the customized XSLT stylesheets.
6. Now that the extension plugin is created, install it in the DITA Open Toolkit (on page 3256).

Referencing the WebHelp XSLT Stylesheets from Your Customizations

Note that your customization stylesheets should import the original stylesheets that they override. To reference the WebHelp stylesheets, you can use the `plugin:com.oxygenxml.dita-ot.plugin.webhelp` prefix. This prefix is rewritten by an XML catalog to the WebHelp root directory.

**Customizing the `dita2webhelp.xsl` Stylesheet**

The XSLT stylesheet that customizes the WebHelp `dita2webhelp.xsl` stylesheet should look like:

```xml
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:math="http://www.w3.org/2005/xpath-functions/math"
    exclude-result-prefixes="xs math"
    version="2.0">

    <!-- Import the original stylesheet used to produce an HTML file for each topic. -->

    <!-- Add your customization templates here. -->
</xsl:stylesheet>
```

You need to import the following XSLT stylesheet:

```
```

**Customizing the `createMainFiles.xsl` Stylesheet**

The XSLT stylesheet that customizes the WebHelp `createMainFiles.xsl` stylesheet should look like:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:math="http://www.w3.org/2005/xpath-functions/math"
    exclude-result-prefixes="xs math"
    version="2.0">

    <!-- Import the original stylesheet used to produce the main HTML file. -->
</xsl:stylesheet>
```
You need to import the following XSLT stylesheet:

```xml
<xsl:import href="plugin:com.oxygenxml.webhelp.classic:xsl/dita/desktop/createMainFiles.xsl"/>
```

Add your customization templates here.

```xml
</xsl:stylesheet>
```

Customizing the `tocDita.xsl` File

The XSLT stylesheet that customizes the WebHelp `tocDita.xsl` stylesheet should look like:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:math="http://www.w3.org/2005/xpath-functions/math"
    exclude-result-prefixes="xs math"
    version="2.0">
    <!-- Import the original stylesheet used to produce the toc.xml file. -->
    <!-- Add your customization templates here. -->
    </xsl:stylesheet>
```

Miscellaneous Customization Topics

This section contains miscellaneous topics about how to customize the WebHelp Classic output.

How to Disable Caching in WebHelp Classic Output

In cases where a set of WebHelp Classic pages need to be updated on a regular basis to deliver the latest version of the documentation, the WebHelp pages should always be requested from the server upon re-loading it in a Web browser on the client side, rather than re-using an outdated cached version in the browser.
To disable caching in WebHelp Classic output, follow this procedure:

1. Edit the following XSL file for DITA or DocBook WebHelp systems:
   - For DITA WebHelp systems, edit the following file: `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.classic\xsl\createMainFiles.xsl`.
   - For DocBook WebHelp system, edit the following file: `{OXYGEN_INSTALL_DIR}\frameworks\docbook\xsl\com.oxygenxml.webhelp.classic\xsl\createMainFiles.xsl`.

2. Locate the following template in the XSL file: `<xsl:template name="create-toc-common-file">` and add the following code snippet:

   ```xml
   <meta http-equiv="Pragma" content="no-cache" />
   <meta http-equiv="Expires" content="-1" />
   ```

   **Note:** The code should look like this:

   ```xml
   <html>
   <head>
   <xsl:if test="$withFrames">
   <base target="contentwin"/>
   </xsl:if>
   <meta http-equiv="Content-Type" content="text/html; charset=utf-8"/>
   <!-- Disable caching of WebHelp pages in web browser. -->
   <meta http-equiv="Pragma" content="no-cache" />
   <meta http-equiv="Expires" content="-1" />
   ....
   ```

3. Save your changes to the file.
4. Re-run your WebHelp transformation scenario.

How to Flag DITA Content in WebHelp Output

Flagging content in WebHelp output involves defining a set of images that will be used for marking content across your information set.

To flag DITA content, you need to create a filter file that defines properties that will be applied on elements to be flagged. Generally, flagging is supported for *block elements* (on page 3280) (such as paragraphs), but not for phrase-level elements within a paragraph. This ensures that the images that will flag the content are easily scanned by the reader, instead of being buried in the text.
Using Oxygen XML Editor/Author

To flag content in the DITA Map to WebHelp output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Create a DITA filter file (DITAVAL) and add it in a directory of your choice (for example, named myFile.ditaval).
2. Define the property for the elements you want to be flagged. For example, if you want to flag any element that has the audience attribute set to programmer, the content of the DITAVAL file should look like this:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<val>
  <prop att="audience" val="programmer" action="flag"
    img="D:\resource\delta.gif" alt="sample alt text"/>
</val>
```

Note that for an element to be flagged, at least one attribute-value pair needs to have a property declared in the DITAVAL file.
3. Edit a DITA Map to WebHelp transformation scenario.
4. Specify the DITAVAL file in the Filters tab (with the Use DITAVAL File option).
5. Run the transformation scenario.

Using a Script Outside of Oxygen XML Editor/Author

⚠️ Important: Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated for the DITA Open Toolkit or a DocBook XSL Distribution.

To flag content in the DITA Map to WebHelp output using a script outside of Oxygen XML Editor/Author, follow this procedure:

1. Create a DITA filter file (DITAVAL) and add it in a directory of your choice (for example, named myFile.ditaval).
2. Define the property for the elements you want to be flagged. For example, if you want to flag any element that has the audience attribute set to programmer, the content of the DITAVAL file should look like this:
Note that for an element to be flagged, at least one attribute-value pair needs to have a property declared in the DITAVAL file.

3. Use the `args.filter` parameter in your transformation script and set its value to the path of the DITAVAL file you created.

4. Execute the transformation script.

For example:

- **Windows:**

  dita.bat -i c:\mySampleMap.ditamap -f webhelp -Dargs.filter=c:\myFile.ditaval

- **Mac OS X / Linux:**

  dita -i /mySampleMap.ditamap -f webhelp -Dargs.filter=/myFile.ditaval

**How to Publish WebHelp Classic Output on a SharePoint Site**

Since WebHelp output must be published locally, on the same machine where the WebHelp process is running, to publish your files directly to a SharePoint library you need to map a network drive to connect to SharePoint and change your file extensions to `.aspx`, as described in the steps below.

**Using Oxygen XML Editor/Author**

To publish WebHelp Classic output on a SharePoint site and use a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Map a network drive to connect to your SharePoint library. For more information, see: https://support.microsoft.com/en-us/kb/2616712.

2. Edit the WebHelp transformation scenario and open the Parameters tab.

   - For a DITA transformation, set the `args.outext` parameter to `.aspx`.
   - For a DocBook transformation, set the `html.ext` parameter to `.aspx`.

3. Run the WebHelp transformation scenario to generate the output.
Using a Script Outside of Oxygen XML Editor/Author

**Important:** Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated for the DITA Open Toolkit or a DocBook XSL Distribution.

To publish WebHelp Classic output on a SharePoint site and use a script outside of Oxygen XML Editor/Author (on page 1789), follow this procedure:

1. Map a network drive to connect to your SharePoint library. For more information, see: https://support.microsoft.com/en-us/kb/2616712.
2. Use the following parameter to change your file extensions to .aspx:
   - For DITA transformations, use the args.outext parameter in your transformation script and set its value to .aspx.
   - For DocBook transformations, use the html.ext parameter in your transformation script and set its value to .aspx.
3. Execute the transformation script.

For example, a DITA script might look like this:

- **Windows:**
  ```cmd
  dita.bat -i c:\mySample.ditamap -f webhelp -Dargs.outext=.aspx
  ```
- **Mac OS X/ Linux:**
  ```bash
  dita -i /mySample.ditamap -f webhelp -Dargs.outext=.aspx
  ```

WebHelp Responsive Output

The WebHelp Responsive features a very flexible layout, is designed to adapt to any screen size to provide an optimal viewing and interaction experience. It is based upon the Bootstrap responsive front-end framework and is available for DITA document types.

The WebHelp Responsive with Feedback variant also includes a feedback system that allows your users to add comments and allows you to manage and reply to them.

WebHelp Responsive output can be generated by using the DITA Map WebHelp Responsive (on page 1644) or DITA Map WebHelp Responsive with Feedback transformation scenario (on page 1644).
WebHelp Responsive Output Layout and Features

This section contains information about the layout and features of the WebHelp Responsive output.

Layout of the Responsive Page Types

You can select from several different styles of layouts (for example, by default, you can select either a tiles or tree style of layout). Furthermore, each layout includes a collection of skins that you can choose from, or you can customize your own.

Figure 616. WebHelp Responsive Output on a Normal Screen

![WebHelp Responsive Output on a Normal Screen](image)

Figure 617. WebHelp Responsive Output on a Narrow Screen
Main Page

The Main Page is the home page generated in the WebHelp Responsive output. The main function of the home page is to display top-level information and provide links that help you easily navigate to any of the top-level topics of the publication. These links can be rendered in either a Tiles or Tree style of layout. The main page also consists of various other components, such as a logo, title, menu, search field, or index link.

Main Page - Tiles Layout

In the tiles presentation mode, a tile component is created for each chapter (first-level topic) in the publication. The tile presents a link to the topic and its short description.

Figure 618. Main Page - Tiles Layout
Main Page - Tree Layout

In the tree presentation mode, links to the first and second level topics in the publication are displayed using a tree-like component.

Figure 619. Main Page - Tree Layout
The layout components displayed in the main page are:

**Publication Title**

The title of the publication. It is usually taken from the DITA map title.

**Logo**
Displays a logo associated with the publication. Additionally you can set a target URL that will be opened when you click on the logo image.

The logo image can be specified using the `webhelp.logo.image` transformation parameter (on page 2004). For the target URL, use the `webhelp.logo.image.target.url` parameter (on page 2004).

**Menu**

Helps you to navigate to your documentation. This component presents a set of links to all topics from your publication. For information about customizing the menu, see How to Customize the Menu (on page 1954) topic.

**Index Terms Link**

Presents a link to the index terms page. You can control if this component is displayed by using the `webhelp.show.indexterms.link` parameter (on page 2007).

**Search Input**

Input text field allowing you to easily enter your search queries.

**Topic Tiles**

A tile associated with a main topic. Each topic tile has three sections that correspond to the topic title, short description, and image.

**Topic Tile Title**

Presents the navigation title of the associated topic.

**Topic Tile Short Description**

Presents the short description of the topic. It may be collected either from the topic or from the DITA map topic meta.

**Topic Tile Image**

Presents an image associated with the topic. The image association (on page 1954) is done in the DITA map.

**Tree Table of Contents**

An area containing topic titles from first and second level of your publication.

**Page Footer**

WebHelp Responsive output footer.
The **Topic Page** is the page generated for each DITA topic in the WebHelp Responsive output. The HTML pages produced for each topic consist of the topic content along with various other additional components, such as a title, menu, navigation breadcrumb, print icon, or side table of contents.

**Figure 620. Topic Page**

Topic Page Components

The layout components displayed in this page are:

Publication Title

The title of the publication. It is usually taken from the DITA map title.

Logo

Displays a logo associated with the publication. Additionally you can set a target URL that will be opened when you click on the logo image.

The logo image can be specified using the webhelp.logo.image transformation parameter (on page 2004). For the target URL, use the webhelp.logo.image.target.url parameter (on page 2004).

Menu

Helps you to navigate to your documentation. This component presents a set of links to all topics from your publication. For information about customizing the menu, see How to Customize the Menu (on page 1954) topic.

Index Terms Link

Presents a link to the index terms page. You can control if this component is displayed by using the webhelp.show.indexterms.link parameter (on page 2007).

Search Input

Input text field allowing you to easily enter your search queries.

Navigation Links
The navigation links (➤ Previous / ➤ Next arrows) can be used to navigate to the previous or next topic. These navigation links are controlled by the `collection-type` attribute. For example, if you set `collection-type="sequence"` on a parent topic reference, navigation links will be generated in the output for that topic and all of its child topics. You can also use the `webhelp.default.collection.type.sequence` parameter and set its value to `yes` to generate navigation links for all topics, regardless of whether or not the `collection-type` attribute is present.

**Tip:** To hide the navigation links, you can edit the transformation scenario and set the value of the `webhelp.show.navigation.links` parameter to `no`.

**Expand/Collapse Sections Button**

Icon that expands or collapses sections listed in the side table of contents within a topic.

**Print Link**

A print icon that opens the print dialog box for your particular browser.

**Breadcrumb**

Presents the path of the current displayed DITA topic in documentation.

**Topic Content**

Presents the content of the associated DITA topic.

**Publication Table of Contents**

A Table of Content for the publication displayed in the left side.

**Topic Table of Contents (On this page links)**

A table of contents for the topic displayed on the right side with a heading named **On this page** and it contains links to each section within the current topic and the section corresponding to the current scroll position is highlighted. This component is generated for any topic that contains at least two `<section>` elements and each `<section>` must have an `@id` attribute.

**Page Footer**

WebHelp Responsive output footer.

**Search Page**

The **Search Page** presents search results in the WebHelp Responsive output. The HTML page consists of a search results component along with various other additional components, such as a title, menu, or index link.
When you enter search terms in the **Search** field, the results are displayed in a results page. When you click on a result, the topic is opened in the main pane and the search results are highlighted. If you want to remove the colored highlights, click the **Toggle Highlights** button at the top-right side of the page. The **Search** field also includes an **autocomplete** feature.

Figure 621. Search Results Page
Search Page Components

The layout components displayed in the search page are:

Publication Title

The title of the publication. It is usually taken from the DITA map title.

Logo

Displays a logo associated with the publication. Additionally you can set a target URL that will be opened when you click on the logo image.

The logo image can be specified using the `webhelp.logo.image` transformation parameter (on page 2004). For the target URL, use the `webhelp.logo.image.target.url` parameter (on page 2004).

Menu

Helps you to navigate to your documentation. This component presents a set of links to all topics from your publication. For information about customizing the menu, see How to Customize the Menu (on page 1954) topic.

Index Terms Link

Presents a link to the index terms page. You can control if this component is displayed by using the `webhelp.show.indexterms.link` parameter (on page 2007).

Search Input

Input text field allowing you to easily enter your search queries.

Search Results

Each result includes the topic title that can be clicked to open that page. Under the title, a breadcrumb is displayed that shows the path of the topic and you can click any of the topics in the breadcrumb to open that particular page.

Page Footer

WebHelp Responsive output footer.

Autocomplete Suggestions in the Search Text Field

When you are typing in the search text field, proposals are presented to help you to compute the search query. The information proposed when you are typing is collected from:

- The search queries from the history of the previous searches.
- The titles collected from your documentation.
• Documentation index terms and keywords. For example, in a DITA topic, the keywords and index terms are specified in the topic prolog section like this:

```xml
<prolog>
  <metadata>
    <keywords><indexterm>databases</indexterm></keywords>
    <keyword>installing</keyword>
    <keyword>uninstalling</keyword>
    <keyword>prerequisites</keyword>

**Missing Terms**

If you enter multiple search terms (other than *stop words*), for any result that the search engine found at least one term but not one or more of the other terms, the **Missing** terms will be listed below each result.

**Related Information:**

- WebHelp Responsive Search Engine (*on page 1870*)

**Index Terms Page**

The *Index Terms Page* page consists of an index terms section along with various other additional components, such as a title, menu, or search field.

An alphabet that contains the first letter of the documentation index terms is generated at the top of the index page. Each letter represents a link to a specific indices section. The indexes are presented in multiple columns to make it easier to read this page.

Figure 622. Index Terms Page
Index Terms Page Components

The layout components displayed in this page are:

**Publication Title**

The title of the publication. It is usually taken from the DITA map title.

**Logo**

Displays a logo associated with the publication. Additionally you can set a target URL that will be opened when you click on the logo image.
The logo image can be specified using the `webhelp.logo.image transformation parameter (on page 2004)`. For the target URL, use the `webhelp.logo.image.target.url parameter (on page 2004)`.

**Menu**

Helps you to navigate to your documentation. This component presents a set of links to all topics from your publication. For information about customizing the menu, see **How to Customize the Menu (on page 1954)** topic.

**Index Terms Link**

Presents a link to the index terms page. You can control if this component is displayed by using the `webhelp.show.indexterms.link parameter (on page 2007)`.

**Index Terms Alphabet**

An alphabet that contains the first letter of index terms. Each letter represents a link to a specific indices section.

**Index Terms**

The first letter of the index along with the list of index terms.

**Page Footer**

WebHelp Responsive output footer.

**Search Engine**

Search engine has two main components:

**Search indexer**

It is also known as a **spider**. This component is active when you publish your documentation to WebHelp and it is responsible for creating the **search index**. This component traverses all HTML pages (for DITA topics) to gather information.

**Search interface**

This component is an interface between the user and the **search index**. It helps the user to search through the **search index** and displays results in the search page.

**Search Field and Results Page**

When you enter search terms in the **Search** field, the results are displayed in a results page. When you click on a result, the topic is opened in the main pane and the search results are highlighted. If you want to remove the colored highlights, click the **Toggle Highlights** button at the top-right side of the page. The **Search** field also includes an **autocomplete** feature.
Each result includes the topic title that can be clicked to open that page. Under the title, a breadcrumb is displayed that shows the path of the topic and you can click any of the topics in the breadcrumb to open that particular page.

If you enter multiple search terms (other than stop words), for any result that the search engine found at least one term but not one or more of the other terms, the Missing terms will be listed below each result.

5-Star Rating Mechanism and Sorting

The Search feature is also enhanced with a rating mechanism that computes scores for every result that matches the search criteria. These scores are then translated into a 5-star rating scheme and the stars are displayed to the right of each result. The search results are sorted depending on the following:

- Search entries that satisfy the phrase search criterion are presented first.
- The number of keywords found in a single page (the higher the number, the better).
- The context (for example, a word found in a title, scores better than a word found in unformatted text). The search ranking order, sorted by relevance is as follows:
  - The search term is included in a meta keyword.
  - The search term is in the title of the page.
  - The search term is in bold text in a paragraph.
  - The search term is in normal text in a paragraph.

Tag Element Scoring Values

HTML tag elements are also assigned a scoring value and these values are evaluated for the search results. For information about editing these values, see How to Change Element Scoring in Search Results (on page 1967).

Search Rules

Rules that are applied during a search include:

- You can use quotes to perform an exact search for multiple word phrases (for example, "grow flowers" will only return results if both words are found consecutively and exactly as they are typed in the search field). This type of search is known as a phrase search.
- Boolean Search is supported using the following operators: and, or, not. When there are two adjacent search terms without an operator, or is used as the default search operator (for example, grow flowers is the same as grow or flowers).
• The space character separates keywords (an expression such as *grow flowers* counts as two separate keywords: *grow* and *flowers*).

• **indexterm** and **keywords** DITA elements are an effective way to increase the ranking of a page (for example, content inside a *keywords* element weighs more than an *H1* HTML element).

• Words composed by merging two or more words with colon (":"), minus ("-"), underline ("_"), or dot ("." ) characters count as a single word.

• Your search terms should contain two or more characters (note that stop words will be ignored). This rule does not apply to CJK (Chinese, Japanese, Korean) languages.

• When searching for multi-word phrases in CJK (Chinese, Japanese, Korean) languages that often have multiple words appear in strings without a space separator, you need to add a space to separate the words. Otherwise WebHelp will not find results. For example, Chinese uses a specialized character for space separators, but the current WebHelp implementation cannot detect such specialized characters, so to search for ### (it translates as "before you begin" or "before start"), you have to enter ## ## (notice the space between the second and third symbols) in the search field.

### Excluded Terms

To improve performance, the **Search** feature excludes certain *stop words*. For example, the English version of the *stop words* includes: *a, an, and, are, as, at, be, but, by, for, if, in, into, is, it, no, not, of, on, or, such, that, the, their, then, there, these, they, this, to, was, will, with.*

#### Related Information:

- [WebHelp Responsive HTML5 Pages: Search Page](on page 1865)

### Feedback System

The **WebHelp Responsive with Feedback** variant contains a **Comments** section at the bottom of each topic. This section is where you can interact with users through a comment system. For information about deploying a feedback-enabled system, see [Deploying a Feedback-Enabled System](on page 1873).

Figure 623. WebHelp Responsive with Feedback Comments Section
To add a new comment, click the Add New Comment button, or click Reply to add a comment to an existing thread. You can click on the Log in button on the right side of this bar to be authenticated as a user and your user name will be included in any comments that you add. If you do not have a user name, you can click on the Sign Up button to create a new user.

After you log in, your name and user name are displayed in the Comments bar, along with the Log off and Edit buttons. Click the Edit button to open the User Profile dialog box where you can customize the following options:

- **Your Name** - You can use this field to edit the initial name that you used to create your user profile.
- **Your email address** - You can use this field to edit the initial email address that you used to create your profile.
- **You can choose to receive an email in the following situations:**
  - When a comment is left on a page that you commented on.
  - When a comment is left on any topic in the WebHelp Classic system.
  - When a reply is left to one of my comments.
- **New Password** - Allows you to enter a new password for your user account.

**Note:** The Current Password field from the top of the User Profile is mandatory if you want to save the changes you make.

If you are an administrator, you can manage user information and comments. For more information, see Managing Users and Comments in a Feedback-Enabled System *(on page 1877)*.

**Related Information:**

- Deploying a Feedback-Enabled System *(on page 1873)*
Deploying a Feedback-Enabled System

System Requirements

The feedback-enabled WebHelp system requires a standard server deployment. You can request this from your server administrator and it requires the following system components:

- A Web server (such as Apache Web Server)
- A MySQL or MariaDB database server
- A database admin tool (such as phpMyAdmin)
- PHP Version 5.1.6 or later

The WebHelp system supports most of the recent versions of the following browsers: Chrome, Firefox, Edge, Internet Explorer, Safari, Opera.

Create WebHelp with Feedback Database

The WebHelp with Feedback system needs a database to store user details and the actual feedback, and a user added to it with all privileges. After this is created, you should have the following information:

- Database name
- Username
- Password

Exactly how you create the database and user depends on your web host and your particular needs.

Example:

The following procedure uses phpMyAdmin to create a MySQL database for the feedback system and a MySQL user with privileges for that database. The feedback system uses these credentials to connect to the database.

Using phpMyAdmin to create a database:

1. Access the phpMyAdmin instance running on your server.
2. Click Databases (in the right frame) and then create a database. You can give it any name you want (for example comments).
3. Create a user with connection privileges for this database.
4. Under localhost, in the right frame, click Privileges and then at the bottom of the page click the reload the privileges link.
Deploying the WebHelp with Feedback Output

If you have a web server configured with PHP and MySQL, you can deploy the WebHelp with Feedback output by following these steps:

1. Connect to your server using an FTP client.
2. Locate the home directory (from now on, referred to as DOCUMENT_ROOT) of your server.
3. Copy the transformation output folder into the DOCUMENT_ROOT folder.
4. Rename it to something relevant (for example, myProductWebHelp).
5. Open the output folder (for example, http://[YOUR_SERVER]/myProductWebHelp/). You are redirected to the installation wizard. Proceed with the installation as follows:
   a. Verify that the prerequisites are met.
   b. Press Start Installation.
   c. Configure the Deployment Settings section. Default values are provided, but you should adjust them as needed.

   Tip: You can change some of the options later. The installation creates a config.php file in [OXYGEN_WEBHELP_INSTALL_DIR]/feedback/resources/php/config/config.php where all your configuration options are stored.

   d. Configure the MySql Database Connection Settings section. Use the information (database name, username, password) from the Create WebHelp with Feedback Database section (on page 1874) to fill-in the appropriate text boxes.

   Warning: Selecting the Create new database structure option will overwrite any existing data in the selected database, if it already exists. Therefore, it is useful the first time you install the WebHelp with Feedback system, but you do not want to select this option on subsequent deployments.

   e. If you are using a domain (such as OpenLDAP or Active Directory) to manage users in your organization, select the Enable LDAP Authentication option. This will allow you to configure the LDAP server, which will provide information and credentials for users who will access the WebHelp system. Also, this will allow you to choose which of the domain users will have administrator privileges.

   f. If the Create new database structure option is selected, the Create WebHelp Administrator Account section becomes available. Here you can set the administrator account data. The administrator is able to moderate new posts and manage WebHelp users.

   The same database can be used to store comments for multiple WebHelp with Feedback deployments. If a topic is available in multiple deployments and there are comments associated with it, you can choose to display the comments in all deployments that share the database. To do this, select the Display comments from other products option. In the Display
comments from section, a list with the deployments sharing the same database is displayed. Select the deployments allowed to share common feedback.

Note: You can restrict the displayed comments of a product depending on its version. If you have two products that use the same database and you restrict one of them to display comments starting from a certain version, the comments of the other product are also displayed from the specified version onwards.

- Press **Next Step**.
- Remove the installation folder from your web server.

**Important:** When you publish subsequent iterations of your WebHelp with Feedback system, you will not upload the /install folder in the output, as you only need it uploaded the first time you create the installation. On subsequent uploads, you will just upload the other output files.

- In your Web browser, go to your WebHelp with Feedback system main page.

### Testing Your WebHelp with Feedback System

To test your system, create a user and post a comment. Check to see if the notification emails are delivered to your email inbox.

Note: To read debug messages generated by the system:

1. Enable JavaScript logging by doing one of the following:
   - Open the `log.js` file, locate the `var log= new Log(Level.NONE);` line, and change the logging level to: `Level.INFO`, `Level.DEBUG`, `Level.WARN`, or `Level.ERROR`.
   - Append `?log=true` to the WebHelp URL.
2. Inspect the PHP and Apache server log files.

### Documentation Product ID and Version

When you run a WebHelp with Feedback transformation scenario, by default you are prompted for a documentation product ID and version number. This is needed when multiple WebHelp systems are deployed on the same server. Think of your WebHelp output as a product. If you have three different WebHelp outputs, you have three different products (each with their own unique documentation product ID). This identifier is included in a configuration file so that comments are tied to a particular output (product ID and version number).

Note: The WebHelp with Feedback installation includes a configuration option (Display comments from other products) that allows you to choose to have comments visible in other specified products.
Related Information:

- Managing Users and Comments in a Feedback-Enabled System (on page 1877)

Refreshing the Content of a Feedback-Enabled System

It is common to update the content of an existing installation of a **WebHelp with Feedback** system on a regular basis. In this case, reinstalling the whole system is not a viable option since it might result in the loss of the comments associated with your topics. Also, reconfiguring the system every time you want to refresh it may be time consuming.

Fortunately, you can refresh just the content without losing the comments or the initial system configuration. To do so, follow these steps:

1. Execute the transformation scenario that produces the **WebHelp with Feedback** output directory.
2. Go to the output directory (specified in the **Output** tab of the transformation scenario), locate the `\feedback\resources\php\config\config.php` file, and delete it.
3. Locate the `\feedback\install` directory and delete it.
4. Copy the remaining structure of the output folder and paste it into your **WebHelp with Feedback** system installation directory, overwriting the existing content.

Managing Users and Comments in a Feedback-Enabled System

When you installed the **WebHelp with Feedback** system the first time (assuming the **Create new database structure** option (on page 1875) was selected), you should have been prompted to create an administrator account (or a user named **administrator** was created by default). As an administrator, you have access to manage comments posted in your feedback-enabled WebHelp system. You can also manage the user information (such as role, status, or notification options).

To manage comments and user information, follow these steps:

1. At the bottom of each specific topic there is a **Comments** navigation bar and on the right side there is a **Log in** button. Click this button and log in with your administrator credentials. This gives you access to an **Admin Panel** button.
2. Click the **Admin Panel** button to display an administration page.

Figure 624. Administrative Page
3. Use this page to manage the following options:

**Delete Orphaned Comments**
Allows you to delete comments that are no longer associated with a topic in your WebHelp system.

**Delete Pending Users**
Allows you to delete user accounts that you do not wish to activate.

**View All Posts**
Allows you to view all the comments that are associated with topics in your WebHelp system.

**Export Comments**
Allows you to export all posts associated with topics in your WebHelp system into an XML file.

**Set Version**
Use this action to display comments starting with a particular version.

**Manage User Information**
To edit the details for a user, click on the corresponding row. This opens a window that allows you to customize the following information associated with the user:

**Name**
The full name of the user.

**Level**
Use this field to modify the privilege level (role) for the selected user. You can choose from the following:

- **User** - Regular user, able to post comments and receive e-mail notifications.
- **Moderator** - In addition to the regular User rights, this type of user has access to the **Admin Panel** where a moderator can view,
delete, export comments, and set the version of the feedback-enabled WebHelp system.

- **Admin** - Full administrative privileges. Can manage WebHelp-specific settings, users, and their comments.

**Company**

The name of the organization associated with the user.

**E-Mail**

The contact email address for the user. This is also the address where the WebHelp system sends notifications.

**WebHelp Notification**

When selected, the user receives notifications when comments are posted anywhere in your feedback-enabled WebHelp system.

**Reply Notification**

When selected, the user receives notifications when comments are posted as a reply to one of their comments.

**Page Notification**

When selected, the user receives notifications when comments are posted on a topic where they previously posted a comment.

**Date**

The date the user registered is displayed.

**Status**

Use this drop-down list to change the status of the user. You can choose from the following:

- **Created** - The user is created but does not yet have any rights for the feedback-enabled WebHelp system.
- **Validated** - The user is able to use the feedback-enabled WebHelp system.
- **Suspended** - The user has no rights for the feedback-enabled WebHelp system.

**Warning:** The key used for identifying the page a comment is attached to is the relative file path to the output page. Since the output file and folder names mirror the source, any change to the file name (or its folder) in the source will affect the comments associated with that WebHelp page. If you change the file name or path, the comment history for that topic will become orphaned (a change to the topic ID does not affect the comment history).
Context-Sensitive WebHelp Responsive System

Context-sensitive help systems assist users by providing specific informational topics for certain components of a user interface, such as a button or window. This mechanism works based on mappings between a unique ID defined in the topic and a corresponding HTML page.

Generating Context-Sensitive Help

When WebHelp Responsive output is generated, the transformation process produces an XML mapping file called `context-help-map.xml` and copies it in the output folder of the transformation. This XML file maps an ID to a corresponding HTML page through an `<appContext>` element, as in the following example:

```xml
<map productID="oxy-webhelp" productVersion="1.1">
  <appContext helpID="myapp-functionid1" path="tasks/app-help1.html"/>
  <appContext helpID="myapp-functionid2" path="tasks/app-help1.html"/>
  ...
</map>
```

The possible attributes are as follows:

**helpID**

A Unique ID provided by a topic from two possible sources (`resourceid` element or `id` attribute):

**resourceid**

The `resourceid` element is mapped into the `appContext` element and can be specified in either the `topicref` within a DITA map or in a `prolog` within a DITA topic. The `resourceid` element accepts the following attributes:

- **appname** - A name for the external application that references the topic. If this attribute is not specified, its value is considered to be empty ("").
- **appid** - An ID used by an application to identify the topic.
- **id** - Specifies a value that is used by a specific application to identify the topic, but this attribute is ignored if an `appid` attribute is used.

**Note:** Multiple `appid` values can be associated with a single `appname` value (and multiple `appname` values can be associated with a single `appid` value), but the values for both attributes work in combination to specify a specific ID for a specific application, and therefore each
combination of values for the `appid` and `appname` attributes should be unique within the context of a single root map (on page 3287). For example, suppose that you need two different functions of an application to both open the same WebHelp page.

**Example: `resourceid` Specified in a DITA Map**

The `resourceid` element can be specified in a `topicmeta` element within a `topicref`.

```xml
<map title="App Help">
  <topicref href="app-help1.dita" type="task">
    <topicmeta>
      <resourceid appname="myapp" appid="functionid1"/>
      <resourceid appname="myapp" appid="functionid2"/>
    </topicmeta>
  </topicref>
</map>
```

**Example: `resourceid` Specified in a DITA Topic**

The `resourceid` element can be specified in a `prolog` element within a DITA topic.

```xml
<task id="app-help1">
  <title>My App Help</title>
  <prolog>
    <resourceid appname="myapp" appid="functionid1"/>
    <resourceid appname="myapp" appid="functionid2"/>
  </prolog>
  ...
</task>
```

For more information about the `resourceid` element, see DITA Specifications: `<resourceid>`.

**id**

If a `resourceid` element is not declared in the DITA map or DITA topic (as described above), the `id` attribute that is set on the topic root element is mapped into the `appContext` element.

⚠️ **Important:** You should ensure that these defined IDs are unique in the context of the entire DITA project. If the IDs are not unique,
the transformation scenario will display warning messages in the transformation console output and the help system will not work properly.

**path**

The path to a corresponding WebHelp page. This path is relative to the location of the context-help-map.xml mapping file.

**productID** *(Applicable only if you are using the WebHelp Responsive with Feedback transformation scenario)*

The ID of the product for your documentation project.

**productVersion** *(Applicable only if you are using the WebHelp Responsive with Feedback transformation scenario)*

The version of the product for your documentation project.

There are two ways of implementing context-sensitive help in your system:

- The XML mapping file can be loaded by a PHP script on the server side. The script receives the contextId value and will look it up in the XML file.
- Invoke the index.html WebHelp system file and pass the contextId parameter with a specific value. The WebHelp system will automatically open the help page associated with the value of the contextId parameter.

```html
index.html?contextId=myDITATopic
```

**Note:** The contextId parameter is not case-sensitive.

**Context-Sensitive Queries**

You can use the URL field in your browser to search for topics in a context-sensitive WebHelp system with the assistance of the following parameters:

**contextId**

The WebHelp JavaScript engine will look for this value in the context-help-map.xml mapping file and load the corresponding help page.

**Note:** You can use an anchor *(on page 3279)* in the contextId parameter to jump to a specific section in a document. For example, contextId=topicID#anchor.

**appname**

You can use this parameter in conjunction with contextId to search for this value in the corresponding appname attribute value in the mapping file.
Another parameter indicates the search query:

**searchQuery**

You can use this parameter to perform a search operation when WebHelp is loaded. For example, if you want to open WebHelp showing all search results for *growing flowers*, the URL should look like this: http://localhost/webhelp/index.html?searchQuery=growing%20flowers.

**Accessibility**

**Oxygen XML WebHelp Responsive** output is compliant with the [Section 508 accessibility standard](https://www.section508.gov/), making the output accessible for people with visual impairment and other disabilities. Documentation and interface components are considered accessible when they have support in place that allows those with disabilities to use assistive technologies to understand the content.

Generally speaking, the WebHelp Responsive output has two major parts: topic content and WebHelp Responsive-related components (publication TOC, breadcrumb, menu). While the WebHelp Responsive components are designed to comply with the accessibility rules, it is important to adhere to some rules when you write DITA topics so that the content is also accessible.

**Related Information:**

- DITA-OT Day 2017 Presentation: Accessibility in DITA-OT

**Writing Guidelines for Accessible Documentation**

To create accessible content, good authoring practices involve following guidelines, such as marking table headers, using semantic elements where available, and using alternative text for images.

**Accessible Images**

Images must have text alternatives that describe the information or function represented by them.

**Short Text Equivalents for Images**

When using the `<image>` element, specify a short alternative text with the `<alt>` element.

```html
<image href="puffin.jpg">
  <alt>Puffin figure</alt>
</image>
```
Long Descriptions of Images

For complex images, when a short text equivalent does not suffice to adequately convey the function or role of an image, provide additional information in a file designated by the `<longdesc>` element.

```xml
<image href="puffin.jpg">
  <alt>Puffin figure</alt>
  <longdesc href="http://www.example.org/birds/puffin.html" scope="external" format="html"/>
</image>
```

Related Information:

- Darwin Information Typing Architecture (DITA) Specification `<image>` element
- Web Accessibility Tutorials: Alt Decision Tree

Accessible Image Maps

For image maps, text alternatives are needed on both the `<image>` element itself (to describe the informative context) and on each of the `<area>` elements (to convey the link destination or the action that will be initiated if the link is followed). The `<xref>` content within the `<area>` element contains the intended alternative text or hover text for that image map area.

```xml
<imagemap id="gear_pump_map">
  <image href="../images/Gear_pump_exploded.png" id="gear_pump_exploded">
    <alt>Gear Pump</alt>
  </image>
  <area>
    <shape>circle</shape>
    <coords>172, 265, 14</coords>
    <xref href="parts/bushings.dita#bushings_topic/bushings" format="dita">Bushings</xref>
  </area>
  <area>
    <shape>circle</shape>
    <coords>324, 210, 14</coords>
  </area>
</imagemap>
```
Accessible Tables

Accessible HTML tables need markup that indicates header cells and data cells and defines their relationship. Header cells must be marked with `<th>`, and data cells with `<td>`, to make tables accessible. For more complex tables, explicit associations may be needed using @scope, @id, and @headers attributes.

When you implement the table, it is best to use the `<table>` element (CALS table or OASIS Table Exchange Model). The `<table>` element includes all that you need to make a fully accessible table.

Table with Header Cells in the Top Row Only

For this type of table, you have to embed the table rows in the `<thead>` element.

**Table 67. Example: Oxygen Events**

<table>
<thead>
<tr>
<th>Event</th>
<th>Date</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Evolution of TC 2018</td>
<td>May 31 - June 1, 2018</td>
<td>Sofia, Bulgaria</td>
</tr>
<tr>
<td>Markup UK</td>
<td>June 9 - 10, 2018</td>
<td>London, United Kingdom</td>
</tr>
<tr>
<td>Balisage 2018 - The Markup Conference</td>
<td>July 31 - August 3, 2018</td>
<td>Rockville, Maryland, USA</td>
</tr>
</tbody>
</table>

```xml
<xmlname href="parts/ports.dita#ports_topic/suction_port" format="dita">  
>Suction Port</xmlname>
</area>
</imagemap>

Related Information:

- Darwin Information Typing Architecture (DITA) Specification `<imagemap>` element

Accessible Tables

Accessible HTML tables need markup that indicates header cells and data cells and defines their relationship. Header cells must be marked with `<th>`, and data cells with `<td>`, to make tables accessible. For more complex tables, explicit associations may be needed using @scope, @id, and @headers attributes.

When you implement the table, it is best to use the `<table>` element (CALS table or OASIS Table Exchange Model). The `<table>` element includes all that you need to make a fully accessible table.

Table with Header Cells in the Top Row Only

For this type of table, you have to embed the table rows in the `<thead>` element.

**Table 67. Example: Oxygen Events**

<table>
<thead>
<tr>
<th>Event</th>
<th>Date</th>
<th>Location</th>

WebHelp Responsive 508 VPAT

WebHelp Responsive was designed to adhere to the U.S. Government Section 508 accessibility standards. This document describes the accessibility features that address the Section 508 Standards. This VPAT (Voluntary Product Accessibility Template) is an informational tool developed by industry and government to help facilitate the understanding of compatibility issues under Section 508.

Table 70. 1194.22 Web-based intranet and internet information and applications.

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Supporting Features</th>

</tr>
</tbody>
</table>

**Note:** This VPAT pertains only to the HTML output generated by the WebHelp Responsive plugin as shipped and not to any customization. It specifically applies to version 20.1 or above and it does not apply to any versions prior to this.
Supported Platforms

All accessibility tests have been carried out in the following environment:

- NVDA (Non Visual Desktop Access) version 2018.1.1 with Firefox version 60.0.1 and Chrome version 66.0.3359.181.
- Windows 10 Narrator with Microsoft Edge browser.

However, this does not mean that WebHelp Responsive-generated output has any issue with other modern, standards-compliant browsers and alternative screen reader solutions. In any case, if you encounter any accessibility-related issue while using WebHelp Responsive generated output, contact the Oxygen support team. All accessibility issues are treated with utmost attention.

Publishing Templates

An Oxygen Publishing Template defines all aspects of the layout and styles for output obtained from the following transformation scenarios:

- WebHelp Responsive
- WebHelp Responsive with Feedback
- DITA Map PDF - based on HTML5 & CSS

It is a self-contained customization package stored as a ZIP archive or folder that can easily be shared with others. It provides the primary method for customizing the output.

Some possible customization methods include:

- Add additional template resources to customize the output (such as logos, Favicons, or CSS files).
- Extend the default processing by specifying one or more XSLT extension points.
- Specify one or more transformation parameters to customize the output.
- Customize various aspects of the output through simple CSS styling.
- For WebHelp Responsive output, change the layout of the main page or topic pages by customizing which components will be displayed and where they will be positioned in the page.

The following graphics are possible sample structure for Oxygen Publishing Template packages:
For information about creating and customizing publishing templates, and how to adjust the WebHelp and PDF output through CSS styling and other customization methods, watch our Webinar: Creating Custom Publishing Templates for WebHelp and PDF Output. The Webinar slides and sample project are also available from that webpage.

- How to Create a Publishing Template (on page 1935)
- How to Edit a Packed Publishing Template (on page 1937)
- How to Add a Publishing Template to the Publishing Templates Gallery (on page 1938)
- How to Share a Publishing Template (on page 2033)
Publishing Templates Gallery

Oxygen XML Editor comes bundled with a variety of built-in templates. You can use one of them to publish your documentation or as a starting point for a new publishing template.

**Built-in Templates**

There are two categories of templates, *Tiles* and *Tree*. You can see the built-in templates in the **Templates** tab when editing a WebHelp Responsive transformation scenario in **Oxygen XML Editor/Author**. Each one also includes an **Online preview** icon in the bottom-right corner that opens a webpage in your default browser that provides a sample of how the main page will look when that particular template is used to generate the output.

**Tiles Templates**

The main page in the WebHelp output presents a tile for each main topic (chapter) of the documentation.

![Tiles Templates](image)

**Tree Templates**

The main page in the WebHelp output presents a tree-like table of contents.
Built-in Templates Location

All built-in templates are stored in the following directory: DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/templates.

Custom Templates

You can use a built-in template as a starting point for creating your own custom template (on page 2029). You can store all of your custom templates in a particular directory. Then, go to Options > Preferences > DITA > Publishing and add your directory to the list, and all the templates stored in that directory will be displayed in the preview pane in the transformation scenario’s Template tab along with all the built-in templates.

Sharing Publishing Template

To share a publishing template with others, following these steps:

1. Copy your template in a new folder.
2. Go to Options > Preferences > DITA > Publishing and add that new folder to the list.
3. Switch the option as the bottom of that preferences page to Project Options.
4. Share your project file (.xpr).

Publishing Template Package Contents for WebHelp Responsive Customizations

An Oxygen Publishing Template package for WebHelp output must contain a template descriptor file and at least one CSS file, and may contain other resources (such as graphics, XHTML files, XSLT files, etc.). All the template resources can be stored in either a ZIP archive or in a folder. It is recommended to use a ZIP archive because it is easier to share with others.
Template Descriptor File

Each publishing template includes a descriptor file that defines the meta-data associated with template. It is an XML file with certain elements that defines all the resources included in a template (such as CSS files, images, JS files, and transformation parameters).

The template descriptor file must have the .opt file extension and must be located in the template's root folder.

A template descriptor might look like this:

```xml
<publishing-template>
   <name>Flowers</name>

   <webhelp>
      <tags>
         <tag>tree</tag>
         <tag>light</tag>
      </tags>
      <preview-image file="flowers-tree.png"/>

      <!-- Resources (CSS, favicon, logo and others) -->
      <resources>
         <!-- Main CSS file -->
         <css file="flowers.css"/>

         <!-- Resources to copy to the output folder -->
         <fileset>
            <include name="resources/**/*"/>
            <exclude name="resources/**/.svn"/>
            <exclude name="resources/**/.git"/>
         </fileset>
      </resources>

      <!-- Parameters -->
      <parameters>
         <parameter name="webhelp.show.main.page.tiles" value="no"/>
         <parameter name="webhelp.show.main.page.toc" value="yes"/>
         <parameter name="webhelp.top.menu.depth" value="3"/>
      </parameters>
   </webhelp>
</publishing-template>
```
Tip: It is recommended to edit the template descriptor in Oxygen XML Editor/Author because it provides content completion and validation support.

Template Name and Description

Each template descriptor file requires a name element. This information is displayed as the name of the template in the transformation scenario dialog box.

Optionally, you can include a description and it displayed when the user hovers over the template in the transformation scenario dialog box.

```xml
<publishing-template>
  <name>Lorem Ipsum</name>
  <description>Lorem ipsum dolor sit amet, consectetur adipiscing elit</description>
  ...
</publishing-template>
```

Template Author

Optionally, you can include author information in the descriptor file and it displayed when the user hovers over the template in the transformation scenario dialog box. This information might be useful if users run into an issue or have questions about a certain template.

If you include the author element, a name is required and optionally you can include email, organization, and organizationUrl information.

```xml
<publishing-template>
  ...
  <author>
    <name>John Doe</name>
    <email>jdoe@example.com</email>
    <organization>ACME</organization>
    <organizationUrl>http://www.example.com/jdoe</organizationUrl>
  </author>
</publishing-template>
```

Webhelp Element

The webhelp element contains various details that define the WebHelp Responsive output. It is a required element if you intend on using a WebHelp Responsive transformation scenario. The elements that are allowed in this webhelp section specify the template tags (on page 1898), template preview image (on page 1898), resources (on page 1899) (such as CSS, JS, fonts, logos), transformation
parameters (on page 1901), HTML fragment extensions (on page 1902) (used to add fragments to placeholders), XSLT extensions (on page 1902), or HTML page layout files (on page 1909).

Template Tags

The tags section provides meta information about the template (such as layout type or color theme). Each tag is displayed at the top of the Templates tab window in the transformation scenario dialog box and they help the user filter and find particular templates.

Template Preview Image

The preview-image element is used to specify an image that will be displayed in the transformation scenario dialog box. It provides a visual representation of the template to help the user select the right
template. The image dimensions should be 200 x 115 pixels and the supported image formats are: JPEG, PNG, or GIF.

You can also include an online-preview-url element to specify the URL of a published sample of your template. This will display an Online preview icon in the bottom-right corner the image in the transformation scenario dialog box and if the user clicks that icon, it will open the specified URL in their default browser.

```xml
<publishing-template>
  ...
  <webhelp>
    ...
    <preview-image file="ashes/ashes-tree.png"/>
    <online-preview-url>https://www.example.com/samples/tiles/ashes</online-preview-url>
  </webhelp>
</publishing-template>
```

Template Resources

The resources section of the descriptor file specifies a set of resources (CSS, JS, fonts, logos, graphics, etc.) that are used to customize various components in generated output. These resources will be copied to the output folder during the transformation process. At least one CSS file must be included, while the other types of resources are optional.

This section is defined using the resources element and the types of resources that can be specified include:

- **CSS files** - One or more CSS files that will define the styles of all generated HTML pages. They are referenced using the css element.
- **Favicon** - You can specify the path to an image for the favicon associated with your website. It is referenced using the favicon element.
- **Logo** - You can specify the path to a logo image that will be displayed in the left side of the output header. It is referenced using the logo element. Optionally, you can also specify:
  - **target-url** - will redirect the user to the specified URL if they click the logo in the output.
  - **alt** - provides an alternate text for the logo image.
- **JavaScript AMD module** - The path to a JavaScript module that uses the AMD (Asynchronous Module Definition) format. This module will be loaded in the output HTML pages using the RequireJS library. It can be referenced using the js-amd-module element. For more information, see How to Insert JavaScript AMD Modules in WebHelp Responsive Output (on page 1949).
- **Additional Resources (graphics, JS, fonts)** - For other resources (such as images referenced in CSS, JS, fonts, etc.) that need to be included in the output, you need to instruct the transformation to include them in the output folder. You can specify one or more sets of additional resources to
be copied to the output folder by using the `fileset` element and you can use one or more `include` and `exclude` elements. This semantic is similar to the ANT FileSet.

```xml
<publishing-template>
  ...
  <webhelp>
    ...
    <resources>
      <css file="css/custom_styles.css"/>
      <css file="css/custom_fonts.css"/>

      <favicon file="images/favicon.png"/>

      <logo
        file="images/logo.png"
        target-url="http://www.example.com"
        alt="Alternate text for the logo image"/>

      <js-amd-module file="js/template-main.js"/>

      <fileset>
        <include name="common/**/**"/>
        <include name="JS/**/**"/>
        <exclude name="**/*.svn"/>
        <exclude name="**/*.git"/>
      </fileset>
    </resources>
  </webhelp>
</publishing-template>
```

**Note:** All relative paths specified in the descriptor file are relative to the template root folder.

The resources specified in the template descriptor are copied to the following output folder: `[WebHelp_OUTPUT_DIR]/oxygen-webhelp/template`. The following graphic illustrates the mapping between the template resources and the location where they will be copied to the output folder:

Figure 627. Template Resources Mapping
Transformation Parameters

You can also set one or more WebHelp transformation parameters in the descriptor file.

```xml
<publishing-template>
  ...
  <webhelp>
    ...
    <parameters>
      <parameter name="webhelp.show.main.page.toc" value="yes"/>
      <parameter name="webhelp.top.menu.depth" value="3"/>
      <parameter name="webhelp.fragment.welcome" value="html-fragment/webhelp.fragment.welcome.html" type="filePath"/>
    </parameters>
  </webhelp>
</publishing-template>
```

The following information can be specified in the `parameter` element:

**Parameter name**

The name of the parameter. It may be one of the WebHelp Responsive transformation parameters *(on page 2003)* or a DITA-OT HTML-based output parameter.

**Note:** It is not recommended to specify an input/output parameter in the descriptor file (such as the input Map, DITAVAL file, or temporary directory).
⚠️ **Attention:** JVM arguments like `-Xmx` cannot be specified as a transformation parameter.

### Parameter Value

The value of the parameter. It should be a relative path to the template root folder for file paths parameters.

### Parameter Type

The type of the parameter: `string` or `filepath`. The `string` value is default.

After creating a publishing template (on page 2029) and adding it to the templates gallery (on page 1938), when you select the template in the transformation scenario dialog box, the **Parameters** tab will automatically be updated to include the parameters defined in the descriptor file. These parameters are displayed in italics.

### XSLT Extension Points

The publishing templates support one or more XSLT extension points. They are helpful when you want to change the structure of the HTML pages that are primarily generated from XSLT processing. They can be specified in the descriptor file using the following structure:

```xml
<publishing-template>
 ...
 <webhelp>
  ...
 <xslt>
   <extension
     id="com.oxygenxml.webhelp.xsl.dita2webhelp"
     file="xsl/customDita2webhelp.xsl"/>

   <extension
     id="com.oxygenxml.webhelp.xsl.createMainPage"
     file="xsl/customMainPage.xsl"/>

 </xslt>
</publishing-template>
```

For more information, and a full list of the available extension points, see: XSLT-Import and XSLT-Parameter Extension Points (on page 2010).

**Note:** You can read the value of a WebHelp transformation parameter from your XSLT extension stylesheets by using the `getParameter(param.name)` function from the `http://www.oxygenxml.com/functions` namespace.
HTML Fragment Extension Points

The HTML pages contain component placeholders that can be used to insert custom HTML fragments (either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment).

You can specify one or more HTML fragment extension points in the descriptor file using the following structure:

```xml
<publishing-template>
  ...
  <webhelp>
    ...
    <html-fragments>
      <fragment>
        file="html-fragments/webhelp_fragment_welcome.html"
        placeholder="webhelp.fragment.welcome"/>
      </fragment>
      <fragment>
        file="html-fragments/webhelp_fragment_footer.html"
        placeholder="webhelp.fragment.footer"/>
      </fragment>
    </html-fragments>
  </webhelp>
  ...
</publishing-template>
```

Some of these placeholders are left empty in the default output configurations, but you can use them to insert custom content.

Each placeholder has an associated parameter value in the transformation. These predefined placeholders are illustrated and described below.

Figure 628. Predefined Placeholders Diagram
Each of these placeholders can hold either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment:

1- webhelp.fragment.head

   In the generated output it inserts a given XHTML fragment in the `<head>` element. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

2- webhelp.fragment.before.body

   In the generated output it displays a given XHTML fragment before the page body. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.
3- `webhelp.fragment.before.logo_and_title`

In the generated output it displays a given XHTML fragment before the logo and title. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

4- `webhelp.fragment.after.logo_and_title`

In the generated output it displays a given XHTML fragment after the logo and title. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

5- `webhelp.fragment.before.top_menu`

In the generated output it displays a given XHTML fragment before the top menu. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

6- `webhelp.fragment.after.top_menu`

In the generated output it displays a given XHTML fragment after the top menu. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

7- `webhelp.fragment.before.main.page.search`

In the generated output it displays a given XHTML fragment before the search field. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

8- `webhelp.fragment.welcome`

In the generated output it displays a given XHTML fragment as a welcome message (or title). The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

9- `webhelp.fragment.after.main.page.search`

In the generated output it displays a given XHTML fragment after the search field. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

10- `webhelp.fragment.before.toc_or_tiles`

In the generated output it displays a given XHTML fragment before the table of contents or tiles in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

11- `webhelp.fragment.after.toc_or_tiles`
In the generated output it displays a given XHTML fragment after the table of contents or tiles in the main page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

### 12- webhelp.fragment.footer

In the generated output it displays a given XHTML fragment as the page footer. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

### 13- webhelp.fragment.after.body

In the generated output it displays a given XHTML fragment after the page body. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

#### Related Information:

- [How to Insert HTML Content in WebHelp Responsive Output](on page 1944)

### WebHelp Responsive Macros

You can use the `whc:macro` layout component to specify a macro value (a variable that will be expanded when the output files are generated).

A macro has the following syntax:

```
${macro-name}
```

or

```
${macro-name(macro-parameter)}
```

A macro name can accept any alphanumeric characters, as well as the following characters: `-` (minus), `_` (underscore), `.` (dot), `:` (colon). The value of a parameter may contain any character except the `}` (close curly bracket) character.

### Implementations

The following macros are supported:

#### i18n

For localizing a string.

```
${i18n(string.id)}
```
param

Returns the value of a transformation parameter.

${param(webhelp.show.main.page.tiles)}

env

Returns the value of an environment variable.

${env(JAVA_HOME)}

system-property

Returns the value of a system property.

${system-property(os.name)}

timestamp

Can be used to format the current date and time. Accepts a string (as a parameter) that determines how the date and time will be formatted (format string or picture string as it is known in the XSLT specification). The format string must comply with the rules of the XSLT format-dateTime function specification.

${timestamp([h1]:[m01] [P] [M01]/[D01]/[Y0001])}

path

Returns the path associated with the specified path ID. The following paths IDs are supported:

- oxygen-webhelp-output-dir - The path to the output directory. The path is relative to the current HTML file.
- oxygen-webhelp-assets-dir - The path to the oxygen-webhelp subdirectory from the output directory. The path is relative to the current HTML file.
- oxygen-webhelp-template-dir - The path to the template directory. The path is relative to the current HTML file.

${path(oxygen-webhelp-template-dir)}

Note: New paths IDs can be added by overriding the wh-macro-custom-path template from com.oxygenxml.webhelp.responsive\xsl\template\macroExpander.xsl:

<-- Extension template for expanding a custom path macro. -->
<xsl:template name="wh-macro-custom-path"
map-xpath
Can be used to execute an XPath expression over the DITA map file from the temporary directory.

Tip: Available in all template layout HTML pages.

${map-xpath(/map/title)}

topic-xpath
Can be used to execute an XPath expression over the current topic.

Tip: Available only in the topic HTML page template (wt_topic.html).

${topic-xpath(string-join(/shortdesc//text(), ' '))}

oxygen-webhelp-build-number
Returns the current WebHelp distribution ID (build number).

${oxygen-webhelp-build-number}

Extensibility

To add new macros, you can add an XSLT extension to overwrite the wh-macro-extension template from the com.oxygenxml.webhelp.responsive\xsl\template\macroExpander.xsl file.

<!-- Extension template for expanding custom macro constructs -->
<xsl:template name="wh-macro-extension">
    <xsl:param name="name"/>
    <xsl:param name="params"/>
    <xsl:param name="contextNode"/>
    <xsl:param name="matchedString"/>

    <xsl:choose>
        <xsl:when test="$contextNode instance of attribute()">
            <xsl:value-of select="$matchedString"/>
        </xsl:when>
        <xsl:otherwise>
            <xsl:message>Cannot expand macro: 
            </xsl:message>
        </xsl:otherwise>
    </xsl:choose>
</xsl:template>
The **`wh-macro-extension`** template has the following parameters:

- **name** - The name of the current *macro*.
- **params** - List of parameters of the current *macro* as string sequence. The current *macros* parsing mechanism only allows *macros* with a maximum of one parameter. Consequently, this list will contain at most one element.
- **contextNode** - The current element or attribute where the *macro* was declared.
- **matchedString** - The entire value of the matched *macro* as specified in the HTML template page.

**HTML Page Layout Files**

The HTML page layout files define the default layout of the generated pages in the output for the built-in template. There are four types of pages (*main*, *search*, *topic*, *index*) and each type of page is a simple HTML file. Each page type has various components that appear by default and each component has a corresponding element and when that element is included in the HTML file, the corresponding components will appear in the output.

⚠️ **Warning:** It is no longer recommended for you to customize these files because if you upgrade to a newer version of *Oxygen*, those files may no longer produce the desired results and if new components have been added, you won't have access to them.

If you do choose to customize these HTML files, each type of page is defined inside an **`html-page-layout-files`** element in the descriptor file.

```xml
<publishing-template>
  ...
  <webhelp>
    ...
  </webhelp>

  <!-- HTML page layout files -->
  <html-page-layout-files>
    <page-layout-file page="main" file="page-templates/wt_index.html"/>
    <page-layout-file page="search" file="page-templates/wt_search.html"/>
    <page-layout-file page="topic" file="page-templates/wt_topic.html"/>
    <page-layout-file page="index-terms" file="page-templates/wt_terms.html"/>
  </html-page-layout-files>
</publishing-template>
```
If you do use the `html-page-layout-files` element, you must specify all four types of pages (`main`, `search`, `topic`, `index`). When not specified, the files from the `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/oxygen-webhelp/page-templates` folder will be used to define the layout of each type of page.

**HTML Page Components**

Each type of page contains various components that control the layout of that page. The rendering of each component depends on the context where it is placed and its content depends on the transformed DITA map (on page 3281).

Some of the components can be used in all four types of pages, while some are only available for certain pages. For instance, the `Publication Title` component can be used in all pages, but the `Navigation Breadcrumb` component can only be used in the `Topic Page`.

To include a component in the output of a particular type of page, you have to reference a specific element in that particular HTML file. All the elements associated with a component should belong to the `http://www.oxygenxml.com/webhelp/components` namespace.

Every component can contain custom content or reference another component. To specify where the component content will be located in the output, you can use the `whc:component_content` element as a descendant of the component element. It can specify the location as before, after, or it can wrap the component content. The following snippet contains an example of each:

```xml
<whc:webhelp_search_input class="navbar-form wh_main_page_search" role="form">
  <div class="custom-content-before">Enter search terms here:</div>
  <div class="custom-wrapper">
    <whc:component_content/>
  </div>
  <div class="custom-content-after">Results will be displayed in a new window.</div>
</whc:webhelp_search_input>
```

**Main Page**

The `Main Page` is the home page generated in the WebHelp Responsive output. The name of the HTML file that defines this page is `wt_index.html` and it is located in the following directory: `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/oxygen-webhelp/page-templates`.

The main function of the home page is to display top-level information and provide links that help you easily navigate to any of the top-level topics of the publication. These links can be rendered in either
a Tiles or Tree style of layout. The HTML page produced for the home page also consists of various other components, such as a logo, title, menu, search field, or index link.

Figure 629. Examples of Main Page Components for a Tiles Style of Layout

![Diagram showing examples of main page components for a tiles style layout]

Figure 630. Examples of Main Page Components for a Tree Style of Layout

![Diagram showing examples of main page components for a tree style layout]
The following components can be referenced in the Main Page (wt_index.html) file:

**Publication Title** (*webhelp_publication_title*)

This component generates the publication title in the output. To generate this component, the *webhelp_publication_title* element must be specified in the HTML file as in the following example:

```html
<whc:webhelp_publication_title
```

In the output, you will find an element with the class: *wh_publication_title*.

**Publication Logo** (*webhelp_logo*)
This component generates a logo image in the output. To generate this component, the `webhelp_logo` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_logo
```

In addition, you must also specify the path of the logo image in the `webhelp.logo.image` transformation parameter (in the Parameters tab in the transformation scenario). You can set the `webhelp.logo.image.target.url` parameter to generate a link to a URL when you click the logo image.

In the output, you will find an element with the class: `wh_logo`.

**Search Input (`webhelp_search_input`)**

This component is used to generate the input widget associated with search function in the output. To generate this component, the `webhelp_search_input` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_search_input
```

In the output, you will find an element with the class: `wh_search_input`.

**Print Link (`webhelp_print_link`)**

This component is used to generate a print icon that opens the print dialog box for your particular browser. To generate this component, the `webhelp_print_link` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_print_link
```

In the output, you will find an element with the class: `wh_print_link`.

**Main Menu (`webhelp_top_menu`)**

This component generates a menu with all the documentation topics. To generate this component, the `webhelp_top_menu` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_top_menu
```

In the output, you will find an element with the class: `wh_top_menu`. 
You can control the maximum level of topics that will be included in the menu using the `webhelp.top.menu.depth` transformation parameter (in the Parameters tab of the transformation scenario).

For information about customizing the menu, see How to Customize the Menu (on page 1954).

**Main Page Topic Tiles (`webhelp_tiles`)**

This component generates the tiles section in the main page. This section will contain a tile for each root topic of the published documentation. Each topic tile has three sections that correspond to the topic title, short description, and image. To generate this component, the `webhelp_tiles` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_tiles
```

In the output, you will find an element with the class: `wh_tiles`.

If you want to control the HTML structure that is generated for a WebHelp tile you can also specify the template for a tile by using the `whc:webhelp_tile` component, as in the following example:

```xml
<whc:webhelp_tile class="col-md-4">
  <!-- Place holder for tile's image -->
  <whc:webhelp_tile_image/>
</whc:webhelp_tile>

<whc:webhelp_tile>
  <!-- Place holder for tile's title -->
  <whc:webhelp_tile_title/>
</whc:webhelp_tile>

  <!-- Place holder for tile's shortdesc -->
  <whc:webhelp_tile_shortdesc/>
</whc:webhelp_tile>
```

For information about customizing the tiles, see How to Configure the Tiles on the WebHelp Responsive Main Page (on page 1959).

**Main Page Table of Contents (`webhelp_main_page_toc`)**

This component generates a simplified Table of Contents. It is simplified because it contains only two levels from the documentation hierarchy. To generate this component,
the `webhelp_main_page_toc` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_main_page_toc
```

In the output, you will find an element with the class: `wh_main_page_toc`.

**Index Terms Link (webhelp_indexterms_link)**

This component can be used to generate a link to the index terms page (`indexterms.html`). If the published documentation does not contain any index terms, then the link will not be generated. To generate this component, the `webhelp_indexterms_link` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_indexterms_link
```

In the output, you will find an element with the class: `wh_indexterms_link`. This element will contain a link to the `indexterms.html` page.

**Link to Skins Resources (webhelp_skin_resources)**

This component can be used to add a link to resources for the current WebHelp skin (such as the CSS file). To generate this component, the `webhelp_skin_resources` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_skin_resources/>
```

In the output, you will find a link to the skin resources.

**Topic Page**

The *Topic Page* is the page generated for each DITA topic in the WebHelp Responsive output. The name of the HTML file that defines this page is `wt_topic.html` and it is located in the following directory: `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/oxygen-webhelp/page-templates`.

The HTML pages produced for each topic consist of the topic content along with various other additional components, such as a title, menu, navigation breadcrumb, print icon, or side table of contents.

Figure 631. Examples of Topic Page Components
poly 74, 13, 18, 58, 17, 123, 73, 124, 72, 50, 149, 49, 148, 13 Publication Logo (on page 1917)
poly 211, 13, 144, 82, 80, 82, 80, 103, 206, 103, 205, 82, 171, 82, 211, 50, 286, 48, 284, 12 Publication Title (on page 1917)
poly 232, 73, 232, 110, 184, 157, 144, 157, 144, 188, 654, 186, 654, 158, 210, 156, 256, 109, 331, 108, 331, 72 Search Input (on page 1917)
poly 418, 13, 417, 50, 348, 83, 349, 101, 738, 102, 736, 81, 586, 80, 516, 13 Main Menu (on page 1919)
poly 601, 11, 601, 50, 701, 50, 748, 81, 741, 85, 742, 101, 771, 101, 772, 82, 702, 13 Index Terms Link (on page 1920)

poly 738, 157, 738, 179, 764, 182, 764, 221, 761, 235, 781, 235, 781, 220, 776, 182, 798, 182, 796, 155 Print Link (on page 1918)
poly 382, 249, 409, 234, 704, 235, 704, 220, 16, 220, 16, 238, 324, 237, 381, 288, 480, 287, 479, 249 Breadcrumb (on page 1917)
poly 34, 480, 34, 518, 150, 518, 149, 479, 95, 479, 96, 429, 171, 428, 171, 261, 18, 262, 20, 427, 84, 430, 85, 480 Publication Table of Contents (on page 1918)
poly 362, 480, 362, 516, 459, 515, 459, 480, 415, 479, 415, 443, 679, 442, 676, 244, 476, 290, 372, 290, 322, 245, 185, 246, 185, 442, 368, 444 Topic Content (on page 1918)
The following components can be referenced in the Topic Page (wt_topic.html) file:

**Publication Title (webhelp_publication_title)**

This component generates the publication title in the output. To generate this component, the `webhelp_publication_title` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_publication_title
```

In the output, you will find an element with the class: `wh_publication_title`.

**Publication Logo (webhelp_logo)**

This component generates a logo image in the output. To generate this component, the `webhelp_logo` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_logo
```

In addition, you must also specify the path of the logo image in the `webhelp.logo.image` transformation parameter (in the Parameters tab in the transformation scenario). You can set the `webhelp.logo.image.target.url` parameter to generate a link to a URL when you click the logo image.

In the output, you will find an element with the class: `wh_logo`.

**Search Input (webhelp_search_input)**

This component is used to generate the input widget associated with search function in the output. To generate this component, the `webhelp_search_input` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_search_input
```

In the output, you will find an element with the class: `wh_search_input`.

**Topic Breadcrumb (webhelp_breadcrumb)**

This component generates a breadcrumb that displays the path of the current topic. To generate this component, the `webhelp_breadcrumb` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_breadcrumb
```
In the output, you will find an element with the class: `wh_breadcrumb`. This element will contain a list with items that correspond to the topics in the path. The first item in the list has a link to the main page with the `home` class. The last item in the list corresponds to the current topic and has the `active` class set.

**Navigation Links (webhelp_navigation_links)**

This component generates navigation links to the next and previous topics. To generate this component, the `webhelp_navigation_links` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_navigation_links
```

In the output, you will find an element with the class: `wh_navigation_links`. This element will contain the links to the next and previous topics.

**Print Link (webhelp_print_link)**

This component is used to generate a print icon that opens the print dialog box for your particular browser. To generate this component, the `webhelp_print_link` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_print_link
```

In the output, you will find an element with the class: `wh_print_link`.

**Topic Content (webhelp_topic_content)**

This component generates the content of a topic and it represent the content of the HTML files as they are produced by the DITA-OT processor. To generate this component, the `webhelp_topic_content` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_topic_content
```

In the output, you will find an element with the class: `wh_topic_content`.

**Publication TOC (webhelp_publication_toc)**

This component generates a mini table of contents for the current topic (on the left side). It will contain links to the children of current topic, its siblings, and all of its ancestors. To generate this component, the `webhelp_publication_toc` element must be specified in the HTML file as in the following example:
In the output, you will find an element with the class: `wh_publication_toc`. This element will contain links to the topics that are close to the current topic.

**Topic TOC (webhelp_topic_toc)**

This component generates a topic table of contents for the current topic (on the right side) with a heading named **On this page**. It contains links to each section within the current topic and the section corresponding to the current scroll position is highlighted. The topic must contain at least two `<section>` elements and each `<section>` must have an `@id` attribute. To generate this component, the `webhelp_topic_toc` element must be specified in the HTML file as in the following example:

```
```

In the output, you will find an element with the class: `wh_topic_toc`. This element will contain links to the topics that are close to the current topic.

**Expand/Collapse Sections (webhelp_expandCollapseSections)**

This component is used to generate an icon that expands or collapses sections listed in the side table of contents within a topic. To generate this component, the `webhelp_expandCollapseSections` element must be specified in the HTML file as in the following example:

```
```

In the output, you will find an element with the class: `webhelp_expandCollapseSections`.

**Topic Feedback (webhelp_feedback)**

This component generates a placeholder for where the comments section will be presented. To generate this component, the `webhelp_feedback` element must be specified in the HTML file as in the following example:

```
```

**Main Menu (webhelp_topMenu)**
This component generates a menu with all the documentation topics. To generate this component, the `webhelp_top_menu` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_top_menu
```

In the output, you will find an element with the class: `wh_top_menu`.

You can control the maximum level of topics that will be included in the menu using the `webhelp.top.menu.depth` transformation parameter (in the Parameters tab of the transformation scenario).

For information about customizing the menu, see How to Customize the Menu (on page 1954).

**Index Terms Link (webhelp_indexterms_link)**

This component can be used to generate a link to the index terms page (`indexterms.html`). If the published documentation does not contain any index terms, then the link will not be generated. To generate this component, the `webhelp_indexterms_link` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_indexterms_link
```

In the output, you will find an element with the class: `wh_indexterms_link`. This element will contain a link to the `indexterms.html` page.

**Child Links (webhelp_child_links)**

For all topics with subtopics (child topics), this component generates a list of links to each child topic. To generate this component, the `webhelp_child_links` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_child_links
```

**Related Links (webhelp_related_links)**

For all topics that contain related links, this component generates a list of related links that will appear in the output. To generate this component, the `webhelp_related_links` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_related_links
```
Link to Skins Resources (webhelp_skin_resources)

This component can be used to add a link to resources for the current WebHelp skin (such as the CSS file). To generate this component, the `webhelp_skin_resources` element must be specified in the HTML file as in the following example:

```html
<whc:webhelp_skin_resources/>
```

In the output, you will find a link to the skin resources.

Search Results Page

The Search Results Page is the page generated that present search results in the WebHelp Responsive output. The name of the HTML file that defines this page is `wt_search.html` and it is located in the following directory: `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/oxygen-webhelp/page-templates`.

The HTML page that is produced consists of a search results component along with various other additional components, such as a title, menu, or index link.

Figure 632. Examples of Search Results Page Components

poly 72, 12, 17, 59, 17, 125, 73, 124, 72, 60, 148, 51, 148, 12 Publication Logo (on page 1922)
The following components can be referenced in the Search Results Page (wt_search.html) file:

**Publication Title (webhelp_publication_title)**

This component generates the publication title in the output. To generate this component, the `webhelp_publication_title` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_publication_title
```

In the output, you will find an element with the class: `wh_publication_title`.

**Publication Logo (webhelp_logo)**

This component generates a logo image in the output. To generate this component, the `webhelp_logo` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_logo
```

In addition, you must also specify the path of the logo image in the `webhelp.logo.image` transformation parameter (in the Parameters tab in the transformation scenario). You can set the `webhelp.logo.image.target.url` parameter to generate a link to a URL when you click the logo image.

In the output, you will find an element with the class: `wh_logo`.

**Search Input (webhelp_search_input)**

This component is used to generate the input widget associated with search function in the output. To generate this component, the `webhelp_search_input` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_search_input
```
In the output, you will find an element with the class: wh_search_input.

**Search Results (webhelp_search_results)**

This component is used to generate a placeholder to signal where the search results will be presented in the output. To generate this component, the `webhelp_search_results` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_search_results
```

In the output, you will find an element with the class: wh_search_results.

**Print Link (webhelp_print_link)**

This component is used to generate a print icon that opens the print dialog box for your particular browser. To generate this component, the `webhelp_print_link` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_print_link
```

In the output, you will find an element with the class: wh_print_link.

**Main Menu (webhelp_top_menu)**

This component generates a menu with all the documentation topics. To generate this component, the `webhelp_top_menu` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_top_menu
```

In the output, you will find an element with the class: wh_top_menu.

You can control the maximum level of topics that will be included in the menu using the `webhelp.top.menu.depth` transformation parameter (in the Parameters tab of the transformation scenario).

For information about customizing the menu, see How to Customize the Menu (on page 1954).

**Index Terms Link (webhelp_indexterms_link)**

This component can be used to generate a link to the index terms page (indexterms.html). If the published documentation does not contain any index terms, then the link will not be generated. To generate this component, the
webhelp_indexterms_link element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_indexterms_link
```

In the output, you will find an element with the class: wh_indexterms_link. This element will contain a link to the indexterms.html page.

**Link to Skins Resources (webhelp_skin_resources)**

This component can be used to add a link to resources for the current WebHelp skin (such as the CSS file). To generate this component, the webhelp_skin_resources element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_skin_resources/>
```

In the output, you will find a link to the skin resources.

### Index Terms Page

The *Index Terms Page* is the page generated that presents index terms in the WebHelp Responsive output. The name of the HTML file that defines this page is wt_terms.html and it is located in the following directory: `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/oxygen-webhelp/page-templates`

The HTML page that is produced consists of an index terms section along with various other additional components, such as a title, menu, or search field.

An alphabet that contains the first letter of the documentation index terms is generated at the top of the index page. Each letter represents a link to a specific indices section.

Figure 633. Example of Index Terms Page Components
The following components can be referenced in the Index Terms Page (wt_terms.html) file:

**Publication Title** ([webhelp_publication_title](#))

This component generates the publication title in the output. To generate this component, the `webhelp_publication_title` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_publication_title
```

In the output, you will find an element with the class: `wh_publication_title`.

**Publication Logo** ([webhelp_logo](#))

This component generates a logo image in the output. To generate this component, the `webhelp_logo` element must be specified in the HTML file as in the following example:
In addition, you must also specify the path of the logo image in the
webhelp.logo.image transformation parameter (in the Parameters tab in the
transformation scenario). You can set the webhelp.logo.image.target.url parameter
to generate a link to a URL when you click the logo image.

In the output, you will find an element with the class: wh_logo.

Search Input (webhelp_search_input)

This component is used to generate the input widget associated with search function in
the output. To generate this component, the webhelp_search_input element must be
specified in the HTML file as in the following example:

```
<whc:webhelp_search_input
```

In the output, you will find an element with the class: wh_search_input.

Print Link (webhelp_print_link)

This component is used to generate a print icon that opens the print dialog box for your
particular browser. To generate this component, the webhelp_print_link element must
be specified in the HTML file as in the following example:

```
<whc:webhelp_print_link
```

In the output, you will find an element with the class: wh_print_link.

Main Menu (webhelp_top_menu)

This component generates a menu with all the documentation topics. To generate this
component, the webhelp_top_menu element must be specified in the HTML file as in the
following example:

```
<whc:webhelp_top_menu
```

In the output, you will find an element with the class: wh_top_menu.

You can control the maximum level of topics that will be included in the menu using
the webhelp.top.menu.depth transformation parameter (in the Parameters tab of the
transformation scenario).
For information about customizing the menu, see How to Customize the Menu (on page 1954).

**Index Terms Link (webhelp_indexterms_link)**

This component can be used to generate a link to the index terms page (indexterms.html). If the published documentation does not contain any index terms, then the link will not be generated. To generate this component, the `webhelp_indexterms_link` element must be specified in the HTML file as in the following example:

```xml
<wc:webhelp_indexterms_link
    xmlns:wc="http://www.oxygenxml.com/webhelp/components"/>
```

In the output, you will find an element with the class: `wh_indexterms_link`. This element will contain a link to the `indexterms.html` page.

**Link to Skins Resources (webhelp_skin_resources)**

This component can be used to add a link to resources for the current WebHelp skin (such as the CSS file). To generate this component, the `webhelp_skin_resources` element must be specified in the HTML file as in the following example:

```xml
<wc:webhelp_skin_resources/>
```

In the output, you will find a link to the skin resources.

**Combining WebHelp Responsive and PDF Customizations in a Template Package**

An *Oxygen Publishing Template* package can contain both a WebHelp Responsive and PDF customization in the same template package and you can use that same template in both types of transformations. The template descriptor file can define the customization for both types by including both a `webhelp` and `pdf` element and some of the resources can be reused. Resources referenced in elements in the `webhelp` element will only be used for WebHelp transformations, and resources referenced in the elements in the `pdf` element will only be used in PDF transformations.

```xml
<publishing-template>
    <name>Flowers</name>
    <description>Flowers themed light-colored template</description>

    <webhelp>
        <tags>
            <tag>purple</tag>
            <tag>light</tag>
        </tags>
    </webhelp>
</publishing-template>
```
Generating WebHelp Responsive Output

The publishing process can be initiated from a transformation scenario within Oxygen XML Editor/Author, from a command line outside Oxygen XML Editor/Author, or from an integration server.

Running from Oxygen XML Editor/Author

To publish to the WebHelp Responsive output from a transformation scenario inside Oxygen XML Editor/Author, use one of the following procedures, depending on whether or not you want a feedback section in your output.
WebHelp Responsive Output

To publish a DITA map as WebHelp Responsive output, follow these steps:

1. Select the Configure Transformation Scenario(s) action from the DITA Maps Manager toolbar.
2. Select the DITA Map WebHelp Responsive scenario from the DITA Map section.
3. If you want to configure the transformation, click the Edit button.

**Step Result:** This opens an Edit scenario configuration dialog box that allows you to configure various options in the following tabs:

- **Templates Tab** - This tab contains a set of built-in skins that you can use for the layout of your WebHelp system output.
- **Parameters Tab** - This tab includes numerous transformation parameters that can be set to customize your WebHelp system output.
- **Filters Tab** - This tab allows you to filter certain content elements from the generated output.
- **Advanced Tab** - This tab allows you to specify some advanced options for the transformation scenario.
- **Output Tab** - This tab allows you to configure options that are related to the location where the output is generated.

4. Click Apply associated to process the transformation.

When the DITA Map WebHelp Responsive transformation is complete, the output is automatically opened in your default browser.

WebHelp Responsive with Feedback Output

To publish a DITA map as a WebHelp Responsive with Feedback system, follow these steps:

1. Select the Configure Transformation Scenario(s) action from the DITA Maps Manager toolbar.
2. Select the DITA Map WebHelp Responsive with Feedback scenario from the DITA Map section.
3. If you want to configure the transformation, click the Edit button.

**Step Result:** This opens an Edit scenario configuration dialog box that allows you to configure various options in the following tabs:

- **Templates Tab** - This tab contains a set of built-in skins that you can use for the layout of your WebHelp system output.
- **Parameters Tab** - This tab includes numerous transformation parameters that can be set to customize your WebHelp system output.
- **Filters Tab** - This tab allows you to filter certain content elements from the generated output.
• **Advanced Tab** - This tab allows you to specify some advanced options for the transformation scenario.

• **Output Tab** - This tab allows you to configure options that are related to the location where the output is generated.

4. Click **Apply associated** to begin the transformation.

5. Enter the documentation product ID (value for the `webhelp.product.id` parameter) and the documentation version (value for the `webhelp.product.version` parameter).

When the DITA Map WebHelp Responsive with Feedback transformation is complete, your default browser opens the `installation.html` file. This file contains information about the output location, system requirements, installation instructions, and deployment of the output. Follow the instructions to complete the system deployment *(on page 1873)*.

### Running from Command Line

To publish to the WebHelp Responsive output from a command line outside of **Oxygen XML Editor/Author**, you can use the `dita` startup script that comes bundled with **DITA-OT** distribution.

#### dita Command Format

**DITA-OT** `dita` command has the following format:

```
DITA-OT-DIR/bin/dita --format=webhelp-responsive --input=input-file options
```

where the arguments are as follows:

- **dita**  
  - **Windows** - The `dita.bat` script located in: `DITA-OT-DIR (on page 3282)\bin\`.  
  - **Linux/Mac OS X** - The `dita` script file located in: `DITA-OT-DIR (on page 3282)/bin/`.  

- **--format = webhelp-responsive**  
  - Specifies the output format (transformation type) for WebHelp Responsive transformation.

- **--input = input-file**  
  - The `input-file` represents the path to the DITA map that you want to process.

- **options**  
  - **options** include the following optional build parameters:

```
--output =dir  
-o dir
```
Specifies the path of the output directory; the path can be absolute or relative to the current directory. By default, the output is written to the `out` subdirectory of the current directory.

`--filter =file`

Specifies filter file(s) used to include, exclude, or flag content.

Relative paths are resolved against the current directory and internally converted to absolute paths.

`--temp =dir`

`-t dir`

Specifies the location of the temporary directory.

`--verbose`

`-v`

Verbose logging.

`--debug`

`-d`

Debug logging.

`--logfile =file`

`-l file`

Write logging messages to a file.

`--parameter =value`

`-D parameter=value`

Specify a value for a DITA-OT or Ant build parameter.

`--propertyfile =file`

Use build parameters defined in the referenced `.properties` file.

Build parameters specified on the command line override those set in the `.properties` file.

**WebHelp and DITA-OT parameters**

In addition to the transformation parameters that are specific to WebHelp Responsive (on page 2003), you can use the common DITA-OT transformation parameters and the HTML-based Output Parameters.
Command-Line Example

• Windows:

```bash
dita.bat
 --format=webhelp-responsive
 --input=c:\path\to\mySample.ditamap
 --output=c:\path\to\output
 -Dwebhelp.logo.image=myLogo.jpg
```

• Linux/Mac OS X:

```bash
dita
 --format=webhelp-responsive
 --input=/path/to/mySample.ditamap
 --output=/path/to/output
 -Dwebhelp.logo.image=myLogo.jpg
```

Related Information:

• DITA-OT Documentation: Publishing DITA Content

• DITA-OT Documentation: HTML-based output parameters

• WebHelp Responsive Output Parameters (on page 2003)

Running from an Integration Server

Oxygen XML Editor can be processed from an automatic publishing system, such as Jenkins or Travis.

Automating DITA to WebHelp Output with Jenkins

To integrate WebHelp output with the Jenkins continuous integration tool, follow these steps:

1. Create a Maven project to incorporate the DITA-OT that already integrates Oxygen XML Editor.
2. Go to the root of your Maven project and edit the pom.xml file to include the following fragment:

```xml
<properties>
```
3. Go to the Jenkins top page and create a new Jenkins job. Configure this job to suit your particular requirements, such as the build frequency and location of the Maven project.

Automating DITA to WebHelp Output with Travis CI

This topic assumes you have a DITA project hosted on a GitHub public or private repository.

The goal of this tutorial is to help you set up a Travis continuous integration job that automatically publishes your DITA project to GitHub pages after every commit. The published website will contain a feedback link on each page that would allow a contributor to easily suggest changes to the documentation by creating a pull request on GitHub with just a few clicks.

Enable the Travis CI Build

1. Sign in to Travis CI with your GitHub account, accepting the GitHub access permissions confirmation.

2. Once you are signed in, and you have synchronized your GitHub repositories, go to your profile page and enable Travis CI for the repository you want to build.
Configure the Travis CI Build in your GitHub Project

1. Checkout your GitHub project locally.
2. Copy the `.travis` folder from here to the root directory of your project.
3. In the root of your GitHub project, add a file called `.travis.yml` with the following content:

```yaml
language: dita
install:
  - echo "Installed"
script:
  - sh .travis/publish.sh
after_success:
  - sh .travis/deploy.sh
env:
  global:
    - DITAMAP=/path/to/your/ditamap/file
    - DITAVAL=/path/to/your/ditaval/file
    - ANT_OPTS=-Xmx1024M

Note: Replace /path/to/your/ditamap/file and /path/to/your/ditaval/file with the appropriate paths to your DITA map and ditaval files.
4. Create a GitHub personal access token by following this procedure.
5. Define an environment variable in the repository settings that has the name GH_TOKEN and the value equal with the GitHub personal access token created earlier.

Register Your License Key

1. Edit your `.gitignore` file (or create it if it does not already exist) and add the following line:

   licenseKey.txt

2. Copy your WebHelp license to the root of your GitHub project in a file called licenseKey.txt.

   Important: The licenseKey.txt file should not be committed to GitHub as it contains a license key that is issued only to you.

3. Encrypt the license key file and add it to the `.travis.yml` configuration file. This way only the Travis CI server will be able to decrypt it during the build process.

Commit to GitHub

1. Commit the following files and folders and push the commit to GitHub:
git add .gitignore licenseKey.txt.enc .travis.yml .travis/
git commit -m "Set up the Travis CI publishing system"
git push

2. Create a gh-pages branch in your GitHub project where the WebHelp output will be published. You can follow the procedure here.

Customizing the WebHelp Responsive Output

Oxygen XML Editor provides support for customizing the WebHelp Responsive output to suit your specific needs. The WebHelp Responsive output is based upon the Bootstrap responsive front-end framework and is available for DITA document types. The WebHelp Responsive with Feedback variant allows your users to add comments to your output.

To change the overall appearance of your WebHelp Responsive output, you can use several different customization methods or a combination of methods. If you are familiar with CSS and coding, you can style your WebHelp output through your own custom style sheets. You can also customize your output by modifying existing templates, create your own layout pages, or by configuring certain options and parameters in the transformation scenario.

This section includes topics that explain various ways to customize your WebHelp Responsive system output, such as how to configure the tiles on the main page, add logos in the title area, integrate with social media, localizing the interface, and much more.

Working with Publishing Templates

An Oxygen Publishing Template (on page 3285) defines all aspects of the layout and styles of the WebHelp Responsive output. It is a self-contained customization package stored as a ZIP archive or folder that can easily be shared with others. It provides the primary method for customizing the output. The recommended method for customizing the WebHelp Responsive output is to use a custom publishing template.

This section contains topics about how to create, edit, publish, and share publishing templates.

Related Information:

How to Create a Publishing Template

To create a customization, you can start from scratch or from an existing template, and then adapt it according to your needs.

Creating a Template Starting from Scratch

To create a new Oxygen Publishing Template, follow these steps:

1. Create a folder that will contain all the template files.
2. In Oxygen XML Editor/Author, open the new document wizard (use File > New or the New toolbar button), then choose the Publishing Template Descriptor template.

3. Save the .opt file into your customization directory.
4. Open the .opt file in the editor and customize it to suit your needs.

Creating a Template Starting from an Existing Template

If you are using a WebHelp Responsive or DITA Map PDF - based on HTML5 & CSS transformation, the easiest way to create a new Oxygen Publishing Template (on page 3285) is to select an existing template in the transformation scenario dialog box and use the Save template as button to save that template into a new template package that can be used as a starting point.

To create a new Oxygen Publishing Template, follow these steps:
1. Open the transformation scenario dialog box and select the publishing template you want to export and use as a starting point.

2. **Optional:** You can set one or more transformation parameters from the **Parameters** tab and the edited parameters will be exported along with the selected template. You will see which parameters will be exported in the dialog box that is displayed after the next step.

3. Click the **Save template as** button.

   **Step Result:** This opens a template package configuration dialog box that contains some options and displays the parameters that will be exported to your template package.

4. Specify a name for the new template.

5. **Optional:** Specify a template description.

6. **Optional:** The same publishing template package can contain both a WebHelp Responsive and PDF customization and you can use the same template in both types of transformations (*DITA Map WebHelp Responsive* or *DITA Map to PDF - based on HTML5 & CSS*). You can use the **Include WebHelp customization** and **Include PDF customization** options to specify whether your custom template will include both types of customizations.

7. **Optional:** For **WebHelp Responsive** customizations, you can select the **Include HTML Page Layout Files** option if you want to copy the default *HTML Page Layout Files (on page 1909)* in your template package. They are helpful if you want to change the structure of the generated HTML pages.

8. In the **Save as** field, specify the name and path of the ZIP file where the template will be saved.

   **Step Result:** A new ZIP archive will be created on disk in the specified location with the specified name.

9. Open the `.opt` file in the editor and customize it to suit your needs.

For more information about creating and customizing publishing templates, watch our video demonstration:

https://www.youtube.com/embed/zNmXfWXwO8

Related Information:

- *Publishing Template Package Contents for PDF Customizations (on page 2023)*

*Publishing Template Package Contents for WebHelp Responsive Customizations (on page 1895)*
How to Edit a Packed Publishing Template

To edit an existing *Oxygen Publishing Template* (on page 3285) package, follow these steps:

1. Unzip the ZIP archive associated with the *Oxygen Publishing Template* in a separate folder.
2. Link the folder associated with the template in the Project view.
3. Using the Project view, you can modify the resources (CSS, JS, fonts) within the *Oxygen Publishing Template* folder to fit your needs.
4. Open the publishing template descriptor file (.opt extension) in the editor and modify to suit your needs.
5. **Optional:** Once you finish your customization, you can archive the folder as a ZIP file.

Related Information:

- **Publishing Template Package Contents for PDF Customizations** (on page 2023)
- **Publishing Template Package Contents for WebHelp Responsive Customizations** (on page 1895)

How to Add a Publishing Template to the Publishing Templates Gallery

To add the publishing template to your templates gallery, follow these steps:

1. Open the transformation scenario dialog box by editing a WebHelp Responsive transformation.
2. In the Templates tab, click the Configure Publishing Templates Gallery link to.
   - This will open the preferences page.
3. Click the Add button and specify the location of your template directory.
   - Your template directory is now added to the Additional Publishing Templates Galleries list.
4. Click OK to return to the transformation scenario dialog box.
   - All the templates contained in your template directory will be displayed in the preview pane along with all the built-in templates.

How to Use a Publishing Template from a Command Line

Before you run the transformation, you need to know if the publishing template has a single or multiple template descriptor files (on page 1895). If you don't know, open the ZIP archive or folder and check for files with the .opt extension.
Using a Publishing Template with a Single Descriptor

A template with a single descriptor is used for a single customization.

To run from a command line, you need to use the webhelp.publishing.template parameter (on page 2003). This parameter specifies the path to the ZIP archive (or root folder) that contains your custom WebHelp Responsive template.

**Command-Line Example:**

- **Windows:**

```bash
dita.bat
    --format=webhelp-responsive
    --input=c:\path\to\mySample.ditamap
    --output=c:\path\to\output
    -Dwebhelp.publishing.template=custom-template
```

- **Linux/Mac OS X:**

```bash
dita
    --format=webhelp-responsive
    --input=/path/to/mySample.ditamap
    --output=/path/to/output
    -Dwebhelp.publishing.template=custom-template
```

Using a Publishing Template with Multiple Descriptors

A template with multiple descriptors contains multiple customizations.

Because the publishing template is self-contained, it is used to reuse resources that are common to multiple publications.

To run from a command line, you need to use the webhelp.publishing.template and webhelp.publishing.template.descriptor parameters.

The webhelp.publishing.template parameter specifies the path to the ZIP archive (or root folder) while the webhelp.publishing.template.descriptor parameter specifies the name of the descriptor you want to use.

**Command-Line Example:**

- **Windows:**

```bash
dita.bat
```
How to Share a Publishing Template

To share a publishing template with others, following these steps:

1. Copy your template in a new folder in your project.
2. Go to **Options > Preferences > DITA > Publishing** and add that new folder to the list.
3. Switch the option as the bottom of that preferences page to **Project Options**.
4. Share your project file (**.xpr**).

Converting Old Templates to Version 20.0 and Newer

With the introduction of the Publishing Template concept in Oxygen XML Editor version 20.0, the old WebHelp output template formats (version 19.1 and older) are no longer supported. However, they can be easily converted to the new format by following this procedure:

1. Set Oxygen XML Editor to point to the DITA-OT distribution that contains your old template:
   a. Go to **Options > Preferences > DITA**.
   b. Select **Custom** in the **DITA Open Toolkit** section and specify the DITA-OT directory that contains your old template.
2. Edit a **WebHelp Responsive** transformation scenario.
3. Select your old custom template in the **Templates** tab.
4. Click on the **Save Template as** button, complete the required fields, and save the template.
5. Edit the **WebHelp Responsive** transformation scenario again.
6. This time, use the **Choose custom template** button to select your old template.
7. Save the scenario and use it to generate the WebHelp Responsive output.
Converting Old Templates with Custom HTML Page Layout Files to Version 21

If you have a custom Publishing Template that was created in Oxygen XML Editor version 20.0 or 20.1 and it includes custom HTML page layout files, the following conversion procedure is required for the template to be compatible with Oxygen XML Editor version 21.0:

1. In the Project view, add the root directory for your custom Publishing Template (you can use a linked folder and the easiest way to do this is to drag and drop the folder).

   Note: If your template is stored as a ZIP archive, you first need to unzip it.

2. Expand your template directory, right-click the page-templates subfolder, and select Refactoring > XML Refactoring.

3. In the XML Refactoring dialog box, scroll to the Publishing Template section and select Migrate HTML Page Layout Files to v21, then click Next.

4. The Scope should be left as Selected project resources.

5. You can use the Preview button to open a comparison panel where you can review all the changes that will be made by the refactoring operation before applying the changes.

6. Click Finish to perform the conversion.

Related Information:

- Converting Old Templates with Custom HTML Page Layout Files to Version 21 (on page 1941)

Troubleshooting: Errors Encountered when Loading Templates

When the Templates tab of a WebHelp Responsive transformation scenario dialog box is opened, all templates (built-in and custom) are loaded and validated. Specifically, certain elements in the template descriptor file are checked for validity. If errors are encountered that prevents the template from loading, the following message will be displayed toward the bottom of the dialog box:

Some templates could not be loaded. More details
If you click the More details link, a window will open with more information about the encountered error. For example, it might offer a hint for which element is missing from the expected descriptor file structure (on page 1895).

Also, if a template could be loaded, but certain elements could not be found in the descriptor file (on page 1895), a warning icon (⚠️) will be displayed on the template's image (in the Templates tab of the transformation dialog box). For example, this happens if a valid preview-image element (on page 1898) cannot be found.

Changing the Layout and Styles

This section contains topics that explain how to customize the output using CSS, inserting HTML fragments, changing the layout of the main page, and more.

How to Use CSS Styling to Customize the Output

The most common way to customize WebHelp Responsive output is to use custom CSS styling. This method can be used to make small, simple styling changes or more advanced, precise changes. To implement the styling in your WebHelp output, you simply need to create the custom CSS file and reference it in your transformation scenario (using an Oxygen Publishing Templater (on page 3285) or a transformation parameter). This custom file will be the final CSS to be applied so its content will override the styles in the other pre-existing CSS files.

Using CSS Inspector to Identify Content for Custom CSS File

You can use your browser's CSS inspector to identify the pertinent code in the current CSS files and you can even make changes directly in the CSS inspector to test the results so that you know exactly what content to use in your custom CSS file.

In most popular browsers (such as Chrome, Firefox, and Edge), you can access the CSS inspector by using F12 or by selecting Inspect Element (or simply Inspect) from the contextual menu.

Tip: When using Safari on Mac OS X, you must first enable the Develop menu by going to the Advanced settings and selecting Show Develop menu in menu bar. Then you can select Show Web Inspector from the Develop menu or click Command + Option + I.

Create the Custom CSS

As a practical example, the following procedure would change the background color of the footer bar in the WebHelp output:

1. Use the browser's CSS inspector to identify the current CSS code that styles the footer bar. In this particular case, the pertinent code that would be identified is:
2. If you want to test the color you want to apply as the background of this particular element, use the browser's CSS inspector to change the value of the `background-color` attribute. After you find a suitable color, copy that new code.

3. Create a custom CSS file and paste or enter the copied code. For example:

```css
.wh_footer {
    background-color: #255890;
}
```

4. Save the custom CSS file at a location of your convenience.

5. Reference the CSS file in a WebHelp Responsive transformation using an Oxygen Publishing Template (on page 1943) or the `args.css` parameter (on page 1944).

Referencing the CSS Using a Publishing Template

1. If you haven't already created a Publishing Template, see Working with Publishing Templates (on page 1935).

2. Using the Project view, copy your custom CSS in a folder inside the publishing template root folder (for example, in the `custom_footer_template/resources` folder).

3. Open the template descriptor file (on page 1895) associated with your publishing template and add your custom CSS in the `resources` section.

```xml
<publishing-template>
    ...
    <webhelp>
        ...
        <resources>
            ...
            <css file="resources/MyCustom.css"/>
        </resources>
    </webhelp>
    ...
</publishing-template>
```

4. Open the DITA Map WebHelp Responsive transformation scenario.

5. Click the Choose Custom Publishing Template link and select your template.

6. Click OK to save the changes to the transformation scenario.

7. Run the transformation scenario.

**Result:** Your custom CSS will be applied as a final layer on top of any existing CSS rules and the output will reflect the changes you made.
Referencing the CSS Using the args.css Parameter

1. Edit the DITA Map WebHelp Responsive transformation scenario and open the Parameters tab.
2. Set the args.css parameter to the path of your custom CSS file.
3. Set the args.copycss parameter to yes to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
4. Click OK to save the changes to the transformation scenario.
5. Run the transformation scenario.

Result: Your custom CSS will be applied as a final layer on top of any existing CSS rules and the output will reflect the changes you made.

How to Insert HTML Content in WebHelp Responsive Output

You can add custom HTML content in the WebHelp Responsive output by inserting it in a well-formed XML file that will be referenced in the transformation (either from an Oxygen Publishing Template (on page 3285) or using one of the HTML fragment parameters (on page 2005)). This content may include references to additional JavaScript, CSS, and other types of resources, or such resources can be inserted inline within the HTML content that is inserted in the XML file.

The XML File

There are several things to consider regarding this XML file:

- **Well-Formedness** - If the file is not a Well-formed XML document (on page 1079) (or fragments are not well-formed), the transformation will fail.

  A common use case is if you want to include several script or link elements. In this case, the XML fragment has multiple root elements and to make it well-formed, you can wrap it in an html element. This element tag will be filtered out and only its children will be copied to the output documents. Similarly, you can wrap your content in head, body, html/head, or html/body elements.

- **Referencing Resources in the XML File** - You can include references to local resources (such as JavaScript or CSS files) by using the built-in `${oxygen-webhelp-output-dir}` macro to specify their paths relative to the output directory:

```xml
<html>
<script type="text/javascript" src="${oxygen-webhelp-output-dir}/js/test.js"></script>
<link rel="stylesheet" type="text/css"
     href="${oxygen-webhelp-output-dir}/css/test.css" />
</html>
```
If you want that the path of your resource to be relative to the templates directory *(on page 1892)*, you can use the `${oxygen-webhelp-template-dir}` macro.

To copy the referenced resources to the output directory, follow the procedure in: How to Copy Additional Resources to Output Directory *(on page 1961)*.

- **Inline JavaScript or CSS Content:**

  **JavaScript:**

  ```
  <script type="text/javascript">
  /* Include JavaScript code here. */

  function myFunction() {
    return true;
  }

  </script>
  ```

  **CSS:**

  ```
  <style>
  /* Include CSS style rules here. */

  *{
    color:red
  }

  </style>
  ```

  **Note:** If you have special characters (for example, &, < ) that break the well-formedness of the XML fragment, it is important to place this content inside an XML comment:

  ```
  <script type="text/javascript">
    <!--
    /* Include JavaScript code here. */

    function myFunction() {
      return true;
    }

    //-->
  </script>
  ```
Using WebHelp Macros Inside an HTML Fragment File

The XML file can use WebHelp macros, which are variables that will be expanded when the content of the HTML fragment file will be copied in the final output.

There are two possibilities for using macros:

- **Directly in attribute values** - For example, if you want to reference a JavaScript file from the Publishing Template directory, you can use the following construct:

  ```html
  <script type="text/javascript" src="${path(oxygen-webhelp-template-dir)}/"></script>
  ```

- **In text content** - Using the `<whc:macro/>` template component:

  ```html
  <script type="text/javascript" xmlns:whc="http://www.oxygenxml.com/webhelp/'>
    var outDirPath = '${path(oxygen-webhelp-output-dir)}/';
    console.log("The output directory path is: ", outDirPath);
  </script>
  ```

The following *macros* are supported:

- **i18n**
  
  For localizing a string.

  ```text
  ${i18n(string.id)}
  ```

- **param**
  
  Returns the value of a transformation parameter.

  ```text
  ${param(webhelp.show.main.page.tiles)}
  ```

- **env**
  
  Returns the value of an environment variable.

  ```text
  ${env(JAVA_HOME)}
  ```

- **system-property**
  
  Returns the value of a system property.

  ```text
  ${system-property(os.name)}
  ```

- **timestamp**
Can be used to format the current date and time. Accepts a string (as a parameter) that determines how the date and time will be formatted (format string or picture string as it is known in the XSLT specification). The format string must comply with the rules of the XSLT `format-dateTime` function specification.

```text
${timestamp([h1]:[m01] [P] [M01]/[D01]/[Y0001])}
```

**path**

Returns the path associated with the specified path ID. The following paths IDs are supported:

- `oxygen-webhelp-output-dir` - The path to the output directory. The path is relative to the current HTML file.
- `oxygen-webhelp-assets-dir` - The path to the `oxygen-webhelp` subdirectory from the output directory. The path is relative to the current HTML file.
- `oxygen-webhelp-template-dir` - The path to the template directory. The path is relative to the current HTML file.

```text
${path(oxygen-webhelp-template-dir)}
```

**Note:** New paths IDs can be added by overriding the `wh-macro-custom-path` template from `com.oxygenxml.webhelp.responsive\xsl\template\macroExpander.xsl`:

```xml
<!-- Extension template for expanding a custom path macro. -->
<xsl:template name="wh-macro-custom-path">
    <xsl:param name="pathId"/>
    <xsl:value-of select="$pathId"/>
</xsl:template>
```

**map-xpath**

Can be used to execute an XPath expression over the DITA map file from the temporary directory.

**Tip:** Available in all template layout HTML pages.

```text
${map-xpath(/map/title)}
```

**topic-xpath**

Can be used to execute an XPath expression over the current topic.

**Tip:** Available only in the topic HTML page template (`wt_topic.html`).
Referencing the HTML fragment using a Publishing Template

1. If you have not already created a Publishing Template, see Working with Publishing Templates (on page 1935).
2. Insert the HTML content in a well-formed XML file (for example, custom-html.html).
3. Using the Project view, copy your custom HTML fragment in a folder inside publishing the template root folder (for example, in the custom_footer_template/html-fragments folder).
4. Open the template descriptor file (on page 1895) associated with your publishing template and add a reference to the custom HTML fragment in the html-fragments section.

```xml
<publishing-template>
  ...
  <webhelp>
    ...
    <html-fragments>
      ...  
      <fragment
          file="html-fragments/custom-html.html"
          placeholder="webhelp.fragment.head"/>
    </html-fragments>
  </webhelp>
</publishing-template>
```

**Note:** If you want to insert the content in another location within the output document, you can reference the XML file from any other HTML Fragment extension points (on page 1902).
5. Open the DITA Map WebHelp Responsive transformation scenario.
6. Click the Choose Custom Publishing Template link and select your template.
7. Click OK to save the changes to the transformation scenario.
8. Run the transformation scenario.

**Results:** Your additional content will be included at the end of the head element of your output document.

Referencing the HTML Fragment using a Transformation Parameter

1. Insert the HTML content in a well-formed XML file.
2. Edit the DITA Map WebHelp Responsive transformation scenario and open the Parameters tab.
3. Edit the value of the `webhelp.fragment.head` parameter and set it to the absolute path of your XML file.

   **Note:** If you want to insert the content in another location within the output document, you can reference the XML file from any other HTML Fragment extension points *(on page 1902).*

4. Click **OK** to save the changes to the transformation scenario.
5. Run the transformation scenario.

**Results:** Your additional content will be included at the end of the `head` element of your output document.

**How to Insert JavaScript AMD Modules in WebHelp Responsive Output**

In the WebHelp Responsive output, you may want to include a JavaScript module that uses the Asynchronous Module Definition (AMD) format. Unlike the traditional JavaScript resources that are loaded using `<script>` tags, these modules are loaded using the RequireJS library. For the traditional JavaScript libraries, the standard procedure to contribute your script to the output would be to use an HTML fragment file as described here *(on page 1944).*

Although following the procedure that uses HTML fragments *(on page 1944)* would result in having your JS file included in the output, loading the JS code in the browser will result in an error. Since your JS module uses the AMD API, it cannot be loaded using a `<script>` element. For example, because many jQuery plugins use the AMD format, it will be difficult for you to use those libraries in your custom WebHelp output.

Normally, a JavaScript AMD module can be loaded in one of the following ways:

- **As a top-level script,** using the `data-main` attribute of the `<script>` element used to load the RequireJS library.

    ```html
    <script data-main="js/template-main.js" src="js/require.js"></script>
    ```

However, since WebHelp already loads its internal JS modules using RequireJS, a top level script is already specified and you cannot specify another top level script in the same page. Therefore,
this approach can not be used to load your custom JS module in Oxygen XML WebHelp, leaving you with only the following option.

- **As a dependency module**, using a `require()` call from the top level (main) script or from one of its dependency modules. This means that you would have to alter one of the WebHelp core JS libraries and inject a `require()` call to load your custom module:

  ```javascript
  require(['js/template-main.js']);
  ```

**Note:** Altering the WebHelp core libraries is not recommended because when you will upgrade the WebHelp plugin to a newer version, those modifications will be lost.

### Contributing JavaScript AMD Modules Using a Publishing Template

Oxygen XML WebHelp provides the ability to contribute a custom JavaScript Asynchronous Module Definition (AMD) resource in the output by referencing it in the Publishing Template descriptor file (on page 1895). This module is automatically copied to the output directory and it is automatically loaded in the output HTML pages using a `require()` call. Thus, you can include your scripts in the output without altering WebHelp’s core JavaScript libraries.

This module may contain all of your custom functionality or can be used to load other AMD JavaScript modules. The additional sub-modules can be stored either locally in your custom Publishing Template or on a remote web server.

**Important:** To enable loading of a JS module you should set the `webhelp.enable.template.js.module.loading` parameter to `yes` (the default value is `no`) in the Publishing Template descriptor file or in the transformation scenario.

### The JavaScript Modules

The JS Modules sample template contains a main JavaScript module (`template-main.js`) that loads other modules stored in the template package or in a remote location on the Internet.

```javascript
define(['require'], function (require) {
    require(['./red', './italic', './tables']);
});
```

Besides the main JavaScript example, the template contains 3 other sub-modules:

- **red.js** - Changes the font color of the publication title.

```javascript
define(['jquery'], function ($) {
    $(document).ready(function () {
        // Make the title red
    });
});
```
• **italic.js** - Changes the font style of your publication title.

```javascript
define(['jquery'], function ($) {
  $(document).ready(function () {
    // Make the title italic
    $('.wh_publication_title a').wrapInner('<i></i>');
  });
});
```

• **tables.js** - Loads the DataTables jQuery plugin from a CDN.

```javascript
define(['jquery',
  'https://cdn.datatables.net/1.10.16/js/jquery.dataTables.min.js'],
  function ($) {

  $(document).ready(function () {
    $('.table').DataTable();
  });
});
```

The JavaScript modules are stored in the Publishing Template package as follows:

```
[template-dir]
[js]
  template-main.js
  italic.js
  red.js
  tables.js
```

**Note:**

• The main module should be referenced in the Publishing Template descriptor file (on page 1895) by specifying its path relative to the base directory of the template.

```xml
<js-amd-module file="js/template-main.js"/>
```

• The main JS module is copied automatically to the output directory, but the sub-modules are not. To instruct the Publishing Template engine to copy those modules to the output directory you should include a `<fileset>` section in the Publishing Template descriptor file (on page 1895).

```xml
<fileset>
```
• The main module can reference other modules bundled in the publishing template package as follows:
  ◦ Relative to template directory - Prefix their paths with the ID of the template directory:
    template-base-dir (for example: template-base-dir/js/italic).
  ◦ Relative to the name of the current JS module - Use ./ to prefix the paths of the referenced modules.
  ◦ The .js extension should be omitted for local modules, because the RequireJS library will add it automatically.

Related Information:

• How to Insert HTML Content in WebHelp Responsive Output (on page 1944)

How to Change Numbering Styles for Ordered Lists

Ordered lists (ol) are usually numbered in XHTML output using numerals. If you want to change the numbering to alphabetical, follow these steps:

1. Define a custom outputclass value and set it as an attribute of the ordered list, as in the following example:

   `<ol outputclass="number-alpha">
   <li>A</li>
   <li>B</li>
   <li>C</li>
   </ol>`

2. Add the following code snippet in a custom CSS file:

   ```
   ol.number-alpha{
   list-style-type:lower-alpha;
   }
   ```

3. Reference the CSS file in a WebHelp Responsive transformation using an Oxygen Publishing Template (on page 1953) or the args.css parameter (on page 1953).
Referencing the Custom CSS from a Publishing Template

1. If you haven’t already created a Publishing Template, see Working with Publishing Templates (on page 1935).
2. Using the Project view, copy your custom CSS in a folder inside the publishing template root folder (for example, in the custom_footer_template/resources folder).
3. Open the template descriptor file (on page 1895) associated with your publishing template and add your custom CSS in the resources section.

```xml
<publishing-template>
  ...
  <webhelp>
    ...
    <resources>
      ...
      <css file="resources/MyCustom.css"/>
    </resources>
  </webhelp>
  ...
</publishing-template>
```

4. Open the DITA Map WebHelp Responsive transformation scenario.
5. Click the Choose Custom Publishing Template link and select your template.
6. Click OK to save the changes to the transformation scenario.
7. Run the transformation scenario.

**Result:** Your custom CSS will be applied as a final layer on top of any existing CSS rules and the output will reflect the changes you made.

Referencing the CSS Using the *args.css* Parameter

1. Edit the DITA Map WebHelp Responsive transformation scenario and open the Parameters tab.
2. Set the *args.css* parameter to the path of your custom CSS file.
3. Set the *args.copycss* parameter to *yes* to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
4. Click OK to save the changes to the transformation scenario.
5. Run the transformation scenario.

**Result:** Your custom CSS will be applied as a final layer on top of any existing CSS rules and the output will reflect the changes you made.

How to Show or Hide Navigation Links in Topic Pages

The topic pages (on page 1862) in WebHelp Responsive output can contain navigation links (◀ Previous / ▶ Next arrows) that can be used to navigate to the previous or next topic.
How to Control Which Topic Pages Include Navigation Links

The navigation links are controlled by the `collection-type` attribute. For example, if you set `collection-type="sequence"` on a parent topic reference in your DITA map, navigation links will be generated in the output for all of its child topics (from children to parent, and from child to previous sibling and next sibling).

```xml
<map id="example_map" title="Example Map">
  <topicref href="../topics/ParentTopic.dita" collection-type="sequence">
    <topicref href="../topics/Childtopic.dita"/>
  </topicref>
</map>
```

How to Generate Navigation Links for All Topics (Ignoring the Collection Type Attribute)

You can use the `webhelp.default.collection.type.sequence` parameter in the transformation and set its value to `yes` to generate navigation links for all topics, regardless of whether or not the `collection-type` attribute is present.

How to Hide All Navigation Links

To hide all navigation links, use the `webhelp.show.navigation.links` parameter in the transformation and set its value to `no`.

How to Change the Main Page Layout

This section contains topics that explain how to customize the layout of the main page in the WebHelp Responsive output.

How to Customize the Menu

By default, the menu component is displayed in all WebHelp Responsive pages. However, you might want to hide it completely, or only display some of its menu entries.

How to Hide Some of the Menu Entries

There are two methods for doing this. One of them involves editing the `DITA map (on page 3281)` and marking the topics that do not need to be included in the menu, and another one that uses a small CSS customization.

Editing the DITA Map
To edit the metadata in the DITA map to control which topics will not be displayed in the menu, follow these steps:

1. Open the DITA map in the Text editing mode of Oxygen XML Editor.
2. Add the following metadata information in the topicref element (or any of its specializations) for each topic you do not want to be displayed in the menu:

   ```xml
   <topicmeta>
   <data name="wh-menu">
     <data name="hide" value="yes"/>
   </data>
   </topicmeta>
   ```

Customizing the CSS

To customize the CSS to control which topics will not be displayed in the menu, follow these steps:

1. Make sure you set an ID on the topic that you do not want to include in the menu.
2. Create a new CSS file that contains a rule that hides the menu entry generated for the topic (identified by the topic ID `growing-flowers` in the following example). The CSS file should have content that is similar to this:

   ```css
   .wh_top_menu *[data-id='growing-flowers'] { display:none; }
   ```

3. Reference the CSS file in a WebHelp Responsive transformation using an Oxygen Publishing Template (on page 1943) or the args.css parameter (on page 1944).

How to Hide the Entire Menu

If you do not want to include a main menu in the pages of the WebHelp Responsive output, you can instruct the transformation scenario to skip the menu generation completely.

Using a Publishing Template

To hide the menu using an Oxygen Publishing Template (on page 1892), follow this procedure:

1. If you haven't already created a Publishing Template, see Working with Publishing Templates (on page 1935).
2. Open the template descriptor file (on page 1895) associated with your publishing template and add the webhelp.show.top.menu parameter in the parameters section with its value set to no.
3. Open the DITA Map WebHelp Responsive transformation scenario.
4. Click the Choose Custom Publishing Template link and select your template.
5. Click OK to save the changes to the transformation scenario.
6. Run the transformation scenario.

**Using a Transformation Scenario in Oxygen XML Editor/Author**

To hide the menu using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Edit the DITA Map WebHelp Responsive transformation scenario and choose a template.
2. Open the Parameters tab and set the webhelp.show.top.menu parameter to no.
3. Click OK to save the changes to the transformation scenario.
4. Run the transformation scenario.

**How to Add a Welcome Message in the WebHelp Responsive Main Page**

The main page of the WebHelp Responsive output contains a set of empty placeholders (on page 1902) that can be used to display customized text fragments. These placeholders are available to you through WebHelp Responsive transformation scenario parameters. For example, the placeholder identified through the webhelp.fragment.welcome parameter displays text content above the search box in the main page.

**Using a Publishing Template**

To add a customized welcome message in the main page of the WebHelp Responsive output using an Oxygen Publishing Template (on page 1892), follow this procedure:

1. If you haven't already created a Publishing Template, see Working with Publishing Templates (on page 1935).
2. Open the template descriptor file (on page 1895) associated with your publishing template and add the webhelp.fragment.welcome parameter in the parameters section with its value set to one of the following:
   - A small well-formed XHTML fragment (such as: `<i>Welcome to the User Guide</i>`).
   - A path to a file that contains well-formed XHTML content.
3. Open the **DITA Map WebHelp Responsive** transformation scenario.
4. Click the **Choose Custom Publishing Template** link and select your template.
5. Click **OK** to save the changes to the transformation scenario.
6. Run the transformation scenario.

**Result:** In the WebHelp output, your custom message will be displayed above the search box in the main page.

### Using a Transformation Scenario in Oxygen XML Editor/Author

⚠️ **Important:** Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin ([https://www.oxygenxml.com/buy_webhelp.html](https://www.oxygenxml.com/buy_webhelp.html)).
- The Oxygen XML WebHelp Plugin must be installed and integrated for the DITA Open Toolkit or a DocBook XSL Distribution.

To add a customized welcome message in the main page of the WebHelp Responsive output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Edit the **DITA Map WebHelp Responsive** transformation scenario and choose a template.
2. Open the **Parameters** tab and set the `webhelp.fragment.welcome` parameter with its value set to one of the following:
   - A small well-formed XHTML fragment (such as: `<i>Welcome to the User Guide</i>`).
   - A path to a file that contains well-formed XHTML content.
3. Click **OK** to save the changes to the transformation scenario.
4. Run the transformation scenario.

**Result:** In the WebHelp output, your custom message will be displayed above the search box in the main page.
How to Create a Custom Footer

The main page of the WebHelp Responsive output contains a set of empty placeholders (on page 1902) that can be used to display customized text fragments. These placeholders are available to you through WebHelp Responsive transformation scenario parameters. For example, the placeholder identified through the webhelp.fragment.footer parameter displays the custom content at the bottom of the page.

Using a Publishing Template

To create a custom footer in the WebHelp Responsive output using an Oxygen Publishing Template (on page 1892), follow this procedure:

1. If you haven’t already created a Publishing Template, see Working with Publishing Templates (on page 1935).
2. Open the template descriptor file (on page 1895) associated with your publishing template and add the webhelp.fragment.footer parameter in the parameters section with its value set to one of the following:
   • A small well-formed XHTML fragment.
   • A path to a file that contains well-formed XHTML content.

3. Open the DITA Map WebHelp Responsive transformation scenario.
4. Click the Choose Custom Publishing Template link and select your template.
5. Click OK to save the changes to the transformation scenario.
6. Run the transformation scenario.

Result: In the WebHelp output, your custom footer will be displayed at the bottom of the page.

Using a Transformation Scenario in Oxygen XML Editor/Author

⚠️ Important: Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:
You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).

The Oxygen XML WebHelp Plugin must be installed and integrated for the DITA Open Toolkit or a DocBook XSL Distribution.

To create a custom footer in the WebHelp Responsive output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Edit the DITA Map WebHelp Responsive transformation scenario and choose a template.
2. Open the Parameters tab and set the webhelp.fragment.footer parameter with its value set to one of the following:
   - A small well-formed XHTML fragment.
   - A path to a file that contains well-formed XHTML content.
3. Click OK to save the changes to the transformation scenario.
4. Run the transformation scenario.

   Result: In the WebHelp output, your custom footer will be displayed at the bottom of the page.

How to Configure the Tiles on the WebHelp Responsive Main Page

The tiles version of the main page of the WebHelp Responsive output displays a tile for each topic found on the first level of the DITA map (on page 3281). However, you might want to customize the way they look or even to hide some of them.

Depending on your particular setup, you can choose to customize the tiles either by setting metadata information in the DITA map or by customizing the CSS that is associated with the DITA map.

How to Hide Some of the Tiles

If your documentation is very large or there is a large number of topics on the first level, you might want to hide some of the tiles. Also, this might be useful if you only want to display the topics in the first page that are most relevant to your intended audience.

There are two methods for doing this. One of them involves editing the DITA map and marking the topics that do not need to be displayed as tiles, and another one that uses a small CSS customization level to hide some tiles identified by the ID of the topic.

Editing the DITA Map

To edit the metadata in the DITA map to control which topics on the first level of the DITA map will not be displayed as a tile, follow these steps:

1. Open the DITA map in the Text editing mode of Oxygen XML Editor.
2. Add the following metadata information in the `topicref` element (or any of its specializations) for each first-level topic that you do not want to be displayed as a tile:

```xml
<topicmeta>
  <data name="wh-tile">
    <data name="hide" value="yes"/>
  </data>
</topicmeta>
```

**Customizing the CSS**

To customize the CSS to control which topics on the first level of the `DITA map` will not be displayed as a tile, follow these steps:

1. Make sure you set an ID on the topic you want to hide.
2. Create a new CSS file that contains a rule that hides the tile generated for the topic (identified in the following example by the topic ID `growing-flowers`). The CSS file should have content that is similar to this:

```css
.wh_tile [data-id='growing-flowers'] {
  display: none;
}
```
3. Reference the CSS file in a `WebHelp Responsive` transformation using an `Oxygen Publishing Template (on page 1943)` or the `args.css` parameter (on page 1944).

**How to Add an Image to the Tiles**

There are two methods that you can use to add an image to a tile. One of them involves editing the `DITA map`, and the other uses a CSS customization.

**Editing the DITA Map**

To edit the metadata in the `DITA map` to set an image to be displayed in a tile, follow these steps:

1. Open the `DITA map` in the `Text` editing mode of Oxygen XML Editor.
2. Add the following metadata information in the `topicref` element (or any of its specializations) for each first-level topic that will have an image displayed in the corresponding tile:

```xml
<topicmeta>
  <data name="wh-tile">
    <data name="image" href="img/tile-image.png" format="png"/>
    <data name="attr-width" value="64"/>
    <data name="attr-height" value="64"/>
  </data>
</topicmeta>
```
Note: The `attr-width` and `attr-height` attributes can be used to control the size of the image, but they are optional.

Customizing the CSS

To customize the CSS to set an image to be displayed in a tile, follow these steps:

1. Make sure you set an ID on the topic that you want the tile include an image.
2. Create a new CSS file that contains a rule that associates an image with a specific tile. The CSS file should have content that is similar to this:
   ```css
   .wh_tile[data-id='growing-flowers'] > div {
     background-image: url('resources/flower.png');
   }
   ```
3. Reference the CSS file in a WebHelp Responsive transformation using an Oxygen Publishing Template (on page 1943) or the `args.css` parameter (on page 1944).

Adding Graphics and Media Resources

This section contains topics that explain how to add media resources to the published output or the output directory.

How to Copy Additional Resources to Output Directory

You can copy additional resources (such as JavaScript, CSS, or other resources) to the output directory either by using an Oxygen Publishing Template (on page 3285) or the `webhelp.custom.resources` parameter.

Copying Additional Resources to the Output Directory using a Publishing Template

1. If you haven't already created a Publishing Template, see Working with Publishing Templates (on page 1935).
2. Add a new `<fileset>` element in the resources section of the template descriptor file (on page 1899).
3. Open the DITA Map WebHelp Responsive transformation scenario.
4. Click the Choose Custom Publishing Template link and select your template.
5. Click OK to save the changes to the transformation scenario.
6. Run the transformation scenario.

**Results:** All files from the custom resources directory will be copied to the WebHelp Output Directory/oxygen-webhelp/template folder.

### Copying Additional Resources to the Output Directory using a Transformation Parameter

1. Place all your resources in the same directory.
2. Edit the DITA Map WebHelp Responsive transformation scenario and open the Parameters tab.
3. Edit the value of the webhelp.custom.resources parameter and set it to the absolute path of the directory in step 1.
4. Click OK to save the changes to the transformation scenario.
5. Run the transformation scenario.

**Results:** All files from the new directory will be copied to the root of the WebHelp output directory.

### How to Add a Logo Image in the Title Area

You can customize WebHelp Responsive output to include a logo in the title area. It will be displayed before the publication title. You can also specify a URL that can be used to send users to a specific website when they click the logo image.

This customization can be done using an Oxygen Publishing Template or using a transformation scenario from within Oxygen XML Editor/Author.

### Using a Publishing Template

To add a logo in the title area of your WebHelp output using an Oxygen Publishing Template (on page 1892), follow this procedure:
1. If you haven’t already created a Publishing Template, see Working with Publishing Templates (on page 1935).

2. Open the template descriptor file (on page 1895) associated with your publishing template and add the webhelp.logo.image parameter in the parameters section with its value set to path of your logo.

3. If you also want to add a link to your website when you click the logo image, set its URL in the webhelp.logo.image.target.url parameter.

   ```xml
   <publishing-template>
     ...
     <webhelp>
       ...
       <parameters>
         <parameter name="webhelp.logo.image" value="c:\myLogo.jpg"/>
         <parameter name="webhelp.logo.image.target.url" value="http://sample.com"/>
       </parameters>
     </webhelp>
   </publishing-template>
   ```

4. Open the DITA Map WebHelp Responsive transformation scenario.

5. Click the Choose Custom Publishing Template link and select your template.

6. Click OK to save the changes to the transformation scenario.

7. Run the transformation scenario.

**Using a Transformation Scenario in Oxygen XML Editor/Author**

To add a logo in the title area of your WebHelp output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Edit the DITA Map WebHelp Responsive transformation scenario and choose a template.
2. Open the Parameters tab and set the webhelp.logo.image parameter to the path of your logo.
3. If you also want to add a link to your website when you click the logo image, set its URL in the webhelp.logo.image.target.url parameter.
4. Click OK to save the changes to the transformation scenario.
5. Run the transformation scenario.

**How to Add a Favicon in WebHelp Systems**

You can add a custom favicon to your WebHelp output by simply using a parameter in the transformation scenario to point to your favicon image.
This customization can be done using an *Oxygen Publishing Template* or using a transformation scenario from within *Oxygen XML Editor/Author*.

**Using a Publishing Template**

To add a *favicon* to your WebHelp output using an *Oxygen Publishing Template (on page 1892)*, follow this procedure:

1. If you haven't already created a Publishing Template, see *Working with Publishing Templates (on page 1935)*.
2. Open the template descriptor file (on page 1895) associated with your publishing template and add the *webhelp.favicon* parameter in the *parameters* section with its value set to path of your image.

   ```xml
   <publishing-template>
       ...
       <webhelp>
           ...
           <parameters>
               <parameter name="webhelp.favicon" value="c:\myFavicon.jpg"/>
           </parameters>
       </webhelp>
   </publishing-template>
   
3. Open the *DITA Map WebHelp Responsive* transformation scenario.
4. Click the *Choose Custom Publishing Template* link and select your template.
5. Click OK to save the changes to the transformation scenario.
6. Run the transformation scenario.

   **Result:** Browsers that provide *favicon* support will display the *favicon* (typically in the browser's address bar, in the list of bookmarks, and in the history).

**Using a Transformation Scenario in Oxygen XML Editor/Author**

To add a *favicon* to your WebHelp output using a transformation scenario from within *Oxygen XML Editor/Author*, follow this procedure:

1. Edit the *DITA Map WebHelp Responsive* transformation scenario and choose a *template*.
2. Open the *Parameters* tab and set the *webhelp.favicon* parameter to the path of your image.
3. Click OK to save the changes to the transformation scenario.
4. Run the transformation scenario.
How to Add Video and Audio Objects in DITA WebHelp Output

You can insert references to video and audio media resources (such as videos, audio clips, or embedded HTML frames) in your DITA topics and then publish them to WebHelp output. The media objects can be played directly in all HTML5-based outputs, including WebHelp systems.

To add media objects in the WebHelp output generated from DITA documents, follow the procedures below.

### Adding Videos to DITA WebHelp Output

1. Edit the DITA topic and insert a reference to the video through one of the following methods:
   
   - Use the [Insert Media Object](on page 3066).
   - Drag (or copy) the video file from your system explorer or the [Project view](on page 333) and drop (or paste) it into your document.
   - Manually add an `object` element, as in one of the following examples:

     ```xml
     <object outputclass="video" type="video/mp4" data="MyVideo.mp4"/>
     ```

     or, instead of the `data` attribute, you can specify the video using a parameter like this:

     ```xml
     <object outputclass="video">
     <param name="src" value="videos/MyVideo.mp4"/>
     </object>
     ```

2. Apply a [DITA to WebHelp](transformation) transformation to obtain the output.

**Result:** The transformation converts the `object` element to an HTML5 `video` element.

```xml
<video controls="controls">
  <source type="video/mp4" src="MyVideo.mp4"></source>
</video>
```

### Adding Audio Clips to DITA WebHelp Output

1. Edit the DITA topic and insert a reference to the audio clip through one of the following methods:

   - Use the [Insert Media Object](on page 3066).
   - Drag (or copy) the audio file from your system explorer or the [Project view](on page 333) and drop (or paste) it into your document.
   - Manually add an `object` element, as in one of the following examples:

     ```xml
     <object outputclass="audio" type="audio/mpeg" data="MyClip.mp3"/>
     ```

     or, instead of the `data` attribute, you can specify the video using a parameter like this:
2. Apply a **DITA to WebHelp** transformation to obtain the output.

**Result:** The transformation converts the *object* element to an HTML5 *audio* element.

```html
<audio controls="controls">
  <source type="audio/mpeg" src="MyClip.mp3"/>
</audio>
```

### Adding Embedded HTML Frames (such as YouTube videos) to DITA WebHelp Output

1. Edit the DITA topic and insert a reference to the embedded object by using the **Insert Media Object** toolbar action ([on page 3066](#)) or by manually adding an *object* element, as in one of the following examples:

```html
<object outputclass="iframe" data="https://www.youtube.com/embed/m_vv2s5Trn4"/>
```

or, instead of the *data* attribute, you can specify the object using a parameter like this:

```html
<object outputclass="iframe">
  <param name="src" value="http://www.youtube.com/embed/m_vv2s5Trn4"/>
</object>
```

2. If you want the video to be allowed to play in full screen mode once the document is converted to XHTML output, also add an *allowfullscreen* parameter and set its value to `true`:

```html
<object outputclass="iframe" data="https://www.youtube.com/embed/m_vv2s5Trn4"/>
  <param name="allowfullscreen" value="true"/>
</object>
```

**Tip:** If you copy the embed code from the source and paste it into the **Insert Media** dialog box ([see the specific instructions: here (on page 3068)](#)), the *allowfullscreen* parameter will automatically be added and all you have to do is set the value to `true`.

3. Apply a **DITA to WebHelp** transformation to obtain the output.

**Result:** The transformation converts the *object* element to an HTML5 *iframe* element.

```html
<iframe controls="controls" src="https://www.youtube.com/embed/m_vv2s5Trn4"/>
```

For more information, see the following video demonstration:
How to Publish MathML Formulas when Generating WebHelp from a Command Line

The DITA-OT distribution that comes bundled with Oxygen includes some additional pre-installed DITA-OT plugins that add support for properly displaying MathML formulas in the WebHelp output. However, if you are generating your WebHelp output from a command line, MathML formulas will not be displayed properly unless you install these plugins manually.

These plugins can be downloaded and installed from DITA 1.3 Support for Open Toolkit (https://github.com/dita-community/dita13-dita-ot-1.x-support). This plugin package adds DITA 1.3 support, including MathML.

How to Add Support for MathML when Generating WebHelp from a Command Line

1. Download and unzip the DITA 1.3 Support for Open Toolkit 1.x distribution package. It includes 4 DITA-OT plugins.
2. Copy the four plugin directories to your DITA-OT-DIR/plugins directory.
3. In the home directory of your DITA-OT installation, run the ant -f integrator.xml command.

Searching the Output

This section contains topics that explain how to use some of the search features in WebHelp Responsive output.

How to Change Element Scoring in Search Results

The WebHelp Search feature is enhanced with a rating mechanism that computes scores for every page that matches the search criteria. HTML tag elements are assigned a scoring value and these values are evaluated for the search results. The WebHelp directory includes a properties file that defines the scoring values for tag elements and this file can be edited to customize the values according to your needs.

To edit the scoring values of HTML tag element for enhancing WebHelp search results, follow these steps:
1. Edit the scoring properties file for DITA. The properties file includes instructions and examples to help you with your customization. The file is located in: \DITA-OT-DIR\plugins \com.oxygenxml.webhelp.responsive\indexer\scoring.properties. The values that can be edited in the scoring.properties file:

   h1 = 10
   h2 = 9
   h3 = 8
   h4 = 7
   h5 = 6
   h6 = 5
   b = 5
   strong = 5
   em = 3
   i = 3
   u = 3
   div.toc = -10
   title = 20
   div.ignore = ignored
   meta_keywords = 20
   meta_indexterms = 20
   meta_description = 25
   shortdesc = 25

2. Save your changes to the file.

3. Re-run your WebHelp transformation.

How to Exclude Certain DITA Topics from Search Results

There are several ways to exclude certain DITA resources from your WebHelp system's search results. This is useful if you have topics in your DITA map (on page 3281) structure that you do not want to be included in search results for your WebHelp system. The first method involves setting a parameter in the WebHelp transformation scenario and the second involves setting an attribute for each DITA topic reference that you want to exclude.

Transformation Parameter Method

To exclude DITA topics from WebHelp search results using a transformation parameter, follow these steps:
1. Create a simple text file that will contain your excluded file patterns. Each pattern must be on a new line. The patterns are considered to be relative to the output directory and they accept wildcards such as `*` (matches zero or more characters) or `?` (matches one character). For more information about the patterns, see [https://ant.apache.org/manual/dirtasks.html#patterns](https://ant.apache.org/manual/dirtasks.html#patterns).

**Example:** Suppose that in your project, you want to exclude all files located in the `resources` directory and all files located in the `topics` directory that have a `.bak` file extension. You could create a simple text file (for example, named `exclude.properties`), and add the following lines:

```
resources/*
topics/*/bak
```

2. Set the `webhelp.search.custom.excludes.file` parameter to specify the path to the file that contains the excluded file patterns (for example, `exclude.properties` in step 1). The parameter can be specified in the *parameters* section of the template descriptor file (on page 1901) associated with your publishing template or in the Parameters tab of the transformation scenario dialog box in Oxygen XML Editor/Author.

3. Run the transformation.

**Search Attribute Method**

The WebHelp Search engine does not index DITA topics that have the `@search` attribute set to `no`.

To exclude DITA topics from WebHelp search results using this attribute, follow these steps:

1. Edit the DITA map and for any `topicref` that you want to exclude from search results, set the `search` attribute to `no`. For example:

   ```
   <topicref href="../topics/internal-topic1.dita" search="no"/>
   ```

2. Save your changes to the DITA map.

3. Run your WebHelp system transformation.

**How to Optimize Search Results**

A DITA Map WebHelp transformation scenario can be configured to produce a `sitemap.xml` file that is used by search engines to aid crawling and indexing mechanisms. A `sitemap` lists all pages of a WebHelp system and allows webmasters to provide additional information about each page, such as the date it was last updated, change frequency, and importance of each page in relation to other pages in your WebHelp deployment.

The structure of the `sitemap.xml` file looks like this:

```xml
<urlset xmlns="http://www.sitemaps.org/schemas/sitemap/0.9">
```
Each page has a `<url>` element structure containing additional information, such as:

- **loc** - The URL of the page. This URL must begin with the protocol (such as `http`), if required by your web server. It is constructed from the value of the `webhelp.sitemap.base.url` parameter from the transformation scenario and the relative path to the page (collected from the `href` attribute of a `topicref` element in the DITA map).

  - **Note:** The value must have fewer than 2,048 characters.

- **lastmod** (optional) - The date when the page was last modified. The date format is `YYYY-MM-DD`.

- **changefreq** (optional) - Indicates how frequently the page is likely to change. This value provides general information to assist search engines, but may not correlate exactly to how often they crawl the page. Valid values are: *always*, *hourly*, *daily*, *weekly*, *monthly*, *yearly*, and *never*. The first time the `sitemap.xml` file is generated, the value is set based upon the value of the `webhelp.sitemap.change.frequency` parameter in the DITA WebHelp transformation scenario. You can change the value in each `url` element by editing the `sitemap.xml` file.

  - **Note:** The value *always* should be used to describe documents that change each time they are accessed. The value *never* should be used to describe archived URLs.

- **priority** (optional) - The priority of this page relative to other pages on your site. Valid values range from 0.0 to 1.0. This value does not affect how your pages are compared to pages on other sites. It only lets the search engines know which pages you deem most important for the crawlers.

  - The first time the `sitemap.xml` file is generated, the value is set based upon the value of the `webhelp.sitemap.priority` parameter in the DITA WebHelp transformation scenario. You can change the value in each `url` element by editing the `sitemap.xml` file.
Creating and Editing the sitemap.xml File

Follow these steps to produce a sitemap.xml file for your WebHelp system, which can then be edited to fine-tune search engine optimization:

1. Edit the transformation scenario you currently use for obtaining your WebHelp output. This opens the Edit DITA Scenario dialog box.
2. Open the Parameters tab and set a value for the following parameters:
   - **webhelp.sitemap.base.url** - The URL of the location where your WebHelp system is deployed.
     - **Note:** This parameter is required for Oxygen XML Editor to generate the sitemap.xml file.
   - **webhelp.sitemap.change.frequency** - How frequently the WebHelp pages are likely to change (accepted values are: always, hourly, daily, weekly, monthly, yearly, and never).
   - **webhelp.sitemap.priority** - The priority of each page (value ranging from 0.0 to 1.0).
3. Run the transformation scenario.
4. Look for the sitemap.xml file in the transformation's output folder. Edit the file to fine-tune the parameters of each page, according to your needs.

How to Index Japanese Content

To optimize the indexing of Japanese content in WebHelp pages, the Lucene Kuromoji Japanese analyzer can be used. This analyzer is included in the Oxygen XML Editor/Author installation kit.

Using a Publishing Template

To add a logo in the title area of your WebHelp output using an Oxygen Publishing Template (on page 1892), follow this procedure:

1. If you haven't already created a Publishing Template, see Working with Publishing Templates (on page 1935).
2. Open the template descriptor file (on page 1895) associated with your publishing template and add the `default.language` parameter in the `parameters` section with its value set to `ja-jp`.

```xml
<publishing-template>
  ...
  <webhelp>
    ...
    <parameters>
      <parameter name="default.language" value="ja-jp"/>
    </parameters>
  </webhelp>
  ...
</publishing-template>
```
3. Open the DITA Map WebHelp Responsive transformation scenario.
4. Click the Choose Custom Publishing Template link and select your template.
5. Click OK to save the changes to the transformation scenario.
6. Run the transformation scenario.

Using a Transformation Scenario in Oxygen XML Editor/Author

To activate the Japanese indexing in your WebHelp output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Edit a DITA to WebHelp transformation scenario and in the Parameters tab, set the value of the default.language parameter to ja-jp.

   **Note:** Alternatively, you could set the xml:lang attribute on the root of the DITA map (on page 3281) and the referenced topics to ja-jp. Another alternative for DITA output is to use the webhelp.search.japanese.dictionary parameter to specify a path to a Japanese dictionary that will be used by the Kuromoji morphological engine (note that the encoding for the dictionary must be UTF8).

2. Run the WebHelp transformation scenario to generate the output.

Localization

This section contains topics that explain how to use the localization support in WebHelp Responsive output.

How to Localize Email Notifications of Feedback System

The feedback-enabled WebHelp Responsive systems use emails to notify users when comments are posted. These emails are based on templates stored in the WebHelp directory. The default messages are in English, French, German, and Japanese. These messages are copied into the WebHelp system deployment directory during the execution of the corresponding transformation scenario.

Using a Publishing Template

To change the language of the emails for DITA Map WebHelp Responsive with Feedback output using an Oxygen Publishing Template (on page 1892), follow this procedure:

1. Create the following directory:
2. Copy all English template files from `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.responsive\oxygen-webhelp\resources\php\templates\en` and paste them into the directory you just created.

3. Edit the HTML files from the `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.responsive\oxygen-webhelp\resources\php\templates\nl` directory and translate the content into your language.

4. Open the template descriptor file (on page 1895) associated with your publishing template and add the `default.language` parameter in the `parameters` section with its value set to the appropriate language code (for example, `nl` for Dutch).

   ![Note: If you set the parameter to a value such as `LanguageCode-CountryCode` (for example, `en-us`), the transformation scenario will only use the language code.]

   ```xml
   <publishing-template>
     ...
     <webhelp>
       ...
       <parameters>
         <parameter name="default.language" value="nl"/>
       </parameters>
     </webhelp>
   </publishing-template>
   
   5. Open the `DITA Map WebHelp Responsive` transformation scenario.
   6. Click the Choose Custom Publishing Template link and select your template.
   7. Click OK to save the changes to the transformation scenario.
   8. Run the transformation scenario.

Using a Transformation Scenario in Oxygen XML Editor/Author

To change the language of the emails for DITA Map WebHelp Responsive with Feedback output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Create the following directory:

   ```
   DITA-OT-DIR\plugins\com.oxygenxml.webhelp.responsive\oxygen-webhelp\resources\php\templates\nl
   ```

2. Copy all English template files from `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.responsive\oxygen-webhelp\resources\php\templates\en` and paste them into the directory you just created.
3. Edit the HTML files from the `DITA-OT-DIR\plugins \com.oxygenxml.webhelp.responsive\oxygen-webhelp\resources\php \templates\nl` directory and translate the content into your language.

4. Edit a DITA Map WebHelp Responsive transformation scenario and open the Parameters tab.

5. In the Parameters tab, look for the default.language parameter and set its value to the appropriate language code (for example, `nl` for Dutch).

   **Note:** If you set the parameter to a value such as `LanguageCode-CountryCode` (for example, `en-us`), the transformation scenario will only use the language code.

6. Run the transformation scenario.

**How to Localize the Interface of WebHelp Responsive Output**

Static labels used in the WebHelp output are stored in translation files that have the `strings-lang1-lang2.xml` name format, where `lang1` and `lang2` are ISO language codes. For example, the US English labels are kept in the `strings-en-us.xml` file.

These translation files are collected from two locations:

- `DITA-OT-DIR/xsl/common` folder - DITA-OT's default translations (generated text for `note`, `fig`, and `table` elements).
- `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/oxygen-webhelp/resources/localization` folder - These translations are contributed by the WebHelp plugin and extend the default ones provided by DITA-OT. The labels defined in this folder take precedence over the DITA-OT defaults.

There are two major reasons you may want to use modify the translation files: to modify the existing strings or to translate to a new language.

---

**Related Information:**

- How to Index Japanese Content *(on page 1971)*
- Customizing Generated Text
Modifying the Existing Strings

To modify the generated text for WebHelp transformations, you need to create a DITA-OT extension plugin that uses the dita.xsl.messages extension point. The following procedure is for changing English labels, but you can adapt it for any language:

1. Create a com.oxygenxml.webhelp.localization plugin directory inside the DITA-OT-DIR/plugins/ location.
2. Create a plugin.xml file inside that com.oxygenxml.webhelp.localization directory with the following content:

```xml
<plugin id="com.oxygenxml.webhelp.localization">
  <require plugin="com.oxygenxml.webhelp.classic"/>
  <require plugin="com.oxygenxml.webhelp.responsive"/>
  <feature extension="dita.xsl.strings" file="webhelp-extension-strings.xml"/>
</plugin>
```

3. Create a webhelp-extension-strings.xml file with the following content:

```xml
<langlist>
  <lang xml:lang="en" filename="strings-en-us.xml"/>
  <lang xml:lang="en-us" filename="strings-en-us.xml"/>
</langlist>
```

4. Copy the strings you want to change from the translation files (on page 1974) to the strings-en-us.xml file. Make sure you leave the name attribute unchanged because this is the key used to look up the string. A sample content might be:

```xml
<strings xml:lang="en-US">
  <str name="Figure">Fig</str>
  <str name="Draft comment">ADDRESS THIS DRAFT COMMENT</str>
</strings>
```

5. Use the Run DITA-OT Integrator transformation scenario (on page 1665) found in the DITA Map section in the Configure Transformation Scenario(s) dialog box (on page 1762).

Adding a New Language

To add a new language for WebHelp transformations, you need to create a DITA-OT extension plugin that uses the dita.xsl.messages extension point. The following sample procedure is for adding translation files for the Polish language, but you can adapt it for any language:
1. Create a `com.oxygenxml.webhelp.localization` plugin directory inside the `DITA-OT-DIR/plugins/` location.

2. Create a `plugin.xml` file inside that `com.oxygenxml.webhelp.localization` directory with the following content:

   ```xml
   <plugin id="com.oxygenxml.webhelp.localization">
   <require plugin="com.oxygenxml.webhelp.classic"/>
   <require plugin="com.oxygenxml.webhelp.responsive"/>
   <feature extension="dita.xsl.strings" file="webhelp-extension-strings.xml"/>
   </plugin>
   ```

3. Create a `webhelp-extension-strings.xml` file with the following content:

   ```xml
   <langlist>
   <lang xml:lang="pl" filename="strings-pl-pl.xml"/>
   <lang xml:lang="pl-PL" filename="strings-pl-pl.xml"/>
   </langlist>
   ```

5. In the `strings-pl-pl.xml` file, change the `@xml:lang` attribute on the root element that conforms with the new language.

   ```xml
   <strings xml:lang="pl-PL">
   ...
   </strings>
   ```

6. Translate the content of each `<str>` element (make sure to leave the `name` attribute unchanged).

   ```xml
   <strings xml:lang="pl-PL">
   ...
   <str name="webhelp.content" js="true" php="false">Polish translation for "Content".</str>
   <str name="webhelp.search" js="true" php="false">Polish translation for "Search"</str>
   ...
   </strings>
   ```

7. Copy the common DITA-OT strings defined in the `DITA-OT-DIR/xsl/common/strings-en-us.xml` file. It defines a set generated text available for HTML-based transformations (such as `note`, `fig`, and `table` elements). Translate the content of each `<str>` element.

   ```xml
   <strings xml:lang="pl-PL">
   ```
8. Use the Run DITA-OT Integrator transformation scenario (on page 1665) found in the DITA Map section in the Configure Transformation Scenario(s) dialog box (on page 1762).

How to Activate Support for Right-to-Left (RTL) Languages

To activate support for RTL (right-to-left) languages in WebHelp output, edit the DITA map (on page 3281) and set the xml:lang attribute on its root element (map). The corresponding attribute value can be set for following RTL languages:

- ar-eg - Arabic
- he-il - Hebrew
- ur-pk - Urdu

Integrating Social Media and Google Tools in the WebHelp Output

This section contains topics that explain how to integrate some of the most popular social media sites in WebHelp output.

How to Add a Facebook Like Button in WebHelp Responsive Output

It is possible to integrate Facebook into your WebHelp Responsive output and you can specify where you want the widget to appear in your WebHelp page.

Using a Publishing Template

To add a Facebook Like widget to your WebHelp output using an Oxygen Publishing Template (on page 1892), follow this procedure:

1. Go to the Facebook Developers website.
2. Fill in the displayed form, then click the Get Code button.
3. Copy the two code snippets and paste them into a `<div>` element inside an XML file called `facebook-widget.xml`. Make sure you follow these rules:

   • The file must be well-formed.
   • The code for each `script` element must be included in an XML comment.
   • The start and end tags for the XML comment must be on a separate line.

   The content of the XML file should look like this:

   ```xml
   <div id="facebook">
   <div id="fb-root"/>
   <script>
   <!--
   (function(d, s, id) {
     var js, fjs = d.getElementsByTagName(s)[0];
     if (d.getElementById(id)) return;
     js = d.createElement(s); js.id = id;
     js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
     fjs.parentNode.insertBefore(js, fjs);
   })(document, 'script', 'facebook-jssdk');
   -->
   </script>
   <div class="fb-like" data-layout="standard" data-action="like"
    data-show-faces="true" data-share="true"/>
   </div>
   ```

4. Open the template descriptor file (on page 1895) associated with your publishing template.

5. Use one of the parameters that begin with `webhelp.fragment` (on page 1902) in the `html-fragments` section of the descriptor file. Set the value of that parameter to reference the `facebook-widget.xml` file that you created earlier.

   ```xml
   <publishing-template>
   ...
   <webhelp>
   ...
   <html-fragments>
   <fragment
    file="HTML-fragments/facebook-widget.xml"
    placeholder="webhelp.fragment.after.toc_or_tiles"/>
   </html-fragments>
   </webhelp>
   </publishing-template>
   ```

6. Open the DITA Map WebHelp Responsive transformation scenario.

7. Click the Choose Custom Publishing Template link and select your template.
8. Click OK to save the changes to the transformation scenario.
9. Run the transformation scenario.

Using a Transformation Scenario in Oxygen XML Editor/Author

To add a Facebook Like widget to your WebHelp output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Go to the Facebook Developers website.
2. Fill in the displayed form, then click the Get Code button.
3. Copy the two code snippets and paste them into a <div> element inside an XML file called facebook-widget.xml. Make sure you follow these rules:
   - The file must be well-formed.
   - The code for each script element must be included in an XML comment.
   - The start and end tags for the XML comment must be on a separate line.

The content of the XML file should look like this:

```xml
<div id="facebook">
  <div id="fb-root"/>
  <script>
    <!--
    (function(d, s, id) {
      var js, fjs = d.getElementsByTagName(s)[0];
      if (d.getElementById(id)) return;
      js = d.createElement(s); js.id = id;
      js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
      fjs.parentNode.insertBefore(js, fjs);
    }(document, 'script', 'facebook-jssdk'));
    -->
  </script>
  <div class="fb-like" data-layout="standard" data-action="like"
    data-show-faces="true" data-share="true"/>
</div>
```

4. Edit the DITA Map WebHelp Responsive transformation scenario and choose a template.
5. Switch to the Parameters tab. Depending on where you want to display the button, edit one of the parameters that begin with webhelp.fragment (on page 1902). Set that parameter to reference the facebook-widget.xml file that you created earlier.
6. Click Ok and run the transformation scenario.
How to Add a Google+ Button in WebHelp Responsive Output

It is possible to integrate Google into your WebHelp Responsive output and you can specify where you want the widget to appear in your WebHelp page.

Using a Publishing Template

To add a Google+ widget to your WebHelp Responsive output using an Oxygen Publishing Template (on page 1892), follow this procedure:

1. Go to the Google Developers website.
2. Fill in the displayed form. The preview area on the right side displays the code and a preview of the widget.
3. Copy the code snippet displayed in the preview area and paste it into a div element inside an XML file called google-plus-button.xml. Make sure that the content of the file is well-formed. The content of the XML file should look like this:

```xml
<div id="google-plus">
  <!-- Place this tag in your head or just before your close body tag. -->
  <script src="https://apis.google.com/js/platform.js" async defer></script>
  <!-- Place this tag where you want the +1 button to render. -->
  <div class="g-plusone" data-annotation="inline" data-width="300"></div>
</div>
```
4. Open the template descriptor file (on page 1895) associated with your publishing template.
5. Use one of the parameters that begin with webhelp.fragment (on page 1902) in the html-fragments section of the descriptor file. Set the value of that parameter to reference the google-plus-button.xml file that you created earlier.

```xml
<publishing-template>
  ...
  <webhelp>
    ...
    <html-fragments>
      <fragment
        file="HTML-fragments/google-plus-button.xml"
        placeholder="webhelp.fragment.after.toc_or_tiles"/>
    </html-fragments>
  </webhelp>
</publishing-template>
```
6. Open the DITA Map WebHelp Responsive transformation scenario.
7. Click the Choose Custom Publishing Template link and select your template.
8. Click OK to save the changes to the transformation scenario.
9. Run the transformation scenario.

**Using a Transformation Scenario in Oxygen XML Editor/Author**

To add a Google+ widget to your WebHelp Responsive output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Go to the Google Developers website.
2. Fill in the displayed form. The preview area on the right side displays the code and a preview of the widget.
3. Copy the code snippet displayed in the preview area and paste it into a div element inside an XML file called google-plus-button.xml. Make sure that the content of the file is well-formed. The content of the XML file should look like this:

```xml
<div id="google-plus">
  <!-- Place this tag in your head or just before your close body tag. -->
  <script src="https://apis.google.com/js/platform.js" async defer></script>
  <!-- Place this tag where you want the +1 button to render. -->
  <div class="g-plusone" data-annotation="inline" data-width="300"></div>
</div>
```
4. Edit the DITA Map WebHelp Responsive transformation scenario and choose a template.
5. Switch to the Parameters tab. Depending on where you want to display the button, edit one of the parameters that begin with webhelp.fragment (on page 1902). Set that parameter to reference the google-plus-button.xml file that you created earlier.
6. Click Ok and run the transformation scenario.

**How to Add Tweet Button in WebHelp Responsive Output**

It is possible to integrate Twitter into your WebHelp Responsive output and you can specify where you want the widget to appear in your WebHelp page.

**Using a Publishing Template**

To add a Twitter Tweet widget to your WebHelp Responsive output using an Oxygen Publishing Template (on page 1892), follow this procedure:

1. Go to the Tweet button generator page.
2. Fill in the displayed form. The Preview and code area displays the code that you will need.
3. Copy the code snippet displayed in the Preview and code area and paste it into a div element inside an XML file called tweet-button.xml. Make sure you follow these rules:
The file must be well-formed.

- The code for each `<script>` element must be included in an XML comment.
- The start and end tags for the XML comment must be on a separate line.

The content of the XML file should look like this:

```xml
<div id="twitter">
  <a href="https://twitter.com/share" class="twitter-share-button">Tweet</a>
  <script>
    <!--
    !function (d, s, id) {
      var js, fjs = d.getElementsByTagName(s)[0], p = /^http:/test(d.location) ? 'http': 'https';
      if (! d.getElementById(id)) {
        js = d.createElement(s);
        js.id = id;
        js.src = p + '://platform.twitter.com/widgets.js';
        fjs.parentNode.insertBefore(js, fjs);
      }
    }
    (document, 'script', 'twitter-wjs');
    -->
  </script>
</div>
```

4. Open the template descriptor file (on page 1895) associated with your publishing template.
5. Use one of the parameters that begin with `webhelp.fragment` (on page 1902) in the `html-fragments` section of the descriptor file. Set the value of that parameter to reference the `tweet-button.xml` file that you created earlier.

```xml
<publishing-template>
  ...
  <webhelp>
    ...
    <html-fragments>
      <fragment
        file="HTML-fragments/tweet-button.xml"
        placeholder="webhelp.fragment.after.toc_or_tiles"/>
    </html-fragments>
  </webhelp>
</publishing-template>
```

6. Open the DITA Map WebHelp Responsive transformation scenario.
7. Click the **Choose Custom Publishing Template** link and select your template.

8. Click **OK** to save the changes to the transformation scenario.

9. Run the transformation scenario.

**Using a Transformation Scenario in Oxygen XML Editor/Author**

To add a Twitter Tweet widget to your WebHelp Responsive output using a transformation scenario from within **Oxygen XML Editor/Author**, follow this procedure:

1. Go to the **Tweet button generator** page.

2. Fill in the displayed form. The **Preview and code** area displays the code that you will need.

3. Copy the code snippet displayed in the **Preview and code** area and paste it into a **div** element inside an XML file called `tweet-button.xml`. Make sure you follow these rules:
   - The file must be well-formed.
   - The code for each **script** element must be included in an XML comment.
   - The start and end tags for the XML comment must be on a separate line.

   The content of the XML file should look like this:

   ```xml
   <div id="twitter">
   <a href="https://twitter.com/share" class="twitter-share-button">Tweet</a>
   <script>
     !function (d, s, id) {
       var js, fjs = d.getElementsByTagName(s)[0], p = /^http:/.test(d.location) ? 'http' : 'https';
       if (!d.getElementById(id)) {
         js = d.createElement(s);
         js.id = id;
         js.src = p + '://platform.twitter.com/widgets.js';
         fjs.parentNode.insertBefore(js, fjs);
       }
     }
     (document,
     'script', 'twitter-wjs');
   -->
   </script>
   </div>
   ```

   4. Edit the **DITA Map WebHelp Responsive** transformation scenario and choose a **template**.
5. Switch to the **Parameters** tab. Depending on where you want to display the button, edit one of the parameters that begin with `webhelp.fragment` (on page 1902). Set that parameter to reference the `tweet-button.xml` file that you created earlier.

6. Click **Ok** and run the transformation scenario.

**How to Integrate Google Analytics in WebHelp Responsive Output**

You can use *Google Analytics* to track and report site data for your *WebHelp Responsive* output.

**Using a Publishing Template**

To integrate *Google Analytics* into your WebHelp Responsive output using an *Oxygen Publishing Template* (on page 1892), follow this procedure:

1. Create a new *Google Analytics account* (if you do not already have one) and log on.
2. Choose the Analytics solution that best fits the needs of your website.
3. Follow the on-screen instructions to obtain a **Tracking Code** that contains your Tracking ID. A Tracking Code looks like this:

```xml
<script>
(function(i,s,o,g,r,a,m){i['GoogleAnalyticsObject']=r;i[r]=i[r]||function()
(i[r].q=i[r].q||[]).push(arguments),i[r].l=1*new Date();a=s.createElement(o),
m=s.getElementsByTagName(o)[0];a.async=1;a.src=g;m.parentNode.insertBefore(a,m)
}(window,document,'script','//www.google-analytics.com/analytics.js','ga'));

ga('create','UA-XXXXXXXX-X','auto');
ga('send','pageview');
</script>
```

4. Save the Tracking Code (obtained in the previous step) in a new XML file called `googleAnalytics.xml`. Note that the file should only contain the tracking code.

5. Open the **template descriptor file** (on page 1895) associated with your publishing template.

6. Use the `webhelp.fragment.after.body` parameter (on page 2005) in the **html-fragments** section of the descriptor file. Set the value of that parameter to reference the `googleAnalytics.xml` file that you created earlier. The content of this file will be copied at the end of all generated output pages, right before the ending `<body>` element. This ensures that the page is loaded before the Google Analytics servers are contacted, thus reducing page loading time.

```xml
<publishing-template>
...
<webhelp>
...
```
7. Open the DITA Map WebHelp Responsive transformation scenario.
8. Click the Choose Custom Publishing Template link and select your template.
9. Click OK to save the changes to the transformation scenario.
10. Run the transformation scenario.

Using a Transformation Scenario in Oxygen XML Editor/Author

To integrate Google Analytics into your WebHelp Responsive output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Create a new Google Analytics account (if you do not already have one) and log on.
2. Choose the Analytics solution that best fits the needs of your website.
3. Follow the on-screen instructions to obtain a Tracking Code that contains your Tracking ID. A Tracking Code looks like this:

```html
<script>
(function(i,s,o,g,r,a,m){i['GoogleAnalyticsObject']=r;i[r]=i[r]|||
function(){
(i[r].q=i[r].q||[]).push(arguments)},i[r].l=1*
new Date();a=s.createElement(o),
m=s.getElementsByTagName(o)[0];a.async=1;a.src=g;m.parentNode.insertBefore(a,m)
}(window,document,'script','//www.google-analytics.com/analytics.js','ga'));

ga('create', 'UA-XXXXXXXX-X', 'auto');
ga('send', 'pageview');
</script>
```
4. Save the Tracking Code (obtained in the previous step) in a new XML file called googleAnalytics.xml. Note that the file should only contain the tracking code.
5. Edit the DITA Map WebHelp Responsive transformation scenario and choose a template.
6. Switch to the Parameters tab. Edit the webhelp.fragment.after.body parameter (on page 2005) and set it to reference the googleAnalytics.xml file that you created earlier. The content of this file will be copied at the end of all generated output pages, right before the ending <body> element. This ensures that the page is loaded before the Google Analytics servers are contacted, thus reducing page loading time.
7. Click Ok and run the transformation scenario.
How to Integrate Google Search in WebHelp Responsive Output

It is possible to integrate the Google Search Engine into your WebHelp Responsive output and you can specify where you want the results to appear in your WebHelp page.

Using a Publishing Template

To integrate the Google Search Engine into your WebHelp Responsive output using an Oxygen Publishing Template (on page 1892), follow this procedure:

1. Go to the Google Custom Search Engine page using your Google account.
2. Select the Create a custom search engine button.
3. Follow the on-screen instructions to create a search engine for your site. At the end of this process you should obtain a code snippet that looks like this:

```html
<script>
(function() {
  var cx = '00088821088975888983:8mn4x_mf-yg';
  var gsc = document.createElement('script');
  gsc.type = 'text/javascript';
  gsc.async = true;
  var s = document.getElementsByTagName('script')[0];
  s.parentNode.insertBefore(gsc, s);
})();
</script>
```
4. Save the script into a well-formed HTML file called googlecse.html.
5. Open the template descriptor file (on page 1895) associated with your publishing template and add the `webhelp.google.search.script` parameter in the parameters section with its value set to reference the googlecse.html file that you created earlier.

```xml
<publishing-template>
...
</publishing-template>

<webhelp>
...
</webhelp>

<parameters>
  ...
  <parameter name="webhelp.google.search.script" value="resources/googlecse.html"/>
  ...
</parameters>
```
6. You can also use the `webhelp.google.search.results` parameter to choose where to display the search results.
   a. Create an HTML file with the following content:
      ```html
      <div class="gcse-searchresults-only" data-autoSearchOnLoad="true" data-queryParameterName="searchQuery"></div>  
      ```
      (you must use the HTML5 version for the GCSE). For more information about other supported attributes, see Google Custom Search: Supported Attributes.
   b. Set the value of the `webhelp.google.search.results` parameter to the file path of the file you just created. If this parameter is not specified, the following code is used:
      ```html
      <div class="gcse-searchresults-only" data-autoSearchOnLoad="true" data-queryParameterName="searchQuery"></div>  
      ```

7. Open the DITA Map WebHelp Responsive transformation scenario.
8. Click the Choose Custom Publishing Template link and select your template.
9. Click OK to save the changes to the transformation scenario.
10. Run the transformation scenario.

Using a Transformation Scenario in Oxygen XML Editor/Author

To integrate the Google Search Engine into your WebHelp Responsive output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Go to the Google Custom Search Engine page using your Google account.
2. Select the Create a custom search engine button.
3. Follow the on-screen instructions to create a search engine for your site. At the end of this process you should obtain a code snippet that looks like this:

   ```javascript
   (function() {
     var cx = '00088210889775888983:8mn4x_mf-yg';
     var gcse = document.createElement('script');
     gcse.type = 'text/javascript';
     gcse.async = true;
     var s = document.getElementsByTagName('script')[0];
     s.parentNode.insertBefore(gcse, s);
   })();
   ```
4. Save the script into a well-formed HTML file called `googlecse.html`

5. Edit the DITA Map WebHelp Responsive transformation scenario and choose a template.

6. Switch to the **Parameters** tab and edit the `webhelp.google.search.script` parameter to reference the `googlecse.html` file that you created earlier.

7. You can also use the `webhelp.google.search.results` parameter to choose where to display the search results.
   a. Create an HTML file with the following content:
      ```html
      <div class="gcse-searchresults-only" data-autoSearchOnLoad="true" data-queryParameterName="searchQuery"></div>
      ```
      (you must use the [HTML5 version for the GCSE](https://developers.google.com/custom-search/v1/overview)). For more information about other supported attributes, see [Google Custom Search: Supported Attributes](https://developers.google.com/custom-search/v1/overview).
   b. Set the value of the `webhelp.google.search.results` parameter to the file path of the file you just created. If this parameter is not specified, the following code is used:
      ```html
      <div class="gcse-searchresults-only" data-autoSearchOnLoad="true" data-queryParameterName="searchQuery"></div>
      ```

8. Click **Ok** and run the transformation scenario.

**XSLT Extensions for WebHelp Responsive Transformations**

Since WebHelp Responsive output is primarily obtained by running XSLT transformations over the DITA input files, one customization method would be to override the default XSLT templates that are used by the WebHelp Responsive transformations.

There are two methods available to override the XSLT stylesheets implied by the WebHelp Responsive transformation.

  **Note**: Use this method if you want to affect only the transformations that use this publishing template.

- Use **XSLT-import extension points** from a DITA-OT extension plugin.

  **Note**: This method will affect all the outputs generated with the WebHelp system.

**Related Information:**

**How to Use XSLT Extension Points from a Publishing Template**

Use Case 1: Add Copyright Information Extracted from a DITA Bookmap

Suppose you want to customize the WebHelp Responsive main page by adding information about the legal rights associated with the book in the footer (for example, copyright dates and owner). This information is specified in the bookmap:

```xml
<bookrights>
  <copyrfirst>
    <year>2002</year>
  </copyrfirst>
  <copyrlast>
    <year>2017</year>
  </copyrlast>
  <bookowner>
    <organization>SyncRO Soft SRL</organization>
  </bookowner>
</bookrights>
```

Figure 635. Example: Copyright information added in the WebHelp footer

The XSLT stylesheet that generates the main page is located in: $DITA-CT-DIR\plugins\com.oxygenxml.webhelp.responsive\xsl\mainFiles\createMainPage.xsl. This XSLT stylesheet declares the `copy_template` mode that processes the main page template (on page 1910) to expand its components. The main page template declares a component for the footer section that looks like this:

```html
<div class="footer-container text-center">
  <whc:include_html href="${webhelp.fragment.footer}"/>
</div>
```

In the following example, the extension stylesheet will add a template that matches this component. It applies the default processing and adds the copyright information at the end.

```xml
<xsl:template match="*:div[contains(@class, 'footer-container')]" mode="copy_template">
  <!-- Apply the default processing -->
```
To add this functionality using a Oxygen Publishing Template, follow these steps:

1. If you haven't already created a Publishing Template, see Working with Publishing Templates (on page 1935).
2. Link the folder associated with the publishing template to your current project in the **Project** view.
   You should have the `custom_footer_template` folder linked in your project.

3. Using the **Project** view, create an `xslt` folder inside the project root folder.
   You should have the `custom_footer_template/xsl` folder in your project.

4. Create your customization stylesheet (for example, `custom_mainpage.xsl`) in the
   `custom_footer_template/xsl` folder. Edit it to override the template that produces the footer section:

   ```xml
   <xsl:template match="*:div[contains(@class, 'Footer-container')]" mode="copy_template">
     <!-- Apply the default processing -->
     <xsl:next-match/>
   </xsl:template>

   <!-- Add a div containing the copyright information -->
   <div class="copyright_info">
     <xsl:choose>
       <!-- Adds the start-end years if they are defined -->
       <xsl:when test="exists($toc/*:topicmeta/*:bookrights/*:copyrfirst) and exists($toc/*:topicmeta/*:bookrights/*:copyrlast)">
         <span class="copyright_years">
           ©<xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:copyrfirst"/>
           -<xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:copyrlast"/>
         </span>
       </xsl:when>
       <!-- Adds only the first year if last is not defined. -->
       <xsl:when test="exists($toc/*:topicmeta/*:bookrights/*:copyrfirst)">
         <span class="copyright_years">
           ©<xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:copyrfirst"/>
         </span>
       </xsl:when>
     </xsl:choose>

     <!-- Adds the bookowner organization if defined -->
     <xsl:if test="exists($toc/*:topicmeta/*:bookrights/*:bookowner/*:organization)">
       <span class="organization">
         <xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:bookowner/*:organization"/>
       </span>
     </xsl:if>
   </div>
   ```
5. Open the template descriptor file *(on page 1895)* associated with your publishing template and set the XSLT stylesheet created in previous step with the `com.oxygenxml.webhelp.xsl.createMainPage` XSLT extension point.

6. Open the DITA Map WebHelp Responsive transformation scenario.

7. Click the Choose Custom Publishing Template link and select your template.

8. Click OK to save the changes to the transformation scenario.

9. Run the transformation scenario.

**Use Case 2: Add generation time in the output footer**

Another possible customization for the main page is to add the generation time in its footer. A transformation parameter is used to control whether or not this customization is active.

**Figure 636. Generation time added in the WebHelp footer**

To add this functionality, follow these steps:
1. In the customization stylesheet that you just created (for example, `custom_mainpage.xsl`), modify the template by adding the following XSLT code at the end.

```xml
<xsl:if test="oxyf:getParameter('webhelp.footer.add.generation.time') = 'yes'">
  <div class="generation_time">
    Generation date: <xsl:value-of select="format-dateTime(current-dateTime(), '[h1]:[m01] [P] on [M01]/[D01]/[Y0001].')"/>
  </div>
</xsl:if>

**Note:** You can read the value of a WebHelp transformation parameter from your XSLT extension stylesheets by using the `getParameter(param.name)` function from the `http://www.oxygenxml.com/functions` namespace.

2. Open the template descriptor file (on page 1895) associated with your publishing template and set the `webhelp.footer.add.generation.time` parameter to the default value.

```xml
<publishing-template>
  ...
  <webhelp>
    ...
    <parameters>
      <parameter
        name="webhelp.footer.add.generation.time"
        value="yes"/>
    </parameters>
  </webhelp>
  ...
</publishing-template>
```

3. Open the DITA Map WebHelp Responsive transformation scenario.

4. In the Parameters tab, you can change the value of the `webhelp.footer.add.generation.time` parameter.

5. Click OK to save the changes to the transformation scenario.

6. Run the transformation scenario.

**How to Use XSLT Extension Points from a DITA-OT Plugin**

In this example, the main page footer is modified by adding copyright information extracted from the DITA bookmap or by adding the output generation time. The first use-case uses an XSLT-Import extension point while the second uses an XSLT-Parameter extension point.
**Note:** This customization is available as a GitHub project at: https://github.com/oxygenxml/com.oxygenxml.webhelp.responsive.custom.footer.

**Use Case 1: WebHelp XSLT-Import extension point to add copyright information extracted from a DITA Bookmap**

Suppose you want to customize the WebHelp Responsive main page by adding information about the legal rights associated with the book in the footer (for example, copyright dates and owner). This information is specified in the bookmap:

```xml
<bookrights>
  <copyrfirst>
    <year>2002</year>
  </copyrfirst>
  <copyrlast>
    <year>2017</year>
  </copyrlast>
  <bookowner>
    <organization>SyncRO Soft SRL</organization>
  </bookowner>
</bookrights>
```

Figure 637. Example: Copyright information added in the WebHelp footer

The XSLT stylesheet that generates the main page is located in: DITA-OT-DIR\plugins\com.oxygenxml.webhelp.responsive\xsl\mainFiles\createMainPage.xsl. This XSLT stylesheet declares the `copy_template` mode that processes the main page template to expand its components. The main page template (on page 1910) declares a component for the footer section that looks like this:

```xml
<div class="footer-container text-center">
  <whc:include_html href="${webhelp.fragment.footer}"/>
</div>
```
In the following example, the extension stylesheet will add a template that matches this component. It applies the default processing and adds the copyright information at the end.

```xml
<xsl:template match="*:div[contains(@class, 'footer-container')]" mode="copy_template">
  <!-- Apply the default processing -->
  <xsl:next-match/>

  <!-- Add a div containing the copyright information -->
  <div class="copyright_info">
    <xsl:choose>
      <!-- Adds the start-end years if they are defined -->
      <xsl:when test="exists($toc/*:topicmeta/*:bookrights/*:copyrfirst) and exists($toc/*:topicmeta/*:bookrights/*:copyrlast)">
        <span class="copyright_years">
          ©<xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:copyrfirst"/>
          -<xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:copyrlast"/>
        </span>
      </xsl:when>
      <!-- Adds only the first year if last is not defined. -->
      <xsl:when test="exists($toc/*:topicmeta/*:bookrights/*:copyrfirst)">
        <span class="copyright_years">
          ©<xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:copyrfirst"/>
        </span>
      </xsl:when>
    </xsl:choose>

    <!-- Adds only the first year if last is not defined. -->
    <xsl:if test="exists($toc/*:topicmeta/*:bookrights/*:bookowner/*:organization)">
      <span class="organization">
        <xsl:if test="exists($toc/*:topicmeta/*:bookrights/*:bookowner/*:organization)">
          <xsl:comment>
            . All rights reserved.</xsl:comment>
        </xsl:if>
      </span>
    </xsl:if>
  </div>
</xsl:template>
```
You can implement this functionality with a WebHelp extension plugin that uses the `com.oxygenxml.webhelp.xsl.createMainPage` extension point (on page 2012). This extension point allows you to specify a customization stylesheet that will override the template described above.

To add this functionality as a DITA-OT plugin, follow these steps:

1. In the `DITA-OT-DIR\plugins\` folder, create a folder for this plugin (for example, `com.oxygenxml.webhelp.responsive.custom.footer`).
2. Create a `plugin.xml` file (in the folder you created in step 1) that specifies the extension point and your customization stylesheet. For example:

   ```xml
   <plugin id="com.oxygenxml.webhelp.responsive.custom.footer">
     <feature extension="com.oxygenxml.webhelp.xsl.createMainPage">
       <file>custom_mainpage.xsl</file>
     </feature>
   </plugin>
   ```

3. Create your customization stylesheet (for example, `custom_mainpage.xsl`), and edit it to override the template that produces the footer section:

   ```xml
   <xsl:template match="*:div[contains(@class, 'footer-container')]" mode="copy_template">
     <!-- Apply the default processing -->
     <xsl:next-match/>
   </xsl:template>

   <!-- Add a div containing the copyright information -->
   <div class="copyright_info">
     <xsl:choose>
       <!-- Adds the start-end years if they are defined -->
       <xsl:when test="exists($toc/*:topicmeta/*:bookrights/*:copyrfirst) and exists($toc/*:topicmeta/*:bookrights/*:copyrlast)">
         <span class="copyright_years">
           ©<xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:copyrfirst"/>
           -<xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:copyrlast"/>
         </span>
       </xsl:when>
       <!-- Adds only the first year if last is not defined. -->
       <xsl:when test="exists($toc/*:topicmeta/*:bookrights/*:copyrfirst)">
         <span class="copyright_years">
           ©<xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:copyrfirst"/>
         </span>
       </xsl:when>
     </xsl:choose>
   </div>
   ```
4. Use the Run DITA-OT Integrator transformation scenario *(on page 1665)* found in the DITA Map section in the Configure Transformation Scenario(s) dialog box *(on page 1762)*.

5. Run a DITA Map WebHelp Responsive transformation scenario to obtain the customized side TOC.

**Use-Case 2: WebHelp XSLT-Parameter extension point to control if generation time is displayed in the output**

Another possible customization for the main page is to add the generation time in its footer. You can use an XSLT-Parameter extension point to control whether or note this customization is active. In this case, you can use the com.oxygenxml.webhelp.xsl.createMainPage.param extension point *(on page 2012)*.

Figure 638. Generation time added in the WebHelp footer

To add this functionality, follow these steps:

1. Create a DITA-OT plugin structure by following the first 3 steps in the procedure above *(on page 1993)*.

2. In the customization stylesheet that you just created (for example, custom_mainpage.xsl), `declare webhelp.footer.add.generation.time` as a global parameter and modify the template by adding the following XSLT code at the end.
3. Edit the plugin.xml file to specify the com.oxygenxml.webhelp.xsl.createMainPage.param extension point and a custom parameter file by adding the following line:

```xml
<feature extension="com.oxygenxml.webhelp.xsl.createMainPage.param" file="params.xml"/>
```

4. Create a custom parameter file (for example, params.xml). It should look like this:

```xml
<dummy>
  <param name="webhelp.footer.add.generation.time" expression="${webhelp.footer.add.generation.time}" if="webhelp.footer.add.generation.time"/>
</dummy>
```

5. Use the Run DITA-OT Integrator transformation scenario (on page 1665) found in the DITA Map section in the Configure Transformation Scenario(s) dialog box (on page 1762).

6. Edit a DITA Map WebHelp Responsive transformation scenario and in the Parameters tab (on page 3205), specify the desired value (yes or no) for your custom parameter (webhelp.footer.add.generation.time).

7. Run the transformation scenario.

Miscellaneous Customization Topics

This section contains miscellaneous topics about how to customize the WebHelp Responsive output.
How to Add an Edit Link to Launch Oxygen XML Web Author

You can embed *Edit* links in the DITA WebHelp Responsive output that will automatically launch a particular document in Oxygen XML Web Author. A reviewer can then simply click the link and they will be redirected to the Oxygen XML Web Author editing page with that particular file open and editable.

**Using a Publishing Template**

To embed an *Edit* link in the DITA Map WebHelp Responsive output using an Oxygen Publishing Template *(on page 1892)*, follow this procedure:

1. If you haven't already created a Publishing Template, see Working with Publishing Templates *(on page 1935)*.
2. Open the template descriptor file *(on page 1895)* associated with your publishing template and add the following parameters with their values set to the URLs:
   - `editlink.remote.ditamap.url` - The URL of the DITA Map suitable for opening in Oxygen XML Web Author.
   - `editlink.web.author.url` - The URL of the Oxygen XML Web Author installation.

   ```xml
   <publishing-template>
     ... 
     <webhelp>
       ... 
       <parameters>
         <parameter name="editlink.remote.ditamap.url" value="webdav-https://dav.box.com/dav/my.ditamap"/>
         <parameter name="editlink.web.author.url" value="https://www.oxygenxml.com/webauthor.html"/>
       </parameters>
     </webhelp>
   </publishing-template>
   ```

3. Open the DITA Map WebHelp Responsive transformation scenario.
4. Click the Choose Custom Publishing Template link and select your template.
5. Click OK to save the changes to the transformation scenario.
6. Run the transformation scenario.

**Result:** In the WebHelp output, all topics will have an *Edit* link to the right side of the title and clicking the link will launch that particular document in Oxygen XML Web Author.

For example:

- **Windows:**
Using a Transformation Scenario in Oxygen XML Editor/Author

To embed an Edit link in the DITA Map WebHelp Responsive output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Edit a DITA Map WebHelp Responsive transformation scenario and open the Parameters tab.
2. Set values for the following parameters:
   - `editlink.remote.ditamap.url` - The URL of the DITA Map suitable for opening in Oxygen XML Web Author.
   - `editlink.web.author.url` - The URL of the Oxygen XML Web Author installation.
3. Run the transformation scenario.

**Result:** In the WebHelp output, all topics will have an Edit link to the right side of the title and clicking the link will launch that particular document in Oxygen XML Web Author.

How to Flag DITA Content in WebHelp Output

Flagging content in WebHelp output involves defining a set of images that will be used for marking content across your information set.

To flag DITA content, you need to create a filter file that defines properties that will be applied on elements to be flagged. Generally, flagging is supported for block elements (on page 3280) (such as paragraphs), but not for phrase-level elements within a paragraph. This ensures that the images that will flag the content are easily scanned by the reader, instead of being buried in the text.
Using a Publishing Template

To flag content in DITA Map to WebHelp output using an Oxygen Publishing Template (on page 1892), follow this procedure:

1. Create a DITA filter file (DITAVAL) and add it in a directory of your choice (for example, named myFile.ditaval.
2. Define the property for the elements you want to be flagged. For example, if you want to flag any element that has the audience attribute set to programmer, the content of the DITAVAL file should look like this:

   ```xml
   <?xml version="1.0" encoding="UTF-8"?>
   <val>
     <prop att="audience" val="programmer" action="flag"
       img="D:\resource\delta.gif" alt="sample alt text"/>
   </val>
   ```

   Note that for an element to be flagged, at least one attribute-value pair needs to have a property declared in the DITAVAL file.
3. Open the template descriptor file (on page 1895) associated with your publishing template and add the args.filter parameter in the parameters section with its value set to the path of the DITAVAL file you created.

   ```xml
   <publishing-template>
     ...
     <webhelp>
       ...
       <parameters>
         <parameter name="args.filter" value="resources/myFile.ditaval"/>
       </parameters>
     </webhelp>
   </publishing-template>
   ```

4. Open the DITA Map WebHelp Responsive transformation scenario.
5. Click the Choose Custom Publishing Template link and select your template.
6. Click OK to save the changes to the transformation scenario.
7. Run the transformation scenario.

Using a Transformation Scenario in Oxygen XML Editor/Author

To flag content in the DITA Map to WebHelp output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:
1. Create a DITA filter file (DITAVAL) and add it in a directory of your choice (for example, named `myFile.ditaval`).

2. Define the property for the elements you want to be flagged. For example, if you want to flag any element that has the `audience` attribute set to `programmer`, the content of the DITAVAL file should look like this:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<val>
  <prop att="audience" val="programmer" action="flag" img="D:\resource\delta.gif" alt="sample alt text"/>
</val>
```

Note that for an element to be flagged, at least one attribute-value pair needs to have a property declared in the DITAVAL file.

3. Edit a DITA Map to WebHelp transformation scenario.

4. Specify the DITAVAL file in the Filters tab (with the Use DITAVAL File option).

5. Run the transformation scenario.

Related Information:

- Filtering Profiling Values with a DITAVAL File (on page 3248)

How to Deploy the Output on a SharePoint Site

Since WebHelp output must be published locally, on the same machine where the WebHelp process is running, to publish your files directly to a SharePoint library you need to map a network drive to connect to SharePoint and change your file extensions to `.aspx`, as described in the steps below.

Using a Script Outside of Oxygen XML Editor/Author

To publish WebHelp Responsive output on a SharePoint site using an Oxygen Publishing Template (on page 1892), follow this procedure:

1. Map a network drive to connect to your SharePoint library. For more information, see: https://support.microsoft.com/en-us/kb/2616712.

2. To allow browsers to open your published files (rather than downloading them), you need to change the file extensions from `.html` to `.aspx`.

3. Open the template descriptor file (on page 1895) associated with your publishing template and add the `args.outext` parameter in the parameters section with its value set to `.aspx`.

```xml
<publishing-template>
  <parameter name="args.outext" value=".aspx"/>
</publishing-template>
```
4. Open the DITA Map WebHelp Responsive transformation scenario.
5. Click the Choose Custom Publishing Template link and select your template.
6. Click OK to save the changes to the transformation scenario.
7. Run the transformation scenario.

Using a Transformation Scenario in Oxygen XML Editor/Author

To publish WebHelp Responsive output on a SharePoint site using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Map a network drive to connect to your SharePoint library. For more information, see: https://support.microsoft.com/en-us/kb/2616712.
2. To allow browsers to open your published files (rather than downloading them), you need to change the file extensions from .html to .aspx. Fortunately, this can be done in the transformation.
   a. Edit the WebHelp transformation scenario and open the Parameters tab.
   b. Set the args.outext parameter to .aspx.
   c. Run the transformation scenario.

WebHelp Responsive Transformation Parameters

In addition to the common DITA-OT transformation parameters and the HTML-based Output Parameters, there are numerous other supported parameters that are specific to the WebHelp Responsive output.

Publishing Template Parameters

webhelp.publishing.template

Specifies the path to the ZIP archive (or root folder) that contains your custom WebHelp Responsive template.

Note: The built-in templates are stored in the DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/templates folder.
**Note:** Relative paths are resolved based on the current working directory.

**webhelp.publishing.template.descriptor**

Specifies the name of the descriptor to be loaded from the WebHelp Responsive template package. If it is not specified, the first encountered descriptor will be automatically loaded.

### Custom Resource Parameters

**webhelp.custom.resources**

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

**webhelp.favicon**

The file path that points to an image to be used as a favicon in the WebHelp output.

**webhelp.logo.image.target.url**

Specifies a target URL that is set on the logo image. When you click the logo image, you will be redirected to this address.

**webhelp.logo.image**

Specifies a path to an image displayed as a logo in the left side of the output header.

**webhelp.logo.image.alt**

Specifies a value that will be set in the alt attribute of the logo image. If the parameter is not specified, the alt attribute will contain the publication title. Note that this parameter makes sense only in conjunction with the webhelp.logo.image parameter.

### Feedback-Enabled Parameters

**webhelp.product.id** *(available only for Feedback-enabled systems)*

This parameter specifies a short name for the documentation target, or product (for example, mobile-phone-user-guide, hvac-installation-guide).

**Note:** You can deploy documentation for multiple products on the same server.

**Restriction:** The following characters are not allowed in the value of this parameter: `< > / ' { } = ; * % + & .`

**webhelp.product.version** *(available only for Feedback-enabled systems)*
Specifies the documentation version number (for example, 1.0, 2.5, etc.). New user comments are bound to this version.

Note: Multiple documentation versions can be deployed on the same server.

Restriction: The following characters are not allowed in the value of this parameter:

\< > / \ ' ( ) { } = ; * % + & .

HTML Fragment Extension Parameters

**webhelp.fragment.after.body**

In the generated output it displays a given XHTML fragment after the page body. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

**webhelp.fragment.after.logo_and_title**

In the generated output it displays a given XHTML fragment after the logo and title. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

**webhelp.fragment.after.main.page.search**

In the generated output it displays a given XHTML fragment after the search field. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

**webhelp.fragment.after.toc_or_tiles**

In the generated output it displays a given XHTML fragment after the table of contents or tiles in the main page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

**webhelp.fragment.after.top_menu**

In the generated output it displays a given XHTML fragment after the top menu. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

**webhelp.fragment.before.body**

In the generated output it displays a given XHTML fragment before the page body. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

**webhelp.fragment.before.logo_and_title**
In the generated output it displays a given XHTML fragment before the logo and title. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.main.page.search**

In the generated output it displays a given XHTML fragment before the search field. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.toc_or_tiles**

In the generated output it displays a given XHTML fragment before the table of contents or tiles in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.top_menu**

In the generated output it displays a given XHTML fragment before the top menu. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.footer**

In the generated output it displays a given XHTML fragment as the page footer. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.head**

In the generated output it inserts a given XHTML fragment in the `<head>` element. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.welcome**

In the generated output it displays a given XHTML fragment as a welcome message (or title). The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**Output Component Parameters**

**webhelp.default.collection.type.sequence**

Specifies if the sequence value will be used by default when the collection-type attribute is not specified. This option is helpful if you want to have Next and Previous navigational buttons generated for all HTML pages. Allowed values are no (default) and yes.

**webhelp.merge.nested.topics.related.links**
Specifies if the related links from nested topics will be merged with the links in the parent topic. Thus the links will be moved from the topic content to the related links component and all of the links from the same group (for example, Related Tasks, Related References, Related Information) are merged into a single group. The default value is yes.

webhelp.show.breadcrumb

Specifies if the breadcrumb component will be presented in the output. The default value is yes.

webhelp.show.changes.and.comments

When set to yes, user comments, replies to comments, and tracked changes are published in the WebHelp output. The default value is no.

webhelp.show.child.links

Specifies if child links will be generated in the output for all topics that have subtopics. The default value is no.

webhelp.show.full.size.image

Specifies if responsive images that are displayed with a smaller dimension than their original size can be clicked to see an enlarged version of the image. The default value is yes.

webhelp.show.indexterms.link

Specifies if an icon that links to the index will be presented in the output. The default value is yes.

webhelp.show.main.page.tiles

Specifies if the tiles component will be presented in the main page of the output. For a tree style layout, this parameter should be set to no.

webhelp.show.main.page.toc

Specifies if the table of contents will be presented in the main page of the output. The default value is yes.

webhelp.show.navigation.links

Specifies if navigation links will be presented in the output. The default value is yes.

webhelp.show.print.link

Specifies if a print link or icon will be presented within each topic in the output. The default value is yes.

webhelp.show.publication.toc
Specifies if a table of contents will be presented on the left side of each topic in the output. The default value is yes.

webhelp.show.topic.toc

Specifies if a topic table of contents will be presented on the right side of each topic in the output. This table of contents contains links to each <section> within the current topic that contains an @id attribute and the section corresponding to the current scroll position is highlighted. The default value is yes.

webhelp.show.top.menu

Specifies if a menu will be presented at the topic of the main page in the output. The default value is yes.

webhelp.publication.toc.hide.chunked.topics

Specifies if the table of contents will contain links for chunked topics. The default value is yes.

webhelp.publication.toc.links

Specifies which links will be included in the table of contents. The possible values are:

- **chapter** (default) - The TOC will include links for the current topic, its children, its siblings, and its direct ancestor (including the direct ancestor's siblings), and the parent chapter.
- **topic** - The TOC will only include links for the current topic and its direct children.
- **all** - The TOC will include all links.

webhelp.publication.toc.tooltip.position

By default, if a topic contains a shortdesc element, its content is displayed in a tooltip when the user hovers over its link in the table of contents. This parameter controls whether or not this tooltip is displayed and its position relative to the link. The possible values are:

- **left** (default)
- **right**
- **top**
- **bottom**
- **hidden** - The tooltip will not be displayed.

webhelp.top.menu.depth

Specifies the maximum depth level of the topics that will be included in the top menu. The default value is 3. A value of 0 means that the menu has unlimited depth.

webhelp.topic.collapsible.elements.initial.state
Specifies the initial state of collapsible elements (tables with titles, nested topics with titles, sections with titles, index term groups). The possible values are collapsed or expanded (default value).

**Search-Related Parameters**

**webhelp.search.japanese.dictionary**

The file path of the dictionary that will be used by the *Kuromoji* morphological engine for indexing Japanese content in the WebHelp pages. The encoding for the dictionary must be UTF8.

**webhelp.search.ranking**

If this parameter is set to false then the 5-star rating mechanism is no longer included in the search results that are displayed on the Search tab (default setting is true).

**webhelp.search.stop.words.exclude**

Specifies a list of words that will be excluded from the default list of stop words that are filtered out before the search processing. Use comma separators to specify more than one word (for example: if,for,is).

**webhelp.sitemap.base.url**

Base URL for all the loc elements in the generated sitemap.xml file. The value of a loc element is computed as the relative file path from the href attribute of a topicref element from the DITA map, appended to this base URL value. The loc element is mandatory in sitemap.xml. If you leave this parameter set to its default empty value, then the sitemap.xml file is not generated.

**webhelp.enable.search.autocomplete**

Specifies if the Autocomplete feature is enabled in the WebHelp search text field. The default value is yes.

**webhelp.search.enable.pagination**

Specifies whether or not search results will be displayed on multiple pages. Allowed values are yes or no.

**webhelp.search.page.numberOfItems**

Specifies the number of search results items displayed on each page. This parameter is only used when the webhelp.search.enable.pagination parameter is enabled.

**webhelp.sitemap.change.frequency**

The value of the changefreq element in the generated sitemap.xml file. The changefreq element is optional in sitemap.xml. If you leave this parameter set to its default empty value, then the changefreq element is not added in sitemap.xml.
Allowed values: <empty string> (default), always, hourly, daily, weekly, monthly, yearly, never.

**webhelp.sitemap.priority**

The value of the `priority` element in the generated `sitemap.xml` file. It can be set to any fractional number between 0.0 (least important priority) and 1.0 (most important priority). For example, 0.3, 0.5, or 0.8. The `priority` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `priority` element is not added in `sitemap.xml`.

**webhelp.google.search.results**

A file path that specifies the location of a well-formed XHTML file containing the Google Custom Search Engine element `gcse:searchresults-only`. You can use all supported attributes for this element. It is recommend to set the `linkTarget` attribute to `frm` for frameless (iframe) version of WebHelp or to `contentWin` for the frameset version of WebHelp. The default value for this attribute is `_blank` and the search results will be loaded in a new window. If this parameter is not specified, the following code will be used: `<gcse:searchresults-only linkTarget="frm"></gcse:searchresults-only>`

**webhelp.google.search.script**

A file path that specifies the location of a well-formed XHTML file containing the Custom Search Engine script from Google.

**Note:** The `fix.external.refs.com.oxygenxml` parameter is not supported when running the transformation from a command line. This parameter is normally used to specify whether or not the application tries to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references.

- Setting DITA-OT Parameters

**WebHelp Responsive XSLT-Import and XSLT-Parameter Extension Points**

XSLT extension points can be used from either from an Oxygen Publishing Template or from a DITA-OT extension plug-in.
Extension Points from an Oxygen Publishing Template

The publishing template allows you to specify one or more XSLT extension points. These extension points will affect only the transformations that use the particular template.

For an example of how to use these extension in a publishing template, see: How to Use a XSLT Extension Point from a Publishing Template *(on page 1988)* topic.

Example:

```xml
<publishing-template>
  ...
  <webhelp>
    ...
    <xslt>
      <extension
          id="com.oxygenxml.webhelp.xsl.createMainPage"
          file="xsl/customMainPage.xsl"/>
    </xslt>
  </webhelp>
  ...
</publishing-template>
```

Extension Points from a DITA-OT Extension Plug-in

The DITA-OT plug-in installer adds an XSLT import statement in the default WebHelp XSLT so that the XSLT stylesheet referenced by the extension point becomes part of the normal build. You can use these extension points to override XSLT processing steps.

Example:

```xml
<plugin id="com.oxygenxml.webhelp.responsive.extension">
  <feature extension="com.oxygenxml.webhelp.responsive.xsl.dita2webhelp"
           file="xsl/fixup.xsl"/>
</plugin>
```

XSLT-Import Extension Points

The following extension points are available:

`com.oxygenxml.webhelp.xsl.dita2webhelp`

Extension point to override the XSLT stylesheet (`dita2webhelp.xsl`) that produces an HTML file for each DITA topic. The location of this file is `DITA-OT_DIR\plugins\com.oxygenxml.webhelp.responsive\xsl\dita2webhelp\dita2webhelp.xsl`
Extension point to override the XSLT stylesheet (`createMainPage.xsl`) that produces the WebHelp Responsive main HTML page (`index.html`). The location of this file is `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/xsl/mainFiles/createMainPage.xsl`.

Extension point to override the XSLT stylesheets that are used to generate navigation links in the WebHelp Responsive pages. These stylesheets can be found in the `navLinks` folder: `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/xsl/navLinks`.

Extension point to override the XSLT stylesheet (`createSearchPage.xsl`) that produces the WebHelp Responsive search HTML page (`search.html`). The location of this file is `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/xsl/mainFiles/createSearchPage.xsl`.

Extension point to override the XSLT stylesheet (`createIndexTermsPage.xsl`) that produces the WebHelp Responsive index terms HTML page (`indexterms.html`). The location of this file is `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/xsl/mainFiles/createIndexTermsPage.xsl`.

Extension point to override the XSLT stylesheet (`tocDita.xsl`) that produces the `toc.xml` file. This file contains information extracted from the `DITA map (on page 3281)` and it is mainly used to construct the WebHelp Table of Contents and navigational links. The path to this stylesheet is: `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/xsl/toc/tocDita.xsl`.

**XSLT-Parameter Extension Points**

If your customization stylesheet declares one or more XSLT parameters and you want to control their values from the transformation scenario, you can use one of the following XSLT parameter extension points:

`com.oxygenxml.webhelp.xsl.dita2webhelp.param`

Use this extension point to pass parameters to the stylesheet specified using the `com.oxygenxml.webhelp.xsl.dita2webhelp extension point (on page 2011).`
Use this extension point to pass parameters to the stylesheet specified using the `com.oxygenxml.webhelp.xsl.createMainPage` extension point (on page 2012).

`com.oxygenxml.webhelp.xsl.createNavLinks.param`

Use this extension point to pass parameters to the stylesheet specified using the `com.oxygenxml.webhelp.xsl.createNavLinks` extension point (on page 2012).

`com.oxygenxml.webhelp.xsl.createSearchPage.param`

Use this extension point to pass parameters to the stylesheet specified using the `com.oxygenxml.webhelp.xsl.createSearchPage` extension point (on page 2012).

`com.oxygenxml.webhelp.xsl.createIndextermsPage.param`

Use this extension point to pass parameters to the stylesheet specified using the `com.oxygenxml.webhelp.xsl.createIndexTermsPage` extension point (on page 2012).

`com.oxygenxml.webhelp.xsl.createTocXML.param`

Use this extension point to pass parameters to the stylesheet specified using the `com.oxygenxml.webhelp.xsl.createTocXML` extension point (on page 2012).

### DITA to PDF Output Customization

Oxygen XML Editor provides support for generating PDF output using transformation scenarios for certain types of documents (for example, DITA, DocBook, TEI, and JATS) and Oxygen XML Editor supports several different types of processors. There are numerous ways to customize the published output to fit your specific needs.

### CSS-based DITA to PDF Customization

Oxygen XML Editor comes bundled with a DITA-OT CSS-based PDF Publishing Plugin that combines all the topics from a map or bookmark and styles the resulting document using CSS. It is the base of the DITA Map PDF - based on HTML5 & CSS transformation scenario.
DITA Map to PDF - based on HTML5 and CSS Transformation Type

This transformation type uses a CSS-based processing engine and HTML5 as an intermediate format. For this transformation, the `pdf-css-html5` transtype is used. Because the structure of the HTML5 intermediate format resembles the one used in WebHelp output, it is possible to reuse parts of your CSS file you developed for a WebHelp customization.

DITA Map PDF - based on DITA and CSS (WYSIWYG) Transformation Type (Deprecated)

This transformation type converts DITA maps to PDF using a CSS-based processing engine and a merged DITA map (one with all topics expanded inline) as an intermediate format. For this transformation, the `pdf-css` transtype is used. This transformation scenario was deprecated starting with version 21.0. It is recommended to use the DITA Map PDF - based on HTML5 & CSS transformation scenario (on page 1657) instead.

Related Information:

- DITA Map to PDF - based on HTML5 and CSS Transformation (on page 1657)

Overview

This section contains topics that provide a basic overview of the DITA-OT CSS-based PDF Publishing Plugin, technical details, and some additional resources to help you with your customizations.

Resources

Customizing the PDF output requires knowledge of CSS, Paged Media, and DITA. The following list provides some resources to help you:

- **CSS** - You can find a good tutorial here: https://developer.mozilla.org/en-US/docs/Learn/CSS/Introduction_to_CSS. Also, the specification is available on the W3C website: https://www.w3.org/Style/CSS/Overview.en.html.
- **CSS Paged Media** - This is a part of the CSS specification that shows how to organize your publication in pages, how to use headers/footers, page breaks, and other page-related issues. The specification is available here: https://www.w3.org/TR/CSS2/page.html. Also, there is a set of hands-on examples in the Oxygen PDF Chemistry user guide: https://www.oxygenxml.com/doc/ug-chemistry/.
• **DITA** - You will need a basic understanding of DITA elements, attributes, and structure. A good resource is *The DITA Style Guide - Best Practices for Authors* by Tony Self. It is available at: [www.ditastyle.com](http://www.ditastyle.com) and: [https://www.oxygenxml.com/dita/styleguide/webhelp-feedback/Artefact/c_DITA_Authoring_Concepts.html](https://www.oxygenxml.com/dita/styleguide/webhelp-feedback/Artefact/c_DITA_Authoring_Concepts.html).

• **HTML5** - For the DITA Map PDF - based on HTML5 & CSS transformation type, you will need a good knowledge of HTML5. You can find resources here: [https://developer.mozilla.org/en-US/docs/Web/Guide/HTML/HTML5](https://developer.mozilla.org/en-US/docs/Web/Guide/HTML/HTML5)

---

**Related Information:**

- **DITA-OT DAY 2017: Using CSS to Style PDF Output**

---

**Supported Processors**

The **DITA-OT CSS-based PDF Publishing Plugin** supports the following CSS processors:

- **Oxygen PDF Chemistry** - This is recommended processor because the built-in CSS files were fine-tuned for this processor. For example, metadata extraction *(on page 2070)* only functions with this processor. If the plugin is started from an **Oxygen XML Editor/Author** distribution, a Chemistry installation is not needed.

---

**Technical Details**

The **DITA-OT CSS-based PDF Publishing Plugin** comes bundled in the **Oxygen XML Editor/Author** distributions. The plugin ID is: `com.oxygenxml.pdf.css`. It is installed in the `[OXYGEN-INSTALL-DIR]/frameworks/dita/DITA-OT3.x/plugins/com.oxygenxml.pdf.css` folder.

It has two transformation types:

- **pdf-css-html5** *(DITA Map PDF - based on HTML5 & CSS transformation)* - CSS styling applied over a merged HTML5 document (the merged DITA converted to HTML5).

- **pdf-css** *(DITA Map PDF - based on DITA & CSS - WYSIWYG transformation)* - CSS styling applied directly over a merged DITA document. **This transformation type was deprecated started with version 21.**

This is how it works:
1. It expands all the topic references into a temporary clone of the map, resolving keys and reused content. This is the standard DITA-OT pre-processing procedure.

2. It generates a structure for the table of contents and index. The result is a merged map with all the references resolved. This is a standard DITA-OT processing procedure, based on the PDF2 plugin.

3. Then it post-processes the merged map. It fixes some of the structure in the TOC and index, moves the *frontmatter* and *backmatter* to the correct places, transforms any change tracking and review processing instructions to elements that can be styled later, etc. The result is another merged map.

4. When using the **DITA Map PDF - based on HTML5 & CSS** transformation type, the merged DITA map is transformed to a single HTML5 file. The generated HTML elements copy the class attributes from the original DITA elements. In this way you can either use selectors that were designed for DITA structure, or ones for the HTML structure - see: *Reusing the Styling for...*
WebHelp and PDF Output (on page 2144). This step can apply customization XSLT extension points (on page 2033) that change the default processing.

5. In the last phase, it uses a collection of CSS files to style the merged map (or for the DITA Map PDF - based on HTML5 & CSS transformation type, the merged map in the HTML5 format with the help of the CSS processor).

**Note:** For the DITA Map PDF - based on DITA & CSS (WYSIWYG) transformation type, the used CSS files are those selected in the Styles drop-down menu from the toolbar in Oxygen XML Editor/Author, and they are processed along with the CSS files specified with the args.css parameter set in the transformation scenario.

**Note:** For the DITA Map PDF - based on HTML5 & CSS transformation type, references to the CSS files are collected from the publishing template (on page 2023).

Increasing Memory Allocation for Java

If you are working with a large project with extensive metadata or key references, you may need to increase the amount of memory that is allocated to the Java process that performs the publishing.

**When the Transformation is Started from Oxygen**

It is possible to alter the memory allocation setting from the transformation scenario:

1. Open the Configure Transformation Scenario(s) dialog box.
2. Select your transformation scenario, then click Edit.
3. Go to the Advanced tab.
4. Locate the JVM Arguments, and increase the default value. For instance, to set 1GB as maximum of memory, you can specify: -Xmx1024m.
When the Transformation is Started from the Command Line

You can change the value of the `ANT_OPTS` environment variable from a command line for a specific session.

**Example:** To increase the JVM memory allocation to 1024 MB for a specific session, issue the following command from a command prompt (depending on your operating system):

- **Windows**
  
  ```
  set ANT_OPTS=%ANT_OPTS% -Xmx1024M
  ```

- **Linux/Mac OS X**
  
  ```
  export ANT_OPTS=$ANT_OPTS -Xmx1024M
  ```

**Tip:** To persistently change the memory allocation, change the value allocated to the `ANT_OPTS` environment variable on your system.

Transformation Parameters

This list includes the most common customization parameters that are available in the DITA Map PDF - based on HTML5 & CSS transformation scenario. Other standard DITA-OT parameters were omitted for clarity, but they are still supported.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>args.css</code></td>
<td>You can use this to specify a list of CSS URLs to be used in addition to those specified in the <code>dita.css.list</code> parameter or publishing template. The files must have URL syntax and be separated using semicolons.</td>
</tr>
<tr>
<td><code>args.css.param.*</code></td>
<td>You can use this parameter pattern to set attributes on the root of the merged map. This means you can activate specific CSS rules from your custom CSS using custom attributes. For examples, see: [Styling Through Custom Parameters](on page 2163).</td>
</tr>
</tbody>
</table>
| `args.css.param.numbering` | You can use this parameter to change the numbering of the chapters and sections. Allowed values:  

  - **shallow** - Only the topics from the first level will be numbered (chapters).
  - **deep** - All the topics from the map will be numbered (chapters and sections).
  - **deep-chapter-scope** - Similar to deep, but in addition, the page numbers, figures, and table numbers are reset at the start of each chapter. The table and figure titles (and the links to
them) are prefixed with the chapter numbers. The generic cross reference links contain both the chapter numbers and the page numbers to avoid ambiguity. This parameter value is only available for the **DITA Map PDF - based on HTML5 & CSS** transformation scenario.

- **deep-chapter-scope-no-page-reset** - Similar to `deep-chapter-scope`, but the page numbers do not reset at the start of each chapter. The generic cross reference links contain only the page number. This parameter value is only available for the **DITA Map PDF - based on HTML5 & CSS** transformation scenario.

For more details, see [Numbering Types (on page 2092)](https://example.com).

<table>
<thead>
<tr>
<th><strong>args.draft</strong></th>
<th>Specifies whether or not the content of <code>&lt;draft-comment&gt;</code> and <code>&lt;required-cleanup&gt;</code> elements is included in the output.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Allowed values:</strong></td>
<td></td>
</tr>
<tr>
<td>• <strong>no</strong> - No draft information is shown in the output. This is the default.</td>
<td></td>
</tr>
<tr>
<td>• <strong>yes</strong> - The draft information is shown in the output.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>args.figurelink.style</strong></th>
<th>Specifies how cross references to figures are styled in output. Allowed values:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>NUMBER</strong> - Only the number of the figures will be shown in links.</td>
<td></td>
</tr>
<tr>
<td>• <strong>TITLE</strong> - Only the title of the figures will be shown in links.</td>
<td></td>
</tr>
<tr>
<td>• <strong>NUMTITLE</strong> (default) - Both the title and number of the figures will be shown in links.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>args.chapter.layout</strong></th>
<th>Specifies whether chapter level TOCs are generated for bookmaps. When set to <strong>MINITOC</strong>, a small section with links is added at the beginning of each chapter. The default is <strong>BASIC</strong>. For details, see: <a href="https://example.com">Table of Contents for Chapters (Mini TOC) (on page 2102)</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Allowed values:</strong></td>
<td></td>
</tr>
<tr>
<td>• <strong>BASIC</strong> - No chapter TOC is created.</td>
<td></td>
</tr>
<tr>
<td>• <strong>MINITOC</strong> - A chapter level TOC will be generated.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>args.gen.task.lbl</strong></th>
<th>Specifies whether or not to generate headings for sections within task topics. Allowed values: <strong>YES</strong> or <strong>NO</strong> (default). When set to yes, headings like &quot;About this task&quot;, &quot;Procedure&quot;, or &quot;What to do next&quot;, are shown in the task contents.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>args.input</strong></td>
<td>Specifies the master DITA map file for your documentation project.</td>
</tr>
<tr>
<td>arg</td>
<td>Description</td>
</tr>
<tr>
<td>-----</td>
<td>-------------</td>
</tr>
<tr>
<td>args.output.base</td>
<td>Specifies the name of the output file without a file extension. By default, the name of the PDF file is derived from the name of the DITA map file. This parameter allows you to override it.</td>
</tr>
<tr>
<td>args.tablelink.style</td>
<td>Specifies how cross references to tables are styled in output. Allowed values:</td>
</tr>
<tr>
<td>- NUMBER</td>
<td>Only the number of the tables will be shown in links.</td>
</tr>
<tr>
<td>- TITLE</td>
<td>Only the title of the tables will be shown in links.</td>
</tr>
<tr>
<td>- NUMTITLE (default)</td>
<td>Both the title and number of the tables will be shown in links.</td>
</tr>
<tr>
<td>clean.temp</td>
<td>Specifies whether the DITA-OT deletes the files in the temporary directory after it finishes a build. Allowed values: yes (default) / no</td>
</tr>
<tr>
<td>css.processor.path.antenna-house</td>
<td>Path to the Antenna House executable file that needs to be run to generate the PDF (for example, C:\path\to\AHFCmd.exe on Windows).</td>
</tr>
<tr>
<td>css.processor.path.chemistry</td>
<td>Path to the Oxygen PDF Chemistry executable file that needs to be run to generate the PDF (for example, C:\path\to\chemistry.bat on Windows). If this parameter is not set, the plugin will use the system's PATH environment variable to locate and start Oxygen PDF Chemistry.</td>
</tr>
<tr>
<td>css.processor.path.prince</td>
<td>Path to the Prince executable file that needs to be run to generate the PDF (for example, C:\path\to\prince.exe on Windows).</td>
</tr>
<tr>
<td>css.processor.type</td>
<td>Specifies the processor to use for the transformation. Allowed values: chemistry (default) / antenna-house / prince.</td>
</tr>
<tr>
<td>default.language</td>
<td>Specifies the default language for source documents. Examples: fr, de, zh, etc. Depending on the transformation type, the actual number of supported languages can vary, see: Localization (on page 2132).</td>
</tr>
<tr>
<td>editlink.remote.ditamap.url</td>
<td>Use this parameter in conjunction with editlink.web.author.url to add an Edit link next to the topic title in the PDF output. When a user clicks the link, the topic is opened in Oxygen XML Web Author where they can make changes that can be saved to a file server. The value should be set as the custom URL of the main DITA map. For example, a GitHub custom URL might look like this: <a href="https://getFileContent/oxyengxml/userguide/master/UserGuide.ditamap">https://getFileContent/oxyengxml/userguide/master/UserGuide.ditamap</a>.</td>
</tr>
<tr>
<td>editlink.web.author.url</td>
<td>This parameter needs to be used in conjunction with editlink.remote.ditamap.url to add an Edit link next to the topic title in the PDF output. When a user clicks the link, the topic is opened in Oxygen XML Web Author where they can make changes that can be saved to a file server. The value should be set as</td>
</tr>
</tbody>
</table>
the URL of the Web Author installation. For example: https://www.oxygenxml.com/oxygen-xml-web-author/.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>figure.title.placement</td>
<td>Controls the title placement of the figures, relative to the image. Possible values include top (default) and bottom.</td>
</tr>
<tr>
<td>generate.named.destinations</td>
<td>When set to yes (default), the @id attributes from the DITA content are used as PDF named destinations</td>
</tr>
<tr>
<td>hide.frontpage.toc.index.glossary</td>
<td>When set to yes, the generated structures (table of contents, index list, front page, etc.) are removed from the output. The default is no.</td>
</tr>
<tr>
<td>show.changes.and.comments</td>
<td>When set to yes, the user comments, colored highlights and track-changes are shown in the output.</td>
</tr>
<tr>
<td>show.changes.and.comments.as.pdf.sticky.notes</td>
<td>When set to yes (default) and the show.changes.and.comments parameter is also set to yes, the user comments and tracked changes are shown in the PDF output as stick note annotations. When set to no, the comments and tracked changes are left in the document model and are styled by the default CSS rules as footnotes. You can override this from your customization CSS (on page 2041).</td>
</tr>
</tbody>
</table>

The following parameters can be used to specify a publishing template:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pdf.publishing.template</td>
<td>Specifies the path to the folder containing the custom PDF template.</td>
</tr>
<tr>
<td>pdf.publishing.template.descriptor</td>
<td>Specifies the name of the descriptor to be loaded from the PDF template folder or package. If it is not specified, the first encountered descriptor will be loaded.</td>
</tr>
</tbody>
</table>

Publishing Templates

An Oxygen Publishing Template defines all aspects of the layout and styles for output obtained from the following transformation scenarios:

- WebHelp Responsive
- WebHelp Responsive with Feedback
- DITA Map PDF - based on HTML5 & CSS

It is a self-contained customization package stored as a ZIP archive or folder that can easily be shared with others. It provides the primary method for customizing the output.

Some possible customization methods include:

- Add additional template resources to customize the output (such as logos, Favicons, or CSS files).
- Extend the default processing by specifying one or more XSLT extension points.
- Specify one or more transformation parameters to customize the output.
Customize various aspects of the output through simple CSS styling.

For WebHelp Responsive output, change the layout of the main page or topic pages by customizing which components will be displayed and where they will be positioned in the page.

The following graphics are possible sample structure for Oxygen Publishing Template packages:

Figure 639. Oxygen Publishing Template Package (WebHelp Responsive)

Figure 640. Oxygen Publishing Template Package (PDF)

For information about creating and customizing publishing templates, and how to adjust the WebHelp and PDF output through CSS styling and other customization methods, watch our Webinar: Creating Custom Publishing Templates for WebHelp and PDF Output. The Webinar slides and sample project are also available from that webpage.

Related Information:

- How to Create a Publishing Template (on page 1935)
- How to Edit a Packed Publishing Template (on page 1937)
- How to Add a Publishing Template to the Publishing Templates Gallery (on page 1938)
An Oxygen Publishing Template for PDF output must contain a template descriptor file and at least one CSS file, and may contain other resources (such as graphics, XSLT files, etc.). All the template resources can be stored in either a ZIP archive or in a folder. It is recommended to use a ZIP archive because it is easier to share with others.

Template Descriptor File

Each publishing template includes a descriptor file that defines the meta-data associated with template. It is an XML file with certain elements that defines all the resources included in a template (such as CSS files, images, and transformation parameters).

The template descriptor file must have the .opt file extension and must be located in the templates' root folder.

A PDF template descriptor might look like this:

```
<publishing-template>
  <name>Flowers</name>

  <pdf>
    <tags>
      <tag>purple</tag>
      <tag>light</tag>
    </tags>
    <preview-image file="flowers-preview.png"/>

    <resources>
      <css file="flowers.css"/>
    </resources>

    <parameters>
      <parameter name="figure.title.placement" value="top"/>
    </parameters>
  </pdf>
</publishing-template>
```
Tip: It is recommended to edit the template descriptor in Oxygen XML Editor/Author because it provides content completion and validation support.

Template Name and Description

Each template descriptor file requires a name element. This information is displayed as the name of the template in the transformation scenario dialog box.

Optionally, you can include a description and it displayed when the user hovers over the template in the transformation scenario dialog box.

```xml
<publishing-template>
  <name>Flowers</name>
  <description>Flowers themed light colored template</description>
...</publishing-template>
```

Template Author

Optionally, you can include author information in the descriptor file and it displayed when the user hovers over the template in the transformation scenario dialog box. This information might be useful if users run into an issue or have questions about a certain template.

If you include the author element, a name is required and optionally you can include email, organization, and organizationUrl information.

```xml
<publishing-template>
  ...
  <author>
    <name>John Doe</name>
    <email>jdoe@example.com</email>
    <organization>ACME</organization>
    <organizationUrl>http://www.example.com/jdoe</organizationUrl>
  </author>
  ...
</publishing-template>
```

PDF Element

The pdf element contains various details about the template and its resources that define the PDF output. It is a required element if you intend on using a DITA Map to PDF transformation scenario. The elements that are allowed in this pdf section specify the template tags (on page 2025), template
Template Tags

The tags section provides meta information about the template (such as color theme). Each tag is displayed at the top of the Templates tab window in the transformation scenario dialog box and they help the user filter and find particular templates.

```
<pdf>
  <tags>
    ...
  </tags>
  <preview-image file="MyPreview.png"/>
</pdf>
```

Template Preview Image

The preview-image element is used to specify an image that will be displayed in the transformation scenario dialog box. It provides a visual representation of the template to help the user select the right template. The image dimensions should be 200 x 115 pixels and the supported image formats are: JPEG, PNG, or GIF.

You can also include an online-preview-url element to specify the URL of a published sample of your template. This will display an Online preview icon in the bottom-right corner of the image in the
transformation scenario dialog box and if the user clicks that icon, it will open the specified URL in their default browser.

```xml
<publishing-template>
  ...
  <pdf>
    ...
    <preview-image file="ashes/ashes-tree.png"/>
    <online-preview-url=https://www.example.com/samples/tiles/ashes</online-preview-url>
  </pdf>
</publishing-template>
```

**Template Resources**

The **resources** section of the descriptor file specifies a set of resources (CSS files) that are used to customize various components in generated output. These resources will be copied to the output folder during the transformation process. At least one CSS file must be included, while the other types of resources are optional.

```xml
<publishing-template>
  ...
  <pdf>
    ...
    <resources>
      <css file="css/custom_styles.css"/>
      <css file="css/custom_fonts.css"/>
    </resources>
  </pdf>
</publishing-template>
```

**Note:** All relative paths specified in the descriptor file are relative to the template root folder.

**Transformation Parameters**

You can also set one or more transformation parameters in the descriptor file.

```xml
<publishing-template>
  ...
  <pdf>
    ...
    <parameters>
      <parameter name="show.changes.and.comments" value="yes"/>
    </parameters>
  </pdf>
</publishing-template>
```
The following information can be specified in the `parameter` element:

**Parameter name**

The name of the parameter. It may be one of the transformation parameters listed in the **Parameters** tab of the **DITA Map to PDF - based on HTML5 & CSS** transformation scenario or a **DITA-OT PDF-based output parameter**.

⚠️ **Note:** It is not recommended to specify an input/output parameter in the descriptor file (such as the input Map, DITAVAL file, or temporary directory).

⚠️ **Attention:** JVM arguments like `-Xmx` cannot be specified as a transformation parameter.

**Parameter Value**

The value of the parameter. It should be a relative path to the template root folder for file paths parameters.

**Parameter Type**

The type of the parameter: `string` or `filepath`. The `string` value is default.

After creating a publishing template (on page 2029) and adding it to the templates gallery (on page 2032), when you select the template in the transformation scenario dialog box, the **Parameters** tab will automatically be updated to include the parameters defined in the descriptor file. These parameters are displayed in italics.

**XSLT Extension Points**

The publishing templates support one or more XSLT extension points. They can be specified in the descriptor file using the following structure:

```xml
<publishing-template>
  ...
  <pdf>
    ...
    <xslt>
      <extension
        id="com.oxygenxml.pdf.css.xsl.merged2html5"
        file="xslt/merged2html5Extension.xsl"/>
      <extension
        id="com.oxygenxml.pdf.css.xsl.merged2merged"
        file="xslt/merged2mergedExtension.xsl"/>
      
    </xslt>
  </pdf>
</publishing-template>
```
For more information about the available extension points, see: XSLT Extensions for PDF Transformations (on page 2033).

Combining PDF and WebHelp Responsive Customizations in a Template Package

An Oxygen Publishing Template package can contain both a PDF and WebHelp Responsive customization in the same template package and you can use that same template in both types of transformations. The template descriptor file can define the customization for both types by including both a `webhelp` and `pdf` element and some of the resources can be reused. Resources referenced in elements in the `webhelp` element will only be used for WebHelp transformations, and resources referenced in the elements in the `pdf` element will only be used in PDF transformations.

```xml
<publishing-template>
  <name>Flowers</name>
  <description>Flowers themed light-colored template</description>

  <webhelp>
    <tags>
      <tag>purple</tag>
      <tag>light</tag>
    </tags>
    <preview-image file="flowers-preview.png"/>
    <resources>
      <css file="flowers-wh.css"/>
      <css file="flowers-page-styling.css"/>
    </resources>
    <parameters>
      <parameter name="webhelp.show.main.page.tiles" value="no"/>
      <parameter name="webhelp.show.main.page.toc" value="yes"/>
    </parameters>
  </webhelp>

  <pdf>
    <tags>
      <tag>purple</tag>
      <tag>light</tag>
    </tags>
    <preview-image file="flowers-preview.png"/>
    <resources>
      <css file="flowers-pdf.css"/>
      <css file="flowers-page-styling.css"/>
    </resources>
  </pdf>
</publishing-template>
```
<parameters>
  <parameter name="show.changes.and.comments" value="yes"/>
</parameters>

<pdf />
</publishing-template>

How to Create a Publishing Template

To create a customization, you can start from scratch or from an existing template, and then adapt it according to your needs.

Creating a Template Starting from Scratch

To create a new Oxygen Publishing Template, follow these steps:

1. Create a folder that will contain all the template files.
2. In Oxygen XML Editor/Author, open the new document wizard (use File > New or the New toolbar button), then choose the Publishing Template Descriptor template.

Figure 641. Choosing the Publishing Template Descriptor Document Template
3. Save the .opt file into your customization directory.
4. Open the .opt file in the editor and customize it to suit your needs.

Creating a Template Starting from an Existing Template

If you are using a WebHelp Responsive or DITA Map PDF - based on HTML5 & CSS transformation, the easiest way to create a new Oxygen Publishing Template (on page 3285) is to select an existing template in the transformation scenario dialog box and use the Save template as button to save that template into a new template package that can be used as a starting point.

To create a new Oxygen Publishing Template, follow these steps:

1. Open the transformation scenario dialog box and select the publishing template you want to export and use as a starting point.
2. Optional: You can set one or more transformation parameters from the Parameters tab and the edited parameters will be exported along with the selected template. You will see which parameters will be exported in the dialog box that is displayed after the next step.
3. Click the Save template as button.

   **Step Result:** This opens a template package configuration dialog box that contains some options and displays the parameters that will be exported to your template package.

4. Specify a name for the new template.
5. Optional: Specify a template description.
6. Optional: The same publishing template package can contain both a WebHelp Responsive and PDF customization and you can use the same template in both types of transformations (DITA Map WebHelp Responsive or DITA Map to PDF - based on HTML5 & CSS). You can use the
Include WebHelp customization and Include PDF customization options to specify whether your custom template will include both types of customizations.

7. **Optional:** For WebHelp Responsive customizations, you can select the Include HTML Page Layout Files option if you want to copy the default HTML Page Layout Files (on page 1909) in your template package. They are helpful if you want to change the structure of the generated HTML pages.

8. In the **Save as** field, specify the name and path of the ZIP file where the template will be saved.

   **Step Result:** A new ZIP archive will be created on disk in the specified location with the specified name.

9. Open the .opt file in the editor and customize it to suit your needs.

For more information about creating and customizing publishing templates, watch our video demonstration:

https://www.youtube.com/embed/zNmXfKWXwO8

**Related Information:**

  Publishing Template Package Contents for WebHelp Responsive Customizations (on page 1895)

**How to Edit a Packed Publishing Template**

To edit an existing Oxygen Publishing Template (on page 3285) package, follow these steps:

1. Unzip the ZIP archive associated with the Oxygen Publishing Template in a separate folder.

2. Link the folder associated with the template in the Project view.

3. Using the Project view, you can modify the resources (CSS, JS, fonts) within the Oxygen Publishing Template folder to fit your needs.

4. Open the publishing template descriptor file (.opt extension) in the editor and modify to suit your needs.

5. **Optional:** Once you finish your customization, you can archive the folder as a ZIP file.

**Related Information:**

- Publishing Template Package Contents for PDF Customizations (on page 2023)
How to Use a Publishing Template in a PDF Transformation

**From Oxygen XML Editor/Author**

A publishing template can be used for PDF output from the **DITA Map PDF - based on HTML5 & CSS** transformation scenario.

The **Templates** tab in the **DITA Map PDF - based on HTML5 & CSS** transformation scenario dialog displays all the templates that are available in your template gallery. To use a particular template in the transformation scenario, simply select it from this tab and then continue configuring the transformation using the other tabs to suit your needs.

To add the publishing template to your templates gallery, follow these steps:

1. Open the transformation scenario dialog box by editing a **DITA Map PDF - based on HTML5 & CSS** transformation.
2. In the **Templates** tab, click the **Configure Publishing Templates Gallery** link to.
   
   **Step Result:** This will open the preferences page.
3. Click the **Add** button and specify the location of your template directory.
   
   **Step Result:** Your template directory is now added to the **Additional Publishing Templates Galleries** list.
4. Click **OK** to return to the transformation scenario dialog box.
   
   **Step Result:** All the templates contained in your template directory will be displayed in the preview pane along with all the built-in templates.

**From Command Line**

You can use the simpler form, in which you use only the **pdf.publishing.template** parameter to point to the *.opt (publishing template) file:

```
dita.bat
   --input=map\test.ditamap
   "-Dpdf.publishing.template=full_path_to_template_dir/my_template.opt"
   --format=pdf-css-html5
   ...
```
Or use the two parameters to indicate the folder containing the publishing templates and the name of the publishing template file relative to that folder:

```

dita.bat
   --input=map\test.ditamap
   "-Dpdf.publishing.template=full_path_to_template_dir"
   "-Dpdf.publishing.template.descriptor=my_template.opt"
   --format=pdf-css-html5
   ...
```

Related Information:

- Transformation Parameters (on page 2018)

How to Share a Publishing Template

To share a publishing template with others, following these steps:

1. Copy your template in a new folder in your project.
2. Go to Options > Preferences > DITA > Publishing and add that new folder to the list.
3. Switch the option as the bottom of that preferences page to Project Options.
4. Share your project file (.xpr).

XSLT Extensions for PDF Transformations

Since PDF output is primarily obtained by running XSLT transformations over the DITA input files, one customization method would be to override the default XSLT templates that are used by the PDF transformation.

The pdf-css-html5 transformation type uses two stages to transform the merged DITA map (the one that aggregates all the topics) to HTML5:

1. **Stage 1**: Makes some changes on the merged map (on page 2042) and the result is a modified merged map. This stage can be altered by implementing the `com.oxygenxml.pdf.css.xsl.merged2merged` XSLT extension point. This extension overrides the stylesheets found in the following folder: `DITA-OT-DIR\plugins\com.oxygenxml.pdf.css\xsl\merged2merged`.

   **Note:** Use this when you need to filter DITA content.
2. **Stage 2**: Transforms the merged map (on page 2042) to HTML5 and the result is a single HTML document. This stage can be altered by implementing the `com.oxygenxml.pdf.css.xsl.merged2html5` XSLT extension point. This extension overrides the stylesheets found in the following folder: `DITA-OT-DIR\plugins\com.oxygenxml.pdf.css\xsl\merged2html5`.

   Note: Use this when you need to change the HTML structures generated for a specific DITA element.

These extension points can be used either from a **Publishing Template** or a DITA-OT extension plugin.

**How to Use XSLT Extension Points for PDF Output from a Publishing Template**

These examples demonstrate how to use XSLT extension points from an **Oxygen Publishing Template**.

**Use Case 1: Styling Codeblocks with a Zebra Effect**

Suppose you want your codeblocks to have a particular background color for one line, and another color for the next line. One advantage of this coloring technique is that you can clearly see when text from the codeblock is wrapped.

This effect can be done by altering the HTML5 output, creating a `div` for each line from the code block, then styling them.

To add this functionality using an **Oxygen Publishing Template**, follow these steps:

1. If you haven't already created a Publishing Template, see [How to Create a Publishing Template](on page 2029).
2. Link the folder associated with the publishing template to your current project in the **Project** view.
3. Using the **Project** view, create an `xslt` folder inside the project root folder.
4. In this folder, create an XSL file (for example, named `merged2html5Extension.xsl`) with the following content:

   ```xml
   <?xml version="1.0" encoding="UTF-8"?>
   <xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
                   xmlns:xs="http://www.w3.org/2001/XMLSchema"
                   exclude-result-prefixes="xs"
                   version="2.0">

   <xsl:template match="*[contains(@class, ' pr-d/codeblock ')]">
     <div class='zebra'>
       <xsl:analyze-string regex="\n" select=".">
         <xsl:matching-substring/>
       </xsl:analyze-string>
     </div>
   </xsl:template>
   ```
5. Open the template descriptor file (on page 2023) associated with your publishing template (the .opt file) and set the XSLT stylesheet created in previous step with the com.oxygenxml.pdf.css.xsl.merged2html5 XSLT extension point:

```xml
<publishing-template>
  ...
  <pdf>
    ...
    <xslt>
      <extension
        id="com.oxygenxml.pdf.css.xsl.merged2html5"
        file="xslt/merged2html5Extension.xsl"/>
    </xslt>
  </pdf>
</publishing-template>
```

6. Create a css folder in the publishing template directory. In this directory, save a custom CSS file with rules that style the codeblock structure. For example:

```css
div.zebra {
  font-family: courier, fixed, monospace;
  white-space: pre-wrap;
}

div.zebra > *:nth-of-type(odd) {
  background-color: silver;
}
```

7. Open the template descriptor file (on page 2023) associated with your publishing template (the .opt file) and reference your custom CSS file in the resources element:

```xml
<publishing-template>
  ...
  <pdf>
    ...
    <resources>
      <css file="css/custom.css"/>
    </resources>
  </pdf>
</publishing-template>
```
8. Edit the DITA Map PDF - based on HTML5 & CSS transformation scenario.
9. In the Templates tab, click the Choose Custom Publishing Template link and select your template.
10. Click OK to save the changes to the transformation scenario.
11. Run the transformation scenario.

Use Case 2: Removing the Related Links Section

Suppose you want the related links sections to be removed from the PDF output.

To add this functionality using an Oxygen Publishing Template, follow these steps:

1. If you haven’t already created a Publishing Template, see How to Create a Publishing Template (on page 2029).
2. Link the folder associated with the publishing template to your current project in the Project view.
3. Using the Project view, create an xslt folder inside the project root folder.
4. In this folder, create an XSL file (for example, named merged2mergedExtension.xsl) with the following content:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    exclude-result-prefixes="xs"
    version="2.0">

    <xsl:template match="*[contains(@class, ' topic/related-links ')]">
        <!-- Remove. -->
    </xsl:template>
</xsl:stylesheet>
```

5. Open the template descriptor file (on page 2023) associated with your publishing template (the .opt file) and set the XSLT stylesheet created in previous step with the following content:

```xml
<publishing-template>
    ...
    <pdf>
        ...
        <xslt>
            <extension
                id="com.oxygenxml.pdf.css.xsl_merged2merged"
                file="xslt/merged2mergedExtension.xsl"/>
        </xslt>
    </pdf>
    ...
</publishing-template>
```
6. Edit the DITA Map PDF - based on HTML5 & CSS transformation scenario.
7. In the Templates tab, click the Choose Custom Publishing Template link and select your template.
8. Click OK to save the changes to the transformation scenario.
9. Run the transformation scenario.

How to Use XSLT Extension Points for PDF Output from a DITA-OT Plugin

These examples demonstrate how to use XSLT extension points from a DITA-OT plugin.

Use-Case 1: Styling Codeblocks with a Zebra Effect

Suppose you want your codeblocks to have a particular background color for one line, and another color for the next line. One advantage of this coloring technique is that you can clearly see when text from the codeblock is wrapped.

This effect can be done by altering the HTML5 output, creating a div for each line from the codeblock, then styling them.

To add this functionality using a DITA-OT plugin, follow these steps:

1. In the DITA-OT-DIR\plugins\ folder, create a folder for this plugin (for example, com.oxygenxml.pdf.custom.codeblocks).
2. Create a plugin.xml file (in the folder you created in step 1) that specifies the extension point and your customization stylesheet. For example:

```xml
<plugin id="com.oxygenxml.pdf.custom.codeblocks">
  <feature extension="com.oxygenxml.pdf.css.xsl.merged2html5">
    <file>custom_codeblocks.xsl</file>
  </feature>
</plugin>
```

3. Create your customization stylesheet (for example, custom_codeblocks.xsl) with the following content:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
     xmlns:xs="http://www.w3.org/2001/XMLSchema"
     exclude-result-prefixes="xs"
     version="2.0">

  <xsl:template match="*[contains(@class, ' pr-d/codeblock ')]">
    <div class='zebra'>
      <xsl:analyze-string regex="\n" select='.'>
        ...
      </xsl:analyze-string>
    </div>
  </xsl:template>
</xsl:stylesheet>
```
Use the Run DITA-OT Integrator transformation scenario (on page 1665) found in the DITA Map section in the Configure Transformation Scenario(s) dialog box.

5. Create a custom CSS file with rules that style the codeblock structure. For example:

```css
div.zebra {
    font-family: courier, fixed, monospace;
    white-space: pre-wrap;
}
div.zebra > *:nth-of-type(odd) {
    background-color: silver;
}
```

6. Edit a DITA Map PDF - based on HTML5 & CSS transformation scenario and reference your custom CSS file (using the args.css parameter).

7. Run the transformation scenario.

Use-Case 2: Removing the Related Links Section

Suppose you want the related links sections to be removed from the PDF output.

To add this functionality using a DITA-OT plugin, follow these steps:

1. In the DITA-OT-DIR\plugins\ folder, create a folder for this plugin (for example, com.oxygenxml.pdf.custom.codeblocks).
2. Create a plugin.xml file (in the folder you created in step 1) that specifies the extension point and your customization stylesheet. For example:

```xml
<plugin id="com.oxygenxml.pdf.custom.related.links">
  <feature extension="com.oxygenxml.pdf.css.xsl.merged2merged"
           file="custom_related_links.xsl"/>
</plugin>
```
3. Create your customization stylesheet (for example, custom_related_links.xsl) with the following content:
4. Use the Run DITA-OT Integrator transformation scenario (on page 1665) found in the DITA Map section in the Configure Transformation Scenario(s) dialog box.

5. Run the DITA Map PDF - based on HTML5 & CSS transformation scenario.

Sample Use-cases: Using XSLT and CSS for PDF Transformations

In this section, you will find a series of use-cases that can be used as starting points for other customizations.

How to Use a Bullet Instead of Numbers for Tasks Containing a Single Step

If a DITA Task only contains one step (\texttt{<step>} element), you probably want it to be rendered like an unordered list (displayed with a bullet instead of a number).

\[
\begin{align*}
\ldots \\
\text{<steps>}
\text{<step>}
\text{<cmd>The step</cmd>}
\text{</step>}
\text{</steps>}
\ldots
\end{align*}
\]

Should be rendered as:

- The step

Instead of:

1. The step
To achieve this, you need to create an XSLT template that adds a special @outputclass attribute (with its value set to single) for the single step, then you need to match this attribute from the CSS and change its aspect.

1. In the customization XSL, add:

   <xsl:template match="*[contains(@class, ' task/step ')]*[count(../*[contains(@class, ' task/step ')][]) = 1]">
     <xsl:copy>
       <xsl:copy-of select="@*"/>
       <xsl:attribute name="outputclass" select="concat(@outputclass, ' single ')">
       </xsl:attribute>
       <xsl:apply-templates/>
     </xsl:copy>
   </xsl:template>

2. In your customization CSS (on page 2041), add:

   *[outputclass =~ "single"] {  
     list-style-type: circle !important;
     margin-left: 2em;
   }

Related Information:

- How to Use XSLT Extension Points for PDF Output from a Publishing Template (on page 2034)

DITA-OT Extension Points

The DITA-OT CSS-based PDF Publishing Plugin supports DITA-OT extension points that can be used to expand the functionality of the transformation. The extension points are defined in the plugin.xml file. For more information, see DITA Open Toolkit Extension Points.

Related Information:

- XSLT Extensions for PDF Transformations (on page 2033)
How to Contribute a Custom CSS to the Transformation from a DITA-OT Plugin

This topic is intended for publishing architects/developers that need to deploy a customized DITA-OT.

Usually, the CSS styles can be passed to the transformation by referencing the CSS files using the `args.css` parameter. However, there are cases where you want to add some sort of “built-in” CSS that is applied in conjunction with the publishing template or CSS files referenced in the transformation.

For this, you need to use the `com.oxygenxml.pdf.css.init` extension point and set the value of the `extension.css` ANT property to the path of the custom CSS file:

1. In your `plugin.xml` file, add:

   ```xml
   <feature extension="com.oxygenxml.pdf.css.init" file="init.xml"/>
   ```

2. Create a file named `init.xml` with the following ANT content:

   ```xml
   <root>
   <property name="extension.css"
     value="${dita.plugin.[com.my.plugin.id].dir}/css/my-custom.css"/>
   <!-- add here more init stuff if needed -->
   </root>
   ```

**Note:** The name of the root element does not matter. The content of this element will be copied in an initialization template.

**Important:** Make sure all file references begin with the ANT variable that is expanded to the base directory of your plugin.

Related Information:

- How to Use XSLT Extension Points for PDF Output from a DITA-OT Plugin *(on page 2037)*

Customization CSS

The publishing process is driven by a customization CSS.

To change the styling of the output for the DITA Map PDF - based on HTML5 & CSS transformation scenario:

1. Create the CSS file that will contain all your customizations. It is recommended to create this file in your project directory so you can edit it easily.
2. Add the custom CSS rules. See the various topics in this section for assistance with specific types of customizations.

3. For linking the CSS file, you have two options:
   a. Create a publishing template, create the customization CSS file inside the template folder and link it into the publishing template descriptor. See Publishing Templates (on page 1892).
   b. Choose an existing publishing template, then edit the scenario and set the full path to the custom CSS file as the value of the args.css parameter. The rules from custom CSS will override the rules from the template CSS files.

4. Run the transformation scenario.

**Debugging the CSS**

If you notice that some of the CSS properties were not applied as expected, some of the tips offered in this topic might help you with the debugging process.

**Merged Map File**

Depending on the type of transformation, one or more merged map files are created at some point during the transformation stages. These files could be used to help debug unexpected results.

1. The first thing you should try is to check the file structure of the merged map file. This can be found in the out/pdf-css directory and it has the .merged.xml file extension. For the DITA Map PDF - based on HTML5 & CSS transformation type, you will also find a .merged.html file. You can open these files in Oxygen XML Editor/Author to examine the structure. Optionally, you can use the pretty print feature (Format and Indent) to make the structure easier to read.

2. Check that the CSS selectors are written correctly against the document structure.

3. If you still cannot identify the problem, then inspect how the styles are applied (you can try any of the methods listed below).

**Inspecting the Applied Styles Using the Chrome Browser**

To inspect the applied CSS styles using Chrome:

1. In Chrome, open the file ending in .merged.xml or .merged.html (for the DITA Map PDF - based on HTML5 & CSS transformation type).

2. Click on the element you want to inspect.

3. Activate the Chrome Developer Tools by using More Tools > Developer Tools, or press CTRL +SHIFT+I.

4. Activate the Rendering pane by using More Tools > Rendering:
5. In the **Rendering** pane, select **print** from the **Emulate CSS media** section. This will activate the CSS selectors enclosed in `@media print { .. }`.

- **Note:** This allows you to debug the styling of elements, table of contents, and index, but not the styles of the page margin boxes (headers, footers) or page breaks.

- **Tip:** In the left pane of the **Developer Tools** interface, you can inspect elements and their styles in the **Elements** tab. You can click on any of the links to display the applied CSS files in the **Styles** tab in the right pane. Editing the styles in that pane results in a live preview of how the change will affect the output.

- **CAUTION:** Do not modify the built-in rules directly in the CSS files from the **Oxygen XML Editor/Author** installation. Instead, copy the rules to your own customization CSS.
Inspecting the Applied Styles Using Oxygen XML Editor/Author

To inspect styles:

1. In Oxygen XML Editor/Author, open the file ending in `merged.xml` or `merged.html` (for the DITA Map PDF - based on HTML5 & CSS transformation type).
2. [Optional] From the Styles toolbar, choose the + Print Ready entry. This will activate certain CSS selectors enclosed in `@media print {..}`.
3. Click on the element you want to style. Use the Inspect Styles action from the Contextual Menu. A specialized CSS Inspector view will show the built-in CSS rules.

Tip: With this file opened in Author mode, it might be helpful to switch the Tags Display Mode to Full Tags with Attributes. You might be able to identify the selector you need to style without using the CSS Inspector view.

Note: This allows you to debug styling of elements, but not of the page margin boxes (headers, footers) or page breaks.

CAUTION: Do not modify the built-in rules directly in the CSS files from the Oxygen XML Editor/Author installation. Instead, copy the rules to your own customization CSS.

Other techniques

These are some other techniques you may find useful:

- Add background and borders properties to the specific CSS rule. If they do not appear in the output then there is a problem with the rule selector.
- Try to use the !important notation to the property that is not applied, or make the selector more specific (you can add more parent selectors).
- To figure out how the elements are mapped into PDF, you can use this fragment in the customization CSS:

```css
* {
    border: 1pt solid blue !important;
}

*:before(1000) { 
    content: oxy_name() !important;
    color: orange;
}

*:before(999) {
```
How to Speed up CSS Development and Debugging

You can speed up your CSS development considerably by not invoking the entire pipeline of transforming your DITA maps to PDF. Instead, you can use the merged map (on page 2042) and transform it directly to PDF.

1. Transform your DITA Map to PDF using the DITA Map PDF - based on HTML5 & CSS or DITA Map PDF - based on DITA & CSS transformation scenario.
2. Open the merged file (on page 2042) (*.merged.html or *.merged.xml) that is located in the output directory in the editor.
3. Configure an XML to PDF transformation with CSS scenario. Do not set CSS files here since the merged file already contains pointers to the stylesheets. This scenario uses the Chemistry CSS processor.
4. Optional: Enable the output of the CSS processor using the following preferences page: Options > Preferences > XML > PDF Processors > CSS Processor.

Now you can make incremental changes to the CSS stylesheet and quickly see the results by transforming the merged file directly.

**Fastpath:** If your changes involve only element styling, with no specific paged media CSS rules and properties, you can simply open the merged file in a browser (such as Chrome or Firefox) and refresh at each CSS change, as shown in: Debugging the CSS (on page 2042).

How to Write XPath Expressions

This topic contains some guidelines for writing XPath expressions. They are used to extract the content from the merged DITA map document.

This is an example where the product name meta-information is placed before the front page title:

```xml
*[class="front-page/front-page-title"]:before {
    text-align: left;
    content: oxy_xpath("//*[contains(@class, 'topic/prodname')]/text()"[1]));
    display:block;
}
```
Notes:

- Do not use the DITA element names directly. You must use the DITA `@class` attribute instead, as these attributes are propagated to the merged elements (including HTML `<div>` elements) while the element names can be lost. By using the class selectors, you also cover DITA specializations.
- Use the `[1]` XPath predicate to select the first value from the document. For example, `oxy_xpath("///*[contains(@class, 'topic/prodname')]/text()])[1]`). The meta-information might be copied multiple times in the output, inherited by the `<topicref>` elements, so you can get many more values than expected.
- Do not use strings as values for the pseudo elements content, as the string values are not supported for pseudo elements. Instead, use the XPath directly.
- Use the Oxygen XPath Builder view to test the XPath expressions.

Related Information:

- How to Debug XPath Expressions *(on page 2046)*

How to Debug XPath Expressions

You can use the content extracted from the document using the `oxy_xpath` function in your pseudo elements (`:before`, `:after`) or in string-set variables.

For example, the following XPath finds the publication author, set in the DITA map:

```
<map>
  <title>The Art of Bike Repair</title>
  <topicmeta>
    <author>John Doe</author>
  </topicmeta>
...

:root {
  string-set: author oxy_xpath("///*[contains(@class, "front-page/front-page")]/*[contains(@class, "map/topicmeta")/*[contains(@class, "topic/author")]']/text()";}
```

To debug an XPath expression:

1. Read the XPath Expressions Guidelines *(on page 2045)*.
2. Begin by transforming your document using your customization CSS.
3. In the output folder, you will find a [MAP_NAME].merged.xml file (or if you are using the DITA Map PDF - based on HTML5 & CSS transformation, a [MAP_NAME].merged.html file).
4. Open the merged file in the Oxygen XML Editor/Author.
5. Activate the XPath Builder view (Window > Show View > XPath/XQuery Builder).
6. Paste your XPath expression and press the Execute XPath button. Check if it returns the expected results.

The XPath builder has a function that allows it to display the document path of the current element from the editor (Settings drop-down menu > Update on cursor move). Alternatively, you can right-click the element in the merged document and select the Copy XPath action, then paste it in the XPath builder.

Default Page Definitions

All page definitions are found in: [PLUGIN_DIR]css/print/p-pages-and-headers.css.

Note: This is listed solely for illustration purposes, as the plugin might use something different.

There are pages for the default page, chapter page, front matter page, back matter page, blank pages, index page, and large tables page.

Default Page

The default page imposes a header that contains the publication title, chapter, and section title. They alternate on the left or right side of the page:

```xml
@page :left {
    @top-left {
        content: string(maptitle) string(parttitle) string(chaptertitle)
        string(sectiontitle) " | " counter(page);
        font-size:8pt;
    }
}
```
Tip: To override the default rules defined for named pages (such as chapter or table of contents), you need to use more specific page rules that contain the page name:

```xml
@page: left, table-of-contents: left, chapter: left {
  @top-left {
    content: "...";
  }
}

@page: right, table-of-contents: right, chapter: right {
  @top-right {
    content: "...";
  }
}
```

Chapter Page

This is inherited from the default page. The chapter page is associated to the topics marked as chapters, usually direct children of the map. It clears the header from the first page of each chapter.

```xml
@page chapter{
  /* Currently inherit from the default page.*/
}

/* No headers on the chapter first page. */
@page chapter:first: left{
  @top-left {
    content: none;
  }
}

@page chapter:first: right{
  @top-right {
    content: none;
  }
}
```
Front Matter and Back Matter page

The bookmap front matter and back matter page. It clears the headers.

```xml
@page matter-page {
    @top-left-corner    { content:none }
    @top-left           { content:none }
    @top-center         { content:none }
    @top-right          { content:none }
    @top-right-corner   { content:none }
    @bottom-left-corner { content:none }
    @bottom-left        { content:none }
    @bottom-center      { content:none }
    @bottom-right       { content:none }
    @bottom-right-corner{ content:none }
}
```

Blank Pages

The following example clears the header for the blank pages that may be created by a `page-break-before`, `page-break-after`, or by using double side pagination (on page 2109):

```xml
@page :blank{
    @top-left { content: none;
    }
    @top-right { content: none;
    }
}
```

Index Page

The page that contains the index terms (appears only if there are such items in your topics). It uses a lower roman page number in the footer:

```xml
@page index {
    @top-left-corner   { content:none }
}
```
When transformed, the page layout is spread on two columns.

**Large Tables Page**

The big tables are placed on a rotated page, with orientation landscape:

```xml
@page landscape-page :right {
  size: landscape;

  @top-left {
    content: none
  }
  @top-center {
    content: none
  }
  @top-right {
    content: none
  }
  @right-bottom {
    content: string(maptitle) string(parttitle) string(chaptertitle) string(sectiontitle) " | " counter(page);
    font-size: 8pt;
    transform: rotate(90);
  }
}
```
<p>Page Size</p>

This is where you can find information on how the page sizes are defined.

**Page Size - Built-in CSS rules**

The {PLUGIN_DIR}/css/print/p-page-size.css file contains the default page rules. It uses the US-LETTER size (8.5 X 11 inches). The content of this file is:

```css
@page {
    padding-top: 0.2em;
    padding-bottom: 0.2em;
    size: us-letter;
}
```
How to Change the Page Size

Suppose you want to publish using the standard A4 page size, with a margin of 2cm.

In your customization CSS (on page 2041), use:

```css
@page {
    size: A4;
    margin: 2cm;
}
```

If you need different margins depending on the page side:

```css
@page {
    size: A4;
    margin: 2cm;
}
@page :left{
    margin-right: 4cm;
}
@page :right{
    margin-left: 4cm;
}
```

This would only increase the gutter margins or the inside margins needed for binding of the final book. The other margins would remain 2cm.

How to Change the Page Orientation

Suppose you want to publish on a landscape page. The default is portrait, so you need to change it by using the size property. This will contain both the physical measurements and the orientation. In your customization CSS (on page 2041), use:

```css
@page {
    size: us-letter landscape;
}
```
How to Change the Page Settings for a Specific Element

Suppose your publication is mainly using a portrait page orientation, but there are some topics that have wide images. To avoid having the images bleeding outside of the page, you could use a wider page setting (landscape).

1. Mark the topic with an `@outputclass` attribute and give it a distinct value (for example, `wide`).
   You can set the attribute on the root element of the topic, or on the `<topicref>` element from the map.

   **Note:** The `outputclass` values from the `topicref` automatically propagate to the root of the topic from the merged map (on page 2042).

2. In your customization CSS (on page 2041), match the output class and associate it with a named page. This page has landscape orientation and small margins. This technique works for any element (consider a table or a list) not necessarily a topic.

   ```xml
   *[outputclass = 'wide'] {
     page: wide-page;
   }

   @page wide-page {
     size: letter landscape;
     margin: 0.5in;
   }
   ```

Page Headers and Footers

The page headers and footers use the string sets defined for publication, chapter, and section titles. These string-sets are defined in the numbering CSS (on page 2088):

- **parttitle**
  Set to the title of the current part (only for DITA bookmaps that use parts).

- **chaptitile**
  Set to the title of the current chapter (Shallow and Deep numbering).

- **sectiontitle**
  Set to the title of each section (Deep numbering only).

Although you may define string sets in your customization CSS, you need to take into account the fact that the string-set CSS property is not additive, and matching the same elements will end up breaking the current definitions. A very common use-case is to match the title element that is also used in the default CSS. The best approach in this case is to take a look at the rules from the numbering CSS.
(on page 2088), copy the ones dealing with string sets to your customization, then alter the property definition by adding your definition to the existing ones (and not removing the existing ones).

Related Information:

- Numbering (on page 2088)

Page Headers and Footers - Built-in CSS

The headers and footers are part of the page definitions. To see how the default page layouts are defined, see: Default Page Definitions (on page 2047).

How to Position Text in the Headers and Footers

By default, the name of the publication and chapter titles are placed in the top-left or top-right page margin boxes:

```css
@page :left {
    @top-left {
        content: string(maptitle) string(parttitle) string(chaptertitle) string(sectiontitle) " | " counter(page);
    }
}

@page :right{
    @top-right {
        content: string(maptitle) string(parttitle) string(chaptertitle)
        string(sectiontitle) " | " counter(page);
    }
}
```

If you want to change this, you should use the content CSS properties of other page margin boxes, and inhibit the ones in the above content. For example, to set the chapter title in the page top left corner, you can use:

```css
@page :left {
    @top-left {
        content:none;
    }
    @top-left-corner {
```
Note: The corner page margin boxes are fixed and limited as the available space. Above, the `text-align` and `white-space` properties are used to make the text bleed out of these boxes towards the center of the page. If you plan to add an image or artwork background, you should consider using the technique described in: How to Decorate the Header by Using a Background Image on the Entire Page (on page 2060).

How to Change the Size of Headers and Footers

This is directly related to the page margins and size.

The headers and footers are placed in the so called page margin boxes, a series of rectangular areas residing in the page margins.

To affect the margins of all page definitions, you may use the following rule:

```css
@page {
  margin-top:3cm !important;
  margin-bottom:3cm !important;
  margin-left:2cm !important;
  margin-right:2cm !important;
}
```
If you want to affect only a specific page, like the first page from chapters for instance, you must use more specific page selectors. See the Default Page Definitions (on page 2047) for details.

Note that the page margin boxes fill the entire page margin. This means the margin-top, for example, dictates the height of the @top-left-corner, @top-left, @top-center, @top-right, @top-right-corner margin boxes. These cannot have margins on themselves, so to change the position of the content inside them, you must use padding properties:

```css
@page {
  @top-left {
    content: "...
    padding: 1cm;
  }
}
```

How to Change the Font of the Headers and Footers

To change the font for all the headers and footers, in your customization CSS (on page 2041), add a CSS rule similar to this:

```css
@page {
  font-size: 12pt;
  font-family: "Arial";
}
```

⚠️ **Important:** These settings apply to all page margin boxes, but not to the text inside the page.

If you want to change the settings only for a specific page type (for example, the table of contents), use the name of the page:

```css
@page table-of-contents {
  font-size: 12pt;
  font-family: "Arial";
}
```

**Related Information:**

- How to Change the Header of the Table of Contents (on page 2099)
How to Add a Multi-line Copyright Notice to the Footer

Suppose you want to add a footer with the following two lines of text at the end of each page that is shown on the right side:

© 2017 - My Company Ltd
All rights reserved

For this, you need to specify a rule that matches all the right pages and adds that content in the bottom-center. In your customization CSS (on page 2041), add the following CSS rule:

```css
@page :right {
    @bottom-center {
        content: "© 2017 - My Company Ltd \A All rights reserved";
        font-size: 0.5em;
        color: silver;
    }
}
```

**Note:** Other page rules (such as the table-of-contents) override the contents of the @bottom-center because they are more specific. If you need to also print the copyright in the TOC pages, then use this as the selector:

```css
@page :right, table-of-contents:right {
    ...
}
```

**Note:** To use new lines (\n characters) in your headers or footers, use the \A notation, as in the example above.

How to Add a Group of Topics to the Footer

To create a footer that contains the content of several topic files, but only on the last page, there are two possible approaches:

**Method 1: Using the position:fixed CSS Property**

1. Group all the footer topics under a single parent topic, under the last topic from your DITA map. For example, you can have the following map structure:

```dita
...
End topic
    Footer container topic
```
2. Add an `<outputclass>=footer` on the `<topic>` root element of the footer container topic, or on its `<topicref>` in the map.

3. Use the CSS `position: fixed` property to position this topic to the bottom of the page:

```css
*[outputclass ~= "footer"] {
    position: fixed;

    bottom: 0.5in;
    left: 0.5in;

    width: 5in;
    height: 200pt;
}
```

**Note**: Make sure the width and height are enough for the content of the footer to fit. Be careful because the content might bleed out of the page. Use bottom and left values to position the block in the page.

**Method 2: Using the float:footnote CSS Property**

The second approach would be to declare the footer block as a footnote. Assuming the same DITA Map structure as above, you can use the following CSS fragment:

```css
*[outputclass ~= "footer"] {
    float: footnote;
}

*[outputclass ~= "footer"]:footnote-call{
    color: transparent;
    font-size: 0;
}

*[outputclass ~= "footer"]:footnote-marker{
    color: transparent;
    font-size: 0;
}
```

**Note**: Use transparent colors and/or zero size font to avoid the display of the footnote counters.
How to Add a Background Image to the Header

A common use-case is to add a background image to one of the page corners.

```css
@page :left {
    @bottom-left-corner{
        content: " ";
        background-image: url('https://www.oxygenxml.com/resellers/resources/OxygenXMLEditor_icon.svg');
        background-repeat:no-repeat;
        background-position:50% 50%;
    }
}

⚠️ Important: Always specify a `content` property. If not, the page margin box will not be generated.

Another use-case is to use one of the `@top-left` or `@top-right` page margin boxes. These boxes have an automatic layout and they can be very small if they have no content. If there is no text to be placed over the image, use a series of non-breaking spaces ( \A0 ) to increase the box width as in the following example (alternatively, you can use the technique described in How to Decorate the Header by Using a Background Image on the Entire Page (on page 2060)):

```css
@page :left {
    @top-left{
        content: '\A0\A0\A0\A0\A0\A0\A0\A0\A0\A0';
        background-image: url('https://www.oxygenxml.com/resellers/resources/OxygenXMLEditor_icon.svg');
        background-repeat:no-repeat;
        background-position:50% 50%;
    }
}

‼️ Note: You can use raster image formats (such as PNG or JPEG), but it is best to use vector images (such as SVG or PDF). They scale very well and produce better results when printed. In addition the text from these images is searchable and can be selected (if the glyphs have not been converted to shapes) in the PDF viewer.

- Images and Figures (on page 2150)
How to Decorate the Header by Using a Background Image on the Entire Page

If you want to precisely position artwork and the page margin boxes are not sufficient, it is possible to use a background image for the entire page.

This technique consists of creating an image (SVG is the best since it is a vector image) as wide as the page that would contain the logo and placing other decorations at the desired locations. This offers the best results and the position of the artwork does not depend on the page margin contents.

Example:

```xml
@page :left, chapter:left, chapter:first:left {
  background-image: url('img/page_background_image_with_logos_and_artwork_for_left_page.svg');
  background-repeat: no-repeat;
  background-position: 50% 50%;
}
```

For a list of all the possible page names, see: Default Page Definitions (on page 2047).

Related Information:

• How to Add a Background Image for the Cover (on page 2078)

How to Style a Part of the Text from the Header

If you need to style a fragment of text (for example, a company slogan) with certain colors or font styles, you have several options:

• Use an SVG image as background for a page margin box or for the entire page. See: How to Add a Background Image to the Header (on page 2058).
• Use the oxy_label constructor. This is a function that creates a text label with a set of styles.

```xml
@page {
  @top-right {
    content: oxy_label(text, "My Company", styles, "color:red; font-size: larger;");
  }
}
```
You can combine the `oxy_label` with `oxy_xpath`, to extract and style a piece of text from the document:

```xml
oxy_label(text, oxy_xpath("/some/xpath"), styles, "color:blue; ");
```

Note: These functions work only with the Chemistry CSS processor.

Note: You cannot use `string()` inside an `oxy_label()`. As a workaround, to apply styling on the dynamic text retrieved by a `string()` function you can define some overall styles for the entire page margin box and then use the `oxy_label` to style differently the static text.

```css
@page {
  @top-right {
    color: red;
    content: oxy_label(text, "My Company", styles, "color:black")
      ,
      string(chaptertitle); /* This inherits the styling from @top-right*/
  }
}
```

• Use two adjacent page margin boxes, and style them differently:

```css
@page {
  @top-center {
    content: "First part";
    color: red;
    text-align:right;
  }
  @top-left {
    content: "- Second part";
    color: blue;
    text-align:left;
  }
}
```
How to Simplify the Header (Keep Only the Chapter Title)

The headers display information such as map title, part title, chapter title, and section title, ending in the page number.

```css
counter: string(maptitle) string(parttitle) string(chaptertitle) string(sectiontitle) " |
    counter(page);
```

This might be too much if you have long titles. The solution is to override the default header content.

In your customization CSS (on page 2041), add the following CSS rule:

```css
$page :left {  
    @top-left {  
        content: string(chaptertitle) " | " counter(page);  
    }  
}  
$page :right {  
    @top-right {  
        content: string(chaptertitle) " | " counter(page);  
    }  
}
```

⚠️ **Important:** Some of the CSS default page rules are more important. If you see that the content does not change:

- Try to also specify the name of the page, to increase the specificity of the rules:

  ```css
  @page :left, table-of-contents:left, chapter:left {  
    ...  
  }  
  @page :right, table-of-contents:right, chapter:right {  
    ...  
  }
  ```

- Add an `!important` classifier just before the semi-colon.

  ```css
  @top-right {  
    content: string(chaptertitle) " | " counter(page) !important;  
  }
  ```
How to Change the Header Separators (Between Sections and Chapter Titles)

There are some strings defined for part, chapter, and sections. Each of these strings start with the " | " character as a separator. For example, in the header of a page, you may find a sequence of strings:

| My Publication | Introduction | Getting Started |

1. "My Publication" is the value of the maptitle string.
2. "Introduction" is the value of the chaptertitle string.
3. "Getting Started" is the value of the sectiontitle string.

There might be cases where you want to change this separator. You will need to recompose the header content using the above string sets. Suppose you want to use " - " as a separator. In your customization CSS (on page 2041), add the following CSS rule:

```css
* [class ~="topic/topic"] [is-part] > * [class ~="topic/title"] {  
  string-set: parttitle " - " counter(part, upper-roman) " - " content(),  
  chaptertitle ""; /* Avoid propagating a past chapter title on a new part */
}
* [class ~="topic/topic"] [is-chapter]:not([is-part]) > * [class ~="topic/title"] {  
  string-set: chaptertitle " - " counter(chapter) " - " content();
}
```

If you enabled the deep numbering for chapters and subsections (on page 2092), then use:

```css
/*  
 * Alter the string sets that are shown in the header of the page.  
 */
* [class ~="map/map"] [p|numbering~='deep'] * [class ~="topic/topic"] [is-part] > * [class ~="topic/title"] {  
  string-set: parttitle " - " counter(part, upper-roman) " - " content(),  
  chaptertitle ""; /* Avoid propagating a past chapter title on a new part */
}
* [class ~="map/map"] [p|numbering~='deep'] * [class ~="topic/topic"] [is-chapter]:not([is-part]) > * [class ~="topic/title"] {  
  string-set: chaptertitle " - " counter(chapter) " - " content(), sectiontitle "";
}
* [class ~="map/map"] [p|numbering~='deep'] * [class ~="topic/topic"] [is-chapter]:not([is-part]) > * [class ~="topic/title"] > * [class ~="topic/title"] {  
  string-set: sectiontitle " - " counter(chapter) "." counter(section1) " - " content();
}
```
How to Change the Header Styling Depending on Page Side

To modify the styling of the default page headers, add the following CSS rule in your customization CSS (on page 2041):

```
@page :left {
    @top-left {
        color: navy;
        font-style: italic;
    }
    @top-right {
        color: red;
    }
}
```

If you intend to modify just the headers of the table of contents, use the `table-of-contents` page rule selector:

```
@page table-of-contents: left {
    @top-left {
        color: navy;
        font-style: italic;
    }
    @top-right {
        color: red;
    }
}
```

How to Use XPath Computed Data or Images in the Header or Footer

A very simple approach is to use the `oxy_xpath` directly in the `content` property:

```
@page front-page {
    @top-center {
        content: "Created: " oxy_xpath('//*'[contains(@class, " topic/created "])[1]');
    }
}
```

Example 1: Compute the Number of Words

The following example computes the number of words from the publication. It counts all the words, including the ones from the TOC, but does not take the static labels into account:

```
@page front-page {
```
Note: The XPath expression from the page rules is evaluated in the context of the document root element, so you will need to use absolute expressions starting with / or // . This is different from the case when the oxy_xpath is used in CSS rules that match an element. In this case, the XPath expressions are evaluated in the context of the matched element and you can use relative paths.

Tip: XPath 2.0 is supported (not schema aware).

Example 2: Retrieve Image from a Document and Insert it in the Header

Another example is to use an image from the document in the publication header:

```xml
<bookmeta>
  <metadata>
    ...
    <data name="cover">
      <image href="product-cover.png" outputclass="cover-image"/>
    </data>
    ...
  </metadata>
</bookmeta>
```

```css
@page {
  @top-center {
    content: url("oxy_xpath('//*[contains(@outputclass, "cover-image")/@href"]");
  }
}
```

If the URL returned by oxy_xpath is not absolute, it is considered to be relative to the CSS file. To obtain an absolute URL from one relative to the XML document, you can use in the XPath expression functions like resolve-uri and document-uri:

```css
@page {
  @top-center {
    content: url(oxy_xpath("resolve-uri('//*[contains(@outputclass, 'cover-image')]/@href"), document-uri(/))");
  }
}
```
Example 3: Insert the Current Date in the Footer

Another example is to use the `oxy_xpath` function to compute the current date and insert it in the publication footer:

```xml
@page {
  @bottom-left {
    content: oxy_xpath('current-date()');
  }
}
```

• Oxygen User Guide: `oxy_xpath()` Function

How to Change Header Images for Each Chapter

It is possible to dynamically change an image in the header depending on the chapter. For this, you need to define an image reference in the metadata section of each chapter. One way is to specify it in the DITA map by using the `<topicmeta>` element for the `<chapter>` topic reference:

```xml
...<chapter href="topics/installing.dita">
  <topicmeta>
    <data name="header-image" value="img/installing.png"/>
  </topicmeta>
..."
```

In the above example, there is a set of key value pairs with the name `header-image`. The `img/installing.png` is an image reference relative to the DITA map URI. This information is automatically copied into the content in the merged map file (on page 2042), like this:

```xml
<topic is-chapter="true" ...>
  <title class="--topic/title">Installing</title>
```
You install components to make them available for your solution.

This information can be picked up from CSS:

```css
/* Define the string set variable that contains an URL */
*[^class ~="topic/topic"][^class ~="topic/data"][^name="header-image"] {
    string-set: imgst oxy_url(oxy_xpath(`/@xtrf`), attr(value));
}

/* Using the value='none' stops applying the image. */
*[^class ~="topic/topic"][^class ~="topic/data"][^name="header-image"][^value="none"] {
    string-set: imgst "";
}

/* Use the string set variable in one of the page margin boxes. */
@page chapter {
    @top-left-corner {
        content: string(imgst);
        font-size:0; /* remove the font ascent and descent */
    }
}
```

**Details:** The `@value` attribute is used to build a URL relative to the URI of the DITA map. To determine the base URI of the DITA map, the `@xtrf` attribute was used from the root element of the merged map document, extracted using the `oxy_xpath` function.

**Notes:**

- The image is always aligned vertically to the middle of available space from the page margin box.
- Make sure you use an image of the correct size. For example, if you want to place the image in the top-left corner of the page, assuming the top and left page margins are 1 in, then make sure the image is a square having a size of 1 in.
- The image is applied to all pages that follow the data element, until another data element changes it:
To clear the image, use the `none` value:

```
...<data name="header-image" value="none"/>
...
```

### How to Add a Line Under the Header

There are two ways to add a horizontal line under the header.

#### Method 1: Add a Border in the Page Margin Boxes

To add a horizontal line that would stretch across the width of the page, add a bottom border to each of the 5 margin boxes in the top side of the page (`top-left-corner`, `top-left`, `top-center`, `top-right`, `top-right-corner`).

If you consider that the space between the header and the bottom border is too large, you could also change the alignment by adding a `vertical-align: bottom;` declaration in the page margin boxes.

For example, if you need to set some text as a header in the top-left margin box and insert a horizontal line under it, the customization CSS would look something like this:

```css
@page chapter, chapter:first: left: right, front-page{
...
Note: The `padding-top: 1em;` is used to avoid the border at the bottom of the header that joins with the page content.

**Method 2: Use a Background Image**

An alternative method is to add a horizontal line/border under an existing header (or in any other part of the page) using an SVG image, as described in How to Add a Background Image to the Header (on page 2058).
Metadata

DITA has a solid vocabulary for specifying metadata. There are `<prolog>` elements in the topics, and `<topicmeta>`, `<bookmeta>` elements in the bookmaps. They can be used to define authors, dates, audiences, organizations, etc. See: https://www.oxygenxml.com/dita/1.3/specs/archSpec/base/metadata-in-maps-and-topics.html

It is up to you to decide where this information should be presented, in the PDF content or in the PDF document properties.

Metadata - XML Fragment

In the merged map file (on page 2042), the metadata section is placed inside the `<oxy:front-page>` element. This is different from the original placement in the map or bookmap - after the title, but allows usage of information from it in the title page.

Bookmaps

This is an example of a section taken from a merged bookmap. It only contains some of the possible metadata elements. The `<bookmeta>` metadata section is inherited from `<topicmeta>`:

```xml
         xmlns:opentopic-index="http://www.idiominc.com/opentopic/index" cascade="merge"
         class="- map/map bookmap/bookmap "
         ditaarch:DITAArchVersion="1.3">

        <bookmeta xmlns:dita-ot="http://dita-ot.sourceforge.net/ns/201007/dita-ot"
                   class="- map/topicmeta bookmap/bookmeta ">

            <author class="- topic/author ">Howe Tuduit</author>
            <bookid class="- topic/data bookmap/bookid">
                <isbn class="- topic/data bookmap/isbn ">071271271X</isbn>
                <booknumber class="- topic/data bookmap/booknumber ">SG99-9999-00</booknumber>
                <maintainer class="- topic/data bookmap/maintainer ">
                    <organization class="- topic/data bookmap/organization ">ACME Tools</organization>
                    <person class="- topic/data bookmap/person ">
                    </person>
                </maintainer>
            </bookid>

        </bookmeta>

    </oxy:front-page>
</bookmap>
```

...
For the DITA Map PDF - based on HTML5 & CSS transformation type, the merged map is further processed resulting in a collection of HTML5 `<div>` elements. These elements preserve the original DITA `@class` attribute values and add a new value derived from the DITA element name.
Maps

The maps have a more simple structure, they use the `<topicmeta>` element for metadata sections. This is also a simplified example, as there may be many more elements in the metadata section:

```xml
     xmlns:opentopic-index="http://www.idiominc.com/opentopic/index"
     cascade="merge" class="- map/map "
     ditaarch:DITAArchVersion="1.3">
    ...
</map>

   <topicmeta class="- map/topicmeta ">
      <author class="- topic/author ">Dan C</author>
   </topicmeta>
   ...
</oxy:front-page>
```

For the DITA Map PDF - based on HTML5 & CSS transformation type, the merged map is further processed resulting in a collection of HTML5 `<div>` elements:

```xml
     xmlns:opentopic-index="http://www.idiominc.com/opentopic/index"
     cascade="merge" class="- map/map "
     ditaarch:DITAArchVersion="1.3">
    ...
</div>

<div class=" front-page/front-page front-page">
   ...
</div>

<div class="- map/topicmeta topicmeta">
   <div class="- topic/author author">
      Dan C
   </div>
</div>
```
Metadata - Built-in CSS rules

The [PLUGIN_DIR]/css/print/p-meta.css file contains the rules that extract metadata.

How to Add the Publication Audience to the Custom PDF Metadata

The audience element indicates the users the publication is addressing. This can be placed inside a <topicmeta> element in a <map> as in the following example:

```xml
<map>
  ...
  <topicmeta>
    ...
    <audience type="programmer" job="programming" experiencelevel="expert"/>
  </topicmeta>
</map>
```

To collect the @type attribute, add the following in your customization CSS (on page 2041):

```css
*[^class ~= "map/map"] > *[^class ~= "map/topicmeta"] > *[^class ~= "topic/audience"] {
  -oxy-pdf-meta-custom: "Audience" attr(type);
}
```

**Note:** It is best to use the class selector (such as *[^class ~= "map/topicmeta"]*) instead of topicmeta to cover cases where the elements are specialized (for instance, in a bookmap the bookmeta is a topicmeta, so your selector will also function for bookmaps, not only simple maps.

**Note:** The selector begins with map > to choose the <topicmeta> that is a direct child of the map, not other <topicmeta> elements from other <topicref> elements.

The metadata is displayed in the Custom tab of the Document Properties dialog box from Acrobat Reader:
How to Show Metadata in the Cover Page

Suppose you need to present the **author** and the **ISBN** just under the publication title. Your bookmap contains:

```xml
<bookmap id="taskbook">
  <booktitle>
    <booklibrary>Retro Tools</booklibrary>
    <mainbooktitle>Product tasks</mainbooktitle>
    <booktitlealt>Tasks and what they can do</booktitlealt>
  </booktitle>
  <bookmeta>
    <author>Howe Tuduit</author>
    <critdates>
      <created date="1/1/2015"/>
      <revised modified="3/4/2016"/>
      <revised modified="3/5/2016"/>
    </critdates>
    <bookid>
      <isbn>071271271X</isbn>
      <booknumber>SG99-9999-00</booknumber>
    </bookid>
  </bookmeta>
</bookmap>
```
The entire `<booktitle>` element content is displayed on the first page of the PDF, so suppose you need to add the information after it.

In your customization CSS (on page 2041), add the following CSS rules:

```css
*[class =~ "bookmap/booktitle"]:after {
    display:block;
    content: "by " oxy_xpath('//*[contains(@class, " bookmap/bookmeta ")]//
*[contains(@class, " topic/author ")]//text()');
    margin-top: 4em;
    text-align: center;
    color: gray;
}
*[class =~ "bookmap/booktitle"]:after(2) {
    display:block;
    content: "ISBN " oxy_xpath('//*[contains(@class, " bookmap/isbn ")]//text()');
    text-align: center;
    color: gray;
}
```

The following CSS extensions were used in this example:

- **oxy_xpath** - Executes an XPath expression and returns a string content. Use this whenever you need to extract data from elements other than the one matched by the CSS rule selector.
- **:after(N)** - Creates more than one `after` pseudo element. The argument value represents how far the generated content is from the real content. In the example above, the content of the `:after` is closer to the title (upper) than the content of the `:after(2)`.

Note: The `attr()` CSS function can also be used but is limited to extracting attribute values from the matched element.

**Generating Synthetic Pages for Metadata.**

Suppose you need to show this information on a page that follows the title page, instead of on the title page. In this case, you need to prepare a named page and place the content on it. In your customization CSS (on page 2041), add the following CSS rules:

```css
@page page-for-meta {
    background-color: yellow; /* Just to see it better*/
    @top-left-corner {
        content:""; /* Remove the default header */
    }
```
How to Show Metadata in the Header or Footer

The header and footer are composed of page margin boxes that can be populated with static text by using string-sets.

If you need to add some of the map metadata to the header of the front page (for example, the creation date), add the following CSS rules in your customization CSS (on page 2041):

```css
 *[class ~= "bookmap/booktitle"]:after {
   page: page-for-meta;
 }
 *[class ~= "bookmap/booktitle"]:after(2) {
   page: page-for-meta;
 }

@page front-page {
  @top-center {
    content: "Created: " string(mapcreated);
  }
}
```

**Note:** The front-page is the name of a page that used to present the element with the class “front-page/front-page”. The above page rule is combined with the default styles.

Cover (Title) Page

Customizing the cover page is one of the most requested customization requests.
The merged map file (on page 2042) contains the <oxy:front-page> element, as a child of the root element. This contains the metadata and an <oxy:front-page-title> element with the title structure.

```xml
<bookmap xmlns:ditaarch="http://dita.oasis-open.org/architecture/2005/" ...
<bookmeta xmlns:dita-ot="http://dita-ot.sourceforge.net/ns/201007/dita-ot"
<oxy:front-page-title>
<booktitle xmlns:dita-ot="http://dita-ot.sourceforge.net/ns/201007/dita-ot"
  class="- topic/title bookmap/booktitle ”>
  <booklibrary class="- topic/ph bookmap/booklibrary ”>Retro Tools</booklibrary>
  <mainbooktitle class="- topic/ph bookmap/mainbooktitle ”>Tasks</mainbooktitle>
  <booktitlealt class="- topic/ph bookmap/booktitlealt ”>Product tasks</booktitlealt>
</booktitle>
</oxy:front-page-title>
</oxy:front-page>
```

For the DITA Map PDF - based on HTML5 & CSS transformation type, the merged map is further processed resulting in a collection of HTML5 <div> elements. These elements preserve the original DITA @class attribute values and add a new value derived from the DITA element name.

```xml
<div class="- map/map bookmap/bookmap bookmap">
  <div class=" front-page/front-page front-page front-page">
    <div class="- map/topicmeta bookmap/bookmeta bookmeta">
      ...
    </div>
  </div>
<div class=" front-page/front-page-title front-page-title">
  <div class="- topic/title bookmap/booktitle booktitle">
    <div class="- topic/ph bookmap/booklibrary booklibrary”>Retro Tools</div>
    <div class="- topic/ph bookmap/mainbooktitle mainbooktitle ”>Tasks</div>
    <div class="- topic/ph bookmap/booktitlealt booktitlealt ”>Product tasks</div>
  </div>
</div>
```

...
Cover Page - Built-in CSS rules

The element with the class `frontpage/frontpage` is associated with a page named `front-page` with no headers or footers. The front page title is styled with a bigger font. The built-in CSS rules are in `[PLUGIN_DIR]/css/print/p-front-page.css`.

```css
@media print {

  *[class~="front-page/front-page"] {
    page: front-page;
  }

  *[class~="front-page/front-page-title"] {
    display:block;
    text-align:center;
    margin-top:3in;
    font-size:2em;
    font-family:arial, helvetica, sans-serif;
    font-weight:bold;
  }

  @page front-page {
    @top-left-corner { content:none }
    @top-left { content:none }
    @top-center { content:none }
    @top-right { content:none }
    @top-right-corner { content:none }
    @bottom-left-corner { content:none }
    @bottom-left { content:none }
    @bottom-center { content:none }
    @bottom-right { content:none }
    @bottom-right-corner{ content:none }
  }
}
```

Note: This is listed solely for illustration purposes, as the plugin might use something different.

How to Add a Background Image for the Cover

The simplest way is to create an SVG image as large as the entire physical page and set it as the background for the `front-page`. This makes it very easy to accomplish a good positioning of the
graphical elements or artwork. In the foreground, you can place text fragments using a series of :after pseudo elements bound to the front page title.

To set the size to an SVG image, you should specify the @width and @height attributes on the <svg> root element using specified unit values (in, cm, etc.) This should be enough only if all the coordinates from your drawing have unit identifiers.

If you are using unit-less coordinates in your drawing like the following:

```
<polygon points="17.78 826.21 577.51 ....
```

then make sure you also specify a @viewBox attribute on the <svg> root element that defines the abstract rectangle that contains the drawing:

```
<svg xmlns="http://www.w3.org/2000/svg" width="8.5in" height="11in" viewBox="0 0 600 850">
```

The following SVG document has the @width, @height, and @viewBox attributes. The width and height have physical units (in inches), while the view box and rectangle coordinates are unit-less.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE svg PUBLIC "-//W3C//DTD SVG 1.1//EN" "http://www.w3.org/Graphics/SVG/1.1/DTD/svg11.dtd">
<svg xmlns="http://www.w3.org/2000/svg" width="8.5in" height="11in" viewBox="0 0 110 110">
  <desc>A gradient as big as a page.</desc>
  <defs>
    <linearGradient id="lc"
      x1="0%" y1="0%"
      x2="0%" y2="100%"
      spreadMethod="pad">
      <stop offset="0%" stop-color="#00DD00" stop-opacity="1"/>
      <stop offset="100%" stop-color="#00AA00" stop-opacity="1"/>
    </linearGradient>
  </defs>
  <rect x="5" y="5" width="100" height="100" rx="10" ry="10"
    style="fill:url(#lc); stroke: #005000; stroke-width: 3;"/>
  <text x="33%" y="50%" color="#FFFFAA">Sample</text>
</svg>
```
This example shows a gradient. It is the size of a US-LETTER page and can be used in a publication using this page size.

**Note:** You can use raster image formats (such as PNG or JPEG), but it is best to use vector images (such as SVG or PDF). They scale very well and produce better results when printed. In addition the text from these images is searchable and can be selected (if the glyphs have not been converted to shapes) in the PDF viewer.

In your customization CSS *(on page 2041)*, add the following:

```css
@page front-page {
    background-image: url("us-letter.svg");
    background-position: center;
}
```

For smaller artworks, you can use `background-position` with percentage values to position and center the artwork (for example, a company logo):

```css
@page front-page {
    background-image: url("company-logo.svg");
    background-position: 50% 5%; /* The first is the alignment on the X axis, the second on the Y axis.*/
    background-repeat: no-repeat;
}
```

**Note:** The text from the SVG or PDF background images are searchable in the PDF reader.

How to Change Styling of the Cover Page Title

Match the front page title element in your customization CSS *(on page 2041)* based on its class attribute:

```css
*[class =~ "front-page/front-page-title"] {
    margin-top: 1in;
    font-size: 3em;
}
```
How to Add Text to the Cover Page

If you need to add arbitrary text to the cover page, you can use the front page title element as an anchor and add as many blocks of text as you need after it, and style them differently.

In your customization CSS (on page 2041), add the following:

```css
*[class =~ "front-page/front-page-title"]:after(1) {
  display:block;
  content: "DRAFT VERSION";
  font-size: large;
  color: red;
  text-align:center;
}

*[class =~ "front-page/front-page-title"]:after(2) {
  display:block;
  content: "DO NOT DISTRIBUTE WITHOUT PERMISSION";
  font-size: large;
  color: red;
  text-align:center;
  font-style: italic;
}
```

The result is:

![Result Image]

To use content from the document, you can use the `oxy_xpath` function in the `content` property. For a more complex example, including the generation of a new page for the synthetic `:after` elements, see: How to Show Metadata in the Cover Page (on page 2074).

Related Information:
How to Place Cover on the Right or Left Side

In your customization CSS (on page 2041), add the following CSS rules:

```
*[class ~="front-page/front-page"]{
    page-break-before: left;
}
```

⚠️ **Note:** This will create an empty page at the beginning of the publication, moving the cover content on the needed side.

For more information, see: Oxygen PDF Chemistry: Controlling Page Breaks.

Related Information:

- Double Side Pagination (on page 2109)

How to Add a Specific Number of Empty Pages After the Cover Page

In your customization CSS (on page 2041), add the following CSS rules:

```
@page my-blank-page {
    /* Hide the page numbers */
    @top-left {content: none};
    @top-right {content: none};
}

*[class ~='front-page/front-page']:after(1){
    page:my-blank-page;
    display:block;
    content:'\2002';
    color:transparent;
    page-break-after:always;
}

*[class ~='front-page/front-page']:after(2){
    page:my-blank-page;
    display:block;
```

Note: The \002 character is a space that is not shown on the pages, but gives a value for the content property.

Related Information:

- How to Force an Odd or Even Number of Pages in a Chapter (on page 2110)

How to Add a Copyright Page after the Map Cover (Not for Bookmaps)

Regular DITA maps do not have the concept of a copyright notice. This is available only in the DITA bookmap structure.

If you are constrained to using a regular map and you need to add a copyright page between the front cover and the TOC, use the following technique:

In your customization CSS (on page 2041), declare a new page layout:

```css
@page copyright-notice-page {
  @top-left {
    content:none; /* Clear the headers for the copyright page */
  }
  @top-right {
    content:none;
  }
}
```

The oxy:front-page element contains the title of the publication and generates the cover page. A synthetic :after element is created that follows this element and it is placed on a different page.

```css
front-page:after{
  content: '\002';
  page-break-after:always;
}
```
display:block;

page: copyright-notice-page; /* Moves the synthetic element on a new page. */

margin-top:90%; /* use margins to position the text in the page */
margin-left: 5em;
margin-right: 5em;

content: "Copyright 2018-2019 MyCorp Inc. All rights reserved";

text-align: center; /* More styling */
color: blue;
}

If you need to add more content as blocks, use the :after(2), :after(3) pseudo elements:

front-page:after(2){

display:block;
page: copyright-notice-page; /* Continue on the same page as the first ':after'. */
content: "Some more styled text";
color: red;
}

If you want to extract information from the document, use the oxy_xpath() function. For example, if the copyright info is stored in the map like this:

<map ...>
  <topicmeta>
    <copyright>
      <copyryear year="2018"/>
      <copyrholder>MyCorp Inc.</copyrholder>
    </copyright>
  </topicmeta>
  ...
</map>

Use:

front-page:after(3){

display:block;
page: copyright-notice-page;
content: "Year: oxy_xpath('//*:front-page/topicmeta/copyright/copyryear/@year')"
How to Remove the Cover Page and TOC

If you need to hide or remove the cover page, the table of contents or other structures, match the elements with a "front-page/front-page" and "toc/toc" classes in your customization CSS (on page 2041):

```
/*[class =~ 'map/map'] > *[class =~ 'toc/toc'] {
  display:none !important;
}
/*[class =~ 'map/map'] > *[class =~ 'front-page/front-page']{
  display:none !important;
}
/*[class~='topic/topic'][is-chapter] {
  -oxy-page-group : auto;
}
```

Front Matter and Back Matter

The **front matter** is a series of topics that are usually placed after the cover page and before the TOC or the content.

The **back matter** is a series of topics that are usually placed after the content of the book.

Front Matter and Back Matter - XML Fragment

In the merged map file (on page 2042), the frontmatter topics are wrapped in an `<oxy:front-matter>` element that has the class `bookmap/frontmatter` (it is a clone of the original `<frontmatter>` element from the map):

```
<bookmap xmlns:ditaarch="http://dita.oasis-open.org/architecture/2005/" ...>
    class=" front-page/front-page ">
    ...
  </oxy:front-page>
    class="- map/topicref bookmap/frontmatter ">
    <concept xmlns:dita-ot="http://dita-ot.sourceforge.net/ns/201007/dita-ot"
      class="- topic/topic concept/concept ">
For the **DITA Map PDF - based on HTML5 & CSS** transformation type, the merged map is further processed resulting in a collection of HTML5 `<div>` elements. These elements preserve the original DITA `@class` attribute values and add a new value derived from the DITA element name.

```
<oxy:front-matter
...
</oxy:front-matter>
```

Front Matter and Back Matter - Built-in CSS

The built-in CSS rules are in `[PLUGIN_DIR]/css/print/p-bookmap-frontmatter-backmatter.css`. By default, it associates the top-level topics that do not represent chapters to a `matter-page` style of page layout. Each child topic starts on a new page.

Related Information:

- Page Headers and Footers (on page 2053)

How to Remove Page Breaks Between Front Matter Child Topics

If you do not like the fact that all the topics that enter a bookmap frontmatter start on a new page, you can disable this by using the following rules in your customization CSS (on page 2041):

```
* [class =~ "map/map"] > * [class =~ "topic/topic"]:not([is-chapter]) {
  page-break-before: auto;
}
```
How to Style the Front Matter and Back Matter Topics

Style all the Topics with the Same Aspect

All the topics referenced from the `<frontmatter>` and `<backmatter>` bookmap elements are formatted using the `matter-page` as defined in Default Page Definitions (on page 2047). In the merged file, the `<backmatter>` and `<frontmatter>` elements are omitted, and their child topic content is matched using a CSS rule like the one below:

```
*[class =~ "map/map"] > *[class =~ "topic/topic"]:not([is-chapter]){
    page: matter-page;
    ...
}
```

Style the Topics Depending on Their Role

There might be cases when you need to distinguish between different topics having different roles in your publication:

- Preface
- Notice
- Abstract
- Copyright

These are referenced from the DITA map by specialized `<topicref>` elements, with different class attribute values.

The class attribute values are then passed by the transformation process onto the corresponding topic elements from the merged map content. For example, a topic that was referenced by a `<preface>` map element now has a "bookmap/preface" value in its `@topicrefclass` attribute:

```
<topic class="- topic/topic "
    id="unique_1"
    topicrefclass="- map/topicref bookmap/preface " .. >
    ...
</topic>
```

This can be used to match and apply different styling, or even a different page layout:

```
@page preface-page {
    background-color:silver;
    @top-center{
```
Numbering

The topics in this section contain some technical details in case you need to fine-tune the way the numbering works.

Numbering - Built-in CSS

The built-in CSS rules are in:

- `[PLUGIN_DIR]/css/print/p-numbering-shallow.css`
- `[PLUGIN_DIR]/css/print/p-numbering-deep.css`
- `[PLUGIN_DIR]/css/print/p-numbering-deep-chapter-scope.css`
- `[PLUGIN_DIR]/css/print/p-numbering-deep-chapter-scope-no-page-reset.css`

The first CSS (shallow) contains rules that add a "Chapter NN" before the first-level topics from the publication, the second one (deep) contains rules that add a deep structure of counters on all topics referenced from the map (at any level), the third one (chapter-scope) creates a chapter scope-oriented numbering (meaning that the numbering for pages, tables, figures, and links to them are reset for each chapter), and the last one is similar to the third except that page numbers do not reset. For more details, see Numbering Types (on page 2092).

Numbering - Input XML Fragments

The numbering affects multiple logical parts of your publication, the table of contents, headers/footers, chapter titles, figures and tables titles:

The Table of Contents

The table of contents is a tree of `<topicref>` elements.
Note: The <opentopic:map> element contains the effective table of contents structure.

Note: The TOC items are the elements with the class: - map/topicref.

Note: The ones identified as chapters have the @is-chapter attribute set.

For the DITA Map PDF - based on HTML5 & CSS transformation type, the merged map is further processed resulting in a collection of HTML5 <div> elements. These elements preserve the original DITA @class attribute values and add a new value derived from the DITA element name.
The Header and Footers

These are based on string sets generated for the titles. The complete set of strings is defined in:
[INSTALLATION_DIR]/css/print/p-pages-and-headers.css.

The CSS rules that build the string sets are matching the map title from the front page and the titles from the content.

For the DITA Map PDF - based on HTML5 & CSS transformations:

The main content is organized as follows:
For the DITA Map PDF - based on HTML5 & CSS transformations:

```
<opentopic:map>
  ...
</opentopic:map>

Note: The topic content comes after the `<opentopic:map>` element.

Note: The child topics are the elements that have the class `-topic/topic` included in the parents.
Note: The ones identified as chapters have the @is-chapter attribute set.

The Titles of Chapters

The titles from the content are children of the topics:

```
<topic class="- topic/topic " id="unique_2" oid="dcpp_parameters">
    <title class="- topic/title ">Parameters</title>
    ...
</topic>
```

For the DITA Map PDF - based on HTML5 & CSS transformations:

```
<div class="- topic/topic topic" id="unique_2" oid="dcpp_parameters">
    <div class="- topic/title title ">Parameters</div>
    ...
</div>
```

Note: The title elements have the class: - topic/title. The actual element name can be different.

Numbering Types

The type of numbering is controlled by the parameter args.css.param.numbering.

This parameter activates various sets of CSS rules from the built-in CSS. By default, only the first-level topics (the chapters) are numbered (shallow numbering). The following values are accepted:

<table>
<thead>
<tr>
<th>Value</th>
<th>Chapters</th>
<th>Sections</th>
<th>Figures &amp; Tables</th>
<th>Pages</th>
</tr>
</thead>
<tbody>
<tr>
<td>shallow</td>
<td>numbered</td>
<td>counted from the start of the publication</td>
<td>from the start of the publication</td>
<td></td>
</tr>
<tr>
<td>deep</td>
<td>numbered</td>
<td>numbered</td>
<td>counted from the start of the publication</td>
<td>from the start of the publication</td>
</tr>
<tr>
<td>deep-chapter-scope</td>
<td>numbered</td>
<td>numbered</td>
<td>numbering is restarted at the beginning of each chapter, adds the chapter number in their titles (and in the links to them), and in the list of tables and list of figures sections</td>
<td>restarted at the beginning of each chapter</td>
</tr>
<tr>
<td>deep-chapter-scope-no-page-reset</td>
<td>numbered</td>
<td>numbered</td>
<td>numbering is restarted at the beginning of each chapter, adds the chapter number in their titles</td>
<td>from the start of the publication</td>
</tr>
<tr>
<td>Value</td>
<td>Chapters</td>
<td>Sections</td>
<td>Figures &amp; Tables</td>
<td>Pages</td>
</tr>
<tr>
<td>-------</td>
<td>----------</td>
<td>----------</td>
<td>------------------</td>
<td>-------</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(and in the links to them), and</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>in the list of tables and list of</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>figures sections</td>
<td></td>
</tr>
</tbody>
</table>

Note: The `deep-chapter-scope` and `deep-chapter-scope-no-page-reset` values are only available for the DITA Map PDF - based on HTML5 & CSS transformation scenario.

Examples

**Shallow**

Each chapter is numbered, but sections are not numbered. Figures, tables, and pages are numbered sequentially from the start of the publication and they do not reset.

1. First Chapter
   - Page 1
   - Section
   - Table 1
   - Table 2
   - Section
   - Page 2
   - Table 3
2. Second Chapter
   - Page 3
   - Section
   - Table 4
   - Table 5
   - Section
   - Page 4

**Deep**

Each chapter and section is numbered (sections are prefixed with the chapter number). Figures, tables, and pages are numbered sequentially from the start of the publication and they do not reset.

1. First Chapter
   - Page 1
   - Section 1.1
   - Table 1
   - Section 1.2
   - Table 2
   - Page 2
Deep Chapter Scope

Each chapter is independent (so it can be read separately, as a separate part of your publication). The section, page, figure, and table counters (and links to them) restart at each chapter. The general cross reference links also display the chapter number before the page number to clearly specify the target.

Deep Chapter Scope No Page Reset

Each chapter is independent (so it can be read separately, as a separate part of your publication). The section, figure, and table counters (and links to them) restart at each chapter, but the page numbers do not reset. The generic cross reference links contain only the page number.
How to Remove the 'Chapter NN' Prefix from Table of Contents and Content

If you are using the shallow numbering CSS (this is the default), and you want to hide the "Chapter" prefix, use the following rules in your customization CSS (on page 2041):

For the TOC:

```
*[class ~="map/topicmeta"] > *[class ~="topic/navtitle"]:before {
    display:none !important;
}
```

For the titles in the content, change the content of the title :before (this example just uses the chapter number):

```
*[class ~="topic/topic"][is-chapter]:not([is-part]) > *[class ~="topic/title"]:before {
    
    content: counter(chapter) ". " !important;
}
```

Table of Contents

The table of contents is a hierarchy of topic titles with links to the topic content.

For plain maps, the TOC is automatically generated. For DITA bookmaps, you will need to add a `<toc>` element in the `<booklists>` element (inside the `<frontmatter>`):
<bookmap>
...
</bookmap>

<frontmatter>
  <booklists>
    <toc/>
    <figurelist/>
    <tablelist/>
  </booklists>
</frontmatter>

Related Information:

- Table of Contents for Chapters (Mini TOC) *(on page 2102)*
- List of Tables/Figures *(on page 2106)*
- Index *(on page 2114)*

Table of Contents - XML Fragment

In the merged map file *(on page 2042)*, the `<opentopic:map>` contains a hierarchy of `<topicref>` elements, or other elements (such as `<chapter>` or `<part>`) that are specializations of `<topicref>`.

Each of the `<topicref>` elements include a *metadata* section that includes the topic title.

```xml
<bookmap ...
<oxy:front-page> ...
<oxy:front-matter> ...
<opentopic:map xmlns:opentopic="http://www.idiominc.com/opentopic" class="- toc/toc">
  <booklibrary class="- topic/ph bookmap/booklibrary ">Retro Tools</booklibrary>
  <mainbooktitle class="- topic/ph bookmap/mainbooktitle ">Tasks</mainbooktitle>
```
For the **DITA Map PDF - based on HTML5 & CSS** transformation type, the merged map is further processed resulting in a collection of HTML5 `<div>` elements. These elements preserve the original DITA `@class` attribute values and add a new value derived from the DITA element name.
Note: The <oxy:toc-title> element is used as a placeholder for the name of the TOC. For instance, you can use the string "Contents", specified on a pseudo element, in the CSS.

Table of Contents - Built-in CSS

The built-in CSS rules are in: [PLUGIN_DIR]/css/print/p-toc.css.

Related Information:

- Page Headers and Footers (on page 2053)

How to Style the Table of Contents Entries

Note: Each of the items from the table of contents is an element that has the map/topicref class.

The following example uses the italic font for the label and changes the color and style of the connecting line between the title and the page number.

In your customization CSS (on page 2041), add the following two selectors:
And if you need to alter the indent of the nested table of content items, use the following selector:

```css
*[class =~ "map/topicref"] *{margin-left: 1em;}
```

The numbers can be styled like this:

```css
*[class =~ "map/topicref"] > *[class =~ "map/topicmeta"]:before, *[class =~ "map/topicref"]
  > *[class =~ "map/topicmeta"] > *[class =~ "topic/navtitle"]:before{
    color:blue;
}
```

The following is an example of customizing the font size for the items representing chapters. The chapters are level one topics and are marked in the merged DITA document TOC with the attribute `@is-chapter`.

```css
*[class =~ "map/topicref"][@is-chapter = "true"] > *[class =~ "map/topicmeta"] > *[class =~ "topic/navtitle"]{
  font-size:2em;
}
```

How to Change the Header of the Table of Contents

In the built-in CSS, there is a page named `table-of-contents`. The default is to have the word ‘Contents’ in its header (this is localized, using the `toc-header` string defined in the `p-18n.css`) alternating in the left or right side of the header:

```css
@page table-of-contents: left {
  @top-left {
    
```
If you need to change this string, or change the color, you should use the following `@page` selectors as a starting point in your customization CSS (*on page 2041*):

```css
@page table-of-contents: left {
  @top-left {
    content: "My publication table of contents | " counter(page, lower-roman);
    color: red;
  }
}
@page table-of-contents: right {
  @top-right {
    content: "My publication table of contents | " counter(page, lower-roman);
    color: red;
  }
}
```

**Related Information:**

- Localization (*on page 2132*)

How to Make the Table of Contents Start on an Odd Page

In your customization CSS (*on page 2041*), add the following snippet for the `table-of-contents` page:

```css
@page table-of-contents {
  -oxy-initial-page-number: auto-odd;
}
```

**Related Information:**
How to Display a Topic Before the Table of Contents

To display a topic before the table-of-contents page, follow these steps:

1. Make sure the topic is referenced on the first level in the DITA map.
2. Set the @outputclass to before-toc on the <topicref>.

   `<topicref href="pathToMyTopic" outputclass="before-toc">`

**Result:** When the PDF is processed, the topic will automatically appear before the table of contents.

**Related Information:**

- Controlling the Publication Content (on page 2164)

---

How to Display Short Descriptions in the TOC

To display the short descriptions from the topics in the table of contents, you need to make the <shortdesc> element visible.

The following example only makes the short descriptions associated with the chapters visible. The chapters are level one topics and are marked in the merged DITA document TOC with the attribute @is-chapter.

In your customization CSS (on page 2041), add the following CSS selector:

```css
*[class ~="map/topicref"] [is-chapter = "true"] > *[class ~="map/topicmeta"] > *[class ~="map/shortdesc"] {
  display:block; /* The default is none - the shortdesc is hidden. */
  color:gray;
}
```

**Note:** If you need all the TOC item short descriptions to be visible, remove the [is-chapter] condition.
How to Remove Entries from the TOC

To remove entries from the table of contents, set the @toc="no" attribute on the topicrefs from the map that need to be removed. This is sometimes desirable for the topics listed in the frontmatter or backmatter when using a bookmap.

How to Hide the TOC

To hide the TOC, you have multiple options:

- Use a DITA bookmap instead of a DITA map, and omit the <toc> element from the <booklists>. An example bookmap can be found in the DITA 1.3 Spec. This is the best approach.
- Use the transformation parameter: hide.frontpage.toc.index.glossary (on page 2021).
- Use a display:none property to hide the element that contains the TOC structure, and also remove it from the PDF bookmarks tree:

    ```html
    *[class ~="map/map"] > *[class ~="toc/toc"] { display:none; }
    *[class ~="map/map"] > *[class ~="toc/toc"] > *[class ~="toc/title"]{
      bookmark-label: none;
      -ah-bookmark-label: none;
    }
    ```

Related Information:

- Transformation Parameters (on page 2018)

Table of Contents for Chapters (Mini TOC)

To add a mini table of contents for each chapter, you need to:

- Use DITA bookmaps instead of regular maps.
- Set the args.chapter.layout transformation parameter to the value: MINITOC.

This table of contents is positioned between the chapter title and the chapter child topics. It consists of a list of links pointing to the child topics, positioned in the left side of the page, and a description in the right side. This content is collected from the topic file referenced by the chapter <topicref> in the map.
Chapter 1. Introduction

Topics:

About this framework.

Description

DITA Open Toolkit, or DITA-OT for short, is a set of Java-based, open-source tools that provide processing for content authored in the Darwin Information Typing Architecture.

The DITA Open Toolkit documentation provides information about installing, running, configuring and extending the toolkit.

About this framework.

The framework is DITA.

Description

The framework is composed by a large set of modules.

The above chapter example has the following DITA map fragment:

```dita
<chapter href="topics/chapter-introduction.dita">
  <topicref href="topics/introduction-about.dita" />
  <topicref href="topics/introduction-description.dita" />
</chapter>
```

The `chapter-introduction.dita` file provides the description content that is in the right side of the page. The children `<topicref>` elements generate the mini TOC links.

Table of Contents for Chapters (Mini TOC) - XML Fragment

In the merged XML file, the mini TOC is built from a related links section and some `<div>` elements that wrap the entire mini TOC and the description area.

`chapter/minitoc`

Wraps the entire structure, including the content of the chapter `<topicref>`.

`chapter/minitoc-links`

Wraps the `<related-links>` element. Note that the label of the related links list is internationalized.

`chapter/minitoc-desc`

Contains the entire content of the topic file referenced by the chapter `<topicref>` element in the map.
When using the pdf-css-html5 transformation, this structure is converted to a set of HTML elements, preserving the class values:
DITA Open Toolkit, or DITA-OT for short, is a set of Java-based, open-source tools that provide processing for content authored in the Darwin Information Typing Architecture.

The DITA Open Toolkit documentation provides information about installing, running, configuring and extending the toolkit.
In your customization CSS (on page 2041), add the following selectors:

```css
/* Change from inline to blocks to stack them one over the other. */

*[class~="chapter/minitoc-desc"],
*[class~="chapter/minitoc-links"] {
  display: block;
  width: 100%;
}

/* No need for the 'Topics:' label. */

*[class~="chapter/minitoc-links"] *[class~="topic/desc"] {
  display: none;
}

/* Add background for the links list. */

*[class~="chapter/minitoc-links"] {
  background-color: silver;
  padding: 0.5em;
}

/* Remove the border and the padding from the description. We do not need that separator. */

*[class~="chapter/minitoc-desc"] {
  border-left: none;
  padding-left: 0;
}

/* Add a number before each of the links. */

*[class~="chapter/minitoc-links"] *[class~="topic/link"] {
  display: list-item;
  list-style-type: decimal;
  margin-left: 1em;
}
```

Related Information:

- How to Speed up CSS Development and Debugging (on page 2045)
List of Tables/Figures

To activate these:

1. The map must be a DITA bookmap.
2. There must be a `<figurelist>` or `<tablelist>` in the frontmatter or backmatter. In the following example, both of the lists are added just after the table of contents (the `<toc>` element is the placeholder where the table of contents will be created):

```xml
<frontmatter>
    <booklists>
        <toc/>
        <figurelist/>
        <tablelist/>
    </booklists>
</frontmatter>
```

How to Set a Header for a List of Tables/Figures

Suppose you want to set the headline “Figure List” on the second and subsequent pages associated to a list of figures and something similar for a list of tables.

Start by associating pages to the list of figures and tables from the merged file:

```xml
 *[class~="placeholder/tablelist"] { 
     page:tablelist;
     color:green;
 }

 *[class~="placeholder/figurelist"]{ 
     page:figurelist;
     color:green;
 }
```

![Note:](Note: The "placeholder/tablelist" is the class name of the output generated from the `<tablelist>` bookmap element.

Then define the pages:

```xml
 @page figurelist {
     @top-left { content: none; } 
     @top-center { content: "Figure List"; } 
     @top-right { content: none; }
```
How to Remove the Numbers Before a List of Tables or Figures

Suppose you need to remove the "Figure NN" prefix before each entry of a list of figures.

An entry in the generated list of figures from the merged map looks like this:

```html
<entry class="- listentry/entry " href="#unique_6_Connect_42_fig_rjy_spn_xgb">
  <prefix class="- listentry/prefix ">Figure</prefix>
  <number class="- listentry/number ">4</number>
  <title class="- topic/title ">This is another figure</title>
</entry>
```

For the HTML merged map, the element names are all div elements but they have the same class.

So, to hide the label and the number, use:

```css
*[class="listentry/prefix"],
*[class="listentry/number"] { display:none; }
```

This works for both a list of tables and list of figures since the structure of each entry is the same.
To make it more specific (for example, to apply it only for the list of figures), you can add the selector:

```
*[class~="placeholder/figurelist"] *[class~="listentry/prefix"],
*[class~="placeholder/figurelist"] *[class~="listentry/number"] {
  display:none;
}
```

**Double Side Pagination**

By default, the processor generates pages that are mirror images (the right page has the header on the right side, the left pages have the header on the left side). The chapters follow one another with no constraint on the page side.

**Note:** For a plain DITA map, the chapters are the `<topicref>` elements that are placed on the first level. For bookmaps, the chapters are the topics referenced by a `<chapter>` element.

This section contains information about how to position the start of the chapters on an odd folio number. Some of the CSS rules given here as examples are already listed in: [INSTALLATION_DIRECTORY]/css/print/p-optional-double-side-pagination.css. You may choose to import this file from your customization CSS (on page 2041).

**How to Start Chapters on Odd Pages**

A common use case is to arrange the chapters of the publication to start on an odd page number.

In your customization CSS (on page 2041), add the following:

```css
@page chapter {
  -oxy-initial-page-number: auto-odd;
}
@page table-of-contents {
  -oxy-initial-page-number: auto-odd;
}
```

Supported values for `-oxy-initial-page-number` include: auto, auto-even, auto-odd, or a number.

**How to Style the Empty (Blank) Pages**

By making the chapters start on an odd page, the CSS processor might add blank pages to the previous page sequence as padding.

To style those blank pages add the following code in your customization CSS (on page 2041):

```css
@page chapter:blank, table-of-contents:blank {
  @top-left { content: none; }
}
Note: This just removes the headers and footers, but you can use a background image or a header with "Intentionally left blank" text.

Related Information:

- How to Add a Background Image for the Cover (on page 2078)

How to Force an Odd or Even Number of Pages in a Chapter

Another use case is to specify a number of pages for a section. Suppose that you have a table of contents that follows the cover page and you need to have an even number of pages. Hence, the next chapter would start on an even page.

In your customization CSS (on page 2041), use the -oxy-force-page-count property with an even value:

```css
@page table-of-contents {
  -oxy-force-page-count: even;
}
```

Supported values for -oxy-force-page-count include: even, odd, end-on-even, end-on-odd, auto, no-force.

How to Style the First page of a Chapter

You can use the :first page rule selector to control how the first page of a chapter looks. Suppose that you have defined the following layout for your default page and you want to put the publication title (the maptile string) on the header of the first page (instead of the chapter name that is displayed on this page):

In your customization CSS (on page 2041), add the following:

```css
@page chapter:first {
  @top-right-corner { content: string(maptitle); }
  @top-left { content: none; }
}```
Multiple Column Pages

This section contains information about how to deal with pages that have multiple columns.

How to Use a Two Column Layout

Change Layout for Predefined Pages.

First you need to identify which of the pages need to be changed. Pages are already defined for the cover page, table of contents, chapter content, and others. The complete list is here: Default Page Definitions (on page 2047).

Next, add the column-count and column-gap properties to that page. For example:

```xml
@page chapter{
    column-count:2;
    column-gap:1in;
}
```

If you need some of the elements to expand on all the columns, use the column-span:all CSS property. The next snippet makes the chapter titles span both columns:

```css
*[class ~= "topic/topic"] [is-chapter] > *[class ~= "topic/title"] {
    column-span:all;
}
```

⚠️ Limitation: You cannot use multiple column configurations on the same page. Oxygen XML Editor only takes the column-count and column-gap properties into account if they are set on @page rules, not on elements from the content.

Change Layout for a Specific Topic.

If you need to have a different column layout just for one topic, you can use the following technique:

1. Define an outputclass on the topic root element.

   ```xml
   <topic outputclass="two_columns" ...>
   ```

2. Define a CSS rule that changes the page property for the matching element.

   ```css
   *[class ~= "two_columns"],
   *[outputclass ~= "two_columns"]{
   ```
Tip: In the selector, use the class attribute for the HTML transformation, or outputclass for the direct transformation, or leave them both if you are not sure.

Note: The topics from the first level use the chapter page. You must use !important because the built-in rules are more specific and you need to override the page property.

3. Define a page layout.

```html
@page two_column_page {
  column-count: 2;
}
```

Note that the topic will be separated from other sibling topics with different page layouts by page breaks.

Related Information:

- Page Formatting in oXygen PDF Chemistry

PDF Bookmarks

The PDF Bookmarks are used to generate a hierarchical structure similar to a table of contents in a specialized view of your PDF Reader.

By default, the titles defined in the topics are used as bookmark labels.

PDF Bookmarks - Built-in CSS

The PDF bookmarks are generated by matching the titles from the topics in the content. The built-in CSS rules are in: [PLUGIN_DIR]/css/print/p-bookmarks.css.

How to Change the Bookmark Labels using the Navigation Title

To change the bookmark labels, you can specify a navigation title in a DITA map or topic.

This will be used as the bookmark label instead of the topic title in the table of contents and the bookmark views. There are two possibilities to do specify it:

1. Place a `<navtitle>` element in the topic reference in the DITA map:

   ```xml
   ...
   ```
Note: As a best practice, a `@locktitle` attribute with the value 'yes' is needed to activate the navigation title. The plugin applies the navigation title even if the attribute is missing.

2. Place a `<navtitle>` element in the topic, as a title alternative.

How to Control the Depth of the Sections From the PDF Bookmarks.

By default, the PDF bookmarks are generated for up to 7 levels. If you need to limit them (for example to 2 levels), you can use the following CSS rules in your customization CSS (on page 2041):

```css
*[class~="topic/topic"] *\[class~="topic/topic"] *\[class~="topic/title"] { 
bookmark-label:none;
}
```

These rules clear the labels generated by the titles starting with the depth 3 (the topic nesting level is given by the selectors `*[class="topic/topic"]`).
How to Specify the Open/Closed PDF Bookmark State

If you want to specify the initial state for the bookmarks (opened/expanded or closed/collapsed), you can use the `bookmark-state` property in your customization CSS (on page 2041).

For example, to specify that all bookmarks for the first three levels are opened (expanded) in the initial state, use:

```html
*[class~="topic/topic"] > *[class~="topic/title"],
*[class="topic/topic"] *[class~="topic/topic"] > *[class~="topic/title"],
*[class="topic/topic"] *[class~="topic/topic"] *[class~="topic/topic"] >
  *[class~="topic/title"] {
    bookmark-state:open;
  }
```

How to Remove the Numbering From the PDF Bookmarks

By default, the PDF bookmark labels are generated while taking the text set before the chapters titles into account. Since this usually contains the part, chapter, or section numbers, the PDF Bookmarks will make use of them.

The solution is to remove the `content(before)` from the `bookmark-label`, leaving just the `content(text)`.

In your customization CSS (on page 2041), add the following CSS rules:

```html
*[class~="topic/topic"] > *[class~="topic/title"] {
  bookmark-label: content(text);
  -ah-bookmark-label: content();
}
```

⚠️ Important: This is a simple example that does not use the possible navigation titles, just the content of the `<title>` element. Copy and modify the built-in CSS for the full CSS rule that matches the `<title>` and `<titlealts>` elements:

```html
*[class~="topic/topic"]:has(*[class~="topic/titlealts"])) > *[class~="topic/title"]
{...
```

Related Information:

- Numbering (on page 2088)
Index

The content of an `<indexterm>` element is used to produce an index entry in the generated index. You can nest `<indexterm>` elements to create multi-level indexes. The content is not output as part of the topic content, only as part of the index tree.

To add an index to your publication, you just need to add `<indexterm>` elements inside the `<prolog>` section (inside a `<metadata>` element):

```
<title>The topic title.</title>
<prolog>
  <metadata>
    <keywords>
      <indexterm>Installing <indexterm>Water Pump</indexterm></indexterm></indexterm>
    </keywords>
  </metadata>
</prolog>
<body>
  .....  
```

or in the content itself:

```
...  
<p>Open the lid then turn the body pump to the right.</p>  
<indexterm>Installing <indexterm>Water Pump</indexterm></indexterm>
</p>  
...  
```

If you are using a bookmap, you need to specify where the index list should be presented (for instance in the `backmatter` of the book. Technically, it is possible to also add it to the frontmatter, but this is unusual). This is done using an `<indexlist>` element in the `<booklists>` element (inside the `<backmatter>`):

```
<bookmap>
  ...
  <chapter href="tasks/troubleshooting.dita">
    ...
  </chapter>
  ...
</bookmap>

<backmatter>
  <booklists>
    <indexlist/>
  </booklists>
</backmatter>  
```
For plain maps, the index list is automatically added at the end of the publication, with no need to modify the map.

Index - XML Fragment

In the merged map file (on page 2042), the structure that holds the index tree is the `<opentopic-index:index.groups>` element.

```xml
<map class="- map/map ">
  <oxy:front-page>...
  </oxy:front-page>
  <opentopic:map xmlns:opentopic="http://www.idiominc.com/opentopic">
    ...
  </opentopic:map>
  <topic class="- topic/topic ">
    <title class="- topic/title ">Request Support</title>
    ...
  </topic>
  <opentopic-index:index.groups id="d16e5548">
    ...
  </opentopic-index:index.groups>
</map>
```

Each of the groups contain:

- A label, the starting letter ("T" in the following example).
- A tree of `<opentopic-index:index.entry>` elements.

```xml
<opentopic-index:index.group>
  <opentopic-index:index.label>T</opentopic-index:index.label>
  <opentopic-index:index.entry value="table of contents">
    <opentopic-index:formatted-value>table of contents</opentopic-index:formatted-value>
    <opentopic-index:refID value="table of contents:">[d16e3988]
      <oxy:index-link xmlns:oxygen="http://www.oxygenxml.com/extensions/author" href="#d16e3988">[d16e3988]
```
Each of the entries contain:

- The formatted value (`<opentopic-index:formatted-value>`).
- A link to the publication content (`<opentopic-index:refID>/<oxy:index-link>`).
- Possibly other child entries.

For the DITA Map PDF - based on HTML5 & CSS transformation type, the merged map is further processed resulting in a collection of HTML5 `<div>` elements. These elements preserve the original DITA `@class` attribute values and add a new value derived from the DITA element name.
The index group content becomes:

```html
<div class="index/group group">
  <div class="index/label label">T</div>
  <div class="index/entry entry">
    <div class="index/formatted-value formatted-value">table of contents</div>
    <div class="index/refid refid">
      <div class="index/link link" href="#d16e3988">[d16e3988]</div>
    </div>
  </div>
</div>
```

```html
<div class="index/entry entry">
  <div class="index/formatted-value formatted-value">change header</div>
  <div class="index/refid refid">
    <div class="index/link link" href="#d16e4176">[d16e4176]</div>
  </div>
</div>
```

```html
<div class="index/entry entry">
  <div class="index/formatted-value formatted-value">style</div>
  <div class="index/refid refid">
    <div class="index/link link" href="#d16e4120">[d16e4120]</div>
  </div>
</div>
```

**Index - Built-in CSS**

All index styling is found in: [PLUGIN_DIR]css/print/p-index.css.
How to Style the Index Page Title and the Grouping Letters

In your customization CSS (on page 2041), add the following CSS rules:

```css
*[^index/groups] *[^index/group] *[^index/label] {
  font-size: 1.5em;
  color: navy;
}

[^index/groups]:before {
  content: "- Index - ";
  color: navy;
  font-size: 4em;
}
```

The result is:

```
- Index -
```

How to Style the Index Terms Labels

In your customization CSS (on page 2041), add the following CSS rule:

```css
[^index/groups] *[^index/formatted-value] {
  font-style: oblique;
  color: gray;
}
```

The result is:
How to Add Filling Dots Between the Index Labels and the Page Numbers

Suppose you want the leader CSS content to generate a row of dots. It is necessary that the parent entry has the text justified.

In your customization CSS (on page 2041), add the following CSS rule:

```css
*[class~="index/formatted-value"],
*[class="index/refid"] {
  display:inline;
}

/* Hide the sequences of links that actually do not contain links. */
*[class="index/group"] *[class ~="index/entry"] > *[class="index/refid"]{
  display:none;
}
*[class="index/group"] *[class ~="index/entry"] > *[class="index/refid"]:has(*[class="index/link"]){
  display:inline;
}

*[class="index/group"] *[class="index/entry"] {
  text-align:justify;
}
*[class="index/group"] *[class ~="index/entry"] > *[class="index/refid"]:before{
  content:leader('');?>;
}
```

The output now contains the dots:
How to Change the Index Page Number Format and Reset its Value

The page number is reset at the beginning of the index page by the built-in CSS rule:

```css
* [class ~="index/groups"] {
    counter-reset: page 1;
}
```

If you want to start the page counter from a different initial number, just change the value of this counter. For example, to continue the normal page counting, use:

```css
* [class ~="index/groups"] {
    counter-reset: none;
}
```

If you need to style the page number differently (for example, using decimals), add the following CSS rule in your customization CSS (on page 2041):

```css
@page index {
    @bottom-center  {
        content: counter(page, decimal) }
}
```

How to Impose a Table-like Index Layout

In case you need to place the index labels and links on the same line but with some extra alignment constraints, you can use inline blocks to give the index a table-like appearance:
You need to place the elements that have the following class on the same line:

- `index/formatted-value`
  - This is the text of the index term.
- `index/refid`
  - This element contains a list of links.

A fixed width is used for the formatted value and the links container (almost half of the available width). To achieve the index hierarchical layout, set progressive padding to the formatted value text.

In your customization CSS (on page 2041), add the following CSS rule:

```css
*[class~="index/formatted-value"],
*[class~="index/refid"]{
    display:inline-block;
}

*[class~="index/formatted-value"]{
    width:45%;
}
*[class~="index/refid"] {
    width:45%;
}

/* Hide the sequences of links that actually do not contain links. */
```
To avoid bleeding of the index term label, you may need to mark it as being hyphenated:
To activate hyphenation, see: How to Enable Hyphenation for Entire Map (on page 2128).

Footnotes

Footnotes are pieces of information placed at the bottom of the page. A footnote has a number that is left in the content (the footnote call) and the same value placed before the footnote text (the footnote marker).

Footnotes - Built-in CSS

Footnote properties are defined in [PLUGIN_DIR]css/print/p-foot-notes.css.

How to Change Style of the Footnote Markers and Footnote Calls

To bold the footnotes numbers and use some colors, add the following rules to your customization CSS (on page 2041):

```css
*[class =~ "topic/fn"]:footnote-call {
  font-weight: bold;
  color:red;
}

*[class =~ "topic/fn"]:footnote-marker {
  font-weight: bold;
  color:red;
}
```

Related Information:

How to Add a Separator Above the Footnotes

The @footnote part of a @page declaration controls the style of the separator between the page content and the footnotes. For the content, you should set a leader. The leader uses a letter or a line style to fill the entire width of the page.

```xml
$page {
  margin:0.5in;
  ....
}
```
To create a dotted line, you can use the dot character: `leader('.')`. Other commonly used characters are: "-" (dash) and "_" (underscore).

How to Reset the Footnotes Counter

There are cases where you want to reset the footnote counter.

For example, if you need to reset it at the beginning of each chapter, add the following rules to your customization CSS (on page 2041):

```css
*[class ~="bookmap/chapter"],
*[class ~="topic/topic"]{is-chapter} {
  counter-reset: footnote 1;
}
```

Or you can mark any element with an `@outputclass` value, match that value, and reset the counter at any point in your counter:

```css
<p outputclass="reset-footnotes"/>

*[outputclass ~="reset-footnotes"] {
  counter-reset: footnote 1;
}
```

Page Breaks

The page breaks can be controlled in multiple ways:

1. By creating an `@page` and assigning it to an element will create a page break between this element and the sibling elements that have a different page.
3. In your DITA topic, set the `@outputclass` attribute on the topic root (or any element) to contain one of the `page-break-before`, `page-break-after`, or `page-break-avoid` values. If you want to control the page breaking from the DITA map, use the `@outputclass` attribute on the `<topicref>`, with any of the values mentioned above.
Page Breaks - Built-in CSS

Page break properties are used in: \[PLUGIN_DIR\]css/print/p-page-breaks.css.

How to Avoid Page Breaks in Lists and Tables

To avoid splitting elements over two pages, you can use the page-break-inside CSS property. For example, if you want to impose this on tables and lists, then add the following rules to your customization CSS (on page 2041):

*\[class ~="topic/table"]\{*
  page-break-inside:avoid;
*
*\[class ~="topic/ol"]\{*
  page-break-inside:avoid;
*
*\[class ~="topic/ul"]\{*
  page-break-inside:avoid;
*

\[Note:\] Since the task steps are inherited from topic/ol, they will also not be split over two separate pages. However, if you want to allow this, add the following CSS rule:

*\[class ~="task/steps"]\{*
  page-break-inside:auto;
*

\[Note:\] Another way to do this is to mark the element with an @outputclass set to page-break-avoid.

How to Force a Page Break Before or After a Topic or Another Element

If you want to force a page break, mark the topic (or any other element you need to control page breaking for) with an @outputclass set to one of these values:
**page-break-before**

Use this for a page break before the marked element.

**page-break-after**

Use this for a page break after the marked element.

**page-break-avoid**

Use this to avoid page breaks inside the marked element.

For example, to force a page break before a certain topic, you should use:

```xml
<topic outputclass="page-break-before" ...
```

**Note:** You can set the output class on the `<topicref>` element from the DITA map instead of the `<topic>` element. In this way you can reuse the topic in another context where the page breaking is not necessary.

You can also control page breaking for lists, paragraphs, or any other block type elements. The following example avoids page breaks inside an ordered list:

```xml
<ol outputclass="page-break-avoid" ...
```

**How to Add a Blank Page After a Topic**

If you want to add a new blank page after a topic, add the following rules to your customization CSS *(on page 2041).*

Style the separating blank page:

```css
@page topic-separating-page{
  @top-left {
    content: "";
  }
  @top-right {
    content: "";
  }
  @top-center {
    content: "This page is blank";
  }
}
```

Associate this page to the `:after` pseudo element of the topic:

```css
*[class="topic/topic"]*[outputclass="add-separator-page"]:after {
```
In the XML content, on the `<topic>` element, set the `@outputclass` to the `add-separator-page` value.

```xml
<topic outputclass="add-separator-page"> ... </topic>
```

The `:after` pseudo element will be created next to the topic content and will be placed on the `topic-separating-page`.

Use the page margin box selectors to override the default content from the headers/footers.

⚠️ **Note:** You can set the output class on the `<topicref>` element from the DITA map instead of the `<topic>` element. This allows you to reuse the topic in another context where the page breaking is not necessary.

### How to Enforce a Number of Lines from Paragraphs that Continue in Next Page

In typography, an *orphan* is the first line of a paragraph that appears alone at the bottom of a page (the paragraph continues on a following page), while a *widow* is the last line of a paragraph that appears alone at the top of a page. The default is 2 for each of them. You can control this number by adding the following to your customization CSS (on page 2041):

```css
:root {
    widows: 4;
    orphans: 4;
}
```

### Hyphenation

Hyphenation specifies how words should be hyphenated when text wraps across multiple lines.

#### How to Enable Hyphenation for Entire Map

To enable hyphenation for your entire map:

1. Make sure you set an `@xml:lang` attribute on the root of your map, or set the `default.language` parameter in the transformation.
2. In your customization CSS (on page 2041), add:

```css
:root {
    hyphens: auto;
}
```
3. To except certain elements from being hyphenated, use `hyphens:none`. The following example excludes the `<keyword>` elements from being hyphenated:

```css
*[class =~ "topic/keyword"] {
    hyphens: none;
}
```

How to Enable/Disable Hyphenation for Tables

To enable hyphenation for your entire map:

1. Make sure you set an `@xml:lang` attribute on the root of your map or your table elements.
2. In your customization CSS (on page 2041), add:

```css
*[class =~ "topic/table"] {
    hyphens: auto;
}
```
3. To except certain elements from being hyphenated, use `hyphens:none`. The following example excludes the `<keyword>` elements from being hyphenated:

```css
*[class =~ "topic/keyword"] {
    hyphens: none;
}
```

Accessibility

By default, the PDF documents produced using this plugin are partially accessible in the sense that most of the paragraphs, tables, lists, headers, and footers are tagged automatically so a PDF reader can use this information to present the content.

Related Information:
- Oxygen PDF Chemistry: Accessibility

Accessibility - Built-in CSS

Accessibility properties are defined in [PLUGIN_DIR]css/print/p-accessibility.css.
How to Create Fully Accessible Documents

To make your documents fully accessible (PDF/UA1), do the following:

1. In your customization CSS (on page 2041), specify fonts for all elements and for all page margin boxes. There should be no text that falls back to the basic provided fonts (Times, Courier, etc.). For instance, you can use:

```css
:root { font-family: Arial }
@page {
    @top-left {font-family: Arial }
    ...
}
```

2. Specify an `@alt` attribute with a description on any image, or better, use the `<alt>` DITA element.

3. Change the Chemistry invocation from the `build.xml` file, adding the argument `-pdf-ua`. There are two targets to change: `chemistry` and `chemistry.embedded`.

Fonts

Fonts are an important part of the publication. Your font selection should take into consideration both design and the targeted ranges of characters.

To use them in the customization CSS (on page 2041):

- You can place the font files in the same folder as your CSS and use a `@font-face` definition to reference them.
- You can use web fonts (for example, Google Fonts), and import the CSS snippet into your CSS.
- You can use system fonts.

All these techniques are explained in: Oxygen PDF Chemistry User Manual: Fonts.

How to Avoid Characters Being Rendered as #

When the processor renders text with a font that does not include certain characters, those characters are replaced with the `#` symbol.

To prevent this, make sure you use the proper font.

As an example, suppose the right arrow character is used in a definition list like this:

```xml
<dlentry>
    <dt>→</dt>
    <dd><ph>This is the right arrow.</ph></dd>
</dlentry>
```
If the font does not include this character, the output will look something like this:

```
#
This is the right arrow.
```

To fix this, use a fallback font. For example, if you use *Times New Roman* for the entire publication, you could add *Symbol* as the fallback font. In your *customization CSS (on page 2041)*, add:

```
*[class =~ "topic/dlentry"] {  
  font-family: "Times New Roman", Symbol;
}
```

**Tip:** On Windows, one simple way to determine the font needed to display the text is to copy the text fragment that has rendering problems from the DITA source document and paste it into Microsoft WordPad or Word. It will automatically select a font capable of rendering the text. Simply click on the text to see the name of the font from the "Font" ribbon toolbar. Then you can use it as a fallback font in the CSS. Make sure there are no licensing restrictions on that particular font.

**How to Set Fonts in Titles and Content**

Suppose that in your *customization CSS (on page 2041)*, you have defined your font (for example, *Roboto*) using a Google web font:

```
@import url('https://fonts.googleapis.com/css?family=Roboto');
```

You can force a font on all elements, then style the ones that need to be different. The advantage of this method is that you do not need to trace all elements that have a font family defined in the built-in CSS files, you just reset them all.

In your *customization CSS (on page 2041)*, add an `!important` rule that associates a font to all the elements from the document:

```
*{
  font-family:"Roboto" !important;
}
```

**Note:** If you want to use the `:root` selector instead of the `*` sector, without the `!important` qualifier, the elements that have a predefined font specified in the built-in CSS will keep that font. If your content uses non-Latin glyphs, it is possible that the built-in fonts do not render them.

Next, identify the selectors for the elements that need to be styled with a different font than the one associated above. For information on how to do this, see: *Debugging the CSS (on page 2042).*
For example, if you want the titles or the pre-formatted text to have a different font from the rest, matched by the above `*` selector, you need to use more specific CSS selectors:

```css
* [class~="front-page/front-page-title"],
* [class~="topic/title"] {
  font-family: Arial !important;
}

* [class~="pr-d/codeph"],
* [class~="topic/pre"] {
  font-family: monospace !important;
}
```

Related Information:

- How to Change the Font of the Headers and Footers (on page 2056)

How to Use Fonts for Asian Languages

For Asian languages, you must use a font or a sequence of fonts that cover the needed character ranges. If the characters are not found, the `#` symbol is used.

When you specify a sequence of fonts, if the glyphs are not found in the first font, the next font is selected until one that includes all the glyphs is found. A common font sequence for Asian languages is as follows:

```css
font-family: Calibri, SimSun, "Malgun Gothic", "Microsoft JhengHei";
```

To apply this font sequence, see: How to Set Fonts in Titles and Content (on page 2131).

Some of the Asian fonts do not have italic, bold, or bold-italic variants. In this case, you may use the regular font file with multiple font face definitions to simulate (synthesize) the missing variants. You need to use the `-oxy-simulate-style:yes` CSS property in the font face definition as explained in: Using Simulated/Synthetic Styles in Oxygen Chemistry

Localization

Depending on the transformation type, based on HTML5 or using a direct DITA transformation, there are different localization capabilities. If you are just starting your customization, we strongly recommend using the pdf-css-html5 transformation, since it supports out of the box a large number of languages.
Localization - Transformation Based on HTML5 and CSS

This section applies to the **DITA Map PDF - based on HTML5 & CSS** transformation type.

In this type of transformation, the intermediary merged DITA map is transformed to HTML5 using the DITA-OT built-in support, so the customization of the internationalization (the labels for chapters, parts, figures, tables, notes, etc.) can be achieved by following the DITA-OT recommendations: Customizing Generated Text.

It is recommended that you do this customization on a DITA-OT distribution deployed outside of the Oxygen installation. Otherwise, you will lose the customization when upgrading Oxygen. You can contact the Oxygen support team to ask for the Oxygen Publishing Engine package.

Supported Languages (HTML5 and CSS)

There are supported over 20 languages. For the full list of supported languages (and their codes), see the list: [https://www.dita-ot.org/3.2/topics/globalization-languages.html](https://www.dita-ot.org/3.2/topics/globalization-languages.html).

How to Select a Language (HTML5 and CSS)

There are two ways to switch the labels to a specific language:

- Alter the DITA maps and/or topics to have the `@xml:lang` attribute set to the root element, to one of a supported value (i.e. "fr", "de", "zh", "ru").
- If changing the files is not an option, you can alter the value of the transformation parameter `default.language` to the desired language code.

How to Add Support for a New Language (HTML5 and CSS)

If the list of supported languages does include the language you need, you can create a custom dictionary for this transformation.

The DITA-OT documentation offers a good insight on how to do it: [https://www.dita-ot.org/3.2/topics/plugin-addgeneratedtext.html](https://www.dita-ot.org/3.2/topics/plugin-addgeneratedtext.html)

In addition to that, you need to alter your CSS. Some of the labels come from CSS files located in:

```
[PLUGIN_DIR]/css/print/i18n/
```

You should use one of the files as a template and copy its rules to your customization CSS ([on page 2041](#)) and translate the labels. Make sure you change also the `:lang` selector to match your language code.
Localization - Transformation Based on DITA and CSS

The DITA Map PDF - based on DITA & CSS - WYSIWYG transformation type supports fewer languages than the one based on HTML5 (on page 2132).

Supported Languages (DITA and CSS)

The list of supported languages for the DITA Map PDF - based on DITA & CSS - WYSIWYG transformation type includes: English, German, French (en, de, fr).

How to Select a Language (DITA and CSS)

There are two ways to switch the labels to a specific language for the DITA Map PDF - based on DITA & CSS - WYSIWYG transformation type:

- Alter the DITA maps and/or topics to have the @xml:lang attribute set to the root element, to one of a supported value (i.e. "fr", "en", "de").
- If changing the files is not an option, you can alter the value of the transformation parameter default.language to the desired language code.

How to Add Support for a New Language (DITA and CSS)

For the DITA Map PDF - based on DITA & CSS - WYSIWYG transformation type, the built-in CSS rules are in two directories. For example, the French translation is in:

```
[PLUGIN_DIR]/css/core/-i18n-fr.css
[PLUGIN_DIR]/css/print/i18n/p-i18n-fr.css
```

1. Copy and then rename the English translation files next to your customization CSS (on page 2041).

   - i18n-en.css -> i18n-nl.css
   - p-i18n-en.css -> p-i18n-nl.css

2. Reference these two files from your customization CSS (on page 2041).

3. Change the rules to match your language code and translate each of the strings. For example, for Dutch, the rules should contain the :lang(nl) selector:

   ```
   /* Title in the Index page */
   *[class =~ "index/groups"]:lang(nl):before {
     content: "Trefwoordenregister";
   }
   ```
Comments and Tracked Changes

The comments and tracked changes can be made visible in the PDF output by setting the `show.changes.and.comments` transformation parameter to `yes`.

Figure 642. Chemistry Annotations in Acrobat Reader

By default, they are shown as PDF text annotations (sticky notes). These are graphical markers in the document content and are also listed in the Comments section when opening the output file in Acrobat Reader.

**Note:** Comments with the Mark as Done flag selected appear with a checkmark in the Comments section and with a Completed label (✓ John Doe Completed).

To avoid rendering the elements as PDF annotations and show them as footnotes instead, you can use the `show.changes.and.comments.as.pdf.sticky.notes` transformation parameter set to `no`.

The comments and changes are included in the merged map file (on page 2042) either as XML elements (`<oxy-insert>`, `<oxy-delete>`, `<oxy-comment>`, `<oxy-attributes>`) in the case of the XML merged map, or as HTML elements with similar classes (`oxy-insert`, `oxy-delete`, `oxy-comment`, `oxy-attributes`) in the case of the HTML merged map. Sub-elements contain meta-information about each change.

**Tip:** These elements are automatically recognized and transformed in PDF annotations when using Chemistry as PDF processor.

**Note:** The inserted text, deleted text, and deleted markup are included in the sticky notes.

**Related Information:**

- Transformation Parameters (on page 2018)
Comments and Tracked Changes - XML Fragment

This section contains information about how each type of tracked change is structured in the merged map XML file (on page 2042).

Insertions

For an insertion type of tracked change, the structure that defines the insertion details is inside the range (oxy-range-start to oxy-range-end), the inserted text is highlighted by an oxy-insert-hl element, and the details are stored in the oxy-insert element.

```
<oxy:oxy-range-start id="sc_1" hr_id="1"/>

<oxy:oxy-insert href="#sc_1" hr_id="1">
  
  <oxy:oxy-author>dan</oxy:oxy-author>
  <oxy:oxy-content>insert</oxy:oxy-content>
  <oxy:oxy-date>2018/03/15</oxy:oxy-date>
  <oxy:oxy-hour>09:38:29</oxy:oxy-hour>
  <oxy:oxy-tz>+02:00</oxy:oxy-tz>
</oxy:oxy-insert>

<oxy:oxy-insert-hl>This is an insert!!</oxy:oxy-insert-hl>

<oxy:oxy-range-end hr_id="1"/>
```

Comments

Similar to insertions, comments are defined in a range (oxy-range-start to oxy-range-end), the comment details is in the oxy-comment element, and the highlighted content is wrapped in the oxy-comment-hl element.

```
<oxy:oxy-range-start id="sc_1" hr_id="1"/>

<oxy:oxy-comment href="#sc_1" hr_id="1">
  
  <oxy:oxy-author>dan</oxy:oxy-author>
  <oxy:oxy-comment-text>This is a comment.</oxy:oxy-comment-text>
  <oxy:oxy-date>2018/03/15</oxy:oxy-date>
  <oxy:oxy-hour>09:56:59</oxy:oxy-hour>
</oxy:oxy-comment>
```
Note: Comments that are marked as done have a `flag="done"` attribute:

```xml
<oxy:oxy-comment href="#sc_6" hr_id="6" flag="done">
```

### Attribute changes

The attribute changes are more complex. The `range` is empty, and is directly above the affected element (the one that has modified attributes). The `<oxy-attributes>` element contains details about multiple attribute changes, each stored in the `<oxy-attributed-change>` element.

```xml
<oxy:oxy-attributes href="#sc_3" hr_id="3">

  <oxy:oxy-attribute-change type="inserted" name="platform">
    <oxy:oxy-author>dan</oxy:oxy-author>
    <oxy:oxy-current-value>windows</oxy:oxy-current-value>
    <oxy:oxy-date>2018/03/15</oxy:oxy-date>
    <oxy:oxy-hour>10:05:04</oxy:oxy-hour>
    <oxy:oxy-tz>+02:00</oxy:oxy-tz>
  </oxy:oxy-attribute-change>
  
  ...  

  <oxy:oxy-attribute-change type="removed" name="audience">
  
  ...  

</oxy:oxy-attributes>
```

```xml
</element>
```
Deletions

For a deletion, there are some elements that define the start and end of the deletion, and the highlighted text is wrapped in the `<oxy-delete-hl>` element.

```xml
<oxy:oxy-range-start id="sc_2" hr_id="2"/>
<oxy:oxy-delete-hl>This is a deleted text. </oxy:oxy-delete-hl>
<oxy:oxy-range-end hr_id="2"/>
```

There is a structure that offers details about the deletion change, using the `<oxy-delete>` element. This is linked to the above deletion range by the same ID value:

```xml
<oxy:oxy-delete href="#sc_2" hr_id="2">
  <oxy:oxy-author>dan</oxy:oxy-author>
  <oxy:oxy-content><image href="../img/ex.gif"></oxy:oxy-content>
  <oxy:oxy-date>2018/03/14</oxy:oxy-date>
  <oxy:oxy-hour>11:38:06</oxy:oxy-hour>
  <oxy:oxy-tz>+02:00</oxy:oxy-tz>
</oxy:oxy-delete>
```

Colored Highlights

To show some text as highlighted with a background color:

```xml
<oxy:oxy-color-hl color="rgba(140,255,140,50)">Some colored text.</oxy:oxy-color-hl>
```

Comments and Tracked Changes - HTML Fragment

This section contains information about how each type of tracked change is structured in the merged map HTML file (on page 2042).

Insertions

For an insertion type of tracked change, the structure that defines the insertion details is inside a `range` (oxy-range-start to oxy-range-end), the inserted text is highlighted by a `<span>` element with the class `oxy-insert-hl`, and the details are stored in a `<span>` element with the `oxy-insert` class.

```xml
<span class="oxy-range-start" id="sc_1" hr_id="1"/>

<span class="oxy-insert" href="#sc_1" hr_id="1">
  <span class="oxy-author">dan</span>
</span>
```
Comments

Similar to insertions, comments are defined in a range (oxy-range-start to oxy-range-end), the comment details in an element with the class oxy-comment, and the highlighted content is wrapped in the oxy-comment-hl element.

Attribute changes

The attribute changes are more complex. The range is empty, and is directly above the affected element (the one that has modified attributes). The element with the class oxy-attributes contains details about multiple attribute changes, each stored in an element with the class oxy-attribute-change.
Deletions

For a deletion, there are some elements that define the start and end of the deletion, and the highlighted text is wrapped in an element with the class `oxy-delete-hl`.

There is a structure that offers details about the deletion change, using the element with the class `oxy-delete`. This is linked to the above deletion range by the same ID value:
**Colored Highlights**

To show some text as highlighted with a background color:

```html
<span class="oxy-color-hl" color="rgba(140,255,140,50)">Some colored text.</span>
```

**Comments and Tracked Changes - Built-in CSS**

The built-in CSS that controls the way tracked changes and comments are displayed is found in:

```
[PLUGIN_DIR]css/print/p-side-notes.css
```

**How to Style Changed or Commented Text**

To style the highlighted text from the document content, use the `<oxy-comment-hl>` element (or `<oxy-delete-hl>`, `<oxy-insert-hl>`, respectively, by local name or class name):

```css
oxy-comment-hl,
.oxy-comment-hl {
  color:magenta;
}
```

**Note**: The class name selector is useful when using the DITA Map PDF - based on HTML5 & CSS transformation scenario.

If you want to change the small labels that define the affected start and end ranges (they are a number formatted like: “[n] .. [/n]” where n is the number of the change), you can use the following selectors:

```css
oxy-range-start:before,
.oxy-range-start:before {
  display:inline;
  content:'[ ' attr(hr_id) ' ]';
  color:red;
}
oxy-range-end:before,
.oxy-range-end:before {
  display:inline;
  content:'[/ ' attr(hr_id) ' ]';
  color:red;
}
```

Use `display:none` if you want to hide them.
If you want to change the background color of the comment footnote (assuming you set the `show.changes.and.comments.as.pdf.sticky.notes` transformation to `no`), add the following snippet in your customization CSS (on page 2041):

```
oxy-comment,
  .oxy-comment {
    background-color: inherit;
    border: 2pt solid yellow;
  }
```

Similarly, you can style the other footnotes for `<oxy-attributes>`, `<oxy-delete>`, and `<oxy-insert>` elements.

### How to Hide Tracked Change Footnotes

This topic is relevant if you have set the `show.changes.and.comments.as.pdf.sticky.notes` transformation parameter to `no`, and therefore the changes are shown as footnotes instead of PDF annotations.

In some cases, when your document contains a lot of tracked changes, you may need to hide the footnotes associated with the insertions, deletions, or attribute changes. Using the following example, the deletions and insertions are hidden, but the comments remain visible. In your customization CSS (on page 2041), add:

```
oxy-attributes,
oxy-delete,
oxy-insert{
  float: none;
  display: none;
}
```

### Draft Watermarks

A *watermark* is an image displayed as the background of a printed document and it is faded enough to keep the publication text readable. *Draft watermarks* are used to indicate that a document is under construction or has not yet been approved.

### How to Add a Draft Watermark on All Pages

To add a draft watermark to all of your publication pages, you can use the following page selector in your customization CSS (on page 2041):

```
@page {
```
If you have already set a background image for other pages (for example, the front-page or table-of-contents), the above selector won’t change them, as they are more specific.

The best practice is to use a different draft.css CSS file that imports the customization CSS where the rest of the style changes reside. If you need to publish as draft, use the draft.css in your transformation scenario, otherwise directly reference the customization CSS (on page 2041).

Related Information:

• Images and Figures (on page 2150)

How to Add a Draft Watermark Depending on Metadata

Suppose you want to apply a Draft watermark until your DITA bookmap is approved and the map is approved when an <approved> element has been added to the metadata section (for example, in the bookmeta/bookchangehistory element).

Use oxy_xpath every time you need to probe the value from an element other than the one matched by the CSS selector, and test the expression on the merged HTML file using the Oxygen XPath Builder view.

You can either use a page selector that imposes the draft watermark on the entire page surface (recommended):
or use an element selector that restricts the watermark image only to the page area covered by that element:

```css
:root, body{
  ...
/* same as properties above */
}
```

The `body` selector is used here in case you want to apply the DITA Map PDF - based on HTML5 & CSS transformation type. You can use another element selector to target a specific part of your publication (for example, marking only the tables as drafts).

### Related Information:

- Metadata *(on page 2070)*
- How to Debug XPath Expressions *(on page 2046)*

### Styling the Content

If you need to change the styles of the elements from the topic contents, you should create a customization CSS *(on page 2041)* and then add CSS rules. To create the CSS rules, you can use the development tools described in Debugging the CSS *(on page 2042)*.

### Reusing the Styling for WebHelp and PDF Output

If you are using the `pdf-css-html5` transformation type, then the generated HTML5 document that is later converted to PDF is very similar to the generated HTML5 pages from the WebHelp Responsive output.

This is an output example from the WebHelp transformation:

```html
<h1 class="title topictitle1" id="ariaid-title2">Care and Preparation</h1>
```
When caring ...

When caring for your flower garden you want ...

It makes sense to reuse the same CSS rules you developed for one transformation type to the other. The main rule is to use the short class names instead of the long ones. For example, to style the short descriptions with italic font, use:

```
.shortdesc {
    font-style: italic;
}
```

The rule of thumb is that if you have a CSS rule that successfully styles an element in WebHelp, it should apply without any modification in the PDF output.

**Equations**

This processor supports MathML equations.

**How to Change the Font of MathML Equations**

Suppose that you need to change the font of MathML equations from the documentation, and also add some padding. The MathML fragments are wrapped in elements that have the class `equation-d/equation-block` or `equation-d/equation-inline`, so you can match them with:

```
*[class ~="equation-d/equation-block"],
*[class ~="equation-d/equation-inline"]{
    font-family:"courier new";
    font-size:1.5em;
    padding:1em;
}
```

**Note:** Some of the fonts may not be supported. In that case, a default serif font is used.
Lists

You can style the list item markers, or other properties.

How to Style the List Markers

For the media print, the default CSS rules for the list items use the :marker pseudo-class.

```css
@media print {
  *[class~="topic/li"]:marker {
    text-align: center;
    font-weight: bold;
  }
  *[class~="topic/li"] {
    margin-left: 0.25in;
  }
}
```

To eliminate the bold font weight for the items form ordered lists then add the following rules to your customization CSS (on page 2041):

```css
*[class~="topic/ol"] > *[class~="topic/li"]:marker {
  font-weight: normal;
}
```

For the unordered lists:

```css
*[class~="topic/ul"] > *[class~="topic/li"]:marker {
  font-weight: normal;
}
```

How to Change the Numbering System of Ordered Lists

It is possible to change all lists to have a different numbering system and there are several methods that can be used to achieve this.

Use the list-style-type CSS Property.

The Chemistry engine supports the following types: decimal, decimal-leading-zero, lower-roman, upper-roman, lower-latin, upper-latin, lower-alpha, upper-alpha.

```css
*[class =~ "topic/ol"] {
  list-style-type: lower-roman;
}
```
Change the Content of the :marker CSS Pseudo Element.

The following example emulate the Cyrillic numbering for the list items for an ordered list that has the @outputclass attribute set to cyrillic:

⚠️ Important: This example will work only for lists up to 28 items. You will have to extend it for longer lists!

```
*{class =~ "topic/ol"}[outputclass =~ "cyrillic"] > *{class =~ "topic/li"}:marker {
  width:3em;
}

*{class =~ "topic/ol"}[outputclass =~ "cyrillic"] > *{class =~ "topic/li"}:nth-of-type(1):marker{ content:"а" }
*{class =~ "topic/ol"}[outputclass =~ "cyrillic"] > *{class =~ "topic/li"}:nth-of-type(2):marker{ content:"а" }
*{class =~ "topic/ol"}[outputclass =~ "cyrillic"] > *{class =~ "topic/li"}:nth-of-type(3):marker{ content:"а" }
*{class =~ "topic/ol"}[outputclass =~ "cyrillic"] > *{class =~ "topic/li"}:nth-of-type(4):marker{ content:"а" }
*{class =~ "topic/ol"}[outputclass =~ "cyrillic"] > *{class =~ "topic/li"}:nth-of-type(5):marker{ content:"а" }
*{class =~ "topic/ol"}[outputclass =~ "cyrillic"] > *{class =~ "topic/li"}:nth-of-type(6):marker{ content:"а" }
*{class =~ "topic/ol"}[outputclass =~ "cyrillic"] > *{class =~ "topic/li"}:nth-of-type(7):marker{ content:"а" }
*{class =~ "topic/ol"}[outputclass =~ "cyrillic"] > *{class =~ "topic/li"}:nth-of-type(8):marker{ content:"а" }
*{class =~ "topic/ol"}[outputclass =~ "cyrillic"] > *{class =~ "topic/li"}:nth-of-type(9):marker{ content:"а" }
*{class =~ "topic/ol"}[outputclass =~ "cyrillic"] > *{class =~ "topic/li"}:nth-of-type(10):marker{ content:"а" }
*{class =~ "topic/ol"}[outputclass =~ "cyrillic"] > *{class =~ "topic/li"}:nth-of-type(11):marker{ content:"а" }
*{class =~ "topic/ol"}[outputclass =~ "cyrillic"] > *{class =~ "topic/li"}:nth-of-type(12):marker{ content:"а" }
*{class =~ "topic/ol"}[outputclass =~ "cyrillic"] > *{class =~ "topic/li"}:nth-of-type(13):marker{ content:"а" }
```

- Oxygen PDF Chemistry User Guide: Lists

Links

Links allow the users to navigate through the documentation.
How to Remove 'on page NNN' Link Label

For printed material, it is usually desirable for the links to display a label after the text content (such as "on page 54"). This makes it easier the user to identify the target page. However, if the produced PDF is not printed and is intended only for electronic use, this label may create clutter and make the document harder to read. To eliminate this label, add the following in your customization CSS (on page 2041):

```css
*[class ~="topic/xref"] [href]:after,
*[class ~="topic/link"] [href]:after {
  content: none !important;
}
```

Another use-case is to remove the labels only from links shown in tables cells, and leave the others as they are. For this, you could use a more specific selector:

```css
*[class ~="topic/entry"] *[class ~="topic/xref"] [href]:after{
  content: none !important;
}
```

How to Change Link Styles

Suppose you want the links to be bold and with an underline. In your customization CSS (on page 2041), add this snippet:

```css
*[class ~="topic/xref"] [href]:after,
*[class ~="topic/link"] [href]:after {
  font-weight: bold;
  text-decoration: underline;
}
```

How to Hide Descriptions in Related Links Sections

The link descriptions that come from DITA relationship tables or related link elements within topics, are structured in the merged map (on page 2042) like this:

```xml
<related-links class="- topic/related-links ">
  <linkpool class="- topic/linkpool ">

```
Images and Figures

Images are an important part of a publication.

**Note:** You can use raster image formats (such as PNG or JPEG), but it is best to use vector images (such as SVG or PDF). They scale very well and produce better results when printed. In addition the text from these images is searchable and can be selected (if the glyphs have not been converted to shapes) in the PDF viewer.

Images - Built-in CSS

Image properties are defined in [PLUGIN_DIR]css/print/p-images.css.

```css
*[class =~ "topic/image"] {  
  prince-image-resolution: 120dpi;  
  -ah-image-resolution: 120dpi;  
  image-resolution: 120dpi;  
  /* The US-letter page size minus page margins. See p-page-size.css for the  
  current page size. */  
  max-width: 6.5in;  
}
```

How to Fix Image Bleeding - Control Image Size

Sometimes the images may be too big for the page. The built-in CSS rules specify a maximum size for images, limiting to the width of the parent block. But if the parent block is itself too wide and bleeds out of page, you might consider specifying a length.

In your customization CSS (on page 2041), add the following snippet:

```css
*[class =~ "topic/image"] {  
  /*  
   
   */  
}
```
How to Change Image Resolution

This is a good technique to change the size of all raster images from your documentation. This will not work for vector images, such as PDF or SVG. If the images (PNG, for example) contain the image resolution in their metadata, this will be taken into account. For all other images, the default resolution is 120dpi.

If the default resolution is not good (suppose you need a higher pixel density of 300dpi), you can change it by adding the following in your customization CSS (on page 2041):

```css
*[class ~="topic/image"] {
    prince-image-resolution: 300dpi;
    -ah-image-resolution: 300dpi;
    image-resolution: 300dpi;
}
```

How to Place Big Images on Rotated Pages

Very wide images may bleed out of the page. One solution for this is to use landscape pages for these wide images.

In your customization CSS (on page 2041), add:

```css
*[class~="topic/image"][outputclass='land'] {
    page: landscape-page;
}
```

Setting the attribute @outputclass = 'land' on the table element will force the table on a new landscape page.

Another solution is to set an @outputclass attribute on the image, then create a rule that matches it, and associate a landscape page for it.

How to Place a Text and Image Side by Side

If you need to align text and an image side by side, you can use the following technique:

1. Organize your text and image under a <div> element like this:
...  
```html
<div outputclass="side-by-side">
  <p>This will be in the left side, the next figure in the right. </p>
  <fig>
    <image href="cactus.jpeg"/>
  </fig>
</div>
...  
```

**Note:** You can use the `@outputclass` attribute to mark the `<div>` elements that have this special layout.

2. In your customization CSS *(on page 2041)*, add:

```css
*[@outputclass = "side-by-side"] > *[class = "topic/p"] {
  display:inline-block;
  width: 45%;
}

*[@outputclass = "side-by-side"] > *[class = "topic/fig"] {
  display:inline-block;
  width: 45%;
}

The image should fill the entire width of the parent `<fig>` element:

```css
*[@outputclass = "side-by-side"] > *[class = "topic/fig"] > *[class = "topic/image"] {
  width:100%;
}
```

By default, the bottom of the image is on the same line as the text baseline. If you want the text and the image to be aligned at the top, add these lines:

```css
*[@outputclass = "side-by-side"] > *[class = "topic/p"] {
  vertical-align:top;
}

*[@outputclass = "side-by-side"] > *[class = "topic/fig"] {
  vertical-align:top;
  font-size:0pt;
}
```
**Note:** The `font-size:0pt` is needed to remove the font ascent and descent around the image rectangle.

### How to Control the Image Size in Complex Static Content

It is common to have text and images mixed together in a `:before` or `:after` pseudo element. For example, for notes you may have both artwork and text:

```css
*[class ~="topic/note"]::before {
  content: url('note.png') "Some text";
}
```

If you want to change the size of the image, you have two options:

1. **Use the `image-resolution` CSS property:**

   ```css
   *[class ~="topic/note"] {
     image-resolution:300dpi;
   }
   ```

2. **Separate the image from the text and apply the width and height CSS properties only on the image,** using the width and height properties. You could use multiple `:before` pseudo-elements for that, considering that the farthest content presented before the actual content of an element is matched by the `:before` with the highest number in the brackets:

   ```css
   *[class ~="topic/note"]:before(2) {
     content: url('note.png') ;
     width:0.5in;
   }

   *[class ~="topic/note"]:before(1) {
     content: "Some text";
   }
   ```

### How to Center Images

DITA defines a `@placement` attribute for the `<image>` elements. The implicit value is `inline`. Suppose that you need to center the images that have the placement set to `break` (for example, they are not on the same line with other content and the images from the `<fig>` element).

In your customization CSS *(on page 2041)*, add:
How to Change/Reset the Figure Numbering

**Note:** This topic is applicable for the DITA Map PDF - based on HTML5 & CSS transformation type.

There are cases when you need to change the aspect of the figure counter that is shown before the figure titles. By default, the figure titles are formatted like this:

```
Figure NN. Lore Ipsum Title
```

NN is the number of the figure that starts being counted from the beginning of the publication.

One use-case is to have the NN counter be incremented only within one chapter (for example, the first chapter contains "Figure 1" and "Figure 2", and second chapter starts over with "Figure 1" instead of incrementing to "Figure 3").

You should reset the figure counter on each topic marked as chapter, then hide the label from the figure `<figcaption>` (this is an HTML element generated by the XSL transformation), and create another label using a `:before` selector on the `<figcaption>`.

```
*[class =~ "topic/topic"] {is-chapter} {
  counter-reset: figcount;
}
```
Tables

Tables are widely used in technical documentation. This section contains information about the CSS rules that are used to style them and how to fix some problems.

Tables - Built-in CSS

There is a combination of CSS files that address tables:

- [PLUGIN_DIR]/css/core/-table-html-cals.css
- [PLUGIN_DIR]/css/print/p-tables.css

How to Deal With Wide Tables - Page Rotation

Some of the tables can have a large number of columns. In this case, the table may bleed out of the page. One solution is to use landscape pages for these tables.

Setting the attribute \texttt{@orient = 'land'} on the table element will force the table on a new landscape page.

Another solution is to use automatic detection of wide tables (5 or more columns):

```css
*[class~="topic/table"] > *[class="topic/tgroup"][cols='5'],
*[class~="topic/table"] > *[class="topic/tgroup"][cols='6'],
*[class~="topic/table"] > *[class="topic/tgroup"][cols='7'],
*[class~="topic/table"] > *[class="topic/tgroup"][cols='8'] { 
    page: landscape-page;
    max-width: 100%;
    page-break-before: avoid;
}
```
**Note:** The landscape-page page layout is defined in the `[PLUGIN_DIR]css/print/p-pages-and-headers.css`.

If you want to rotate the entire topic that contains the big table, use:

```
*{class~="topic/table"} > *{class="topic/tgroup"}[cols='5'],
*{class="topic/table"} > *{class="topic/tgroup"}[cols='6'],
*{class="topic/table"} > *{class="topic/tgroup"}[cols='7'],
*{class="topic/table"} > *{class="topic/tgroup"}[cols='8'] {
  max-width: 100%;
  table-layout: auto;
}
```

```
*{class="topic/topic"}:has(*:not([class="topic/topic"]) > *{class="topic/table"} > *{class="topic/tgroup"}[cols='5']),
*{class="topic/topic"}:has(*:not([class="topic/topic"]) > *{class="topic/table"} > *{class="topic/tgroup"}[cols='6']),
*{class="topic/topic"}:has(*:not([class="topic/topic"]) > *{class="topic/table"} > *{class="topic/tgroup"}[cols='7']),
*{class="topic/topic"}:has(*:not([class="topic/topic"]) > *{class="topic/table"} > *{class="topic/tgroup"}[cols='8'] ),
*{class="topic/topic"}:has(*:not([class="topic/topic"]) > *:not([class="topic/topic"]) > *{class="topic/table"} > *{class="topic/tgroup"}[cols='5'] ),
*{class="topic/topic"}:has(*:not([class="topic/topic"]) > *:not([class="topic/topic"]) > *{class="topic/table"} > *{class="topic/tgroup"}[cols='6'] ),
*{class="topic/topic"}:has(*:not([class="topic/topic"]) > *:not([class="topic/topic"]) > *{class="topic/table"} > *{class="topic/tgroup"}[cols='7'] ),
*{class="topic/topic"}:has(*:not([class="topic/topic"]) > *:not([class="topic/topic"]) > *{class="topic/table"} > *{class="topic/tgroup"}[cols='8'] ),
*{class="topic/topic"}:has(*:not([class="topic/topic"]) > *:not([class="topic/topic"]) > *:not([class="topic/topic"]) > *{class="topic/table"} > *{class="topic/tgroup"}[cols='5'] ),
*{class="topic/topic"}:has(*:not([class="topic/topic"]) > *:not([class="topic/topic"]) > *:not([class="topic/topic"]) > *{class="topic/table"} > *{class="topic/tgroup"}[cols='6'] ),
*{class="topic/topic"}:has(*:not([class="topic/topic"]) > *:not([class="topic/topic"]) > *:not([class="topic/topic"]) > *{class="topic/table"} > *{class="topic/tgroup"}[cols='7'] ),
*{class="topic/topic"}:has(*:not([class="topic/topic"]) > *:not([class="topic/topic"]) > *:not([class="topic/topic"]) > *{class="topic/table"} > *{class="topic/tgroup"}[cols='8'] );
```
How to Fix Text Bleeding From Table Cells

Slim tables or tables that have many columns make the text from the cells to be confined to a small horizontal space. Long words would bleed outside the cell boundaries. To fix this, you should enable hyphenation in your tables, thus making the words spread on multiple lines. In your customization CSS (on page 2041), add:

```css
*[^])="topic/table"]{ 
  hyphens:auto;
}
```

Related Information:

- Hyphenation (on page 2128)

How to Enable the Automatic Table Layout

The DITA specification indicates that tables should have a fixed layout. However, you can get a more optimal arrangement of the cells using the automatic layout. In your customization CSS (on page 2041), add:

```css
*[^])="topic/tgroup"]{ 
  table-layout:auto !important;
}
```

If you want to control which table you want this layout, you can set the @outputclass attribute on the `<table>` element:

```xml
<table outputclass='auto_tbl'> ... </table>
```

Then, in the CSS, use a rule that matches the @outputclass:

```css
*[^])="topic/table"][@outputclass='auto_tbl'] > *[^])="topic/tgroup"]{ 
  table-layout:auto !important;
}
```

⚠️ Important: Make sure the tables have no column width specified.
How to Rotate Content from a Table Cell

There are cases where you want to style the first column as a kind of table header, with vertical text.

There is an important thing to remember: you can rotate an element from a table cell, but not the cell itself. So, your DITA table cell should contain a `<div>` or a `<p>` element that will be rotated. The cell has to be marked somehow so that it can be matched from the CSS. One way is to set an `@outputclass` attribute on it, another will be to mark the table and then match the first entries from it.

```xml
<row>
  ...
  <entry outputclass="rotated">
    <p>Rotated</p>
  </entry>
  ...
</row>
```

In your customization CSS (on page 2041), use the following rule that matches the child of the entry:

```css
*[outputclass =~ "rotated"] > * {
  display: block;
  transform: rotate(-90deg) !important;
  text-align: left !important;

  padding:0;
  margin:0;

  white-space: nowrap;

  width:150px;
  height:80px;
}
```

The padding and margins are set to zero to clear any space that may come from other rules. The width is required - it will become the height of the cell. If this is not specified, the vertical rotated text will bleed out of the cell. The height is optional.

How to Add Horizontal Lines to a Choice Table

To add horizontal lines that separate the options within a `<choicetable>`, you can use borders set on each of the rows. The following CSS styles the top header and the first column with some background colors. In a choice table, the first column represents the choice labels.
Note: Using the frame attribute on the choice table will make these selectors apply partially. Please make sure you are designing your customization CSS taking into account all possible values for the frame attribute.

Code Blocks

Code blocks are used to render section of programming code.

How to Enable Code Syntax Highlighting

This topic refers only to the DITA Map PDF - based on HTML5 & CSS transformation type.

You can use syntax highlighting to make it easier to read your code snippets by displaying each type of code in different colors and fonts. In the DITA topics, set the @outputclass attribute on the <codeblock> elements to one of these values:

- language-bourne
- language-c
- language-cpp
For example, for a java snippet:

```csharp
<codeblock outputclass="language-java">
  for (int i=0; i <100; i++) {
    // do something
  }
</codeblock>
```

The resulting HTML fragment in the merged HTML5 document is:

```html
<pre class="+ topic/pre pr-d/codeblock pre codeblock language-java"
 xml:space="preserve">
  <strong class="hl-keyword" style="color:#7f0055">for</strong>
  <strong class="hl-keyword" style="color:#7f0055">int</strong> i=<span class="hl-number">0</span>; i &lt;100; i++) {
    <em class="hl-comment" style="color:#006400">// do something</em>
  }
</pre>
```

And in the output, it will be rendered as:

```
for (int i=0; i <100; i++) {
    // do something
}
Changing the Colors for the Syntax Highlighting

As you can see in the above example, the HTML elements `<span>` and `<strong>` are used to color the content. Since they have a `@style` attribute set, the overriding properties need to be marked with `!important`.

Suppose you want to color the keywords in red and the comments in blue. To do so, add the following to your customization CSS (on page 2041):

```css
.hl-keyword {
    color: red !important;
}
.hl-comment {
    color: blue !important;
}
```

How to Disable Line Wrapping in Code Blocks

By default, code blocks have the content wrapped to avoid the bleeding of long lines out of the page. To avoid wrapping, add the following in your customization CSS (on page 2041):

```css
 *[class~="pr-d/codeblock"] {
     white-space: pre;
 }
```

For the DITA Map PDF - based on HTML5 & CSS transformation type, the best solution to distinguish between lines is to leave them wrapped, but color each line with a different background (zebra coloring). An example is provided here: XSLT Extensions for PDF Transformations (on page 2033).

How to Deal with Unwanted Returns in Code Blocks

There are cases where the source file contains long lines of code that need to continue onto the next line in the rendered PDF (to wrap visually).

When the user copies the block from the PDF reader, they get two separated lines. This means that the command fails when users copy it from the PDF to the command-line terminal (because it comes in as two commands).

For example, the command:

```
$gist = ls -l * | count -n | some more
```

May be rendered in the PDF on two lines:
$gist = ls -l * | count -n
| some more

And this is invalid when used in the terminal.

There is no CSS workaround for this, but to manually format the command line, add a line continuation character like this:

$gist = ls -l * | count -n \
| some more

⚠️ Note: For Linux/Mac OSX, the continuation character is the backslash \. For Windows, this is the shift character ^.

The command-line processor will now recognize that the first line is continuing on to the next one.

Notes

Notes contain an additional piece of information that calls attention to particular content. They may have various types (tip, caution, danger, restriction, important, warning).

For information on how to add and manage mixed content before the note icons and labels, see How to Control the Image Size in Complex Static Content (on page 2153).

How to Change Note Icons

The recommended icon format is SVG.

To change the default icons for notes that do not have a type attribute, add the following rule to your customization CSS (on page 2041):

```css
div.note > span.note__title{
    background-image: url("../img/note.svg") !important;
}
```

For a note with a type attribute set to warning, caution, or trouble, add the following corresponding CSS rule:

```css
div.warning > span.note__title{
    background-image: url("../img/warning.svg") !important;
}
div.caution > span.note__title{
    background-image: url("../img/caution.svg") !important;
}
```
Abbreviated Forms

When using the `<abbreviated-form>` element in your content, it is possible to style the subsequent occurrences differently than the first occurrence. To achieve this, add something similar to the following rule in your customization CSS (on page 2041):

```css
a:has(dfn[class ~="abbreviated-form"]) {
    color: oxy_xpath("let $cdf:= dfn return if (preceding::dfn[@keyref = $cdf/@keyref]) then 'black' else 'red'");
    text-decoration: oxy_xpath("let $cdf:= dfn return if (preceding::dfn[@keyref = $cdf/@keyref]) then 'none' else 'underline'");
}
```

This example would render the first occurrence with a red color and an underline, while the subsequent occurrences would be rendered with a black color and no underline.

Styling Through Custom Parameters

You can activate parts of your CSS by using custom transformation parameters that start with the `args.css.param` prefix.

These parameters are recognized by the publishing pipeline and are forwarded as synthetic attributes on the root element of the merged map. The last part of the parameter name will become the attribute name, while the value of the parameter will become the attribute value. The namespace of these synthetic attributes is: http://www.oxygenxml.com/extensions/publishing/dita/css/params.

**Notes:**

- Use only Latin alphanumeric characters for parameter names.
- You can set multiple styling parameters at the same time.

How to Limit the Depth of the TOC Using a Parameter

In the following example, a custom parameter is used to switch from a full depth table of contents to a flat one that shows only the titles of the first-level topics (such as chapters, preface, notices).

The custom parameter is:
The CSS that hides the topicrefs at level 2 or more:

@namespace a "http://www.oxygenxml.com/extensions/publishing/dita/css/params";

:root[a|only-chapters-in-toc='yes'] *[class =~ "toc/toc"]
   > *[class =~ "map/topicref"] > *[class =~ "map/topicref"] {
     display: none;
   }

The selector :root[a|only-chapters-in-toc='yes'] makes the rule activate only when the attribute is set.

How to Change the Page Size Using a Parameter

In the next example, a custom parameter is used to modify the page size. The parameter is defined in the transformation scenario:

args.css.param.page-size="A4"

Then in the CSS, the attribute value is extracted and used:

@page {
   size: oxy_xpath('/@*[local-name()="page-size"]');
}

Controlling the Publication Content

Using a plain DITA map, the transformation will produce a publication with a front page, a table of contents, chapters with content, and an index at the end. This is appropriate for most cases, but there are use cases where some adjustments are necessary. For example, if you want to do one of the following:

- Remove the TOC or index.
- Add a glossary.
- Change the position of the TOC or the index relative to the sibling topics.
- Add a preface, frontmatter, or backmatter with copyright notices, abstracts, list of tables, list of figures, etc.

All of these can be achieved using a DITA bookmap.
A bookmap has a more elaborate structure than a regular map. You should start by defining the title structure, with a main title and alternative title:

```xml
<!DOCTYPE bookmap PUBLIC "-//OASIS//DTD DITA BookMap//EN" "bookmap.dtd">
<bookmap id="taskbook">
    <booktitle>
        <mainbooktitle>Publication Title</mainbooktitle>
        <booktitlealt>A very short description of the publication</booktitlealt>
    </booktitle>
</bookmap>
```

Then you may define a front matter. In this, you may link the topics that need to appear before the main content. You may also define the location where the table of contents will be placed. In the example below, it appears between the "abstract" and "foreword" topics:

```xml
<frontmatter>
    <topicref href="topics/abstract.dita"/>
    <booklists>
        <toc/>
    </booklists>
    <topicref href="topics/foreword.dita"/>
</frontmatter>
```

**Note:** To remove the TOC from the publication, just omit the `<toc>` element from the `<booklists>`.

Next, the topics are grouped into chapters:

```xml
...<chapter href="topics/installation.dita" />
...
```

At the end, you could define the structure of the backmatter. Just like for the frontmatter, you can include some topics and some generated content, such as the index. In the example below, it is defined that the glossary should come after the index, followed by a list of figures and list of tables. At the very end, there is a topic with some thank you notes.

```xml
<backmatter>
    <topicref href="topics/conclusion.dita"/>
    <booklists>
        <indexlist/>
        <glossarylist>
            <topicref href="topics/xp.dita" keys="xp" print="yes"/>
        </glossarylist>
    </booklists>
</backmatter>
```
As you can see, the bookmap offers a much better control over the final content of the publication. It also offers more options in controlling the metadata that will go into the PDF (see the Metadata (on page 2070) topic).

How to Omit the Front Page, TOC, Glossary, Index for a Plain DITA Map

For a plain DITA map, there are no elements that allow you to control if and where to place the generated content such as the title page, table of contents, list of tables, glossary, or index. For the most common use-case, when you want to hide them all and just keep the content, you can use the transformation parameter hide.frontpage.toc.index.glossary. See: Transformation Parameters (on page 2018).

Related Information:

• How to Remove Entries from the TOC (on page 2101)

• How to Hide the TOC (on page 2102)

How to Make Chapters Look Like Individual Publications

Note: This topic is only applicable for the DITA Map PDF - based on HTML5 & CSS transformation scenario.

Sometimes you want to make each chapter independent (i.e. it can be read separately, as a separate part of your publication). For this, you need the page counter, figure, and table counters to restart at each chapter. You can control this by using the args.css.param.numbering (on page 2088) command line parameter.

In addition to numbering, you can force the creation of a chapter TOC (on page 2102).
Troubleshooting

This section contains information about fixing various publishing problems.

Error Parsing CSS File - Caused by a Networking Problem

Problem

My custom styles are not applied and in the transformation results console, I get an error containing one of the following: I/O exception, Unknown host, Error parsing.

Cause

One of the CSS files contains references to resources from another website that is currently inaccessible. These resources may include:

- Fonts
- Images
- Other CSS files

Note: If you exported one of the built-in publishing templates from the transformation scenario dialog, it is possible that the associated CSS files use an imported Google Font.

Remedy

1. Check your proxy settings (ask the system administrator for help).

2. If the server is still inaccessible from the transformation process, download the remote resources using a web browser, save them in the customization CSS file folder, and refer them directly from your CSS.

Note: If the problem is caused by a remote font, see Using Local Fonts.

XSL FO-based DITA to PDF Customization

Oxygen XML Editor comes bundled with the DITA Open Toolkit that provides a mechanism for converting DITA maps (on page 3281) to PDF output. Oxygen XML Editor includes a built-in DITA Map PDF - based on XSL-FO (on page 1662) transformation scenario that converts DITA maps to PDF using an xsl:fo processor.

There are several methods that can be used to customize DITA to PDF output:
• Create a customization directory that contains your customized files and reference that directory in the PDF transformation scenario (using the `customization.dir` parameter).
• Creating a DITA Open Toolkit plugin that adds extensions to the PDF output. More details can be found in the DITA Open Toolkit Documentation.

**Tip:** Some sample plugins are available on GitHub that could help you to get started with creating a plugin:
- Sample Plugin: DITA-OT PDF Customization Plugin for Oxygen User Manual
- Sample Plugin: DITA-OT PDF2 - Generate Numbers Before Topic's Title

### Using a Customization Directory

One way to customize the PDF output generated by the DITA Map to PDF - based on XSL-FO (on page 1662) transformation scenario is to create a dedicated folder to store customized files. With this approach, you will copy the contents of the built-in customization directory to a new directory where you can customize the files according to your needs and reference the new directory using the `customization.dir` parameter in the transformation scenario. The biggest advantage of this method is that the contents of your customization directory will remain unaffected when the DITA-OT is upgraded.

### How to Create a Customization Directory

Follow this procedure to create a customization directory:

1. Copy all the entire `DITA-OT-DIR\plugins\org.dita.pdf2\Customization` directory to another location where you have write access.
2. Modify any of the files in whatever way necessary to achieve your specific goal. For inspiration, see Embedding a Company Logo (on page 2169) for a specific example of how you can modify contents of the directory to embed a logo in the output.

**Tip:** For other specific examples, see DITA-OT Documentation - PDF Customization Plugin.
3. Edit the DITA Map to PDF - based on XSL-FO (on page 1662) transformation scenario, go to the Parameters tab, and set the `customization.dir` parameter to point to the location of your customization directory.

**Related Information:**

- Automatic PDF plugin customization generator by Jarno Elovirta.
Embedding a Company Logo

The following procedure explains how to embed a company logo image in the front matter of the book.

1. Create a customization directory (on page 2168) (if you haven’t already done so).
2. Create a `cfg\common\artwork` directory structure in your customization directory and copy your logo to that directory (for example, `C:\Customization\cfg\common\artwork\logo.png`).

   **Important:** Make sure that your logo image is named: `logo.png`.

3. Rename `Customization\catalog.xml.orig` to: `Customization\catalog.xml`.
4. Open the `catalog.xml` in Oxygen XML Editor and *uncomment* this line:

   ```xml
   <!--uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/-->  
   ```

   It now looks like this:

   ```xml
   <uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/>
   ```

5. Rename the file `Customization\fo\xsl\custom.xsl.orig` to: `C:\Customization\fo\xsl\custom.xsl`.
6. Open the `custom.xsl` file in Oxygen XML Editor and create the template called `createFrontCoverContents` for DITA-OT 3.3.1.

   **Tip:** You can copy the same template from `DITA-OT-DIR\plugins\org.dita.pdf2\xsl\fo\front-matter.xsl` and modify it in whatever way necessary to achieve your specific goal. This new template in the `custom.xsl` file will override the same template from `DITA-OT-DIR\plugins\org.dita.pdf2\xsl\fo\front-matter.xsl`.

   **Example:**

   For example, the `custom.xsl` could look like this:

   ```xml
   <?xml version='1.0'?>
   <xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
                   xmlns:fo="http://www.w3.org/1999/XSL/Format"
                   version="2.0">
    <xsl:template name="createFrontCoverContents">
    <!-- set the title -->
   ```
7. Edit the DITA Map to PDF - based on XSL-FO (on page 1662) transformation scenario, go to the Parameters tab, and set the customization.dir parameter to point to the location of your customization directory.
Tip: For other specific examples, see DITA-OT 3.x Documentation - Customizing PDF Output.

Related Information:

- Using a Customization Directory (on page 2168)

Customizing the Header and Footer in PDF Output

The XSLT stylesheet \texttt{DITA-OT-DIR/plugins/org.dita.pdf2/xsl/fo/static-content.xsl} contains templates that output the static header and footers for various parts of the PDF such as the prolog, table of contents, front matter, or body.

The templates for generating a footer for pages in the body are called \texttt{insertBodyOddFooter} or \texttt{insertBodyEvenFooter}.

These templates get the static content from resource files that depend on the language used for generating the PDF. The default resource file is \texttt{DITA-OT-DIR/plugins/org.dita.pdf2/cfg/common-vars/en.xml}. These resource files contain variables (such as \textit{Body odd footer}) that can be set to specific user values.

Instead of modifying these resource files directly, they can be overwritten with modified versions of the resources in a PDF customization directory.

1. Create a customization directory (on page 2168) (if you haven't already done so).
2. Locate the stylesheets and templates listed above in your customization directory and modify them in whatever way necessary to achieve your specific goal.

Tip: For more information and examples, see the Oxygen PDF Customization Plugin project on GitHub.

3. Edit the DITA Map to PDF - based on XSL-FO (on page 1662) transformation scenario, go to the Parameters tab, and set the customization.dir parameter to point to the location of your customization directory.

Related Information:

- Using a Customization Directory (on page 2168)
Adding a Watermark to PDF Output

To add a watermark to the PDF output of a DITA Map PDF - based on XSL-FO (on page 1662) transformation scenario, follow this procedure:

1. Create a customization directory (on page 2168) (if you haven’t already done so).
2. Create a cfg\common\artwork directory structure in your customization directory and copy your watermark image to that directory (for example, C:\Customization\cfg\common\artwork\watermark.png).
3. Rename the Customization\catalog.xml.orig file to Customization\catalog.xml.
4. Open the catalog.xml in Oxygen XML Editor and uncomment this line:

   <!--uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/-->

   The uncommented line should look like this:

   <uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/>

5. Rename the file: Customization\fo\xsl\custom.xsl.orig to Customization\fo\xsl\custom.xsl.
6. Open the Customization\fo\xsl\custom.xsl file in Oxygen XML Editor to overwrite two XSLT templates:

   • The first template is located in the XSLT stylesheet DITA-OT-DIR\plugins\org.dita.pdf2\xsl\fo\static-content.xsl. Override by copying the original template content in the custom.xsl and specifying a watermark image for every page in the PDF content, using a block-container element that references the watermark image file:

     ```xml
     <fo:static-content flow-name="odd-body-header">
       <fo:block-container absolute-position="absolute"
         top="-2cm" left="-3cm" width="21cm" height="29.7cm"
         background-image="{concat($artworkPrefix,'Configuration/OpenTopic/cfg/common/artwork/watermark.png')}">
         <fo:block/>
       </fo:block-container>
       <fo:block xsl:use-attribute-sets="__body__odd__header">
         <xsl:call-template name="insertVariable">
           <xsl:with-param name="theVariableID" select="'Body odd header'"/>
           <xsl:with-param name="theParameters">
             <prodname>
               <xsl:value-of select="$productName"/>
             </prodname>
             <heading>
               <!--... -->
             </heading>
           </xsl:with-param>
         </xsl:call-template>
       </fo:block>
     </fo:static-content>
     ```
The second template to override is located in the XSLT stylesheet `DITA-OT-DIR\plugins\org.dita.pdf2\xsl\fo\commons.xsl` and is used for styling the first page of the output. Override it by copying the original template content in the `custom.xsl` and adding the `block-container` element that references the watermark image file:

```xml
<xsl:template name="createFrontMatter_1.0">
  <fo:page-sequence master-reference="front-matter"
                   xsl:use-attribute-sets="__force__page__count">
    <xsl:call-template name="insertFrontMatterStaticContents"/>
    <fo:flow flow-name="xsl-region-body">
      <fo:block-container absolute-position="absolute"
                           top="-2cm" left="-3cm" width="21cm" height="29.7cm"
                           background-image="{concat($artworkPrefix,
                                            'Configuration/OpenTopic/cfg/common/artwork/watermark.png')}">
        <fo:block/>
      </fo:block-container>
      <fo:block xsl:use-attribute-sets="__frontmatter">
        <!-- set the title -->
      </fo:block>
      <fo:block xsl:use-attribute-sets="__frontmatter__title">
        <xsl:choose>
          <xsl:when test="$map/*[contains(@class,' topic/title ')][1]">
            <xsl:apply-templates select="$map/*[contains(@class,' topic/title ')][1]"/>
          </xsl:when>
          <xsl:when test="$map/*[contains(@class,' bookmap/mainbooktitle ')][1]">
            <xsl:apply-templates select="$map/*[contains(@class,' bookmap/mainbooktitle ')][1]"/>
          </xsl:when>
        </xsl:choose>
      </fo:block>
    </fo:flow>
  </fo:page-sequence>
</xsl:template>
```
7. Edit the DITA Map to PDF - XSL-FO (on page 1662) transformation scenario, go to the Parameters tab, and set the customization.dir parameter to point to the location of your customization directory.
Adding an Edit Link in PDF Output to Launch Oxygen XML Web Author

You can embed *Edit* links in the DITA Map PDF output that will automatically launch a particular document in Oxygen XML Web Author. A reviewer can then simply click the link and they will be redirected to the Oxygen XML Web Author editing page with that particular file open and editable.

To embed an *Edit* link in the DITA Map PDF output, follow these steps:

1. Edit a DITA Map to PDF - based on XSL-FO (on page 1662) transformation scenario and open the Parameters tab.
2. Set values for the following parameters:
   - `editlink.remote.ditamap.url` - The URL of the DITA Map suitable for opening in Oxygen XML Web Author.
   - `editlink.web.author.url` - The URL of the Oxygen XML Web Author installation, for example https://www.oxygenxml.com/oxygen-xml-web-author/
3. Run the transformation scenario.

**Result:** In the PDF output, all topics will have an *Edit* link to the right side of the title and clicking the link will launch that particular document in Oxygen XML Web Author.

**Force Page Breaks Between Two Block Elements in PDF Output**

Suppose that in your DITA content you have two block elements (on page 3280), such as two paragraphs:

```xml
<p>First para</p>

<p>Second para</p>
```

and you want to force a page break between them in the PDF output.

Here is how you can implement a DITA Open Toolkit plugin (on page 3285) that would achieve this:

1. Define your custom processing instruction that marks the place where a page break should be inserted in the PDF, for example:

```xml
<p>First para</p>

<?pagebreak?>

<p>Second para</p>
```

2. Locate the DITA Open Toolkit distribution and in the plugins directory create a new plugin folder (for example, DITA-OT-DIR/plugins/pdf-page-break).
3. In this new folder, create a new `plugin.xml` file with the following content:

```xml
<plugin id="com.yourpackage.pagebreak">
  <feature extension="package.support.name" value="Force Page Break Plugin"/>
  <feature extension="package.support.email" value="support@youremail.com"/>
  <feature extension="package.version" value="1.0.0"/>
  <feature extension="dita.xsl.xslfo" value="pageBreak.xsl" type="file"/>
</plugin>
```

The most important feature in the `plugin` is that it will add a new XSLT stylesheet to the XSL processing that produces the PDF content.

4. In the same folder, create an XSLT stylesheet named `pageBreak.xsl` with the following content:

```xml
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
                 xmlns:fo="http://www.w3.org/1999/XSL/Format" version="1.0">
  <xsl:template match="processing-instruction('pagebreak')">
    <fo:block break-after="page"/>
  </xsl:template>
</xsl:stylesheet>
```

5. Install your `plugin` in the DITA Open Toolkit. (on page 3256)

The source code for the plugin can be found on GitHub here: https://github.com/dita-community/org.dita-community.pdf-page-break.

Customizing Note Images in PDF

To customize the images that appear next to each type of note in the PDF output, use a PDF customization folder (on page 2168) with the following procedure:

1. Create a customization directory (on page 2168) (if you haven't already done so).
2. Create a `cfg\common\vars` directory structure in your customization directory and copy the contents of `DITA-OT-DIR\plugins\org.dita.pdf2\cfg\common\vars` into that created directory.
3. Locate the `DITA-OT-DIR\plugins\org.dita.pdf2\cfg\common\vars\en.xml` file in your customization directory (for example, `custom_org.dita.pdf2\cfg\common\vars \en.xml`).
4. Create a `cfg\common\artwork` directory structure in your customization directory and add your custom `notice` image (for example, `Customization\cfg\common\artwork\notice.gif`).
5. Locate and edit the `Customization\cfg\common\vars\en.xml` file and modify the appropriate note element. For example, modify the path to the image for `<note>` element with the `type` attribute set to `notice` from:
6. Edit the DITA Map to PDF - based on XSL-FO (on page 1662) transformation scenario, go to the Parameters tab, and set the path for the customization.dir property to point to the customization folder. Also, set the com.oxygenxml.use.custom.note.images parameter to no.

Show Comments and Tracked Changes in PDF Output

To include comments and tracked changes (stored within your DITA topics) in the PDF output, follow these steps:

1. Edit a DITA Map to PDF transformation scenario.
2. In the Parameters tab, set the value of the show.changes.and.comments parameter to yes.
3. Optionally, you can configure any of these other parameters to adjust the colors of the comments and tracked changes:
   - **ct.insert.color** - Specifies the color for insertion type tracked changes, as a plain color (e.g. red, yellow, blue), or with a hexadecimal equivalent (e.g. #FFFFFF). The default value is 'blue'.
   - **ct.delete.color** - Specifies the color for deletion type tracked changes, as a plain color (e.g. red, yellow, blue), or with a hexadecimal equivalent (e.g. #FFFFFF). The default value is 'red'.
   - **ct.comment.bg.color** - Specifies the background color for comment type tracked changes, as a plain color (e.g. red, yellow, blue), or with a hexadecimal equivalent (e.g. #FFFFFF). The default value is 'yellow'.
4. Click OK and then the Apply Associated button to run the transformation scenario.

   **Result:** Comment threads and tracked changes will now appear in the PDF output. Details about each comment or change will be available in the footer section for each page.

Set a Font for PDF Output Generated with FO Processor

When a DITA map (on page 3281) is transformed to PDF using an FO processor and it contains some Unicode characters that cannot be rendered by the default PDF fonts, a font that is capable of rendering these characters must be configured and embedded in the PDF result.

The settings that must be modified for configuring a font for the built-in FO processor are detailed in Add a Font to the Built-in FO Processor - Advanced Version (on page 1740).
DITA OT PDF Font Mapping

The DITA OT contains a file `DITA-OT-DIR/plugins/org.dita.pdf2/cfg/fo/font-mappings.xml` that maps logical fonts used in the XSLT stylesheets to physical fonts that will be used by the FO processor to generate the PDF output.

The XSLT stylesheets used to generate the XSL-FO output contain code like this:

```
<xsl:attribute name="font-family">monospace</xsl:attribute>
```

The font-family is defined to be `monospace`, but `monospace` is just an alias. It is not a physical font name. Therefore, another stage in the PDF generation takes this `monospace` alias and looks in the `font-mappings.xml`.

If it finds a mapping like this:

```
<aliases>
  <alias name="monospace">Monospaced</alias>
</aliases>
```

then it looks to see if the `monospace` has a `logical-font` definition and if so, it will use the `physical-font` specified there:

```
<logical-font name="Monospaced">
  <physical-font char-set="default">
    <font-face>Courier New, Courier</font-face>
  </physical-font>
  ............
</logical-font>
```

⚠️ **Important:**

If no alias mapping is found for a font-family specified in the XSLT stylesheets, the processing defaults to `Helvetica`.

Related Information:

Adding Libraries to the Built-in FO Processor (DITA-OT)

Starting with Oxygen XML Editor version 20.0, both hyphenation and PDF image support are enabled by default in the built-in DITA-OT FO processor. For older version of Oxygen XML Editor, use the following procedures to enable such support.

Adding Hyphenation Support for DITA-OT Transformation Scenarios

1. Download the pre-compiled JAR (on page 3283) from OFFO.
2. Edit the DITA-OT transformation scenario and switch to the Advanced tab.
3. Click the Libraries button and add the path to the fop-hyph.jar library.

Adding Support for PDF Images

1. Download the fop-pdf-images JAR libraries.
2. Edit the DITA-OT transformation scenario and switch to the Advanced tab.
3. Click the Libraries button and add the path to the libraries.

Adding Support for CGM Images

1. Go to the JCGM page and download the jcgm-image-0.1.1.jar and jcgm-core-0.2.0.jar libraries.
2. Edit the DITA-OT transformation scenario and switch to the Advanced tab.
3. Click the Libraries button and add the path to the libraries.

Debugging DITA PDF Transformations

To debug a DITA PDF transformation scenario using the XSLT Debugger follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79), go to XML > XML Catalog, click Add, and select the file located at DITA-OT-DIR\plugins \org.dita.pdf2\cfg\catalog.xml.

2. Open the map in the DITA Maps Manager (on page 2990) and create a DITA Map PDF - XSL-FO transformation scenario.

3. Edit the scenario, go to the Parameters tab and change the value of the clean.temp parameter to no.

4. Run the transformation scenario.
5. Open the `stage1.xml` file located in the temporary directory and format and indent (on page 863) it.

6. Create a transformation scenario for this XML file by associating the `topic2fo_shell_fop.xsl` stylesheet located at `DITA-OT-DIR\plugins\org.dita.pdf2\xsl\fo\topic2fo_shell_fop.xsl`. If you are specifically using the RenderX XEP or Antenna House FO processors to build the PDF output, you should use the XSL stylesheets `topic2fo_shell_xep.xsl` or `topic2fo_shell_axf.xsl` located in the same folder.

**Note:** For validation purposes, you need to add the main debugged stylesheet (usually `topic2fo_shell_fop.xsl`) to the Master Files folder (on page 729) in the Project view.

7. In the transformation scenario, edit the XSLT Processor combo box choose the Saxon EE XSLT processor (the same processor used when the DITA OT transformation is executed).

8. In the transformation scenario, edit the Parameters list and set the parameter `locale` with the value `en_GB` and the parameter `customizationDir.url` to point either to your customization directory or to the default DITA OT customization directory. Its value should have a URL syntax like this: `file://c:/path/to/DITA-OT-DIR/plugins/org.dita.pdf2/cfg`.

9. Debug the transformation scenario.

**Related Information:**

- Debugging XSLT Stylesheets and XQuery Documents (on page 2290)
- How to Enable Debugging for FO Processor Transformations (on page 1742)

---

**DocBook to PDF Output Customization**

When the default layout and output of the DocBook to PDF transformation needs to be customized, follow these steps:

   You should start from a copy of the file `[DocBook XSL directory]/fo/titlepage.templates.xml` and customize it. The instructions for the spec file can be found here.

   An example of spec file:
2. Generate a new XSLT stylesheet from the title spec file from the previous step. Apply [DocBook XSL directory]/template/titlepage.xsl to the title spec file. The result is an XSLT stylesheet (for example, mytitlepages.xsl).

3. Import mytitlepages.xsl in a DocBook customization layer. The customization layer is the stylesheet that will be applied to the XML document. The mytitlepages.xsl should be imported with an element like this:

   ```xml
   <xsl:import href="dir-name/mytitlepages.xsl"/>
   ```

5. Apply the customization layer to the XML document. A quick way is to duplicate the transformation scenario DocBook PDF that is included with Oxygen XML Editor and set the customization layer in the XSL URL property of the scenario (on page 1675).

Related Information:

- Video demonstration for creating a DocBook customization layer in Oxygen XML Editor.
11.

Working with XPath Expressions

XPath is a language for addressing specific parts of a document. XPath models an XML document as a tree of nodes. An XPath expression is a mechanism for navigating through and selecting nodes from the document. An XPath expression is, in a way, analogous to an SQL query used to select records from a database.

**Note:** If an XPath expression is run over a JSON document, it is converted to XML and the XPath is executed over the converted XML document.

There are various types of nodes, including element nodes, attribute nodes, and text nodes. XPath defines a way to compute a string-value for each type of node.

XPath defines a library of standard functions for working with strings, numbers and boolean expressions.

**Examples:**

- `child::*` - Selects all children of the root node.
- `./name` - Selects all elements having the name "name", descendants of the current node.
- `/catalog/cd[price>10.80]` - Selects all the `cd` elements that have a price element with a value larger than 10.80.

To find out more about XPath, see [http://www.w3.org/TR/xpath](http://www.w3.org/TR/xpath).

**Related Information:**

- Content Completion in XPath Expressions (*on page 1192*)
- Find/Replace in Multiple Files (*on page 745*)
- Find/Replace Dialog Box (*on page 740*)
XPath Toolbar

XPath is a query language for selecting nodes from an XML document. To use XPath expressions effectively, you need a good understanding of the XPath Core Function Library.

XPath Toolbar

Oxygen XML Editor provides an XPath toolbar to let you query XML documents fast and easy using XPath expressions.

Figure 643. XPath Toolbar

The XPath toolbar includes the following features:

**XPath version chooser drop-down menu**

You can choose the XPath version from the drop-down menu available in the left side of the toolbar. Available options include XPath 1.0, XPath 2.0, XPath 2.0 SA, XPath 3.1, XPath 3.1 SA.

Note: The XPath 2.0 SA and XPath 3.1 SA options have some limitations. These options only offer information about the beginning part of the matching result. For example, if you search for an element, it will only highlight the start tag.

Warning: Oxygen XML Editor uses Saxon to execute XPath 3.1 expressions, but implements a part of the 3.1 functions. When using a function that is not implemented, Oxygen XML Editor can return a compilation error.

**XPath scope menu**

Oxygen XML Editor allows you to define a scope for which the XPath operation will be executed. You can choose where the XPath expression will be executed:

- Current file - Current selected file only.
- Project - All the files in the project.
- Selected project resources - The files selected in the project.
- All opened files - All files opened in the application.
- Current DITA Map hierarchy - All resources referenced in the currently selected DITA map, opened in the DITA Maps Manager view (on page 2990).
- Opened archive - Files open in the Archive Browser view (on page 2191).
- Working sets - The selected working sets (on page 3288).
At the bottom of the scope menu the following scope configuration actions are available:

- **Configure XPath working sets** - Allows you to configure and manage collections of files and folders, encapsulated in logical containers called *working sets* (on page 3288).
- **XPath file filter** - You can filter the files from the selected scope for which the XPath expression will be executed. By default, the XPath expression will be executed only on XML or JSON files, but you can also define a set of patterns that will filter out files from the current scope. If you select the **Include archive** option, the XPath expression will also be executed on the files in any archive (including EPUB and DocX) found at the current scope.

**History drop-down list**

The XPath combo box keeps a history of the last 15 expressions that were used so that you can easily choose them again.

**Settings menu**

The following actions are available in this drop-down menu:

- **XPath update on cursor move**

  When selected and you navigate through a document, the XPath expression corresponding to the XML node at the current cursor position is displayed. For JSON documents, it displays the XPath expression for the current property.

- **Evaluate XPath as you type**

  When you select this option, the XPath expression you are composing is evaluated in real time.

  **Note:** This option and the automatic validation are disabled when you edit huge documents (on page 781) or when the scope is other than Current file.

- **XPath Options**

  Opens the Preferences page of the currently selected processing engine.

- **Switch to XPath Builder View**

  Opens the XPath Builder view (on page 2185).

  **Note:** During the execution of an XPath expression, the XPath toolbar displays a **Stop** button. Press this button to stop the XPath execution.
When you type expressions longer than 60 characters, a dialog box opens that offers you the possibility to switch to the **XPath Builder view (on page 2185)**.

Related Information:
- XPath Expression Results View (on page 2188)

## XPath Builder View

The **XPath/XQuery Builder** view allows you to compose complex XPath expressions and execute them over the currently edited XML document. For XPath 2.0 / 3.1, you can use the `doc()` function to specify the source file for which the expressions are executed. When you connect to a database, the expressions are executed over that database. If you are using the **XPath/XQuery Builder view** and the current file is an XSLT document, Oxygen XML Editor executes the expressions over the XML document in the associated scenario.

**Note:** If an XPath expression is run over a JSON document, it is converted to XML and the XPath is executed over the converted XML document.

If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu. You can also open it simply by pressing the **Switch to XPath Builder View** button that is located on the **XPath toolbar (on page 2182)**.

The upper part of the view contains the following actions:

### XPath version chooser drop-down menu

A drop-down menu that allows you to select the type of the expression you want to execute. You can choose between:

- XPath 1.0 (Xerces-driven)
- XPath 2.0, XPath 2.0 SA, XPath 3.1, XPath 3.1 SA, Saxon-HE XQuery, Saxon-PE XQuery, or Saxon-EE XQuery (all of them are Saxon-driven)
- Custom connection to XML databases that can execute XQuery expressions

**Note:** The results returned by XPath 2.0 SA and XPath 3.1 SA have a location limited to the line number of the start element (there are no column information and no end specified).

**Note:** Oxygen XML Editor uses Saxon to execute XPath 3.1 expressions. Since Saxon implements a part of the 3.1 functions, when using a function that is not implemented, Oxygen XML Editor returns a compilation error.
Execute XPath button

Use this button to start the execution of the XPath or XQuery expression you are editing. The result of the execution is displayed in the Results view (on page 357).

Favorites button

Allows you to save certain expressions that you can later reuse. To add an expression as a favorite, press the star button and enter a name for it. The star turns yellow to confirm that the expression was saved. Expand the drop-down menu next to the star button to see all your favorites. Oxygen XML Editor automatically groups favorites in folders named after the method of execution.

History drop-down menu

Keeps a list of the last 15 executed XPath expressions. Use the Clear history action from the bottom of the list to remove them.

Settings drop-down menu

Contains the following three options:

- Update on cursor move
  When selected and you navigate through a document, the XPath expression corresponding to the XML node at the current cursor position is displayed. For JSON documents, it displays the XPath expression for the current property.

- Evaluate as you type
  When you select this option, the XPath expression you are composing is evaluated in real time.

  Note: This option and the automatic validation are disabled when you edit huge documents (on page 781) or when the scope is other than Current file.

- Options
  Opens the Preferences page of the currently selected processing engine.

XPath scope menu

Oxygen XML Editor allows you to define a scope for which the XPath operation will be executed. You can choose where the XPath expression will be executed:

- Current file - Current selected file only.
- Project - All the files in the project.
- Selected project resources - The files selected in the project.
• **All opened files** - All files opened in the application.

• **Current DITA Map hierarchy** - All resources referenced in the currently selected *DITA map*, opened in the [DITA Maps Manager view](on page 2990).

• **Opened archive** - Files open in the [Archive Browser view](on page 2191).

• **Working sets** - The selected *working sets* (on page 3288).

At the bottom of the scope menu the following scope configuration actions are available:

• **Configure XPath working sets** - Allows you to configure and manage collections of files and folders, encapsulated in logical containers called *working sets* (on page 3288).

• **XPath file filter** - You can filter the files from the selected scope for which the XPath expression will be executed. By default, the XPath expression will be executed only on XML or JSON files, but you can also define a set of patterns that will filter out files from the current scope. If you select the *Include archive* option, the XPath expression will be also executed on the files in any archive (including EPUB and DocX) found at the current scope.

Figure 644. XPath/XQuery Builder View
While you edit an XPath or XQuery expression, Oxygen XML Editor assists you with the following features:

- **Content Completion Assistant (on page 3280)** - It offers context-dependent proposals and takes into account the cursor position in the document you are editing. The set of functions proposed by the Content Completion Assistant also depends on the engine version. Select the engine version from the drop-down menu available in the toolbar.

- **Syntax Highlighting** - Allows you to identify the components of an expression. To customize the colors of the components of the expression, open the Preferences dialog box (Options > Preferences) (on page 79) and go to Editor > Syntax Highlight (on page 178).

- **Automatic validation of the expression as you type.**

  - *Note:* When you type invalid syntax, a red serrated line underlines the invalid fragments.

- **Function signature and documentation balloon,** when the cursor is located inside a function.

The usual edit actions (Cut, Copy, Paste, Select All, Undo, Redo) are available in the contextual menu of the top editable part of the view.

**Related Information:**

- XPath Expression Results View (on page 2188)

### XPath Expression Results View

When you run an XPath expression, Oxygen XML Editor displays the results of its execution in the Results view (on page 357).

This view contains the following columns:

- **Description** - The result that Oxygen XML Editor displays when you run an XPath expression.
- **XPath location** - The path to the matched node.
- **Resource** - The name of the document that you run the XPath expression on.
- **System ID** - The path to the document itself.
- **Location** - The location of the result in the document.

To arrange the results depending on a column, click its header. To group the results by their resource, or by their system ID, right-click the header of any column in the Results view and select Group by "Resource" or Group by "System ID". If no information regarding location is available, Oxygen XML Editor displays Not available in the Location column. Oxygen XML Editor displays the results in a valid XPath expression format.
The **Results** view also includes various toolbar and contextual menu actions. For more information, see **Results View (on page 357)**.

**Example:**

The following snippets are taken from a DocBook book based on the DocBook XML DTD. The book contains a number of chapters. To return all the chapter nodes of the book, enter `//chapter` in the XPath expression field and press **(Enter)**. This action returns all the `chapter` nodes of the DocBook book in the **Results View**. Click a record in the **Results View** to locate and highlight its corresponding chapter element and all its children nodes in the document you are editing.

To find all `example` nodes contained in the `sect2` nodes of a DocBook XML document, use the following XPath expression: `//chapter/sect1/sect2/example`. Oxygen XML Editor adds a result in the **Results View** for each `example` node found in any `sect2` node.

For example, if the result of the above XPath expression is:

```
- /chapter[1]/sect1[3]/sect2[7]/example[1]
```

it means that in the edited file, the `example` node is located in the first chapter, third section level one, seventh section level 2.

**Figure 645. XPath Results Highlighted in Editor Panel with Character Precision**
XPath and XML Catalogs

The evaluation of the XPath expression tries to resolve the locations of documents referenced in the expression through XML Catalogs (on page 3289). These catalogs are configured in the XML Catalog preferences (on page 189) pages and the XML Parser preferences (on page 191).

Example:

As an example, consider the evaluation of the collection(URIofCollection) function (XPath 2.0). To resolve the references from the files returned by the collection() function with an XML catalog, specify the class name of the catalog-enabled parser for parsing these collection files. The class name is ro.sync.xml.parser.CatalogEnabledXMLReader. Specify it as it follows:

```xml
let $docs := collection(iri-to-uri{
    "file:///D:/temp/test/XQuery-catalog/mydocsdir?recurse=yes;select=*.xml;
    parser=ro.sync.xml.parser.CatalogEnabledXMLReader")
```

XPath Prefix Mapping

To define default mappings between prefixes (that you can use in the XPath toolbar (on page 2182)) and namespace URIs go to the XPath preferences page (on page 214) and enter the mappings in the Default prefix-namespace mappings table. The same preferences panel allows you to configure the default namespace used in XPath 2.0 expressions.

⚠️ Important: If you define a default namespace, Oxygen XML Editor binds this namespace to the first free prefix from the list: default, default1, default2, and so on. For example, if you define the default namespace xmlns="something" and the prefix default is not associated with another namespace, you can match tags without prefix in an XPath expression typed in the XPath toolbar by using the prefix default. To find all the level elements when you define a default namespace in the root element, use this expression: //default:level in the XPath toolbar.
12.

Working with Archives

Oxygen XML Editor includes a useful Archive Browser view (on page 2191) that offers the means to work with files directly from various types of archives (for example, opening and saving files directly in archives, or browsing and modifying archive structures). The archive support is available for all ZIP-type archives, including:

- ZIP archives
- EPUB books
- JAR archives (on page 3283)
- Office Open XML (OOXML) files
- Open Document Format (ODF) files
- IDML files (on page 3283)

You can transform, validate, and perform many other operations on files directly from an archive. For instance, you can transform, or validate files directly from OOXML or ODF packages, and the structure and content of the ZIP archives can be opened, edited, and saved, similar to any other ZIP archive browsing tool. Also, when browsing for a URL in various dialog boxes, you can use the Browse for archived file action to browse and select files from a particular archive.

For more information about working with an EPUB archive in Oxygen XML Editor, watch our video demonstration:

https://www.youtube.com/embed/OIGTNQw0CI8

Browsing Archives

Oxygen XML Editor includes a helper view called the Archive Browser that allows you to view the contents and structure of an archive, and it offers a variety of toolbar and contextual menu actions. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

To open an archive in the Archive Browser view, use one of the following methods:

- Open an archive from the Project view (on page 333).
- Select an archive in one of the file chooser dialog boxes in Oxygen XML Editor (such as the Open dialog box).
- Drag an archive from a system file explorer and drop it in the Archives Browser view.
When displaying an archive, the **Archive Browser** view locks the archive file. It is then automatically unlocked when the **Archive Browser** view is closed.

**Tip:** If a file is not recognized by Oxygen XML Editor as a supported archive type, you can add it from the **Archive preferences page** (on page 244).

---

**Archive Browser Toolbar Actions**

The following actions are available on the **Archive Browser** toolbar:

- **Open Archive menu**
  
  Provides access to the **Open Archive** action that opens a new archive in the browser. If the extension is not known as an archive extension, you will be directed to the **Archive preferences page** (on page 244) to add a new extension. The sub-menu keeps a list of recently open archive files and a **Clear history** action that allows you to delete the list.

- **Close**
  
  Closes the browsed archive and unlocks the archive file.

- **Validate (available for EPUB archives only)**
  
  Checks the EPUB archive to see if its content and structure is valid.

- **New folder**
  
  Creates a folder as child of the selected folder in the browsed archive.

- **New file**
  
  Creates a file as child of the selected folder in the browsed archive.
Add files

Adds existing files as children of the selected folder in the browsed archive.

Note: You can also add files in the archive by dragging them from the file browser or the Project view (on page 333) and dropping them in the Archive Browser view.

Delete

Deletes the selected resource in the browsed archive.

Open in System Application

Opens the selected resource in the default system application that is associated with that type of file.

Archive Options

Opens the Archive preferences page (on page 244).

Archive Browser Contextual Menu Actions

The following additional actions are available from the contextual menu for resources in the Archive Browser view:

Open

Opens a resource from the archive in the editor.

Extract

Extracts a resource from the archive in a specified folder.

New folder

Creates a folder as child of the selected folder in the browsed archive.

New file

Creates a file as child of the selected folder in the browsed archive.

Add files

Adds existing files as children of the selected folder in the browsed archive.

Note: On OS X, the Add file action is also available and it allows you to add one file at a time.

Rename

Renames a resource in the archive.

Find/Replace in Files
Opens the **Find/Replace in Files** dialog box *(on page 745)* that allows you to search for and replace specific pieces of text inside the archive.

**Cut**
Cut the selected archive resource.

**Copy**
Copies the selected archive resource.

**Paste**
Paste a file or folder into the archive.

**Delete**
Remove a file or folder from archive.

**Preview**
Previews an image contained in the archive. See the **Image Preview** *(on page 721)* topic for more details.

**Copy location**
Copy the URL location of the selected resource.

**Refresh**
Refreshes the selected resource.

**Properties**
Shows the properties of the selected resource.

For more information, watch our video demonstration about working with an EPUB in the **Archive Browser** view:

https://www.youtube.com/embed/OIGTNQw0C18

**Working with Archive Files**

Oxygen XML Editor includes support for working with various types of archives, including the following:

- **EPUB** - An e-book file format that can be used on many types of devices, such as smart phones, tablets, e-readers, or computers.
- **OOXML** - An XML-based file format for representing spreadsheets, charts, presentations, and word processing documents.
- **ODF** - An free and open-source XML-based file format for electronic office documents, such as spreadsheets, charts, presentations, and word processing documents.
When these types of files are opened in the Archive Browser view (on page 2191), their internal components are expanded:

- Document content (XHTML and image files).
- Packaging files.
- Container files.

Figure 647. EPUB File Displayed in the Archive Browser View

When an archive is expanded in the Archive Browser view (on page 2191), you can add or delete files that compose the archive structure. All changes made to the structure of an archive are saved immediately. You can open files from within the archive to edit them in the main editing pane and save changes (on page 2196) back to the archive. You can also use the Open in System Application action to open the archive in the default system application that is associated with that type of file.

EPUB-Specific Validation

When working with EPUB archives, the Archive Browser (on page 2191) includes a Validate action on the toolbar that checks the EPUB archive to make sure the structure and content are valid. Oxygen XML Editor uses the open-source EpubCheck validator to perform the validation. This validator detects many types of errors, including OCF container structure, OPF and OPS mark-up, as well as internal reference consistency.
Creating an Archive

To create an archive from scratch, follow these steps:

1. Go to File > New or click New on the main toolbar.

2. Choose your particular type of archive template. For example, select one of the ODF, OOXML, or EPUB templates.

3. Click Create and choose the name and location of the file.

4. Click Save.
   A skeleton archive is saved on disk and opened in the Archive Browser view (on page 2191).

   Tip: Use toolbar and contextual menu actions to edit, add, and remove resources from the archive. For EPUB archives, you can use the Validate action to verify the integrity of the EPUB archive.

Editing and Saving Files Inside an Archive

You can open files directly from an archive in the Archive Browser view (on page 2191) and then edit them in the main editor pane. To open a file, simply double-click it or select Open from the contextual menu.

When saving the file back to the archive, you are prompted to choose if you want the application to make a backup copy of the archive before saving the new content. If you choose Never ask me again, you will not be asked again to make backup copies. You can re-enable the pop-up message from the Messages preferences page (on page 260).
Migrating Archives to DITA or TEI

Certain types of archives can be converted to DITA or TEI. For example, OOXML (Office Open XML) archive files with the DOCX file extension can be migrated to DITA or TEI.

To migrate DOCX files to DITA or TEI, follow these steps:

1. Open and expand the archive in the Archive Browser (on page 2191).
2. Open the `document.xml` file contained in the archive.
3. Run one of the following built-in transformation scenarios:
   a. **DOCX DITA** to migrate to DITA.
   b. **DOCX TEI P5** to migrate to TEI.
4. You may need to do some manual reconfiguring to map DOCX styles to DITA or TEI content.

**Tip**: Oxygen XML Editor also includes a built-in transformation scenario called **ODT TEI P5** for converting ODF archive files with the ODT file extension to TEI and a similar process can be used to migrate ODT files to TEI.
13. Databases and SharePoint

Oxygen XML Editor provides support for connecting and integrating with various databases and Microsoft SharePoint. This section includes information about the database-related features in Oxygen XML Editor. It explains how to connect with the supported databases, presents the actions that are available for each type, and includes information about SharePoint integration.

Working with Databases

XML is a storage and interchange format for structured data and is supported by all major database systems. Oxygen XML Editor offers the means for managing the interaction with some of the most commonly used databases (both Relational and Native XML databases). Through this interaction, Oxygen XML Editor helps users with browsing, content editing, importing from databases, using XQuery with databases, SQL execution, and generating XML Schema from a database structure.

The types of connections that are supported in Oxygen XML Editor include:

- IBM DB2 (on page 2204)
- Microsoft SQL Server (on page 2209)
- Oracle Database (on page 2213)
- PostgreSQL (on page 2218)
- Berkeley DB XML (on page 2222)
- eXist (on page 2229)
- MarkLogic (on page 2234)
- MySQL (on page 2244)
- Generic JDBC (on page 2246)
- JDBC-ODBC (on page 2247)
- BaseX (on page 2249)
- WebDAV (on page 2254)
- Microsoft SharePoint (on page 2268)

Related Information:

- Integration with Microsoft SharePoint (on page 2268)
Data Source Explorer View

The **Data Source Explorer** view displays your database connections. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

You can connect to a database simply by expanding the connection node (click the connection). The database structure can be expanded to resource level, or even all the way to column level for tables inside relational databases. Oxygen XML Editor supports multiple simultaneous database connections and the connection tree in the **Data Source Explorer** view provides an easy method for browsing them.

![Data Source Explorer View](image)

The objects (nodes) that are displayed in the **Data Source Explorer** view depend on the connection type and structure of the database. Various contextual menu actions are available for each hierarchical level and for some connections you can add or move resources in a container by simply dragging them from the **Project view (on page 333)**, a file browsing application, or another database.

**Toolbar Actions**

The following actions are available in the toolbar of this view:

- **Filters**
  
  Opens the **Data Sources / Table Filters preferences page (on page 233)**, allowing you to decide which table types are displayed in the **Data Source Explorer** view.

- **Configure Database Sources**
  
  Opens the **Data Sources preferences page (on page 229)** where you can configure both data sources and connections.
Database-Specific Contextual Menu Actions

Each specific type of database will also include its own specific contextual menu actions in the Data Source Explorer view. The actions depend on the type of database, the type of node, or the hierarchical level of the node in which the contextual menu is invoked.

For more information on the specific actions that are available, see the topics in this section for each specific type of database.

Related Information:

- Data Sources Preferences (on page 229)

Table Explorer View

Relational databases tables in the Data Source Explorer view (on page 2198) can be displayed and edited in the Table Explorer view by selecting the Edit action from the contextual menu of a Table node or by double-clicking one of its fields. To modify the content of a cell, double-click it and start typing. When editing is complete, Oxygen XML Editor attempts to update the database with the new cell content.

Figure 649. Table Explorer View

You can sort the content of a table by one of its columns by clicking its column header.

Note the following:

- The first column is an index (not part of the table structure).
- Every column header contains the field name and its data type.
- The primary key columns are marked with this symbol: 🟢.
• Multiple tables are presented in a tabbed manner.

For performance issues, you can set the maximum number of cells that are displayed in the Table Explorer view (using the Limit the number of cells option in the Data Sources Preferences page (on page 233)). If a table that has more cells than the value set in the options is displayed in the Table Explorer view, a warning dialog box informs you that the table is only partially shown.

You are notified if the value you have entered in a cell is not valid (and thus cannot be updated).

• If the content of the edited cell does not belong to the data type of the column, the cell is marked by a red square and remains in an editing state until a correct value is inserted. For example, in the following figure propID contains LONG values. If a character or string is inserted, the cell will look like this:

Figure 650. Cell Containing an Invalid Value

• If the constraints of the database are not met (for instance, primary key constraints), an information dialog box will appear, notifying you of the reason the database has not been updated. For example, in the table below, trying to set the second record in the primary key propID column to 8, results in a duplicate entry error since that value has already been used in the first record:

Figure 651. Duplicate Entry for Primary Key
Table Explorer Contextual Menu Actions

Common editing actions (Cut, Copy, Paste, Select All, Undo, Redo) are available in the contextual menu of an edited cell.

The contextual menu, available on every cell in the Table Explorer view, also includes the following actions:

Set NULL

Sets the content of the cell to null. This action is not available for columns that cannot have a value of null.

Insert row

Inserts an empty row in the table.

Duplicate row

Makes a copy of the selected row and adds it in the Table Explorer view. Note that the new row will not be inserted in the database table until all conflicts are resolved.

Commit row

Commits the selected row.

Delete row

Deletes the selected row.

Copy

Copies the content of the cell.

Paste

Pastes copied content into the selected cell.
Table Explorer Toolbar Actions

The toolbar of the Table Explorer view also includes the following actions:

- **Export to XML**
  
  Opens the Export Criteria dialog box (a thorough description of this dialog box can be found in the Import from database (on page 2282) chapter).

- **Refresh**
  
  Performs a refresh for the sub-tree of the selected node.

- **Insert row**
  
  Inserts an empty row in the table.

- **Duplicate row**
  
  Makes a copy of the selected row and adds it in the Table Explorer view. Note that the new row will not be inserted in the database table until all conflicts are resolved.

- **Commit row**
  
  Commits the selected row.

- **Delete row**
  
  Deletes the selected row.

Related Information:

- Data Source Explorer View (on page 2198)

Database Connection Support

Oxygen XML Editor offers support for a variety of Relational and Native XML database connections. The database drivers and connections for various types of database are configured in the Data Sources preferences page (on page 229) and once configured, the database connections can be viewed and managed in the Data Source Explorer view (on page 2198). Oxygen XML Editor also includes a Database perspective (on page 300) that helps you to manage databases.

The database support in Oxygen XML Editor offers a variety of capabilities, including:

- Browsing the structure of databases in the Data Source Explorer view (on page 2198).
- Viewing relational tables in the Table Explorer view (on page 2200).
- Executing SQL queries against databases.
- Calling stored procedures with input and output parameters.
- XQuery execution with databases.
- Exporting data from databases to XML.

Relational Database Support

Relational databases use a relational model and are based on tables linked by a common key. Oxygen XML Editor offers support for the most commonly used relational databases, including:

- IBM DB2
- Oracle 11g
- Microsoft SQL Server
- PostgreSQL
- MySQL

Oxygen XML Editor also offers generic support (table browsing and execution of SQL queries) for any JDBC-compliant database (for example, MariaDB).

Native XML Database Support

Native XML databases have an XML-based internal model and their fundamental unit of storage is XML. They use XML as an interface to specify documents as tree structured data that may contain unstructured text, but on disk the data is stored as optimized binary files. This makes query and retrieval processes faster. Oxygen XML Editor offers support for the most commonly used native XML databases, including:

- Berkeley DB XML
- eXist
- MarkLogic
- Oracle XML DB
- Base X

Related Information:

- WebDAV Connections (on page 2254)
- Integration with Microsoft SharePoint (on page 2268)
IBM DB2 Database Connections

Oxygen XML Editor includes support for IBM DB2 database connections. Oxygen XML Editor allows you to browse the structure of an IBM DB2 database in the Data Source Explorer view (on page 2198), open tables in the Table Explorer view (on page 2200), and perform various operations on the resources in the repository.

Figure 652. IBM DB2 Database Connection

Configuring an IBM DB2 Database Connection

To configure the support for the IBM DB2 database, follow this procedure:

1. Go to the IBM website and in the DB2 Clients and Development Tools category select the DB2 Driver for JDBC and SQLJ download link. Fill out the download form and download the zip file. Unzip the zip file and use the db2jcc.jar and db2jcc_license_cu.jar files in Oxygen XML Editor for configuring a DB2 data source (on page 2205).
2. Configure IBM DB2 Data Source drivers (on page 2205).
3. Configure an IBM DB2 Server Connection (on page 2207).
4. To view your connection, go to the Data Source Explorer view (on page 2198) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 3285).

How to Configure IBM DB2 Data Source Drivers

Available in the Enterprise edition only.
To configure a data source for connecting to an IBM DB2 server, follow these steps:

1. Go to the IBM website and in the DB2 Clients and Development Tools category select the DB2 Driver for JDBC and SQLJ download link. Fill out the download form and download the zip file.

2. Unzip the downloaded archive.

3. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.

4. Click the + New button in the Data Sources panel.

The dialog box for configuring a data source is opened.

Figure 653. Data Source Drivers Configuration Dialog Box

5. Enter a unique name for the data source.

6. Select DB2 in the driver Type drop-down menu.

7. Click the Add Files button and select the IBM DB2 driver files from the archive that you downloaded and unzipped.

The IBM DB2 driver files are:

- db2jcc.jar
- db2jcc_license_cisuz.jar
• db2jcc_license_cu.jar

8. Select the most appropriate **Driver class**.

9. Click the **OK** button to finish the data source configuration.

10. Continue on to configure your IBM DB2 connection (on page 2207).

## How to Configure an IBM DB2 Connection

The support to create an IBM DB2 connection is available in the Enterprise edition only.

To configure a connection to an IBM DB2 server, follow these steps:

1. Open the **Preferences** dialog box (Options > Preferences) (on page 79) and go to **Data Sources**.

2. Click the **+ New** button in the **Connections** panel.

   The dialog box for configuring a database connection is displayed.

   **Figure 654. Connection Configuration Dialog Box**

3. Enter a unique name for the connection.

4. Select an **IBM DB2** data source in the **Data Source** drop-down menu.

5. Enter the connection details.
   a. Enter the URL to the installed IBM DB2 engine.
   b. Enter the user name to access the IBM DB2 engine.
   c. Enter the password to access the IBM DB2 engine.
6. Click the **OK** button to finish the connection configuration.

7. To view your connection, go to the **Data Source Explorer view (on page 2198)** (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database perspective (on page 3285)**.

### IBM DB2 Contextual Menu Actions

#### General Contextual Menu Actions

For relational databases, the following general actions are available in the contextual menu of the **Data Source Explorer view (on page 2198)**, depending on the node in which it is invoked:

- **Refresh**
  
  Performs a refresh on the selected node.

- **Disconnect (available on Connection nodes)**
  
  Closes the current database connection. If a table is already open, you are warned to close it before proceeding.

- **Configure Database Sources (available on Connection nodes)**
  
  Opens the **Data Sources preferences page (on page 229)** where you can configure both data sources and connections.

- **Edit (available on Table nodes)**
  
  Opens the selected table in the **Table Explorer view (on page 2200)**.

- **Export to XML (available on Table nodes)**
  
  Opens the **Export Criteria** dialog box (a thorough description of this dialog box can be found in the **Import from Database (on page 2282)** chapter).

#### Database-Specific Contextual Menu Actions

In addition to the general contextual menu actions in the **Data Source Explorer view (on page 2198)**, the various nodes in IBM DB2 connections include the following additional contextual menu actions:

- **XML Schema Repository Level Nodes**

  - **Register**
    
    Opens a dialog box for adding a new schema file in the DB XML repository.

    In this dialog box, you enter a collection name and the necessary schema...
files. Schema dependencies management can be done by using the Add and Remove buttons.

**Schema Level Nodes**

**Unregister**

Removes the selected schema from the XML Schema Repository.

**View**

Opens the selected schema in Oxygen XML Editor.

**Microsoft SQL Server Database Connections**

Oxygen XML Editor includes support for Microsoft SQL Server database connections. Oxygen XML Editor allows you to browse the structure of a SQL Server database in the Data Source Explorer view (on page 2198), open tables in the Table Explorer view (on page 2200), and perform various operations on the resources in the repository.

**Configuring a Microsoft SQL Server Connection**

To configure the support for a Microsoft SQL Server database, follow this procedure:

2. Configure MS SQL Server Data Source drivers (on page 2209).
3. Configure a MS SQL Server Connection (on page 2210).
4. To view your connection, go to the Data Source Explorer view (on page 2198) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 3285).

**How to Configure Microsoft SQL Server Data Source Drivers**

Available in the Enterprise edition only.

To configure a data source for connecting to a Microsoft SQL server, follow these steps:

2. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.
3. Click the New button in the Data Sources panel.

The dialog box for configuring a data source is opened.

Figure 655. Data Source Drivers Configuration Dialog Box

4. Enter a unique name for the data source.

5. Select SQLServer in the driver Type drop-down menu.

6. Click the Add Files button and select the Microsoft SQL Server driver file that you downloaded.
   The SQL Server driver file is called sqljdbc.jar.

7. Select the most appropriate Driver class.

8. Click the OK button to finish the data source configuration.

9. Continue on to configure your Microsoft SQL Server connection (on page 2210).

How to Configure a Microsoft SQL Server Connection

The support to configure a Microsoft SQL Server connection is available in the Enterprise edition only.

To configure a connection to a Microsoft SQL Server, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.
2. Click the **New** button in the **Connections** panel.

   The dialog box for configuring a database connection is displayed.

   **Figure 656. Connection Configuration Dialog Box**

   ![Connection Configuration Dialog Box](image)

3. Enter a unique name for the connection.

4. Select the *SQL Server* data source in the **Data Source** drop-down menu.

5. Enter the connection details.

   a. Enter the URL of the SQL Server.

      If you want to connect to the server using Windows integrated authentication, you must add `;integratedSecurity=true` to the end of the URL. The URL will look like this:

      ```
      jdbc:sqlserver://localhost;instanceName=SQLEXPRESS;integratedSecurity=true;
      ```

      **Note:** For integrated authentication, leave the **User** and **Password** fields empty.

   b. Enter the user name for the connection to the SQL Server.

   c. Enter the password for the connection to the SQL Server.

6. Click the **OK** button to finish the connection configuration.

7. To view your connection, go to the **Data Source Explorer view** *(on page 2198)* (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database perspective** *(on page 3285)*.
General Contextual Menu Actions

For relational databases, the following general actions are available in the contextual menu of the Data Source Explorer view (on page 2198), depending on the node in which it is invoked:

- **Refresh**
  Performs a refresh on the selected node.

- **Disconnect (available on Connection nodes)**
  Closes the current database connection. If a table is already open, you are warned to close it before proceeding.

- **Configure Database Sources (available on Connection nodes)**
  Opens the Data Sources preferences page (on page 229) where you can configure both data sources and connections.

- **Edit (available on Table nodes)**
  Opens the selected table in the Table Explorer view (on page 2200).

- **Export to XML (available on Table nodes)**
  Opens the Export Criteria dialog box (a thorough description of this dialog box can be found in the Import from Database (on page 2282) chapter).

Database-Specific Contextual Menu Actions

In addition to the general contextual menu actions in the Data Source Explorer view (on page 2198), the resource level nodes in Microsoft SQL Server connections include the following additional contextual menu action:

- **XML Schema Repository Level Nodes**
  
  - **Register**
    Opens a dialog box for adding a new schema file in the DB XML repository. In this dialog box, you enter a collection name and the necessary schema files. Schema dependencies management can be done by using the Add and Remove buttons.

- **Schema Level Nodes**
  
  - **Add**
    Adds a new schema to the XML Schema files.
### Unregister

Removes the selected schema from the XML Schema Repository.

### View

Opens the selected schema in Oxygen XML Editor.

### Oracle Database Connections

The Oracle database is a common relational type of database system. Oxygen XML Editor comes with built-in support for the 11g version of the database system. The Oracle database also includes an Oracle XML DB component that adds native XML support. Oxygen XML Editor allows you to browse Oracle repositories in the **Data Source Explorer view** (on page 2198), open tables in the **Table Explorer view** (on page 2200), and perform various operations on the resources in the repository.

![Figure 657. Oracle Database Connection](image)

- Using XQuery with Oracle XML DB

### Configuring an Oracle 11g Database Connection

To configure the support for an Oracle 11g database, follow this procedure:

2. Configure Oracle 11g **Data Source drivers** (on page 2214).
3. Configure an Oracle 11g **Connection** (on page 2215).
4. To view your connection, go to the Data Source Explorer view (on page 2198) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 3285).

How to Configure Oracle 11g Data Source Drivers

Available in the Enterprise edition only.

To configure a data source for connecting to an Oracle 11g server, follow these steps:

2. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.

3. Click the + New button in the Data Sources panel.

   The dialog box for configuring a data source is opened.

   Figure 658. Data Source Drivers Configuration Dialog Box

   ![Data Source Drivers Configuration Dialog Box]

4. Enter a unique name for the data source.

5. Select Oracle in the driver Type drop-down menu.
6. Click the Add Files button and select the Oracle driver file that you downloaded. The Oracle driver file is called ojdbc5.jar.

7. Select the most appropriate Driver class.

8. Click the OK button to finish the data source configuration.

9. Continue on to configure your Oracle connection (on page 2215).

How to Configure an Oracle 11g Connection

Available in the Enterprise edition only.

To configure a connection to an Oracle 11g server, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.

2. Click the New button in the Connections panel.

   The dialog box for configuring a database connection is displayed.

   Figure 659. Connection Configuration Dialog Box

3. Enter a unique name for the connection.

4. Select the Oracle 11g data source in the Data Source drop-down menu.

5. Enter the connection details.
   a. Enter the URL of the Oracle server.
   b. Enter the user name for the connection to the Oracle server.
c. Enter the password for the connection to the Oracle server.

6. Click the **OK** button to finish the connection configuration.

7. To view your connection, go to the **Data Source Explorer view** *(on page 2198)* (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database perspective** *(on page 3285)*.

**Oracle Database Contextual Menu Actions**

**General Contextual Menu Actions**

For relational databases, the following general actions are available in the contextual menu of the **Data Source Explorer view** *(on page 2198)*, depending on the node in which it is invoked:

- **Refresh**
  
  Performs a refresh on the selected node.

- **Disconnect (available on Connection nodes)**
  
  Closes the current database connection. If a table is already open, you are warned to close it before proceeding.

- **Configure Database Sources (available on Connection nodes)**
  
  Opens the **Data Sources preferences page** *(on page 229)* where you can configure both data sources and connections.

- **Edit (available on Table nodes)**
  
  Opens the selected table in the **Table Explorer view** *(on page 2200)*.

- **Export to XML (available on Table nodes)**
  
  Opens the **Export Criteria** dialog box (a thorough description of this dialog box can be found in the **Import from Database** *(on page 2282)* chapter).

**Database-Specific Contextual Menu Actions**

In addition to the general contextual menu actions in the **Data Source Explorer view** *(on page 2198)*, the various nodes in Oracle database connections include the following additional contextual menu actions:

- **XML Schema Repository Level Nodes**
  
  **Register**
Opens a dialog box for adding a new schema file in the XML repository.
To add an XML Schema, enter the schema URI and location on your file system. *Local* scope means that the schema is visible only to the user who registers it. *Global* scope means that the schema is public.

**Note:** Registering a schema may involve dropping/creating types. Hence you need type-related privileges such as DROP TYPE, CREATE TYPE, and ALTER TYPE. You need privileges to delete and register the XML schemas involved in the registering process. You need all privileges on XMLType tables that conform to the registered schemas. For XMLType columns, the ALTER TABLE privilege is needed on corresponding tables. If there are schema-based XMLType tables or columns in other database schemas, you need privileges such as the following:

- CREATE ANY TABLE
- CREATE ANY INDEX
- SELECT ANY TABLE
- UPDATE ANY TABLE
- INSERT ANY TABLE
- DELETE ANY TABLE
- DROP ANY TABLE
- ALTER ANY TABLE
- DROP ANY INDEX

To avoid having to grant all these privileges to the schema owner, Oracle recommends that the registration be performed by a DBA if there are XML schema-based XMLType table or columns in other user database schemas.

**XML Repository Level Nodes**

**Add container**

Adds a new child container to the current one.

**Add resource**

Adds a new resource to the folder.

**Container Level Nodes**

**Add container**

Adds a new child container to the current one.

**Add resource**
Adds a new resource to the folder.

**Delete**

Deletes the current container.

**Properties**

Shows various properties of the current container.

**Resource Level Nodes**

**Open**

Opens the selected resource in the editor.

**Open in System Application**

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the Data Source Explorer view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

**Rename**

Renames the current resource

**Move**

Moves the current resource to a new container (also available through drag and drop).

**Delete**

Deletes the current container.

**Copy location**

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

**Properties**

Shows various properties of the current container.

**Compare**

Compares two selected resources using the Compare Files tool (on page 2770).
PostgreSQL Database Connections

Oxygen XML Editor includes support for PostgreSQL database connections. Oxygen XML Editor allows you to browse the structure of a PostgreSQL database in the Data Source Explorer view (on page 2198), open tables in the Table Explorer view (on page 2200), and perform various operations on the resources in the repository.

Figure 660. PostgreSQL Database Connection

Configuring a PostgreSQL Database Connection

To configure the support for a PostgreSQL database, follow this procedure:

1. Go to http://jdbc.postgresql.org/download.html and download the PostgreSQL 8.3 JDBC3 driver.
2. Configure PostgreSQL Data Source drivers (on page 2219).
3. Configure a PostgreSQL Connection (on page 2220).
4. To view your connection, go to the Data Source Explorer view (on page 2198) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 3285).

How to Configure PostgreSQL 8.3 Data Source Drivers

To configure a data source for connecting to a PostgreSQL server, follow these steps:

1. Go to http://jdbc.postgresql.org/download.html and download the PostgreSQL 8.3 JDBC3 driver.
2. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.
3. Click the + New button in the Data Sources panel.

The dialog box for configuring a data source is opened.

4. Enter a unique name for the data source.

5. Select PostgreSQL in the driver Type drop-down list.

6. Click the Add Files button and select the PostgreSQL driver file that you downloaded.

   The PostgreSQL driver file is called postgresql-8.3-603.jdbc3.jar.

7. Select the most appropriate Driver class.

8. Click the OK button to finish the data source configuration.

9. Continue on to configure your PostgreSQL connection (on page 2220).

How to Configure a PostgreSQL 8.3 Connection

To configure a connection to a PostgreSQL 8.3 server, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.

2. Click the + New button in the Connections panel.

   The dialog box for configuring a database connection is displayed.

Figure 661. Connection Configuration Dialog Box
3. Enter a unique name for the connection.

4. Select the *PostgreSQL 8.3* data source in the **Data Source** drop-down menu.

5. Enter the connection details.
   a. Enter the URL of the PostgreSQL 8.3 server.
   b. Enter the user name for the connection to the PostgreSQL 8.3 server.
   c. Enter the password for the connection to the PostgreSQL 8.3 server.

6. Click the **OK** button to finish the connection configuration.

7. To view your connection, go to the **Data Source Explorer view (on page 2198)** (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database perspective (on page 3285)**.

**PostgreSQL Contextual Menu Actions**

**General Contextual Menu Actions**

For relational databases, the following general actions are available in the contextual menu of the **Data Source Explorer view (on page 2198)**, depending on the node in which it is invoked:

- **Refresh**
  Performs a refresh on the selected node.

- **Disconnect (available on ![Connection nodes])**
  Closes the current database connection. If a table is already open, you are warned to close it before proceeding.

- **Configure Database Sources (available on ![Connection nodes])**
  Opens the **Data Sources preferences page (on page 229)** where you can configure both data sources and connections.

- **Edit (available on ![Table nodes])**
  Opens the selected table in the **Table Explorer view (on page 2200)**.

- **Export to XML (available on ![Table nodes])**
  Opens the **Export Criteria** dialog box (a thorough description of this dialog box can be found in the **Import from Database (on page 2282)** chapter).
Database-Specific Contextual Menu Actions

In addition to the general contextual menu actions in the **Data Source Explorer view** *(on page 2198)*, the resource level nodes in PostgreSQL connections include the following additional contextual menu action:

- **Resource Level Nodes**

  **Compare**

  Compares two selected resources using the **Compare Files tool** *(on page 2770)*.

Berkeley DB XML Database Connections

Oxygen XML Editor includes support for Berkeley DB XML database connections. Oxygen XML Editor allows you to browse the structure of a Berkeley DB XML database in the **Data Source Explorer view** *(on page 2198)* and perform various operations on the resources in the repository.

Oracle Berkeley DB XML is an open source, embeddable XML database with XQuery-based access to documents stored in containers and indexed based on their content. It is built on top of the Oracle Berkeley DB and inherits its features and attributes, along with native XML support. A detailed description can be found at: [http://www.oracle.com/us/products/database/berkeley-db/xml/overview/index.html](http://www.oracle.com/us/products/database/berkeley-db/xml/overview/index.html).

Figure 662. Berkeley DB XML Connection

Configuring a Berkeley DB XML Database Connection

Follow this procedure to configure the support for a Berkeley DB XML database:
1. Configure Berkeley DB XML Data Source drivers (on page 2223).
2. Configure a Berkeley DB XML Connection (on page 2223).
3. To view your connection, go to the Data Source Explorer view (on page 2198) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 3285).

How to Configure Berkeley DB XML Data Source Drivers

For this procedure, you need to already have a Berkeley DB XML database installed on your system.

Oxygen XML Editor supports Berkeley DB XML versions 2.3.10, 2.4.13, 2.4.16 & 2.5.16. To configure a data source for a Berkeley DB XML database, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.
2. Click the + New button in the Data Sources panel.
3. Enter a unique name for the data source.
4. Select Berkeley DBXML from the driver Type drop-down menu.
5. Click the Add Files button to add the Berkeley DB driver files.

   The driver files for the Berkeley DB database (and their locations) are as follows:
   - db.jar (check for it in [DBXML_DIR]/lib or [DBXML_DIR]/jar)
   - dbxml.jar (check for it in [DBXML_DIR]/lib or [DBXML_DIR]/jar)

   Where [DBXML_DIR] is the Berkeley DB XML database root directory. For example, in Windows it is: C:\Program Files\Oracle\Berkeley DB XML <version>.
6. Click the OK button to finish the data source configuration.
7. Continue on to configure your Berkeley DB XML connection (on page 2223).

How to Configure a Berkeley DB XML Connection

Oxygen XML Editor supports Berkeley DB XML versions 2.3.10, 2.4.13, 2.4.16 & 2.5.16. To configure a connection to a Berkeley DB XML database, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.
2. Click the + New button in the Connections panel.
3. Enter a unique name for the connection.
4. Select a previously configured Berkeley data source from the Data Source drop-down menu.
5. Enter the connection details.
a. Set the path to the Berkeley DB XML database directory in the Environment home directory field. Use a directory with write access. DO NOT use the installation directory where Berkeley DB XML is installed if you do not have write access to that directory.

b. Select the Verbosity level: DEBUG, INFO, WARNING, or ERROR.

c. Optionally, you can select the Join existing environment checkbox. If selected, an attempt is made to join an existing environment in the specified home directory and all the original environment settings are preserved. If that fails, try reconfiguring the connection with this option unchecked.

6. Click the OK button to finish the connection configuration.

7. To view your connection, go to the Data Source Explorer view (on page 2198) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 3285).

Berkeley DB XML Contextual Menu Actions

While browsing Berkeley DB XML connections in the Data Source Explorer view (on page 2198), the various nodes include the following contextual menu actions:

Connection Level Nodes

- **Configure Database Sources**
  
  Opens the Data Sources preferences page (on page 229) where you can configure both data sources and connections.

- **Disconnect**
  
  Stops the connection.

- **New Collection**
  
  Opens a Container configuration dialog box that allows you to add a new container in the repository.

Figure 663. Container Configuration Dialog Box
This dialog box allows you to configure the following:

- **Name** - The name of the new container.

- **Container type** - At creation time, every container must have a type defined for it. This container type identifies how XML documents are stored in the container. As such, the container type can only be determined at container creation time. You cannot change it when subsequent container opens. You can select one of the following types:
  - **Node container** - XML documents are stored as individual nodes in the container. Each record in the underlying database contains a single leaf node, its attributes and attribute values (if any), and its text nodes (if any). Berkeley DB XML also keeps the information it requires to reassemble the document from the individual nodes stored in the underlying databases. This is the default selection and is the preferred container type.
  - **Whole document container** - The container contains entire documents. The documents are stored without any manipulation of line breaks or whitespace.

- **Allow validation** - If selected, documents will be validated when they are loaded into the container. The default behavior is to not validate documents.

- **Index nodes** - If selected, indices for the container will return nodes rather than documents. The default is to index at the document level. This property has no meaning if the container type is **Whole document container**.

**Refresh**

Performs a refresh on the selected node.

**Properties**
Shows various properties of the current container.

**Find/Replace in Files**

Opens the Find/Replace in Files dialog box (on page 745) that allows you to find and replace text in multiple files from the connection.

**Container Level Nodes**

**Import Files**

Allows you to add a new file on the connection, in the current folder.

**Export**

Allows you to export the folder on the remote connection to a local folder.

**Cut**

Removes the current selection and places it in the clipboard.

**Paste**

Pastes the copied selection.

**Rename**

Renames the current resource

**Delete**

Deletes the current container.

**Edit indices**

Opens a Container Indices dialog box that allows you to configure indices properties for the selected Berkeley container.

Figure 664. Container Indices Dialog Box
This dialog box allows you to configure the following properties:

- **Granularity** - A measure of the level of details of your data in the database. You can select one of the following:
  - **Document level** - Good option for retrieving large documents.
  - **Node level** - Good option for retrieving nodes from within documents.
- **Node** - The name of the node.
- **Namespace** - The index namespace.
- **Index type**:
  - **Uniqueness** - Indicates whether or not the indexed value must be unique within the container.
  - **Path type** - Drop-down menu that allows you to select from the following:
    - **node** - Indicates that you want to index a single node in the path.
    - **edge** - Indicates that you want to index the portion of the path where two nodes meet.
  - **Node type** - Drop-down menu that allows you to select from the following:
    - **element** - An element node in the document content.
    - **attribute** - An attribute node in the document content.
● **metadata** - A node found only in the metadata content of a document.
  ◦ **Key type** - Drop-down menu that allows you to select from the following:
    ● **equality** - Improves the performances of tests that look for nodes with a specific value.
    ● **presence** - Improves the performances of tests that look for the existence of a node regardless of its value.
    ● **substring** - Improves the performance of tests that look for a node whose value contains a given sub-string.
  ◦ **Syntax** - The syntax describes the type of data the index contains and is mostly used to determine how indexed values are compared. The default value is **string**.

**Refresh**
Performs a refresh on the selected node.

**Properties**
Shows various properties of the current container.

**Find/Replace in Files**
Opens the **Find/Replace in Files** dialog box (on page 745) that allows you to find and replace text in multiple files from the connection.

**Resource Level Nodes**

**Open**
Opens the selected resource in the editor.

**Open in System Application**
When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the **Data Source Explorer** view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

**Cut**
Removes the current selection and places it in the clipboard.
Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

**Rename**

- Renames the current resource

**Delete**

- Deletes the current container.

**Refresh**

- Performs a refresh on the selected node.

**Properties**

- Shows various properties of the current container.

**Find/Replace in Files**

- Opens the Find/Replace in Files dialog box (on page 745) that allows you to find and replace text in multiple files from the connection.

**Compare**

- Compares two selected resources using the Compare Files tool (on page 2770).

**Debugging with Berkeley DB XML**

The Berkeley DB XML database added a debugging interface starting with version 2.5. The current version is supported in the Oxygen XML Editor XQuery Debugger. The same restrictions and peculiarities (on page 2241) apply for the Berkeley debugger as for the MarkLogic debugger.

**eXist Database Connections**

Oxygen XML Editor includes support for eXist database connections. Oxygen XML Editor allows you to browse the structure of a eXist database in the Data Source Explorer view (on page 2198) and perform various operations on the resources in the repository.

Figure 665. eXist Database Connection
Configuring an eXist Database Connection

There are two ways to configure the support for an eXist database:

- Use the dedicated Create eXist-db XML connection wizard.
- Use the Data Sources preferences page to manually configure your connection.

How to Configure an eXist Connection Using the Built-in Wizard

To configure a connection for an eXist database using the dedicated Create eXist-db XML connection wizard, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79), go to Data Sources and click the Create eXist-db XML connection link.
2. Enter your connection details in the connection wizard and click OK.

⚠ Important: To create an eXist connection using this wizard, Oxygen XML Editor expects the exist/webstart/exist.jnlp path to be accessible at the provided Host and Port.
3. To view your connection, go to the Data Source Explorer view (on page 2198) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 3285).

How to Configure an eXist Connection Manually

⚠ Attention: For this manual procedure, you need to already have an eXist database server installed.
Tip: There is an easier way to configure an eXist database connection using a built-in wizard. For more information, see How to Configure an eXist Connection Using the Built-in Wizard (on page 2230).

Step 1: Configure eXist Data Source Drivers

Oxygen XML Editor supports eXist database server versions up to and including version 4.5. To configure a data source for an eXist database, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.
2. Click the New button in the Data Sources panel.
3. Enter a unique name for the data source.
4. Select eXist from the driver Type drop-down menu.
5. Click the Add Files button to add the eXist driver files. The following driver files should be added and they are found in the installation directory of the eXist database server. Make sure you copy the files from the installation of the eXist server where you want to connect from Oxygen XML Editor.
   - The exist.jar file located in the base directory.
   - All JAR files in the lib/core/ directory.
6. Click the OK button to finish the data source configuration.

Step 2: Configure an eXist Connection

To configure a connection to an eXist database, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.
2. Click the New button in the Connections panel.
3. Enter a unique name for the connection.
4. Select a previously configured eXist data source from the Data Source drop-down menu.
5. Enter the connection details:
   a. Set the URI to the installed eXist engine in the XML DB URI field.
   b. Set the user name in the User field.
   c. Set the password in the Password field.
   d. Enter the start collection in the Collection field.

   eXist organizes all documents in hierarchical collections. Collections are like directories. They are used to group related documents together. This text field allows the user to set the default collection name.
6. Click the OK button to finish the connection configuration.
7. To view your connection, go to the Data Source Explorer view (on page 2198) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 3285).

For more information about running XQuery against an eXist XML database, watch our video demonstration:

https://www.youtube.com/embed/Yoc5h1zSddA

eXist Contextual Menu Actions

While browsing eXist database connections in the Data Source Explorer view (on page 2198), the various nodes include the following contextual menu actions:

**Connection Level Nodes**

- **Configure Database Sources**
  
  Opens the Data Sources preferences page (on page 229) where you can configure both data sources and connections.

- **Disconnect**
  
  Stops the connection.

- **Refresh**
  
  Performs a refresh on the selected node.

- **Find/Replace in Files**
  
  Opens the Find/Replace in Files dialog box (on page 745) that allows you to find and replace text in multiple files from the connection.

**Container Level Nodes**

- **New File**
  
  Creates a new file on the connection, in the current folder.

- **New Collection**
  
  Creates a new collection on the connection.

- **Import Folders**
  
  Imports folders on the server.

- **Import Files**
  
  Allows you to add a new file on the connection, in the current folder.

- **Export**
Allows you to export the folder on the remote connection to a local folder.

**Cut**
Removes the current selection and places it in the clipboard.

**Paste**
Paste the copied selection.

**Refresh**
Performs a refresh on the selected node.

**Properties**
Shows various properties of the current container.

**Find/Replace in Files**
Opens the Find/Replace in Files dialog box (on page 745) that allows you to find and replace text in multiple files from the connection.

**Resource Level Nodes**

**Open**
Opens the selected resource in the editor.

**Open in System Application**
When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the Data Source Explorer view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

**Save As**
Allows you to save the selected resource as a file on disk.

**Cut**
Removes the current selection and places it in the clipboard.

**Copy**
Copies the current selection into the clipboard.

**Copy location**
Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

**Rename**

Renames the current resource

**Delete**

Deletes the current container.

**Refresh**

Performs a refresh on the selected node.

**Properties**

Shows various properties of the current container.

**Find/Replace in Files**

Opens the Find/Replace in Files dialog box (on page 745) that allows you to find and replace text in multiple files from the connection.

**Compare**

Compares two selected resources using the Compare Files tool (on page 2770).

MarkLogic Database Connections

Oxygen XML Editor Enterprise edition includes support for MarkLogic database connections. Once you configure a MarkLogic connection (on page 2236), you can use the Data Source Explorer view (on page 2198) to display all the application servers that are configured on the MarkLogic server. You can expand each application server and view all of its configured modules, and the Data Source Explorer view (on page 2198) allows you to open and edit these modules.

**Note:** To browse modules located in a database, directory properties must be associated with them. These directory properties are generated automatically if the directory creation property of the database is set to automatic. If this property is set to manual or manual-enforced, add the directory properties of the modules manually, using the XQuery function `xdmp:directory-create()`. For example, for two documents with the `/code/modules/main.xqy` and `/code/modules/imports/import.xqy` IDs, run the following query:

```
(xdmp:directory-create('/code/modules/'), xdmp:directory-create('/code/modules/imports/'))
```

For more information about directory properties, go to: [http://blakeley.com/blogofile/2012/03/19/directory-assistance/](http://blakeley.com/blogofile/2012/03/19/directory-assistance/).
MarkLogic and XQuery

MarkLogic connections can be used in conjunction with XQuery scripts to debug and solve problems with XQuery transformations. XQuery modules can also be validated using a MarkLogic server to allow to you to spot possible issues without the need of actually executing the XQuery script.

When debugging XQuery files with MarkLogic (on page 2239), you can use the Data Source Explorer view (on page 2198) to open the files from the application server that is involved in the debugging process. By using the Data Source Explorer view (on page 2198), any imported modules are better identified by the MarkLogic server. You can also use step actions and breakpoints (on page 2241) in the modules to help identify problems.

Modules Container

For each Application server (for example: Bill (HTTP port:8060)), you have access to the XQuery modules that are visible to that server. When editing, executing, or debugging XQuery it is recommended to open the XQuery files from this Modules container.

Note: You can also manage resources for a MarkLogic database through a WebDAV connection, although it is not recommended if you work with XQuery files since imported modules may not be resolved correctly.

Requests Container

Each MarkLogic application server includes a Requests container. In this container, Oxygen XML Editor displays both queries that are stopped for debugging purposes and queries that are still running. To clean up the entire Requests container at the end of your session, right-click it and use the Cancel all requests action (on page 2243).

Figure 666. MarkLogic Connection in Data Source Explorer
Configuring a MarkLogic Database Connection

Note that this feature is available in Oxygen XML Editor Enterprise edition only.

Follow this procedure to configure the support for a MarkLogic database connection:

1. Download the MarkLogic driver from MarkLogic Community site.
2. Configure MarkLogic Data Source drivers (on page 2236).
3. Configure a MarkLogic Connection (on page 2236).
4. To view your connection, go to the Data Source Explorer view (on page 2198) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 3285).

Related Information:

• MarkLogic Development in Oxygen XML Editor (on page 2237)

How to Configure MarkLogic Data Source Drivers

Available in the Enterprise edition only.

Note: Oxygen XML Editor supports MarkLogic version 4.0 or later.

To configure a data source for MarkLogic, follow this procedure:

2. Unzip the downloaded archive.
3. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.
4. Click the + New button in the Data Sources panel.
5. Enter a unique name for the data source.
6. Select MarkLogic from the driver Type drop-down list.
7. Click the Add Files button and select the MarkLogic driver file from the lib folder of the archive that you downloaded and unzipped. The driver file name is marklogic-xcc-{server_version}.jar, where {server_version} is the MarkLogic server version.
8. Click the OK button to finish the data source configuration.
9. Continue on to configure your MarkLogic Connection (on page 2236).

How to Configure a MarkLogic Connection

Available in the Enterprise edition only.
Note: Oxygen XML Editor supports MarkLogic version 4.0 or later.

To configure a connection to a MarkLogic database, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.
2. Click the + New button in the Connections panel.
3. Enter a unique name for the connection.
4. Select a previously configured MarkLogic data source from the Data Source drop-down menu.
5. Enter the connection details.
   a. The host name or IP address of the installed MarkLogic engine in the XDBC Host field. Oxygen XML Editor uses XCC connector to interact with MarkLogic XDBC server and requires the basic authentication schema to be set. Starting with version MarkLogic 4.0 the default authentication method when you create an HTTP or WebDAV Server is digest, so make sure to change it to basic.
   b. Set the port number of the MarkLogic engine in the Port field. A MarkLogic XDBC application server must be configured on the server on this port. This XDBC server will be used to process XQuery expressions against the server. Later, if you want to change the XDBC server, instead of editing the configuration just use the Use it to execute queries action (on page 2242) from Data Source Explorer.
   c. Set the user name to access the MarkLogic engine in the User field.
   d. Set the password to access the MarkLogic engine in the Password field.
   e. Optionally, in the WebDAV URL field, set the URL used for browsing the MarkLogic database in the Data Source Explorer view (on page 2198). The Database field specifies the database for which the XQuery expressions are executed. If you set this option to default, the database associated to the application server of the configured port is used.
6. Click the OK button to finish the connection configuration.
7. To view your connection, go to the Data Source Explorer view (on page 2198) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 3285).

MarkLogic Development in Oxygen XML Editor

The Oxygen XML Editor support for MarkLogic includes features designed for developers, such as debugging XQuery transformations, remote and collaborative debugging, XQuery editing and validation, and an XQuery builder (on page 1343) that helps to improve productivity.
Working with XQuery Files

MarkLogic supports working with XQuery files to create queries over stored XML content. You can open an XQuery file, configure a transformation scenario to match your MarkLogic connection, write the XQuery, and then execute it.

When editing XQuery modules stored on the MarkLogic server, the Outline view (on page 1341) collects and displays all the functions from all imported modules. The Content Completion Assistant (on page 3280) also presents all of these functions along with the latest built-in XQuery functions in accordance with the server version.

When developing queries for MarkLogic, it is best to open the resources from the Data Source Explorer view (on page 2198). When you execute or debug XQuery files opened from this view, imported modules can be resolved better by the MarkLogic server. Another advantage is that validation is automatically performed on the MarkLogic server, including any imported modules.

XQuery Debugging

Oxygen XML Editor allows you to use MarkLogic connections to debug real applications that use XQuery (for example, web applications that trigger XQuery executions). By setting the server in debug mode, you can intercept all the XQuery scripts that run on that server. Oxygen XML Editor connects to the MarkLogic server, shows you the running XQuery scripts, and allows you to debug them. The remote debugging support also allows you to debug collaboratively. Multiple users can participate in the same debugging session. You can start a debugging session and another user can continue it, and vice versa.

Working with Modules

MarkLogic has a concept of two types of XQuery modules, library and main modules. A library module is used to define functions. Library modules cannot be evaluated directly. They are imported, either from other library modules or from main modules. A main module is used as an entry point that can be executed as an XQuery program. For more information on these types of modules, see XQuery Library Modules and Main Modules.

When working with library modules, you need to create a validation scenario and associate it with the module. In the validation scenario you need to specify a main module as the entry point for validation. The modules need to be deployed on a MarkLogic server because Oxygen XML Editor will request the server to validate the modules.

To validate library modules stored on a MarkLogic server, follow these steps:

1. Configure a MarkLogic database connection (on page 2236).
2. Expand the MarkLogic connection in the Data Source Explorer view (on page 2198) and open the library modules. The main module must also be opened from the Data Source Explorer view (on page 2198).

3. Configure a validation scenario (on page 1094) for each library module. Specify the main module in the URL of the file to validate field.

Result: Validation is done on the server that contains the main module. The main module and all other library modules involved in the validation must be saved. Otherwise, the server will validate what was saved on the server, without the uncommitted changes. Also, the Content Completion Assistant (on page 3280) and the Outline view (on page 1341) should now present the functions from all the modules.

Related Information:

- Debugging with MarkLogic (on page 2239)
- Configuring a MarkLogic Database Connection (on page 2236)

### Debugging with MarkLogic

Oxygen XML Editor includes support for debugging XQuery transformations that are executed against a MarkLogic database.

To use a debugging session against the MarkLogic engine, follow these steps:

1. Configure a MarkLogic data source (on page 2236) and a MarkLogic connection (on page 2236).

2. Make sure that the debugging support is enabled in the MarkLogic server that Oxygen XML Editor accesses. On the server side, debugging must be activated in the XDBC server and in the Task Server section of the server control console (the switch debug allow). If the debugging is not activated, the MarkLogic server reports a DBG-TASKDEBUGALLOW error.

**Note:** An XDBC application server must be running to connect to the MarkLogic server and this XDBC server will be used to process XQuery expressions against the server. You can change the XDBC application server that Oxygen XML Editor uses to process XQuery expressions by selecting the Use It to execute queries action (on page 2242) from the contextual menu in the Data Source Explorer view (on page 2198).

3. Open the XQuery file and start the debugging process.
   - If you want to debug an XQuery file stored on the MarkLogic server, it is recommend to use the Data Source Explorer view (on page 2198) and open the file from the application
server that is involved in the debugging process. This improves the resolving of any imported modules.

- The MarkLogic XQuery debugger integrates seamlessly into the XQuery Debugger perspective (on page 299). If you have a MarkLogic validation scenario configured for the XQuery file, you can choose to debug the scenario (on page 2309) directly.

- Otherwise, switch to the XQuery Debugger perspective (on page 3285), open the XQuery file in the editor, and select the MarkLogic connection in the XQuery engine selector from the debug control toolbar (on page 2293).

For general information about how a debugging session is started and controlled, see the Working with the Debugger (on page 2309) section.

In a MarkLogic debugging session, you can use step actions and breakpoints (on page 2313) to help identify problems. When you add a breakpoint (on page 2314) on a line where the debugger never stops, Oxygen XML Editor displays a warning message. These warnings are displayed for breakpoints you add either in the main XQuery (which you can open locally or from the server) or for breakpoints you add in any XQuery that is opened from the connection that participates in the debugging session. For more information, see Using Breakpoints for Debugging Queries that Import Modules with MarkLogic (on page 2241).

**Remote Debugging with MarkLogic**

Oxygen XML Editor allows you to debug remote applications that use XQuery (for example, web applications that trigger XQuery executions). Oxygen XML Editor connects to a MarkLogic server, shows you the running XQuery scripts and allows you to debug them. You can even pause the scripts so that you can start the debugging queries in the exact context of the application. You can also switch a server to debug mode to intercept all XQuery scripts.

Oxygen XML Editor also supports collaborative debugging. This feature allows multiple users to participate in the same debugging session. You can start a debugging session and at a certain point, another user can continue it.

⚠️ **Important:** When using the remote debugging feature, the HTTP and the XDBC servers involved in the debugging session must have the same module configuration.

For more information about the XQuery debugger for MarkLogic, watch our video demonstration:

[https://www.youtube.com/embed/eQ4ThDZq1bk](https://www.youtube.com/embed/eQ4ThDZq1bk)

**Related Information:**

- MarkLogic Development in Oxygen XML Editor (on page 2237)
Using Breakpoints for Debugging Queries that Import Modules with MarkLogic

When debugging queries that imports modules stored in the database, it is recommended to place breakpoints in the modules. When starting a new debugging session, make sure that the modules that you will debug are already opened in the editor. This is necessary so that the breakpoints in all the modules will be considered. Also, make sure that there are no other opened modules that are not involved in the current debugging session.

To place breakpoints in the modules, use the following procedure:

1. In the Data Source Explorer view (on page 2198), open all the modules from the Modules container of the XDBC application server (on page 2237) that performs the debugging.
2. Set breakpoints (on page 2314) in the module as needed.
3. Continue debugging (on page 2309) the query.

If you get a warning that the breakpoints failed to initialize, try the following solutions:

• Check the Breakpoints view (on page 2297) and make sure there are no older breakpoints (set on resources that are not part of the current debugging context).
• Make sure you open the modules from the context of the application server that does the debugging and place breakpoints there.

Related Information:

• MarkLogic Database Connections (on page 2234)
• MarkLogic Development in Oxygen XML Editor (on page 2237)

Peculiarities and Limitations of the MarkLogic Debugger

MarkLogic debugger has the following peculiarities and limitations:

• Debugging support is only available for MarkLogic server versions 4.0 or newer.
• For MarkLogic server versions 4.0 or newer, there are three XQuery syntaxes that are supported: '0.9-ml' (inherited from MarkLogic 3.2), '1.0-ml', and '1.0'.
• All declared variables are presented as strings. The Value column of the Variables view contains the expression from the variable declaration. It can be evaluated by copying the expression with
the **Copy value** action from the contextual menu of the **Variables view** *(on page 2307)* and pasting it in the **XWatch view** *(on page 2299)*.

- There is no support for **output to source mapping** *(on page 2310)*.
- There is no support for **showing the trace** *(on page 2304)*.
- You can only set **breakpoints** *(on page 2297)* in imported modules in one of the following cases:
  - When you open the module from the context of the application server involved in the debugging, using the **Data Source Explorer view** *(on page 2198)*.
  - When the debugger automatically opens the modules in the Editor.
- **No breakpoints** *(on page 2313)* are set in modules from the same server that are not involved in the current debugging session.
- **No support for profiling** *(on page 2314)* when an XQuery transformation is executed in the debugger.

**MarkLogic Contextual Menu Actions**

While browsing MarkLogic connections in the **Data Source Explorer view** *(on page 2198)*, the various nodes include the following contextual menu actions:

### Connection Level Nodes

- **Configure Database Sources**
  Opens the **Data Sources preferences page** *(on page 229)* where you can configure both data sources and connections.

- **Disconnect**
  Stops the connection.

- **Refresh**
  Performs a refresh on the selected node.

- **Find/Replace in Files**
  Opens the **Find/Replace in Files dialog box** *(on page 745)* that allows you to find and replace text in multiple files from the connection.

### Container Level Nodes

- **Enable Debug Mode**
  Switches the server to a debugging mode. For more information, see **MarkLogic debugging sessions** *(on page 2239)*.

- **Use it to Execute Queries**
  The server will be used to process XQuery expressions against it.
Refresh
Performs a refresh on the selected node.

Module or Folder Level Nodes

Export
Allows you to export the folder on the remote connection to a local folder.

Refresh
Performs a refresh on the selected node.

Requests Level Nodes

Refresh
Performs a refresh on the selected node.

Cancel all requests
Cancels all queries that are either running or stopped on the application server. You can use this action to clean up the entire Requests container at the end of your sessions.

Resource Level Nodes

Open
Opens the selected resource in the editor.

Open in System Application
When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the Data Source Explorer view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

Copy location
Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Refresh
Performs a refresh on the selected node.

Compare
Compares two selected resources using the Compare Files tool (on page 2770).

MySQL Database Connections

Oxygen XML Editor includes support for MySQL database connections. Oxygen XML Editor allows you to browse the structure of a SQL Server database in the Data Source Explorer view (on page 2198), open tables in the Table Explorer view (on page 2200), and perform various operations on the resources in the repository.

Configuring a MySQL Database Connection

To configure the support for a MySQL database, follow this procedure:

1. Configure MySQL Data Source drivers (on page 2244).
2. Configure a MySQL Connection. (on page 2245)
3. To view your connection, go to the Data Source Explorer view (on page 2198) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 3285).

How to Configure MySQL Data Source Drivers

To connect to a MySQL server, you need to create a generic JDBC type data source based on the MySQL JDBC driver available on the MySQL website.

To configure this data source, follow these steps:

1. Go to https://www.oxygenxml.com/database_drivers.html and download the appropriate MySQL driver.
2. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.
3. Click the New button in the Data Sources panel.
The dialog box for configuring a data source is opened.

Figure 667. Data Source Drivers Configuration Dialog Box

![Data Source Drivers Configuration Dialog Box]

4. Enter a unique name for the data source.

5. Select *Generic JDBC* in the driver **Type** drop-down list.

6. Click the **Add Files** button and select the MySQL driver file that you downloaded.
   The driver file for the MySQL server is called `mysql-com.jar`.

7. Select the most appropriate **Driver class**.

8. Click the **OK** button to finish the data source configuration.

9. Continue on to configure your MySQL connection *(on page 2245)*.

**How to Configure a MySQL Connection**

To configure a connection to a MySQL server, follow these steps:

1. Open the **Preferences** dialog box (**Options > Preferences**) *(on page 79)* and go to **Data Sources**.

2. Click the **+ New** button in the **Connections** panel.
The dialog box for configuring a database connection is displayed.

Figure 668. Connection Configuration Dialog Box

3. Enter a unique name for the connection.

4. Select the MySQL data source in the Data Source drop-down list.

5. Enter the connection details.
   a. Enter the URL of the MySQL server.
   b. Enter the user name for the connection to the MySQL server.
   c. Enter the password for the connection to the MySQL server.

6. Click the OK button to finish the connection configuration.

7. To view your connection, go to the Data Source Explorer view (on page 2198) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 3285).

Generic JDBC Database Connections

Oxygen XML Editor includes support for Generic JDBC database connections.

Configuring a Generic JDBC Database Connection

To configure the support for a generic JDBC database, follow this procedure:

1. Configure Generic JDBC Data Source drivers (on page 2247).
2. Configure a Generic JDBC Connection (on page 2247).

3. To view your connection, go to the Data Source Explorer view (on page 2198) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 3285).

How to Configure Generic JDBC Data Source Drivers

Starting with version 17, Oxygen XML Editor comes bundled with Java 8, which does not provide built-in access to JDBC-ODBC data sources. To access such sources, you need to find an alternative JDBC-ODBC bridge or use a platform-independent distribution of Oxygen XML Editor along with a Java VM version 7 or 6.

To configure a generic JDBC data source, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.
2. Click the + New button in the Data Sources panel.
3. Enter a unique name for the data source.
4. Select Generic JDBC in the driver Type drop-down list.
5. Add the driver file(s) using the Add Files button.
6. Select the most appropriate Driver class.
7. Click the OK button to finish the data source configuration.
8. Continue on to configure a generic JDBC connection (on page 2247).

How to Configure a Generic JDBC Connection

To configure a connection to a generic JDBC database, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.
2. Click the + New button in the Connections panel.
3. Enter a unique name for the connection.
4. Select the Generic JDBC data source in the Data Source drop-down menu.
5. Enter the connection details.
   a. Enter the URL of the generic JDBC database, with the following format: jdbc:<subprotocol>:<subname>.
   b. Enter the user name for the connection to the generic JDBC database.
   c. Enter the password for the connection to the generic JDBC database.
6. Click the OK button to finish the connection configuration.
7. To view your connection, go to the Data Source Explorer view (on page 2198) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 3285).
JDBC-ODBC Database Connections

Oxygen XML Editor includes support for JDBC-ODBC database connections.

How to Configure a JDBC-ODBC Connection

Starting with version 17, Oxygen XML Editor comes bundled with Java 8, which does not provide built-in access to JDBC-ODBC data sources. To access such sources, you need to find an alternative JDBC-ODBC bridge or use a platform-independent distribution of Oxygen XML Editor along with a Java VM version 7 or 6.

To configure a connection to an ODBC data source, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.

2. Click the + New button in the Connections panel.

   The dialog box for configuring a database connection is displayed.

   Figure 669. Connection Configuration Dialog Box

3. Enter a unique name for the connection.

4. Select JDBC-ODBC Bridge in the Data Source drop-down list.

5. Enter the connection details.
   a. Enter the URL of the ODBC source.
   b. Enter the user name of the ODBC source.
   c. Enter the password of the ODBC source.
6. Click the **OK** button to finish the connection configuration.

7. To view your connection, go to the **Data Source Explorer view (on page 2198)** (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database perspective (on page 3285)**.

BaseX Database Connections

Oxygen XML Editor includes support for BaseX database connections using a WebDAV connection. BaseX is a light-weight XML database engine and XQuery processor. Oxygen XML Editor allows you to browse the structure of a BaseX database in the **Data Source Explorer view (on page 2198)** and perform XQuery executions.

How to Configure a BaseX Connection

To configure a BaseX connection, follow these steps:

1. First of all, make sure the BaseX HTTP Server is started. For details about starting the BaseX HTTP server, go to [http://docs.basex.org/wiki/Startup#BaseX_HTTP_Server](http://docs.basex.org/wiki/Startup#BaseX_HTTP_Server). The configuration file for the HTTP server is named `.basex` and is located in the BaseX installation directory. This file helps you to find out which port the HTTP server using. The default port for BaseX WebDAV is 8984.

2. To ensure that everything is functioning, open a WebDAV URL inside a browser and check to see if it works. For example, the following URL retrieves a document from a database named TEST: [http://localhost:8984/webdav/TEST/etc/factbook.xml](http://localhost:8984/webdav/TEST/etc/factbook.xml).

3. Once you are sure that the BaseX WebDAV service is working, you can configure the WebDAV connection in Oxygen XML Editor as described in **How to Configure a WebDAV Connection (on page 2254)**. The WebDAV URL should resemble this: `http://{hostname}:{port}/webdav/`. If the BaseX server is running on your own machine and it has the default configuration, the data required by the WebDAV connection is:
   - **WebDAV URL**: `http://localhost:8984/webdav`
   - **User**: `admin`
   - **Password**: `admin`

4. Once the WebDAV connection is created, to view your connection, go to the **Data Source Explorer view (on page 2198)** (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database perspective (on page 3285)**.

BaseX Contextual Menu Actions

While browsing BaseX connections in the **Data Source Explorer view (on page 2198)**, the various nodes include the following contextual menu actions:
Connection Level Nodes

Configure Database Sources

Opens the Data Sources preferences page (on page 229) where you can configure both data sources and connections.

Disconnect

Stops the connection.

New Folder

Creates a new folder on the connection.

Import Files

Allows you to add a new file on the connection, in the current folder.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the Find/Replace in Files dialog box (on page 745) that allows you to find and replace text in multiple files from the connection.

Folder Level Nodes

New File

Creates a new file on the connection, in the current folder.

New Folder

Creates a new folder on the connection.

Import Folders

Imports folders on the server.

Import Files

Allows you to add a new file on the connection, in the current folder.

Export

Allows you to export the folder on the remote connection to a local folder.

Cut

Removes the current selection and places it in the clipboard.

Copy

Copies the current selection into the clipboard.
**Paste**

Pastes the copied selection.

**Rename**

Renames the current resource.

**Delete**

Deletes the current container.

**Refresh**

Performs a refresh on the selected node.

**Find/Replace in Files**

Opens the Find/Replace in Files dialog box (on page 745) that allows you to find and replace text in multiple files from the connection.

**Resource Level Nodes**

**Open**

Opens the selected resource in the editor.

**Open in System Application**

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the Data Source Explorer view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

**Cut**

Removes the current selection and places it in the clipboard.

**Copy**

Copies the current selection into the clipboard.

**Copy location**

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

**Rename**

Renames the current resource.
Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the Find/Replace in Files dialog box (on page 745) that allows you to find and replace text in multiple files from the connection.

Compare

Compares two selected resources using the Compare Files tool (on page 2770).

Base X XQJ Connection

XQuery execution is possible in a BaseX connection through an XQJ connection.

⚠️ Important: The XQJ connector is only capable of running XQuery 1.0 scripts, therefore XQuery 3.0 and 3.1 scripts are not supported.

BaseX XQJ Data Source

First of all, create an XQJ data source as described in How to Configure an XQJ Data Source (on page 2253). The BaseX XQJ API-specific files that must be added in the configuration dialog box are xqj-api-1.0.jar, xqj-2-0.1.0.jar and basex-xqj-1.2.3.jar (the version names of the JAR file may differ). These libraries can be downloaded from xqj.net/basex/basex-xqj-1.2.3.zip. As an alternative, you can also find the libraries in the BaseX installation directory, in the lib sub-directory.

BaseX XQJ Connection

The next step is to create an XQJ connection (on page 2253).

For a default BaseX configuration, the following connection details apply (you can modify them when necessary):

- **Port**: 1984
- **serverName**: localhost
- **user**: admin
- **password**: admin
**XQuery Execution**

Now that the XQJ connection is configured, open the XQuery file you want to execute in Oxygen XML Editor and create an [XQuery Transformation](on page 1749). In the **Transformer** drop-down menu, select the name of the XQJ connection you created. Apply the transformation scenario and the XQuery will be executed.

**How to Configure an XQJ Data Source**

Any transformer that offers an XQJ API implementation can be used when validating XQuery or transforming XML documents. An example of an XQuery engine that implements the XQJ API is [Zorba](https://zorba.io).

1. If your XQJ Implementation is native, make sure the directory containing the native libraries of the engine is added to your system environment variables: to **PATH** - on Windows, to **LD_LIBRARY_PATH** - on Linux, or to **DYLD_LIBRARY_PATH** - on OS X. Restart Oxygen XML Editor after configuring the environment variables.

2. Open the [Preferences dialog box (Options > Preferences)](on page 79) and go to **Data Sources**.

3. Click the **New** button in the **Data Sources** panel.

4. Enter a unique name for the data source.

5. Select **XQuery API for Java (XQJ)** in the **Type** combo box.

6. Press the **Add** button to add XQJ API-specific files.
   You can manage the driver files using the **Add, Remove, Detect,** and **Stop** buttons.
   Oxygen XML Editor detects any implementation of `javax.xml.xquery.XQDataSource` and presents it in **Driver class** field.

7. Select the most suited driver in the **Driver class** combo box.

8. Click the **OK** button to finish the data source configuration.

9. Continue on to configure the XQJ connection *(on page 2253)*.

**How to Configure an XQJ Connection**

The steps for configuring an XQJ connection are the following:

1. Open the [Preferences dialog box (Options > Preferences)](on page 79) and go to **Data Sources**.

2. Click the **New** button in the **Connections** panel.
3. Enter a unique name for the connection.

4. Select one of the previously configured XQJ data sources (on page 2253) in the Data Source combo box.

5. Fill-in the connection details.
   The properties presented in the connection details table are automatically detected depending on the selected data source.

6. Click the OK button to finish the connection configuration.

WebDAV Connections

Oxygen XML Editor includes support for WebDAV server connections. Oxygen XML Editor allows you to browse the structure of a WebDAV connection in the Data Source Explorer view (on page 2198) and perform various operations on the resources in the repository.

How to Configure a WebDAV Connection

By default, Oxygen XML Editor contains built-in data source drivers for WebDAV connections. Based on this data source, you can create a WebDAV connection for browsing and editing data from a database that provides a WebDAV interface. The connection is available in the Data Source Explorer view (on page 2198).

To configure a WebDAV connection, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.

2. Click the + New button in the Connections panel.

3. Enter a unique name for the connection.

4. Select one of the WebDAV data sources in the Data Source drop-down menu.

5. Enter the connection details:
   a. Set the URL to the WebDAV repository in the field WebDAV URL.
   b. Set the user name that is used to access the WebDAV repository in the User field.
   c. Set the password that is used to access the WebDAV repository in the Password field.

6. Click the OK button to finish the connection configuration.

7. To view your connection, go to the Data Source Explorer view (on page 2198) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 3285).
For more information about the WebDAV support in Oxygen XML Editor, watch our video demonstration:

https://www.youtube.com/embed/vDXO36CqbyM

WebDAV Contextual Menu Actions

While browsing WebDAV connections in the Data Source Explorer view (on page 2198), the various nodes include the following contextual menu actions:

**Connection Level Nodes**

- **Configure Database Sources**
  - Opens the Data Sources preferences page (on page 229) where you can configure both data sources and connections.

- **Disconnect**
  - Stops the connection.

- **New Folder**
  - Creates a new folder on the connection.

- **Import Files**
  - Allows you to add a new file on the connection, in the current folder.

- **Refresh**
  - Performs a refresh on the selected node.

- **Find/Replace in Files**
  - Opens the Find/Replace in Files dialog box (on page 745) that allows you to find and replace text in multiple files from the connection.

**Folder Level Nodes**

- **New File**
  - Creates a new file on the connection, in the current folder.

- **New Folder**
  - Creates a new folder on the connection.

- **Import Folders**
  - Imports folders on the server.

- **Import Files**
Allows you to add a new file on the connection, in the current folder.

**Export**

Allows you to export the folder on the remote connection to a local folder.

**Cut**

Removes the current selection and places it in the clipboard.

**Copy**

Copies the current selection into the clipboard.

**Paste**

Pastes the copied selection.

**Rename**

Renames the current resource

**Delete**

Deletes the current container.

**Refresh**

Performs a refresh on the selected node.

**Find/Replace in Files**

Opens the *Find/Replace in Files* dialog box (on page 745) that allows you to find and replace text in multiple files from the connection.

**Resource Level Nodes**

**Open**

Opens the selected resource in the editor.

**Open in System Application**

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the *Data Source Explorer* view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

**Cut**

Removes the current selection and places it in the clipboard.

**Copy**
Copies the current selection into the clipboard.

**Copy location**

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

**Rename**

Renames the current resource

**Delete**

Deletes the current container.

**Refresh**

Performs a refresh on the selected node.

**Properties**

Shows various properties of the current container.

**Find/Replace in Files**

Opens the Find/Replace in Files dialog box (on page 745) that allows you to find and replace text in multiple files from the connection.

**Compare**

Compares two selected resources using the Compare Files tool (on page 2770).

### SQL Execution Support

The database support in Oxygen XML Editor includes support for writing SQL statements, syntax highlighting, folding (on page 3282), and dragging and dropping from the Data Source Explorer view (on page 2198). It also includes transformation scenarios for executing the statements, and the results are displayed in the Table Explorer view (on page 2200).

### Drag and Drop from Data Source Explorer View

Dragging operations from the Data Source Explorer view (on page 2198) and dropping them in the SQL Editor allows you to create SQL statements quickly by inserting the names of tables and columns in the SQL statements.

1. Configure a database connection (see the specific procedure for your database server in the Database Connection Support (on page 2203) section).

2. Browse to the table you will use in your statement.
3. Drag the table or a column of the table into the editor where a SQL file is open.

Drag and drop actions are available both on the table and on its fields. A pop-up menu is displayed in the SQL editor.

Figure 670. SQL Statement Editing with Drag and Drop

4. Select the type of statement from the pop-up menu.

Depending on your choice, dragging a table results in one of the following statements being inserted into the document:

- **SELECT `field1`, `field2`, .... FROM `catalog`.`table`** (for example: SELECT `DEPT`, `DEPTNAME`, `LOCATION` FROM `camera`.`cameraDesc`)

- **UPDATE `catalog`.`table` SET `field1`=, `field2`=,....** (for example: UPDATE `camera`.`cameraDesc` SET `DEPT`=, `DEPTNAME`=, `LOCATION`=)

- **INSERT INTO `catalog`.`table` ( `field1`, `field2`, ....) VALUES (, , )** (for example: INSERT INTO `camera`.`cameraDesc` ( `DEPT`, `DEPTNAME`, `LOCATION`) VALUES (, , ))

- **DELETE FROM `catalog`.`table`** (for example: DELETE FROM `camera`.`cameraDesc`)

Depending on your choice, dragging a column results in one of the following statements being inserted into the document:
• SELECT `field` FROM `catalog`.`table` (for example: SELECT `DEPT` FROM `camera`.`cameraDesc`)
• UPDATE `catalog`.`table` SET `field` = (for example: UPDATE `camera`.`cameraDesc` SET `DEPT` = )
• INSERT INTO `catalog`.`table` (`field`) VALUES () (for example: INSERT INTO `camera`.`cameraDesc` (`DEPT`) VALUES ( )
• DELETE FROM `catalog`.`table` (for example: DELETE FROM `camera`.`cameraDesc` WHERE `DEPT` = )

SQL Validation

SQL validation support is offered for IBM DB2. Note that if you choose a connection that does not support SQL validation, you will receive a warning when trying to validate. The SQL document is validated using the connection from the associated transformation scenario.

Executing SQL Statements

The steps for executing an SQL statement on a relational database are as follows:

1. Configure a transformation scenario (on page 1640) using the Configure Transformation Scenario(s) action from the toolbar or the Document > Transformation menu.
   A SQL transformation scenario needs a database connection. You can configure a connection using the Preferences button from the SQL transformation dialog box.
   The dialog box contains the list of existing scenarios that apply to SQL documents.

2. Set parameter values for SQL placeholders using the Parameters button from the SQL transformation dialog box.
   For example, in SELECT * FROM `test`.`department` where DEPT = ? or DEPTNAME = ? the two parameters can be configured for the placeholders (?) in the transformation scenario.

   When the SQL statement is executed, the first placeholder is replaced with the value set for the first parameter in the scenario, the second placeholder is replaced by the second parameter value, and so on.

   **Restriction:** When a stored procedure is called in an SQL statement executed on an SQL Server database, mixing inline parameter values with values specified using the Parameters button of the scenario dialog box is not recommended. This is due to a limitation of the SQL Server driver for Java applications. An example of stored procedure that is not recommended: call dbo.Test(22, ?).

3. Execute the SQL scenario by clicking the OK or Apply associated button.
The result of a SQL transformation is displayed in a view (on page 357) at the bottom of the Oxygen XML Editor window.

4. View more complex return values of the SQL transformation in a separate editor panel.
A more complex value returned by the SQL query (for example, an XMLTYPE or CLOB value) cannot be displayed entirely in the result table.

   a. Right-click the cell containing the complex value.

   b. Select the action Copy cell from the contextual menu.
      The action copies the value in the clipboard.

   c. Paste the value into an appropriate editor.
      For example, you can paste the value in an opened XQuery editor panel of Oxygen XML Editor.

XQuery and Databases

XQuery is a native XML query language that is useful for querying XML views of relational data to create XML results. It also provides the mechanism to efficiently and easily extract information from Native XML Databases (NXD) and relational data. The following database systems supported in Oxygen XML Editor offer XQuery support:

- **Native XML Databases**:
  - Berkeley DB XML
  - eXist
  - MarkLogic (validation support available starting with version 5)

- **Relational Databases**:
  - IBM DB2
  - Microsoft SQL Server (validation support not available)
  - Oracle (validation support not available)

Related Information:

- Editing XQuery Documents (on page 1337)
Build Queries with Drag and Drop from the Data Source Explorer View

When a query is edited in the XQuery editor, the XPath expressions can be composed quickly by dragging them from the Data Source Explorer view (on page 2198) and dropping them into the editor panel.

1. Configure the data source drivers (on page 2203) for the particular relational database in the Data Sources preferences page (on page 229).
2. Configure the connection (on page 2203) for the particular relational database in the Data Sources preferences page (on page 229).
3. Browse the connection in the Data Source Explorer view (on page 2198), expanded to the table or column that you want to insert in the query.
4. Drag the table or column name to the XQuery editor panel.
5. Drop the table or column name where the XPath expression is needed.

An XPath expression that selects the dragged name is inserted in the XQuery document at the cursor position.

XQuery Validation When Connected to a Database

With Oxygen XML Editor, you can validate your XQuery documents when connected to a database. When you open an XQuery document from a connection that supports validation (for example, MarkLogic, or eXist), by default Oxygen XML Editor uses this connection for validation. If you open an XQuery file using a MarkLogic connection, the validation resolves imports better.

Related Information:
- XQuery Validation (on page 1337)

XQuery Transformation for Databases

XQuery is designed to retrieve and interpret XML data from any source, whether it is a database or document. Data is stored in relational databases but it is often required that the data be extracted and transformed as XML when interfacing to other components and services. Also, it is an XPath-based querying language supported by most NXD vendors. To perform a query, you need an XQuery transformation scenario.

1. Configure the data source drivers and the connection (on page 2203) for the particular database.
2. Configure an XQuery transformation scenario.
a. Click the Configure Transformation Scenario toolbar button or go to menu Document > Transformation > Configure Transformation Scenario.

The Configure Transformation Scenario dialog box (on page 1762) is opened.

b. Click the New button toward the bottom of the dialog box.

c. Select XML Transformation with XQUERY (on page 1690).

The New Scenario dialog box for configuring an XQuery scenario is opened.

Figure 671. New Scenario Dialog Box

d. Insert the scenario name in the dialog box for editing the scenario.

e. Choose the database connection in the Transformer drop-down list.

f. Configure any other parameters as needed.

For an XQuery transformation, the output tab has an option called Sequence that allows you to run an XQuery in lazy mode. The amount of data extracted from the database is controlled from the Size limit on Sequence view option (on page 208) in the XQuery preferences page. If you choose Perform FO Processing in the FO Processor tab, the Sequence option is ignored.

g. Click the OK button to finish editing the scenario.
Once the scenario is associated with the XQuery file, the query can include calls to specific XQuery functions that are implemented by that engine. The available functions depend on the target database engine selected in the scenario. For example, for eXist and Berkeley DB XML, the Content Completion Assistant (on page 3280) lists the functions supported by that database engine. This is useful for only inserting calls to the supported functions (standard XQuery functions or extension ones) into the query.

Note: An XQuery transformation is executed against a Berkeley DB XML server as a transaction using the query transaction support of the server.

3. Run the transformation scenario.

To view a more complex value returned by the query that cannot be entirely displayed in the XQuery query result table at the bottom of the Oxygen XML Editor window (for example, an XMLTYPE or CLOB value), do the following:

- Right-click that table cell.
- Select the Copy cell action from the contextual menu to copy the value into the clipboard.
- Paste the value wherever you need it (for example, in an opened XQuery editor panel of Oxygen XML Editor).

Related Information:

- XML Transformation with XQuery (on page 1690)
- XQuery XQJ Transformation (on page 2263)

XQuery XQJ Transformation

XQuery API for Java (XQJ) refers to the common Java API for the XQuery 1.0 specification. The XQJ API enables you to execute XQuery against an XML data source.

Important: The XQJ connector is only capable of running XQuery 1.0 scrips, therefore XQuery 3.0 and 3.1 scripts are not supported.

Oxygen XML Editor supports any transformer that offers an XQJ API implementation and it be used for validating XQuery or transforming XML documents.

To configure the support for XQJ, do the following:

1. Configure an XQJ Data Source (on page 2253).
2. Configure an XQJ Connection (on page 2253).
To view your connection, go to the Data Source Explorer view (on page 2198) (if the view is not
displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the
Database perspective (on page 3285).

How to Configure an XQJ Data Source

Any transformer that offers an XQJ API implementation can be used when validating XQuery or
transforming XML documents. An example of an XQuery engine that implements the XQJ API is
Zorba.

1. If your XQJ Implementation is native, make sure the directory containing the native libraries
of the engine is added to your system environment variables: to PATH - on Windows, to
LD_LIBRARY_PATH - on Linux, or to DYLD_LIBRARY_PATH - on OS X. Restart Oxygen XML Editor
after configuring the environment variables.

2. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.

3. Click the New button in the Data Sources panel.

4. Enter a unique name for the data source.

5. Select XQuery API for Java (XQJ) in the Type combo box.

6. Press the Add button to add XQJ API-specific files.
   You can manage the driver files using the Add, Remove, Detect, and Stop buttons.
   Oxygen XML Editor detects any implementation of javax.xml.xquery.XQDataSource and presents
it in Driver class field.

7. Select the most suited driver in the Driver class combo box.

8. Click the OK button to finish the data source configuration.

9. Continue on to configure the XQJ connection (on page 2253).

How to Configure an XQJ Connection

The steps for configuring an XQJ connection are the following:

1. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.

2. Click the New button in the Connections panel.

3. Enter a unique name for the connection.
4. Select one of the previously configured XQJ data sources (on page 2253) in the Data Source combo box.

5. Fill-in the connection details. The properties presented in the connection details table are automatically detected depending on the selected data source.

6. Click the OK button to finish the connection configuration.

XQuery Database Debugging

Oxygen XML Editor includes a debugging interface that helps you to detect and solve problems with XQuery transformations that are executed against MarkLogic and Berkeley DB XML databases.

For more information about the debugging support in Oxygen XML Editor, see Debugging XSLT Stylesheets and XQuery Documents (on page 2290).

Debugging with MarkLogic

Oxygen XML Editor includes support for debugging XQuery transformations that are executed against a MarkLogic database.

To use a debugging session against the MarkLogic engine, follow these steps:

1. Configure a MarkLogic data source (on page 2236) and a MarkLogic connection (on page 2236).

2. Make sure that the debugging support is enabled in the MarkLogic server that Oxygen XML Editor accesses. On the server side, debugging must be activated in the XDBC server and in the Task Server section of the server control console (the switch debug allow). If the debugging is not activated, the MarkLogic server reports a DBG-TASKDEBUGALLOW error.

   ![Note](image)
   
   An XDBC application server must be running to connect to the MarkLogic server and this XDBC server will be used to process XQuery expressions against the server. You can change the XDBC application server that Oxygen XML Editor uses to process XQuery expressions by selecting the Use it to execute queries action (on page 2242) from the contextual menu in the Data Source Explorer view (on page 2198).

3. Open the XQuery file and start the debugging process.

   • If you want to debug an XQuery file stored on the MarkLogic server, it is recommend to use the Data Source Explorer view (on page 2198) and open the file from the application server that is involved in the debugging process. This improves the resolving of any imported modules.
The MarkLogic XQuery debugger integrates seamlessly into the XQuery Debugger perspective (on page 299). If you have a MarkLogic validation scenario configured for the XQuery file, you can choose to debug the scenario (on page 2309) directly.

Otherwise, switch to the XQuery Debugger perspective (on page 3285), open the XQuery file in the editor, and select the MarkLogic connection in the XQuery engine selector from the debug control toolbar (on page 2293).

For general information about how a debugging session is started and controlled, see the Working with the Debugger (on page 2309) section.

In a MarkLogic debugging session, you can use step actions and breakpoints (on page 2313) to help identify problems. When you add a breakpoint (on page 2314) on a line where the debugger never stops, Oxygen XML Editor displays a warning message. These warnings are displayed for breakpoints you add either in the main XQuery (which you can open locally or from the server) or for breakpoints you add in any XQuery that is opened from the connection that participates in the debugging session. For more information, see Using Breakpoints for Debugging Queries that Import Modules with MarkLogic (on page 2241).

**Remote Debugging with MarkLogic**

Oxygen XML Editor allows you to debug remote applications that use XQuery (for example, web applications that trigger XQuery executions). Oxygen XML Editor connects to a MarkLogic server, shows you the running XQuery scripts and allows you to debug them. You can even pause the scripts so that you can start the debugging queries in the exact context of the application. You can also switch a server to debug mode to intercept all XQuery scripts.

Oxygen XML Editor also supports collaborative debugging. This feature allows multiple users to participate in the same debugging session. You can start a debugging session and at a certain point, another user can continue it.

⚠️ **Important:** When using the remote debugging feature, the HTTP and the XDBC servers involved in the debugging session must have the same module configuration.

For more information about the XQuery debugger for MarkLogic, watch our video demonstration:

https://www.youtube.com/embed/eQ4ThDZq1bk

**Related Information:**

- MarkLogic Development in Oxygen XML Editor (on page 2237)
Using Breakpoints for Debugging Queries that Import Modules with MarkLogic

When debugging queries that import modules stored in the database, it is recommended to place breakpoints in the modules. When starting a new debugging session, make sure that the modules that you will debug are already opened in the editor. This is necessary so that the breakpoints in all the modules will be considered. Also, make sure that there are no other opened modules that are not involved in the current debugging session.

To place breakpoints in the modules, use the following procedure:

1. In the Data Source Explorer view (on page 2198), open all the modules from the Modules container of the XDBC application server (on page 2237) that performs the debugging.
2. Set breakpoints (on page 2314) in the module as needed.
3. Continue debugging (on page 2309) the query.

If you get a warning that the breakpoints failed to initialize, try the following solutions:

• Check the Breakpoints view (on page 2297) and make sure there are no older breakpoints (set on resources that are not part of the current debugging context).
• Make sure you open the modules from the context of the application server that does the debugging and place breakpoints there.

Related Information:

• MarkLogic Database Connections (on page 2234)

• MarkLogic Development in Oxygen XML Editor (on page 2237)

Peculiarities and Limitations of the MarkLogic Debugger

MarkLogic debugger has the following peculiarities and limitations:

• Debugging support is only available for MarkLogic server versions 4.0 or newer.
• For MarkLogic server versions 4.0 or newer, there are three XQuery syntaxes that are supported: '0.9-ml' (inherited from MarkLogic 3.2), '1.0-ml', and '1.0'.
• All declared variables are presented as strings. The Value column of the Variables view contains the expression from the variable declaration. It can be evaluated by copying the expression with
the **Copy value** action from the contextual menu of the **Variables view** *(on page 2307)* and pasting it in the **XWatch view** *(on page 2299)*.

- There is no support for **output to source mapping** *(on page 2310)*.
- There is no support for **showing the trace** *(on page 2304)*.
- You can only set **breakpoints** *(on page 2297)* in imported modules in one of the following cases:
  - When you open the module from the context of the application server involved in the debugging, using the **Data Source Explorer view** *(on page 2198)*.
  - When the debugger automatically opens the modules in the Editor.
- No **breakpoints** *(on page 2313)* are set in modules from the same server that are not involved in the current debugging session.
- No support for **profiling** *(on page 2314)* when an XQuery transformation is executed in the debugger.

**Debugging with Berkeley DB XML**

The Berkeley DB XML database added a debugging interface starting with version 2.5. The current version is supported in the Oxygen XML Editor XQuery Debugger. The **same restrictions and peculiarities** *(on page 2241)* apply for the Berkeley debugger as for the MarkLogic debugger.

**Integration with Microsoft SharePoint**

Oxygen XML Editor provides support for browsing and managing SharePoint connections in the **Data Source Explorer view** *(on page 2198)*. You can easily create new resources on the repository, copy and move them using contextual actions or the drag and drop support, or edit and transform the documents in the editor.

**Note:** You can access documents stored on SharePoint Online for Office 365 sites that use either **Cloud identity (default)** or **Federated identity (ADFS)** as the authentication method.

**Restriction:** The SharePoint connection is only available in the Enterprise edition of Oxygen XML Editor.

Figure 672. SharePoint Connection
By default, Oxygen XML Editor contains built-in data source drivers for SharePoint. Use this data source to create a connection to a SharePoint server that will be available in the Data Source Explorer view (on page 2198).

To configure a SharePoint connection, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Data Sources.

2. In the Connections panel click the + New button.

3. Enter a unique name for the connection.

4. Select SharePoint in the Data Source combo box.

5. Fill-in the connection details:
   a. Set the URL to the SharePoint repository in the field SharePoint URL.
b. Set the server domain in the **Domain** field. If you are using a SharePoint 365 account, leave this field empty.

c. Set the user name to access the SharePoint repository in the **User** field.

d. Set the password to access the SharePoint repository in the **Password** field.

6. To view your connection, go to the **SharePoint Browser view** (on page 2270) (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu).

For more information about connecting to repository located on a SharePoint server, watch our video demonstration:

https://www.youtube.com/embed/1u2xBtBp1mQ

**SharePoint Browser View**

The **SharePoint Browser** view allows you to connect to a SharePoint repository and perform SharePoint-specific actions on the available resources. To display this view, go to **Window > Show View > SharePoint Browser**.

Figure 673. SharePoint Browser View

The view is split in several functional areas:
Connection Area

The following controls are available:

- The **Site** combo box allows you to select and connect to an already **defined SharePoint connection (on page 2269)**.
- The **Disconnect** action terminates the current connection.
- The **Settings** drop-down menu contains actions that help you to quickly define a new connection or manage the existing ones from the **Data Source** options page: **New SharePoint Connection** and **Configure Database Sources**. Also, here you can choose one of the predefined view layouts.

SharePoint Site Navigation Area

If there is no connection selected in the **Site** combo box, this area is left blank and promotes the actions that allow you to quickly add SharePoint connections. Otherwise, the navigation area presents the SharePoint site structure in a tree-like fashion with various node types (such as *sites*, *libraries*, and *folders*).

Depending on the type of node, a contextual menu offers customized actions that can be performed on that node. The contextual menu of a folder allows you to create new folders and documents, import folders and files, and to rename and delete the folder.

**Note:** The rename and delete actions are not available for library root folders (*folders located at first level in a SharePoint library*).

Each library node displays a drop-down menu next to its name where you can select what you want to display for the current library node. This functionality is also available on the contextual menu of the node.

![Figure 674. Drop-Down Menu to Select Which Items to Display](image)

Folder Content Area

The content of a folder is displayed in a tabular form, where each row represents the properties of a folder or document. The list of columns and the way the documents and folders are organized depends on the currently selected view of the parent library.
### Table 72. Contextual Menu Actions for the Folder Area

| Action      | Description                                                                 | Available for | |                      |
|-------------|-----------------------------------------------------------------------------|---------------|-----------------------|
| Open        | Displays the content of the currently selected folder.                      |               |                      |
|             | Opens the current document for editing.                                     |               |                      |
| Rename      | Renames the current node on server.                                         |               |                      |
| Import      | Import files or folders into the currently selected folder.                 |               |                      |
| Delete      | Deletes the current node from the server.                                   |               |                      |
| Copy Location | Copies to clipboard the URL of the current node.                           |               |                      |
| Check Out   | Reserves the current document for your use so that other users cannot change it while you are editing it. |               |                      |
| Check In    | Commits on the server the changes you made to the document, so that other users can see them. It also makes the document available for editing to other users. |               |                      |
| Discard Check Out | Discards the previous checkout operation, making the file available for editing to other users. |               |                      |
| Refresh     | Queries the server to refresh the available properties of the current node. |               |                      |
| Drag and Drop | You can drag documents from the SharePoint Browser view and drop them in the main editor area to open them with ease. |               |                      |

You can filter and sort the displayed items. To display the available filters of a column, click the filter widget located on the column header. You can apply multiple filters at the same time.

**Note:** A column can be filtered or sorted only if it was configured this way on the server side.

Figure 675. Column Filter

![Column Filter](image)

**Related Information:**

- How to Configure a SharePoint Connection *(on page 2269)*
SharePoint Contextual Menu Actions

While browsing SharePoint connections in the Data Source Explorer view (on page 2198), the various nodes include the following contextual menu actions:

Connection Level Nodes

- **Configure Database Sources**
  
  Opens the Data Sources preferences page (on page 229) where you can configure both data sources and connections.

- **Disconnect**
  
  Stops the connection.

- **New Folder**
  
  Creates a new folder on the connection.

- **Import Files**
  
  Allows you to add a new file on the connection, in the current folder.

- **Refresh**
  
  Performs a refresh on the selected node.

- **Find/Replace in Files**
  
  Opens the Find/Replace in Files dialog box (on page 745) that allows you to find and replace text in multiple files from the connection.

Folder Level Nodes

- **New File**
  
  Creates a new file on the connection, in the current folder.

- **New Folder**
  
  Creates a new folder on the connection.

- **Import Folders**
  
  Imports folders on the server.

- **Import Files**
  
  Allows you to add a new file on the connection, in the current folder.

- **Export**
  
  Allows you to export the folder on the remote connection to a local folder.

- **Cut**
Removes the current selection and places it in the clipboard.

**Copy**

Copies the current selection into the clipboard.

**Paste**

Pastes the copied selection.

**Rename**

Renames the current resource

**Delete**

Deletes the current container.

**Refresh**

Performs a refresh on the selected node.

**Find/Replace in Files**

Opens the Find/Replace in Files dialog box (on page 745) that allows you to find and replace text in multiple files from the connection.

**Resource Level Nodes**

**Open**

Opens the selected resource in the editor.

**Open in System Application**

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the Data Source Explorer view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

**Cut**

Removes the current selection and places it in the clipboard.

**Copy**

Copies the current selection into the clipboard.

**Copy location**
Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

**Check Out**

Checks out the selected document on the server.

**Check In**

Checks in the selected document on the server. This action opens the **Check In** dialog box. In this dialog box, the following options are available:

- **Minor Version** - Increments the minor version of the file on the server.
- **Major Version** - Increments the major version of the file on the server.
- **Overwrite** - Overwrites the latest version of the file on the server.
- **Comment** - Allows you to comment on a file that you check in.

**Discard Check Out**

Discards the previous checkout operation, making the file available for editing to other users.

**Rename**

Renames the current resource

**Delete**

Deletes the current container.

**Refresh**

Performs a refresh on the selected node.

**Properties**

Shows various properties of the current container.

**Find/Replace in Files**

Opens the Find/Replace in Files dialog box (on page 745) that allows you to find and replace text in multiple files from the connection.

**Compare**

Compares two selected resources using the Compare Files tool (on page 2770).
14. Importing Data

Computer systems and databases contain data in incompatible formats and exchanging data between these systems can be very time consuming. Converting the data to XML can greatly reduce the complexity and create data that can be read by various types of applications.

Oxygen XML Editor offers support for importing text files, MS Excel files, Database Data, and HTML files into XML documents. The XML documents can be further converted into other formats using the Transform features (on page 1640).

Import from Text Files

Oxygen XML Editor includes the possibility of importing text files (.txt or .csv file extensions) as XML documents.

To import a text file into an XML file, follow these steps:

1. Go to File > Import > Text File.
   A Select text file dialog box is displayed.

2. Select the URL of the text file (.txt or .csv file extensions).

3. Select the encoding of the text file.

4. Click the Next button.
   The Import Criteria dialog box is displayed.

Figure 676. Import Criteria Dialog Box
5. Configure the settings for the conversion.
   a. Select the Field delimiter for the import settings. You can choose between the following:
      Comma, Semicolon, Tab, Space, or Pipe.
   b. The Import settings section presents the input data in a tabular form. By default, all data items are converted to element content (\rightarrow symbol), but this can be overridden by clicking the individual column headers. Clicking a column header once causes the data from this column to be converted to attribute values (\Rightarrow symbol). Clicking a second time causes the column data to be ignored (\times symbol) when generating the XML file. You can cycle through these three options by continuing to click the column header.
   c. First row contains field names - If this option is selected, the default column headers are replaced (where such information is available) by the content of the first row. In other words, the first row is interpreted as containing the field names. The changes are also visible in the preview panel.
   d. Customize - This button opens a Presentation Names dialog box that allows you to edit the name, XML name, and conversion criterion for the root and row elements. The XML names can be edited by double-clicking the desired item and entering the label. The conversion
criteria can also be modified by selecting one of the following options in the drop-down menu: ELEMENT, ATTRIBUTE, or SKIPPED.

e. **Import Settings** - Clicking this button opens the Import preferences page (on page 221) that allows you to configure more import options.

f. The XML Import Preview panel contains an example of what the generated XML document looks like.

g. **Open in editor** - If selected, the new XML document created from the imported text file is opened in the editor.

h. **Save in file** - If selected, the new XML document is saved in the specified path.

6. Click **Import** to generate the XML document.

**Import from MS Excel Files**

Oxygen XML Editor provides several methods for importing MS Excel files into an XML file. The first method is to use the Oxygen XML Editor Smart Paste mechanism (on page 918) by simply copying data from Excel and pasting it into a document in Author mode (note that this is only supported in DITA, DocBook, TEI, JATS, and XHTML documents). You can also copy data from Excel and paste it into inserted cells in Grid mode, but this is a more manual process. If you want to import an entire Excel file, Oxygen XML Editor also offers a configurable import wizard that works with any type of XML document.

**Smart Paste Method in Author Mode**

If you are importing data into DITA, DocBook, TEI, JATS, or XHTML documents, you can open the Excel spreadsheet in your office application, copy its content, and simply paste it into your document in Author mode.

The Oxygen XML Editor Smart Paste mechanism (on page 918) will convert the pasted content to the equivalent XML markup and considers various pasting solutions to keep the resulting document valid, while preserving the original text styling (such as bold, italics, underline) and formatting (such as lists, tables, paragraphs).

**Grid Mode Method**

The Grid mode in Oxygen XML Editor displays all content in an XML document as a structured grid of nested tables and you can work with the cells in those tables much like you would with any spreadsheet application. When importing Excel data into Grid mode, you first need to insert new cells in the particular nested table and then you can paste data from Excel the same as you would in any table or spreadsheet.
1. Copy the particular cells from your Excel spreadsheet that you want to import into an XML file.
2. Switch to Grid mode in Oxygen XML Editor.
3. Expand the particular nodes and locate the nested table where you want to insert the copied cells.
4. Right-click a particular row or column where you want to insert the data and select Insert row or Insert column, depending on the structure of the copied cells.
5. Paste the copied cells from the clipboard into the newly inserted cells in Grid mode.
6. You may need to make some manual adjustments. For example, if the selection of copied cells contained an empty cell, Oxygen XML Editor might ignore that cell.

**Import Wizard Method**

By default, this method supports importing Excel 97/2000/XP/2003 formats out-of-the-box. To import spreadsheet data from Excel 2007 or newer, additional libraries are needed before using this procedure. See Import Data from MS Excel 2007 or Newer (on page 2281) for instructions on adding more libraries.

To use the Import wizard to import an Excel file into an XML file, follow these steps:

1. Go to File > Import > MS Excel file.
2. Select the URL of the Excel file. The sheets of the document you are importing are presented in the Available Sheets section of this dialog box.
3. Click the Next button to proceed to the next stage of the wizard.

Figure 677. Import Wizard
4. Configure the settings for the conversion. This stage of the wizard offers the following options:

**Import settings section**

Presents the input data in a tabular form. By default, all data items are converted to element content (├ symbol), but this can be overridden by clicking the individual column headers. Clicking a column header once causes the data from this column to be converted to attribute values (═ symbol). Clicking a second time causes the column data to be ignored (x symbol) when generating the XML file. You can cycle through these three options by continuing to click the column header.

**First row contains field names**

If this option is selected, the default column headers are replaced (where such information is available) by the content of the first row. In other words, the first row is interpreted as containing the field names. The changes are also visible in the preview panel.

**Customize**
This button opens a **Presentation Names** dialog box that allows you to edit the name, XML name, and conversion criterion for the root and row elements. The XML names can be edited by double-clicking the desired item and entering the label. The conversion criteria can also be modified by selecting one of the following option in the drop-down menu: **ELEMENT**, **ATTRIBUTE**, or **SKIPPED**.

**Import Settings**

Clicking this button opens the **Import preferences page (on page 221)** that allows you to configure more import options.

**Import formatted data (as displayed in Excel)**

If this option is selected, the imported data retains the Excel data formatting (such as the representation of numeric values or dates). If deselected, the data formatting is not imported.

**XML Import Preview panel**

Contains an example of what the generated XML document will look like.

**Open in editor**

If selected, the new XML document created from the imported file is opened in the editor.

**Save in file**

If selected, the new XML document is saved in the specified path.

5. Click **Import** to generate the XML document.

For more information about exchanging data between Oxygen XML Editor and spreadsheet applications, watch our video demonstration:

https://www.youtube.com/embed/8VwsF58zLkJ

**Related Information:**

- Exporting XML Content to Excel (on page 892)

---

**Import Data from MS Excel 2007 or Newer**

To import spreadsheet data from Excel 2007 or newer (.xlsx), Oxygen XML Editor needs additional libraries from the release 3.10 of the Apache POI project.

To add this support, follow this procedure:
1. Go to Help > Install new add-ons to open an add-on selection dialog box.
2. Enter or paste https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml in the Show add-ons from field or select it from the drop-down menu.
3. Select Excel XLSX libraries plugin and click Next.
4. Restart the application.

**Result:** You can now use the Import wizard (on page 2279) to import data from Excel 2007 or newer.

### Alternate Method to Manually Add the Libraries

To manually add the libraries, follow these steps:

3. Copy the following .jar files into the lib directory of the installation folder of Oxygen XML Editor:
   - dom4j-1.6.1.jar
   - poi-ooxml-3.10-FINAL-20140208.jar
   - poi-ooxml-schemas-3.10-FINAL-20140208.jar
   - xmlbeans-2.3.0.jar

**Note:** The .jar files can be found in either the root folder where you unpacked the archive, or in the ooxml-lib subfolder.

**Result:** You can now use the Import wizard (on page 2279) to import data from Excel 2007 or newer.

### Import Database Data as an XML Document

To import the data from a relational database table as an XML document, follow these steps:

1. Go to File > Import > Database Data to start the Import wizard.

   This opens a Select database table dialog box that lists all the defined database connections:

   ![Select database table dialog box](image)

**Figure 678. Select Database Table Dialog Box**
2. Select the connection to the database that contains the appropriate data. Only connections configured in relational data sources can be used to import data.

3. If you want to edit, delete, or add a data source or connection, click the Configure Database Sources button. The Preferences/Data Sources option page is opened.

4. Click Connect.

5. In the list of sources, expand a schema and choose the required table.

6. Click the Next button.

   The Import Criteria dialog box is opened with a default query string in the SQL Query pane.

Figure 679. Import from Database Criteria Dialog Box
7. Configure the settings for the conversion.

   a. **SQL Preview** - If this button is pressed, the **Settings** pane displays the labels that are used in the XML document and the first five lines from the database. By default, all data items are converted to element content (\(<>\) symbol), but this can be overridden by clicking the individual column headers. Clicking a column header once causes the data from this column to be converted to attribute values (\(=\) symbol). Clicking a second time causes the column data to be ignored (\(x\) symbol) when generating the XML file. You can cycle through these three options by continuing to click the column header.

   b. **Customize** - This button opens a **Presentation Names** dialog box that allows you to edit the name, XML name, and conversion criterion for the root and row elements. The XML names can be edited by double-clicking the desired item and entering the label. The conversion criteria can also be modified by selecting one of the following option in the drop-down menu: **ELEMENT**, **ATTRIBUTE**, or **SKIPPED**.

   c. **Import Settings** - Clicking this button opens the **Import preferences page (on page 221)** that allows you to configure more import options.

   d. The **XML Import Preview** panel contains an example of what the generated XML document looks like.
e. **Open in editor** - If selected, the new XML document created from the imported file is opened in the editor.

f. **Save in file** - If selected, the new XML document is saved in the specified path.

g. **Generate XML Schema** - Allows you to specify the path of the generated XML Schema file.

8. Click **Import** to generate the XML document.

---

**Import from HTML Files**

Oxygen XML Editor offers two methods for importing HTML files into an XML document. The first method is to simply copy data from an HTML document and paste it into a document in Author mode, but this is only supported in DITA, DocBook, TEI, JATS, and XHTML documents. Oxygen XML Editor also offers a configurable import wizard that works with any type of XML document.

**Smart Paste Method**

If you are importing data into DITA, DocBook, TEI, JATS, or XHTML documents, you can open the HTML document in your web browser, copy its content, and paste it into your document in Author mode.

The Oxygen XML Editor **Smart Paste mechanism (on page 918)** will convert the pasted content to the equivalent XML markup and considers various pasting solutions to keep the resulting document valid, while preserving the original text styling (such as bold, italics, underline) and formatting (such as lists, tables, paragraphs).

**Import Wizard Method**

To use the **Import** wizard to import from HTML files, follow these steps:

1. Go to File > Import > HTML File. The Import HTML wizard is displayed.
2. Enter the URL of the HTML document.
3. Select the type of the resulting XHTML document:
   - XHTML5
   - XHTML 1.0 Transitional
   - XHTML 1.0 Strict
4. Click the **OK** button.

**Result:** The resulting document is an XHTML file containing a DOCTYPE declaration that references the XHTML DTD definition on the Web. The parsed content of the imported file is transformed to XHTML5, XHTML Transitional, or XHTML Strict depending on the option you chose.
Import Content Dynamically

Along with the built-in support for various useful URL protocols (such as HTTP or FTP), Oxygen XML Editor also provides special support for a convert protocol that can be used to chain predefined processors to dynamically import content from various sources.

A dynamic conversion URL chains various processors that can be applied, in sequence, on a target resource and has the following general syntax:

```
convert:/processor=xslt;ss=urn:processors:excel2d.xsl/processor=excel!/urn:files:my.xls
```

The previous example first applies a processor (excel) on a target identified by the identifier (urn:files:sample.xls) and converts the Excel™ resource to XML. The second applied processor (xslt) applies an XSLT stylesheet identified using the identifier (urn:processors:excel2d.xsl) over the resulting content from the first applied processor. These identifiers are all mapped to real resources on disk via an XML catalog that is configured in the application, as in the following example:

```
<catalog xmlns="urn:oasis:names:tc:entity:xmlns:xml:catalog">
  <rewriteURI uriStartString="urn:files:" rewritePrefix="./resources/"/>
  <rewriteURI uriStartString="urn:processors:" rewritePrefix="./processors/"/>
</catalog>
```

The target resource part of the conversion URL must always follow the !/ pattern. It can be any of the following:

- An absolute URL that points to a resource.
- An identifier that will be resolved to an actual resource via the XML Catalog support in the application. In the example above, the urn:files:sample.xls target resource is resolved via the XML catalog.
- A relative location. This location can only be resolved to an actual resource URL when the application has enough information about the location where the URL is referenced.

For example, for a DITA map (on page 3281) with a topicref such as:

```
<topicref href="convert:/.../processor=excel!/resources/sample.xls"/>
```

the resources/sample.xls path will be resolved relative to the DITA map location.

This type of URL can be opened in the application by using the Open URL action from the File menu. It can also be referenced from existing XML resources via xi:include or as a topic reference from a DITA map.

A GitHub project that contains various dynamic conversion samples for producing DITA content from various sources (and then publishing it) can be found here: https://github.com/oxygenxml/dita-glass.
Conversion Processors

A set of predefined conversion processors is provided in Oxygen XML Editor. Each processor has its own parameters that can be set to control the behavior of the conversion process. All parameters that are resolved to resources are passed through the XML catalog mapping.

The following predefined conversion processors are included:

- **xslt Processor** - Converts an XML input using the Saxon EE XSLT processor. The `ss` parameter indicates the stylesheet resource to be loaded. All other specified parameters will be set as parameters to the XSLT transformation.

```xml
convert:/processor=xslt;ss=urn:processors:convert.xsl;p1=v1!/urn:files:sample.xml
```

- **xquery Processor** - Converts an XML input using the Saxon EE XQuery processor. The `ss` parameter indicates the XQuery script to be loaded. All other specified parameters will be set as parameters to the XSLT transformation.

```xml
convert:/processor=xquery;ss=urn:processors:convert.xquery;p1=v1!/urn:files:sample.xml
```

- **excel Processor** - Converts an Excel™ input to an XML format that can later be converted by other piped processors. It has a single parameter `sn`, which indicates the name of the sheet that needs to be converted. If this parameter is missing, the XML will contain the combined content of all sheets included in the Excel™ document.

```xml
convert:/processor=excel;sn=test!/urn:files:sample.xls
```

- **java Processor** - Converts an input to another format by applying a specific Java method. The `jars` parameter is a comma-separated list of JAR (on page 3283) libraries, or folders that libraries will be loaded from. The `ccn` parameter is the fully qualified name of the conversion class that will be instantiated. The conversion class needs to have a method with the following signature:

```java
public void convert(String systemID, String originalSourceSystemID, InputStream is, OutputStream os, LinkedHashMap<String, String> properties)
    throws IOException
```

```xml
convert:/processor=java;jars=libs;ccn=test.JavaToXML!/urn:files:java/WSEditorBase.java
```

- **js Processor** - Converts an input to another format by applying a JavaScript method. The `js` parameter indicates the script that will be used. The `fn` parameter is the name of the method that will be called from the script. The method must take a string as an argument and return a string. If any of the parameters are missing, an error is thrown and the conversion stops.

```xml
convert:/processor=js;js=script.js;fn=test!/urn:files:sample.js
```
importing data

- **json** Processor - Converts a JSON input to XML. It has no parameters.

  - `convert:/processor=js;js=urn:processors:md.js;fn=convertExternal!/urn:files:sample.md`

- **xhtml** Processor - Converts HTML content to well-formed XHTML. It has no parameters.

  - `convert:/processor=xhtml!/urn:files:test.html`

- **wrap** Processor - Wraps content in a tag name making it well-formed XML. The `rn` parameter indicates the name of the root tag to use. By default, it is `wrapper`. The `encoding` parameter specifies the encoding that should be used to read the content. By default, it is UTF8. As an example, this processor can be used if you want to process a comma-separated values file with an XSLT stylesheet to produce XML content. The CSV file is first wrapped as well-formed XML, which is then processed with an `xslt` processor.

  - `convert:/processor=wrap!/urn:files:test.csv`

- **cache** Processor - Caches the converted content obtained from the original document to a temporary file. The cache will be used on subsequent uses of the same URL, thus increasing the speed for the application returning the converted content. If the original URL points to the local disk, the cache will be automatically invalidated when the original file content gets modified. Otherwise, if the original URL points to a remote resource, the cache will need to be invalidated by reloading (`File > C Reload (F5)`) the URL content that is opened in the editor.

  - `convert:/processor=cache/processor=xslt;...!/urn:files:test.csv`

### Reverse Conversion Processors

All processors defined above can also be used for saving content back to the target resource if they are defined in the URL as reverse processors. Reverse processors are evaluated right to left. These reverse processors allow round-tripping content to and from the target resource.

As an example, the following URL converts HTML to DITA when the URL is opened using the `h2d.xsl` stylesheet and converts DITA to HTML when the content is saved in the application using the `d2h.xsl` stylesheet.

  - `convert:/processor=xslt;ss=h2d.xsl/rprocessor=xslt;ss=d2h.xsl!/urn:files:sample.html`

⚠️ **Important:** If you are publishing a DITA map that has such conversion URL references inside, you need to edit the transformation scenario and set the value of the parameter `fix.external.refs.com.oxygenxml` to `true`. This will instruct Oxygen XML Editor to resolve such references during a special pre-processing stage. Depending on the conversion, you may also require
additional libraries to be added using the **Libaries** button in the **Advanced** tab of the transformation scenario.

Debugging XSLT Stylesheets and XQuery Documents

Oxygen XML Editor includes a powerful debugging interface that helps you to detect and solve problems with XSLT and XQuery transformations.

**XSLT Debugger Perspective**

The XSLT Debugger perspective (on page 3285) allows you to detect problems in an XSLT transformation by executing the process step by step. To switch the focus to this perspective, select the XSLT Debugger button in the top-right corner of the interface or Window > Open perspective > XSLT Debugger.

**XQuery Debugger Perspective**

The XQuery Debugger perspective (on page 3285) allows you to detect problems in an XQuery transformation process by executing the process step by step in a controlled environment and inspecting the information provided in the special views. To switch the focus to this perspective, select the XQuery Debugger button in the top-right corner of the interface or Window > Open perspective > XQuery Debugger.

**XSLT/XQuery Debugging Overview**

The XSLT Debugger and XQuery Debugger perspectives (on page 3285) allows you to test and debug XSLT 1.0 / 2.0 / 3.0 stylesheets and XQuery 1.0 / 3.0 documents including complex XPath 2.0 / 3.0 expressions. The interface presents simultaneous views of the source XML document, the XSLT/XQuery document and the result document. As you go step by step through the XSLT/XQuery document the corresponding output is generated step by step, and the corresponding position in the XML file is highlighted. At the same time, special views provide various types of debugging information and events useful to understand the transformation process.

The following set of features allow you to test and solve XSLT/XQuery problems:

- Support for XSLT 1.0 stylesheets (using Saxon 6.5.5 and Xalan XSLT engines), XSLT 2.0 / 3.0 stylesheets and XPath 2.0 / 3.0 expressions that are included in the stylesheets (using Saxon 9.8.0.12 XSLT engine) and XQuery 1.0 / 3.0 (using Saxon 9.8.0.12 XQuery engine).
• Stepping capabilities: step in, step over, step out, run, run to cursor, run to end, pause, stop.
• Output to source mapping between every line of output and the instruction element / source context that generated it.
• **Breakpoints (on page 2313)** on both source and XSLT/XQuery documents.
• Call stack on both source and XSLT/XQuery documents.
• Trace history on both source and XSLT/XQuery documents.
• Support for XPath expression evaluation during debugging.
• Step into imported/included stylesheets as well as included source entities.
• Available templates and hits count.
• Variables view.
• Dynamic output generation.

For even more information, watch our video demonstration:

https://www.youtube.com/embed/m9d8c4V-LJw

**Debugger Layout**

The XML and XSL files are displayed in **Text mode (on page 827)**. The other modes (**Author mode (on page 402)**, **Grid mode (on page 392)**) are available only in the **Editor perspective (on page 295)**.

The **XSLT/XQuery Debugger perspective (on page 3285)** contains the following components:

- **Source Document View (XML)** - Displays and allows the editing of XML files (documents).
- **XSLT/XQuery Document View (XSLT/XQuery)** - Displays and allows the editing of XSL files (stylesheets) or XQuery documents.
- **Output View** - Displays the output that results from inputting a document (XML) and a stylesheet (XSL) or XQuery document in the transformer. The transformation result is written dynamically while the transformation is processed (using the ➤ **Run** button on the Control toolbar (on page 2295)). Several actions are available in the contextual menu for this view, including **Find/Replace**, **Copy**, and **Format and Indent**. There are two types of output views: a **Text** view (with XML syntax highlights) and **XHTML** view. For large outputs, the XHTML view can be disabled (see **Debugger Settings (on page 212)**).
- **Control Toolbar (on page 2293)** - Contains a variety of actions to help you configure and control the debugging process.
- **Information Views (on page 2296)** - The information views at the bottom of the editor display various types of information to help you understand the transformation process.

**Tip:** The **Output** view and the various other information views are **dockable (on page 3281)** so that you can configure the workspace according to your preferences.

Figure 680. Debugger Interface
XML documents and XSL stylesheets or XQuery documents that were opened in the Editor perspective (on page 3285) are automatically sorted into the first two panes. When multiple files of each type are opened, the individual documents and stylesheets are separated using the familiar tab management system that you are used to in the Editor perspective. Selecting a tab brings the document or stylesheet into focus and enables editing without the need to go back to the Editor perspective.

In Debugger mode, the normal editor toolbar is not available. However, functions are still accessible from the Document menu and the contextual menus.

Bookmarks (on page 306) are replaced in the Debugger perspective by breakpoints (on page 2313).

During debugging, the current execution node is highlighted in both document (XML) and XSLT/ XQuery views.

Related Information:

- Steps in a Typical Debugging Process (on page 2309)
- Identify the XSLT / XQuery Expression that Generated Particular Output (on page 2310)
- Supported Processors for XSLT / XQuery Debugging (on page 2320)
Control Toolbar

The **Control** toolbar contains all the actions that you need to configure and control the debugging process. The following actions are described as they appear in the toolbar from left to right.

**Figure 681. Control Toolbar**

**XML source selector**

The current selection represents the source document used as input by the transformation engine. The selection list contains all opened files (XML files being emphasized). This option allows you to use other file types also as source documents. In an XQuery debugging session this selection field can be set to the default value *NONE*, because usually XQuery documents do not require an input source.

**XSL / XQuery selector**

The current selection represents the stylesheet or XQuery document to be used by the transformation engine. The selection list contains all opened files (XSLT / XQuery files being emphasized).

**Link with editor**

When selected, the XML and XSLT/XQuery selectors display the names of the files opened in the central editor panels. This button is toggled off by default.

**Output selector**

The selection represents the output file specified in the associated transformation scenario. You can specify the path by using the text field, the ![Insert Editor Variables](on page 276) button, or the ![Browse](button).

**Configure parameters**

Opens a dialog box that allows you to configure the XSLT / XQuery parameters to be used by the transformation.

**Edit extensions**

Allows you to add and remove the Java classes and *JARS (on page 3283)* used as XSLT extensions.
Turn on/off profiling

Enables / Disables current transformation profiling.

Enable XHTML output

Enables the rendering of the output in the [XHTML output view](on page 2291) during the transformation process. For performance issues, disable XHTML output when working with very large files. Note that only XHTML conformant documents can be rendered by this view. To view the output result of other formats, such as HTML, save the Text output area to a file and use an external browser for viewing.

When starting a debug session from the Editor perspective (on page 3285) by using the Debug Scenario action, the state of this toolbar button reflects the state of the Show as XHTML output option from the scenario.

Turn on/off output to source mapping

Enables or disables the output to source mapping between every line of output and the instruction element / source context that generated it.

Debugger preferences

Quick link to Debugger preferences page (on page 212).

XSLT / XQuery engine selector

Lists the processors available for debugging XSLT and XQuery transformations (on page 2320).

XSLT / XQuery engine advanced options

If Saxon HE/PE/EE is selected, you can click this button to open the Advanced Saxon Transformation Options page (on page 1679).

Step into

Starts the debugging process and runs until the next instruction is encountered.

Step over

Run until the current instruction and its sub-instructions are over. Usually this will advance to the next sibling instruction.

Figure 682. Step over
Step out

Run until the parent of the current instruction is over. Usually this will advance to the next sibling of the parent instruction.

Figure 683. Step out

Run Shift + F5

Starts the debugging process. The execution of the process is paused when a breakpoint (on page 2297) is encountered or the transformation ends.

Run to cursor

Starts the debugging process and runs until one of the following conditions occur: the line of cursor is reached, a valid breakpoint (on page 2313) is reached or the execution ends.

Run to end

Runs the transformation until the end, without taking into account enabled breakpoints (on page 2313), if any.

Pause

Request to pause the current transformation as soon as possible.

Stop

Request to stop the current transformation without completing its execution.

Show current execution nodes
Reveals the current debugger context showing both the current instruction and the current node in the XML source. Possible displayed states:

- Entering (↩) or leaving (↵) an XML execution node.
- Entering (↩) or leaving (↵) an XSL execution node.
- Entering (↩) or leaving (↵) an XPath execution node.

**Note:** When you set a MarkLogic server as a processor, the Show current execution nodes button is named Refresh current session context from server. Click this button to refresh the information in all the views.

**Note:** For some of the XSLT processors (Saxon-HE/PE/EE) the debugger could be configured to step into the XPath expressions affecting the behavior of the following debugger actions: Step into, Step over or Step Out.

Related Information:

- Advanced Saxon HE/PE/EE XQuery Transformation Options *(on page 1694)*

### Debugging Information Views

The information views at the bottom of the editor is comprised of two panes that are used to display various types of information used to understand the transformation process. For each information type there is a corresponding tab. While running a transformation, relevant events are displayed in the various information views. This enables the developer to obtain a clear view of the transformation progress. By using the debug controls, developers can easily isolate parts of stylesheet. Therefore, they may be more easily understood and modified.

The information types include the following:

Left side information views

- **Breakpoints** view *(on page 2297)*
- **XWatch** view *(on page 2299)*
- **Context** view *(on page 2298)*
- **Messages** view *(on page 2300)* (XSLT only)
- **Variables** view *(on page 2307)*
- **Invocation Tree** view *(on page 2316)*

Right side information views
- **Stack view** *(on page 2301)*
- **Output Mapping Stack view** *(on page 2302)*
- **Trace view** *(on page 2304)*
- **Templates view** *(on page 2305)* *(XSLT only)*
- **Nodes/Values Set view** *(on page 2306)*
- **Hotspots view** *(on page 2318)*

**Tip:** The information views are dockable *(on page 3281)* so that you can configure the workspace according to your preferences.

### Breakpoints View

The **Breakpoints** view lists all *breakpoints* *(on page 2313)* that are set on opened documents. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu. *Breakpoints* can be inserted *(on page 2314)* in the XML source document or the XSLT/XQuery document in debugging sessions.

Once you insert a *breakpoint*, it is automatically added to the list in the **Breakpoints** view and you can edit its associated *condition*. A *breakpoint* can have an associated break condition that represents an XPath expression evaluated in the current debugger context. For them to be processed, their evaluation result should be a boolean value. A *breakpoint* with an associated condition only stops the execution of the Debugger if the *breakpoint condition* is evaluated as **true**.

**Figure 684. Breakpoints View**

The **Breakpoints** view contains the following columns:

- **Enabled** - If selected, the current condition is evaluated and taken into account.
- **Resource** - Resource file and number of the line where the *breakpoint* is set. The Entire path of resource file is available as tooltip.
- **Condition** - XSLT/XQuery expression to be evaluated during debugging. The expression will be evaluated at every debug step.
Clicking a record highlights the breakpoint line in the document.

**Note:** The breakpoints list is not deleted at the end of a transformation (it is preserved between debugging sessions).

The following actions are available in the contextual menu of the table:

**Go to**

Moves the cursor to the source of the breakpoint.

**Run to Breakpoint**

Runs the debugger up to the point of this particular breakpoint and ignores the others (regardless of whether they were previously enabled or disabled).

**Enable**

Enables the breakpoint.

**Disable**

Disables the breakpoint. A disabled breakpoint will not be evaluated by the Debugger.

**Add**

Allows you to add a new breakpoint and breakpoint condition.

**Edit**

Allows you to edit an existing breakpoint.

**Remove**

Deletes the selected breakpoint.

**Enable all**

Enables all breakpoints.

**Disable all**

Disables all breakpoints.

**Remove all**

Removes all breakpoints.

Related Information:

- Using Breakpoints *(on page 2313)*
Context View

The context node is valid only for XSLT debugging sessions and is a source node corresponding to the XSL expression that is evaluated. It is also called the context of execution. The context node implicitly changes as the processor hits various steps (at the point where XPath expressions are evaluated). This node has the same value as evaluating '.' (dot) XPath expression in XWatch view (on page 2299). The value of the context node is presented as a tree in the Context view. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Figure 685. Context node view

The context nodes are presented in a tree-like fashion. Nodes from a defined namespace bound to a prefix are displayed using the qualified name. If the namespace is not bound to a prefix, the namespace URI is presented before the node name. The value of the selected attribute or node is displayed in the right side panel. The Context view also presents the current mode of the XSLT processor if this mode differs from the default one.

The title bar displays the current element index and the number of elements that compose the current context (this information is not available if you choose Xalan or Saxon 6 as processing engine).

XPath Watch (XWatch) View

The XWatch view shows XPath expressions evaluated during the debugging process. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Expressions are evaluated dynamically as the processor changes its source context. When you type an XPath expression in the Expression column, Oxygen XML Editor supports you with syntax highlight and content completion assistance (on page 1192).

Figure 686. XPath Watch View
Table 73. XWatch columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Expression</td>
<td>XPath expression to be evaluated (XPath 1.0 or 2.0 / 3.0 compliant).</td>
</tr>
<tr>
<td>Value</td>
<td>Result of XPath expression evaluation. Value has a type (see the possible values (on page 2307) in the section Variables View (on page 2307)). For Node Set results, the number of nodes in the set is shown in parenthesis.</td>
</tr>
</tbody>
</table>

⚠️ Important: Notes about working with the XWatch view:

- Expressions that reference variable names are not evaluated.
- The expression list is not deleted at the end of the transformation (it is preserved between debugging sessions).
- To insert a new expression, click the first empty line of the Expression column and start typing. As an alternative, right-click and select the Add action. Press (Enter) on the cell to add and evaluate.
- To delete an expression, click its Expression column and delete its content. As an alternative, right-click and select the Remove action. Press (Enter) on the cell to commit changes.
- If the expression result type is a Node Set, click it (Value column) and its value is displayed in the Nodes/Values Set view (on page 2306).
- The Copy, Add, Remove and Remove All actions are available in every row's contextual menu.

Messages View

Using an xsl:message instruction is one way to signal special situations encountered during transformation as well as a raw way of doing the debugging. The Messages view is available only for XSLT debugging sessions and shows all xsl:message calls executed by the XSLT processor during transformation. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Figure 687. Messages View
Table 74. Messages columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Message</td>
<td>Message content.</td>
</tr>
<tr>
<td>Terminate</td>
<td>Signals whether or not the processor terminates the transformation once it encounters the message (yes/no respectively).</td>
</tr>
<tr>
<td>Resource</td>
<td>Resource file where \texttt{xsl:message} instruction is defined and the message line number. The complete path of the resource is available as tooltip.</td>
</tr>
</tbody>
</table>

The following actions are available in the contextual menu:

- **Go to**
  - Highlight the XSL fragment that generated the message.

- **Copy**
  - Copies to clipboard message details (system ID, severity info, description, start location, terminate state).

- **Clear all**
  - Removes all messages from the view.

**Important:**

- Clicking a record from the table highlights the \texttt{xsl:message} declaration line.
- Message table values can be sorted by clicking the corresponding column header. Clicking the column header switches the sorting order between: ascending, descending, no sort.

**Stack View**

The **Stack** view shows the current execution stack of both source and XSLT/XQuery nodes. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

During the transformation, two stacks are managed. One for source nodes being processed and the other for XSLT/XQuery nodes being processed. Oxygen XML Editor shows both node types in one common stack. The source (XML) nodes are preceded by a red color icon while XSLT/XQuery nodes are preceded by a green color icon. The advantage of this approach is that you can always see the
source scope on which an XSLT/XQuery instruction is executed (the last red color node on the stack). The stack is oriented upside down.

Figure 688. Stack View

The contextual menu contains one action: Go to, which moves the selection in the editor panel to the line containing the XSLT element that is displayed on the selected line from the view.

Table 75. Stack Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#</td>
<td>Order number, represents the depth of the node (0 is the stack base).</td>
</tr>
<tr>
<td>XML/XSLT/XQuery Node</td>
<td>Node from source or stylesheet document currently being processed. One particular stack node is the document root, noted as #document.</td>
</tr>
<tr>
<td>Attributes</td>
<td>Attributes of the node (a list of id=&quot;value&quot; pairs).</td>
</tr>
<tr>
<td>Resource</td>
<td>Resource file where the node is located. The entire path is available as tooltip.</td>
</tr>
</tbody>
</table>

⚠️ Important: Remarks:

- Clicking a record from the stack highlights that node’s location inside resource.
- Using Saxon, the stylesheet elements are qualified with XSL proxy, while using Xalan you only see their names. (example: xsl:template using Saxon and template using Xalan).
- Only the Saxon processor shows element attributes.
- The Xalan processor shows also the built-in rules.

Output Mapping Stack View

The Output Mapping Stack view displays context data (on page 2310) and presents the XSLT templates/XQuery elements that generated specific areas of the output. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Figure 689. Output Mapping Stack view
The Go to action of the contextual menu takes you to the line that contains the XSLT element displayed in the Output Mapping Stack view.

### Table 76. Output Mapping Stack Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#</td>
<td>The order number in the stack of XSLT templates/XQuery elements. Number 0 corresponds to the bottom of the stack in the status of the XSLT/XQuery processor. The highest number corresponds to the top of the stack.</td>
</tr>
<tr>
<td>XSL/XQuery Node</td>
<td>The name of an XSLT template/XQuery element that participated in the generation of the selected output area.</td>
</tr>
<tr>
<td>Attributes</td>
<td>The attributes of the XSLT template/XQuery node.</td>
</tr>
<tr>
<td>Resource</td>
<td>The name of the file containing the XSLT template/XQuery element.</td>
</tr>
</tbody>
</table>

**Important:** Remarks:

- Clicking a record highlights that XSLT template definition/XQuery element inside the resource (XSLT stylesheet file/XQuery file).
- Saxon only shows the applied XSLT templates having at least one hit from the processor. Xalan shows all defined XSLT templates, with or without hits.
- The table can be sorted by clicking the corresponding column header. When clicking a column header the sorting order switches between: ascending, descending, no sort.
- Xalan shows also the built-in XSLT rules.

**Related Information:**

- Identify the XSLT / XQuery Expression that Generated Particular Output (on page 2310)
- Stack View (on page 2301)
- Trace View (on page 2304)
Trace View

Usually, the XSLT/XQuery processors signal the following events during transformation:

- Entering a source (XML) node.
- Leaving a source (XML) node.
- Entering an XSLT/XQuery node.
- Leaving an XSLT/XQuery node.

The Trace view catches all of these events, so you can see how the process evolved. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

The red icon lines denote source nodes while the green icon lines denote XSLT/XQuery nodes. It is possible to save the element trace in a structured XML document (using the Export to XML action in the contextual menu). Thus, you have the possibility of comparing the trace results from multiple debug sessions.

Figure 690. Trace History View

The contextual menu contains the following actions:

- **Go to**
  
  Moves the selection in the editor panel to the line containing the XSLT element or XML element that is displayed on the selected line from the view;

- **Export to XML**
  
  Saves the entire trace list in XML format.
Table 77. Trace History Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Depth</td>
<td>Shows you how deep the node is nested in the XML or stylesheet structure. The bigger the number, the more nested the node is. A depth 0 node is the document root.</td>
</tr>
<tr>
<td>XML/XSLT/XQuery Node</td>
<td>Represents the node from the processed source or stylesheet document. One particular node is the document root, noted as #document. Every node is preceded by an arrow that represents what action was performed on it (entering or leaving the node).</td>
</tr>
<tr>
<td>Attributes</td>
<td>Attributes of the node (a list of id=&quot;value&quot; pairs).</td>
</tr>
<tr>
<td>Resource</td>
<td>Resource file where the node is located. The complete path of the resource file is provided as tooltip.</td>
</tr>
</tbody>
</table>

⚠️ **Important**: Remarks:

- Clicking a record highlights that node's location inside the resource.
- Only the Saxon processor shows the element attributes.
- The Xalan processor shows also the built-in rules.

Templates View

The **xsl:template** is the basic element for stylesheets transformation. The **Templates** view is only available during XSLT debugging sessions and shows all **xsl:template** instructions used by the transformation. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

Being able to see the number of hits for each of the templates allows you to get an idea of the stylesheet coverage by template rules with respect to the input source.

Figure 691. Templates view

The contextual menu contains one action: **Go to**, which moves the selection in the editor panel to the line that contains the XSLT template displayed on the selected line from the view.
### Table 78. Templates columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Match</td>
<td>The <code>match</code> attribute of the <code>xsl:template</code>.</td>
</tr>
<tr>
<td>Hits</td>
<td>The number of hits for the <code>xsl:template</code>. Shows how many times the XSLT processor used this particular template.</td>
</tr>
<tr>
<td>Priority</td>
<td>The template priority as established by XSLT processor.</td>
</tr>
<tr>
<td>Mode</td>
<td>The <code>mode</code> attribute of the <code>xsl:template</code>.</td>
</tr>
<tr>
<td>Name</td>
<td>The <code>name</code> attribute of the <code>xsl:template</code>.</td>
</tr>
<tr>
<td>Resource</td>
<td>The resource file where the template is located. The complete path of the resource file is available as tooltip.</td>
</tr>
</tbody>
</table>

**Important**

- Clicking a record highlights that template definition inside the resource.
- Saxon only shows the applied templates having at least one hit from the processor. Xalan shows all defined templates, with or without hits.
- Template table values can be sorted by clicking the corresponding column header. When clicking a column header the sorting order switches between: ascending, descending, no sort.
- Xalan shows also the built-in rules.

### Nodes/Values Set View

The **Nodes/Values Set** view is always used in relation with the [Variables view](on page 2307) and [XWatch view](on page 2299). If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu. It shows an XSLT node set value in a tree form. This view is updated as a response to the following events:

- You click a variable that has a node set value in the [Variables](on page 2307) or [XWatch](on page 2299).
- You click a tree fragment in the [Variables](on page 2307) or [XWatch](on page 2299).
- You click an XPath expression evaluated to a node set in the [Variables](on page 2307) or [XWatch](on page 2299).

Figure 692. Node Set view
The nodes / values set is presented in a tree-like fashion. The total number of items is presented in the title bar. Nodes from a defined namespace bound to a prefix are displayed using the qualified name. If the namespace is not bound to a prefix, the namespace URI is presented before the node name. The value of the selected attribute or node is displayed in the right side panel.

⚠️ Important: Remarks:

- For longer values in the right side panel, the interface displays it with an ellipsis (...) at the end. A more detailed value is available as a tooltip when hovering over it.
- Clicking a record highlights the location of that node in the source or stylesheet view.

Variables View

The Variables view displays variables and parameters (local and global), along with their values. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Variables and parameters play an important role during an XSLT/XQuery transformation. Oxygen XML Editor uses the following icons to differentiate variables and parameters:

- \( \boldsymbol{V} \) - Global variable.
- \( \{V\} \) - Local variable.
- \( \boldsymbol{P} \) - Global parameter.
- \( \{P\} \) - Local parameter.

The following value types are available:

- Boolean
- String
- Date - XSLT 2.0 / 3.0 only.
- Number
- Set
- Object
- **Fragment** - Tree fragment.
- **Any**
- **Undefined** - The value was not yet set, or it is not accessible.

![Note:]

When Saxon 6.5 is used, if the value is unavailable, then the following message is displayed in the **Value** field: "The variable value is unavailable".

When Saxon 9 is used:

- If the variable is not used, the **Value** field displays "The variable is declared but never used".
- If the variable value cannot be evaluated, the **Value** field displays "The variable value is unavailable".

- **Document**
- **Element**
- **Attribute**
- **ProcessingInstruction**
- **Comment**
- **Text**
- **Namespace**
- **Evaluating** - Value under evaluation.
- **Not Known** - Unknown types.

Figure 693. Variables View

![Variables View](image)

**Table 79. Variables Columns**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of variable / parameter.</td>
</tr>
<tr>
<td>Value Type</td>
<td>Type of variable/parameter.</td>
</tr>
<tr>
<td>Value</td>
<td>Current value of variable / parameter.</td>
</tr>
</tbody>
</table>
The value of a variable (the **Value** column) can be copied to the clipboard for pasting it to other editor areas with the **Copy value** action from the contextual menu. This is useful if you have long and complex values that cannot be easily remembered just by looking at them once.

⚠️ **Important:** Remarks:

- Local variables and parameters are the first entries presented in the table.
- Clicking a record highlights the variable definition line.
- Variable values could differ depending on the transformation engine used or stylesheet version set.
- If the value of the variable is a node set or a tree fragment, clicking it causes the **Node Set view** ([on page 2306](#)) to be shown with the corresponding set of values.
- Variable table values can be sorted by clicking the corresponding column header. Clicking the column header switches between the orders: ascending, descending, no sort.

### Multiple Output Documents in XSLT 2.0 and XSLT 3.0

For XSLT 2.0 and XSLT 3.0 stylesheets that store the output in multiple files by using the `xsl:result-document` instruction, the content of the file created in this way is displayed dynamically while the transformation is running in an output view. There is one view for each `xsl:result-document` instruction so that the output is not mixed while still being presented in multiple views.

### Steps in a Typical Debugging Process

Depending on your situation and needs, the debugging process might be more complex, but the following procedure is an example of a typical debugging process:

1. Open the source XML document ([on page 689](#)) and the XSLT/XQuery document. ([on page 689](#))

2. If you are in the Editor **perspective** ([on page 3285](#)), switch to the XSLT Debugger or XQuery Debugger **perspective** ([on page 3285](#)) with one of the following actions:
   - Select **Window > Open perspective > XSLT Debugger/XQuery Debugger** or the ![XSLT Debugger/XQuery Debugger button in the top-right corner of the interface.](#)
   - Select **Document > XML Document > Debug scenario** or use the ![Debug scenario action on the toolbar.](#). This action initializes the Debugger **perspective** ([on page 3285](#)) with the parameters of the transformation scenario. Any modification applied to the scenario parameters (the transformer engine, XSLT parameters, transformer extensions, etc.) will be saved back in the scenario when exiting from the Debugger **perspective**.
3. Select the source XML document in the XML source selector of the Control toolbar (on page 2293). In the case of XQuery debugging, if your XQuery document has no implicit source, set the source selector value to NONE.

4. Select the XSLT/XQuery document in the XSL/XQuery selector of the Control toolbar (on page 2293).

5. Set XSLT/XQuery parameters using the Configure parameters button on the Control toolbar (on page 2293).

6. Set one or more breakpoints (on page 2313).

7. Step through the stylesheet using the following buttons available on the Control toolbar (on page 2294):
   - Step into
   - Step over
   - Step out
   - Run
   - Run to cursor
   - Run to end
   - Pause
   - Stop

8. Examine the data in the information views to find the bug in the transformation process.
   For more information about fixing bugs in the transformation, see: Identify the XSLT / XQuery Expression that Generated Particular Output (on page 2310).

Related Information:

- Identify the XSLT / XQuery Expression that Generated Particular Output (on page 2310)

Identify the XSLT / XQuery Expression that Generated Particular Output

To quickly spot the XSLT templates or XQuery expressions with problems, it is important to know what XSLT template in the XSLT stylesheet (or XQuery expression in the XQuery document) and what element in the source XML document generated a specified area in the output.

Some of the debugging capabilities (for example, Step in) can be used for this purpose. Using Step in, you can see how output is generated and link it with the XSLT/XQuery element being executed in the
current source context. However, this can become difficult on complex XSLT stylesheets or XQuery documents that generate a large output.

You can click particular text in the Output view or XHTML output view and the editor will select the XML source context and the XSLT template/XQuery element that generated that text. Also, inspecting the whole stack of XSLT templates/XQuery elements that determined the state of the XSLT/XQuery processor at the moment of generating the specified output area speeds up the debugging process.

This is an example of a typical procedure for identifying an expression that generated particular output:

1. Switch to the XSLT Debugger or XQuery Debugger perspective (on page 3285) with one of the following actions:
   - Select Window > Open perspective > XSLT Debugger/XQuery Debugger or the XSLT Debugger/XQuery Debugger button in the top-right corner of the interface.
   - Select Document > XML Document > Debug scenario or use the Debug scenario action on the toolbar. This action initializes the Debugger perspective (on page 3285) with the parameters of the transformation scenario. Any modification applied to the scenario parameters (the transformer engine, XSLT parameters, transformer extensions, etc.) will be saved back in the scenario when exiting from the Debugger perspective.

2. Select the source XML document in the XML source selector of the Control toolbar (on page 2293). In the case of XQuery debugging, if your XQuery document has no implicit source, set the source selector value to NONE.

3. Select the XSLT/XQuery document in the XSL/XQuery selector of the Control toolbar (on page 2293).

4. Select the appropriate engine in the XSLT/XQuery engine selector of the Control toolbar (on page 2294).

5. Set XSLT/XQuery parameters using the Configure parameters button on the Control toolbar (on page 2293).

6. Apply the XSLT stylesheet or XQuery transformation using the Run to end button that is available on the Control toolbar (on page 2295).

7. Inspect the mapping by clicking a section of the output in either the Text tab or XHTML tab of the Output view (on page 298).

Figure 694. XHTML Output to Source Mapping
Figure 695. Text Output to Source Mapping
This action will highlight the XSLT / XQuery element and the XML source context. This XSLT template/XQuery element that is highlighted in the XSLT/XQuery editor represents only the top of the stack of XSLT templates/XQuery elements that determined the state of the XSLT/XQuery processor at the moment of generating the clicked output section. In the case of complex transformations, inspecting the whole stack of XSLT templates/XQuery elements speeds up the debugging process. This stack is available in the Output Mapping Stack view (on page 2302).

Related Information:

- Output Mapping Stack View (on page 2302)
- Trace View (on page 2304)
- Templates View (on page 2305)
Using Breakpoints

The Oxygen XML Editor XSLT/XQuery Debugger allows you to interrupt XSLT/XQuery processing to gather information about variables and processor execution at particular points. To ensure breakpoints are persistent between work sessions, they are saved at project level. You can set a maximum of 100 breakpoints per project.

Inserting Breakpoints

To insert a breakpoint, follow these steps:

1. Click the line where you want to insert the breakpoint in the XML source document or the XSLT/XQuery document. Breakpoints are automatically created on the ending line of a start tag, even if you click a different line.
2. Click the vertical stripe on the left side of the editor panel or use Shift+F7.

Result:

Once you insert a breakpoint, it is automatically added to the list in the Breakpoints view and you can edit its associated condition. A breakpoint can have an associated break condition that represents an XPath expression evaluated in the current debugger context. For them to be processed, their evaluation result should be a boolean value. A breakpoint with an associated condition only stops the execution of the Debugger if the breakpoint condition is evaluated as true.

![Example: Breakpoints](image)

Removing Breakpoints

To remove a breakpoint, click its icon (●) in the vertical stripe on the left side of the editor panel or right-click the breakpoint and select Remove or Remove all.

Related Information:

- Breakpoints View (on page 2297)
Performance Profiling of XSLT Stylesheets and XQuery Documents

Whether you are trying to identify a performance issue that is causing your production XSLT/XQuery transformation to not meet customer expectations or you are trying to proactively identify issues prior to deploying your XSLT/XQuery transformation, using the XSLT/XQuery profiler feature is essential to helping you save time and ultimately ensure a better performing, more scalable XSLT/XQuery transformation.

The XSLT/XQuery profiling feature can use any available XSLT/XQuery processor that can be used for debugging and it is available from the debugging perspective (on page 3285).

Enabling the Profiler

Enabling and disabling the profiler is controlled by the Profiler button from the debugger Control toolbar (on page 2294). The XSLT/XQuery profiler is off by default. This option is not available during a debugger session so you need to set it before starting the transformation. For information about a common debugging procedure, see Steps in a Typical Debugging Process (on page 2309).

Profiling Information Views

Immediately after enabling the profiler, two new information views are added to the current debugger information views (on page 2296):

- Invocation tree view (on page 2316) on left side
- Hotspots view (on page 2318) on right side

Profiling data is available only after the transformation ends successfully.

On the left side (Invocation tree view (on page 2316)), you can examine how style instructions are processed. This result view is also named call-tree, as it represents the order of style processing. The profiling result shows the duration time for each of the style-instruction including the time needed for its called children.

On the right side (Hotspots view (on page 2318)), you can immediately spot the time the processor spent in each instruction. As an instruction usually calls other instructions, the used time of the called instruction is extracted from the duration time of the caller (the hotspot only presents the inherent time of the instruction).

Source Backmapping

In either the Invocation tree (on page 2316) or Hotspots view (on page 2318), you can use the backmapping feature to find the XSLT stylesheet or XQuery expression definition. Clicking the
selected item causes Oxygen XML Editor to highlight the XSLT stylesheet or XQuery expression source line where the instruction is defined.

Figure 697. Source Backmapping

Saving and Customizing Profiling Data

The profiling data can be saved (exported) into XML and HTML format. In either the Invocation tree (on page 2316) or Hotspots view (on page 2318), right-click anywhere in the view and select Export to XML or Export to HTML. The HTML report can be customized based upon the profiling raw data. When you select Export to HTML, Oxygen XML Editor will save it as XML and apply an XSLT stylesheet to render the report as XML. You can customize these stylesheets to suit your needs. By default, they are located in: [OXYGEN_INSTALL_DIR]/frameworks/profiler/.

Other Profiling Notes

- If you want to change the XSLT/XQuery profiler settings (on page 213), use the contextual menu and choose the corresponding View settings entry.
- Profiling exhaustive transformations may run into an OutOfMemory error due to the large amount of information being collected. If this is the case, you can close unused projects when running the profiling or use high values for Java VM options -Xms and -Xmx. If this does not help you can shorten your source XML file and try again.
- For more information about the XSLT/XQuery Profiler, watch our video demonstration:

  https://www.youtube.com/embed/4ftHschjLgA
Invocation Tree View

The Invocation Tree view shows a top-down call tree that represents how XSLT instructions or XQuery expressions are processed. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Figure 698. Invocation Tree View

The entries in the invocation tree include a few possible icons that indicate the following:

- ▲ - Points to a call whose inherent time is insignificant compared to its total time.
- ● - Points to a call whose inherent time is significant compared to its total time (greater than 1/3rd of its total time).

Every entry in the invocation tree includes textual information that depends on the XSLT/XQuery profiler settings (on page 213):

- A percentage number of the total time that is calculated with respect to either the root of the tree or the calling instruction.
- A total time measurement in milliseconds or microseconds. This is the total execution time that includes calls into other instructions.
- A percentage number of the inherent time that is calculated with respect to either the root of the tree or the calling instruction.
- An inherent time measurement in milliseconds or microseconds. This is the inherent execution time of the instruction.
- An invocation count that shows how often the instruction has been invoked on this call-path.
- An instruction name that contains also the attributes description.

The Invocation Tree view also includes the following contextual menu actions:

Export to HTML

Selecting this option will save the profiling data as XML and then apply an XSLT stylesheet to render the report as HTML. These stylesheets are included in the
subfolder: \[OXYGEN_INSTALL_DIR\]/frameworks/profiler/. You can use them to customize your own report based on the profiling raw data.

**Export to XML**

Use this option to save the profiling data as an XML file in a specified location.

**View settings**

Opens the XSLT/XQuery Profiler preferences page (on page 213) that allows you to configure various profiling settings.

**Hotspots View**

The Hotspots view displays a list of all instruction calls that lie above the threshold defined in the XSLT/XQuery profiler settings (on page 213). If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Figure 699. Hotspots View

By opening a hotspot instruction entry, the tree of back-traces leading to that instruction call are calculated and shown.

Every hotspot is described by the values from the following columns:

- **Instruction** - The name of the instruction.
- **Time** - The inherent time in milliseconds or microseconds of how much time has been spent in the hotspot, along with a bar whose length is proportional to this value. All calls into this instruction are summed up regardless of the particular call sequence.
- **Hits** - The invocation count of the hotspot entry.

If you click the handle on the left side of a hotspot, a tree of back-traces will be shown.

Every entry in the backtrace tree has textual information attached to it that depends on the XSLT/XQuery profiler settings (on page 213):
• A percentage number that is calculated with respect to either the total time or the called instruction.
• A time measured in milliseconds or microseconds of how much time has been contributed to the parent hotspot on this call-path.
• An invocation count that shows how often the hotspot has been invoked on this call-path.

Note: This is not the number of invocations of this instruction.
• An instruction name that also contains its attributes.

The Hotspots view also includes the following contextual menu actions:

Export to HTML
Selecting this option will save the profiling data as XML and then apply an XSLT stylesheet to render the report as HTML. These stylesheets are included in the subfolder: [OXYGEN_INSTALL_DIR]/frameworks/profiler/. You can use them to customize your own report based on the profiling raw data.

Export to XML
Use this option to save the profiling data as an XML file in a specified location.

View settings
Opens the XSLT/XQuery Profiler preferences page (on page 213) that allows you to configure various profiling settings.

Debugging XSLT that Call Java Extensions
It is possible to debug XSLT that call Java extensions. This is achieved through a transformation scenario in which the Java extensions are specified, and the debugging can be done based upon the same scenario.

To debug XSLT with Java extensions, follow this procedure:

1. Create an XSLT transformation scenario (on page 1722) for your XSLT document (select Configure Transformation Scenario(s) action from the toolbar, then click New, and select XSLT transformation).
2. In the New scenario dialog box, click the Extensions button (in the XSLT tab), specify the Java extensions (JAR libraries) that are needed, and click OK.
3. Once you are finished configuring the transformation scenario, click OK, then select Save and close.
4. Use the Debug scenario action on the toolbar and the debugging will be based upon the same transformation scenario you just configured and saved.
Tip: You could achieve this during a typical debugging process (on page 2309) by specifying the Java extensions using the Edit extensions button on the debugger control toolbar (on page 2293).

Related Information:

- Validating XSLT Stylesheets that Call Java Extensions (on page 1187)

Debugging Java Extensions

The XSLT/XQuery debugger does not step into Java classes that are configured as XSLT/XQuery extensions of the transformation. To step into Java classes, inspect variable values, and set breakpoints (on page 2313) in Java methods, you can set up a Java debug configuration in an IDE (such as the Eclipse SDK) as described in the following steps:

1. Create a debug configuration.
   a. Set at least 256 MB as heap memory for the Java virtual machine (recommended 1024 MB) by setting the -Xmx parameter in the debug configuration (for example, `-Xmx1024m`).
   b. Make sure the [OXYGEN_INSTALL_DIR]/lib/oxygen.jar file and your Java extension classes are on the Java classpath. The Java extension classes should be the same classes that were set as an extension (on page 2293) of the XSLT/XQuery transformation in the debugging perspective (on page 3285).
   c. Set the class ro.sync.exml.Oxygen as the main Java class of the configuration. The main Java class ro.sync.exml.Oxygen is located in the oxygen.jar file.

2. Start the debug configuration.
   Now you can set breakpoints and inspect Java variables as in any Java debugging process executed in the selected IDE (Eclipse SDK, and so on.).

Supported Processors for XSLT / XQuery Debugging

The following built-in XSLT processors are integrated in the debugger and can be selected in the Control Toolbar (on page 2293):

- Saxon 9.8.0.12 HE (Home Edition) - a limited version of the Saxon 9 processor, capable of running XSLT 1.0, XSLT 2.0 / 3.0 basic and XQuery 1.0 transformations, available in both the XSLT debugger and the XQuery one,
• **Saxon 9.8.0.12 PE (Professional Edition)** - capable of running XSLT 1.0 transformations, XSLT 2.0 basic ones and XQuery 1.0 ones, available in both the XSLT debugger and the XQuery one,

• **Saxon 9.8.0.12 EE (Enterprise Edition)** - a schema aware processor, capable of running XSLT 1.0 transformations, XSLT 2.0 / 3.0 basic ones, XSLT 2.0 / 3.0 schema aware ones and XQuery 1.0 / 3.0 ones, available in both the XSLT debugger and the XQuery debugger,

• **Saxon 6.5.5** - capable of running only XSLT 1.0 transformations, available only in the XSLT debugger,

• **Xalan 2.7.2** - capable of running only XSLT 1.0 transformations, available only in the XSLT debugger.
16.
Framework and Author Mode Customization

This section contains information and tutorials about customizing the authoring experience through custom frameworks and customizing the Author editing mode through CSS styling or API extensions.

Creating and Configuring Custom Frameworks

Oxygen XML Editor includes built-in, configured frameworks (on page 3282) for DocBook, DITA, TEI, XHTML, and JATS, but you can also create your own customization to handle other types of documents. A common use case is wanting to customize the interface to accommodate the needs of your authoring team.

Fully configuring a framework usually involves customizing CSS stylesheets, XML schemas, GUI components (menu actions, toolbars, inline components, content completion proposals, and more), configuring other more general settings, then bundling the framework to share with your team. The CSS and GUI components are used to customize the interface, while other general settings can be configured to accommodate custom document templates, XML catalogs, transformation scenarios, and more.

Advanced Framework Customization

Oxygen XML Editor supports individual document types and classes of document types through frameworks (on page 3282). A framework associates a document type or a class of documents with CSS stylesheets, validation schemas, catalog files, new files templates, transformation scenarios, content completion proposals, custom actions, and more.

This section includes information about numerous possibilities for creating and customizing a framework, and how to share your customization with others.

Tip: A sample framework customization package is available that you can dabble with and use to help you get started. It can be downloaded from: https://www.oxygenxml.com/php/get_oxygen_sample_framework.php. The package includes a sample CSS file, XSL file, schema files, document templates, an XML catalog file, custom icons, and other resources.
Creating/Extending a Custom Framework

The easiest way to create a custom framework (on page 3282) (document type) is by extending an existing built-in framework, such as DITA or DocBook, and then making modifications to it. You can then easily share the custom framework (on page 2371) with your team.

To create a custom framework by extending an existing one, follow these steps:

1. In a location where you have full write access, create a folder structure similar to this:
   
   `custom_frameworks/dita-extension`

2. Open the Preferences dialog box (Options > Preferences) (on page 79) and go to Document Type Association > Locations (on page 94). Add the path to your `custom_frameworks` folder in the Additional frameworks directories list and click OK or Apply to save your changes.

3. Go to the Document Type Association preferences page (on page 92) and select an existing framework configuration (for example, DITA) and use the Extend button to create an extension for it.

   **Step Result:** This opens the Document Type Configuration dialog box (on page 95) where you can define the set of rules and settings for your custom framework.

4. Give the extension an appropriate name, select External for the Storage option, click the browsing button (سبق) to specify the location of the custom directory you created in step 1.

5. Continue to configure the extension using the tabs on the bottom half of the dialog box. For details about each of those tabs, see the child topics in the Document Type Configuration dialog box (on page 95) section. For even more information about customizing the extended framework, see the various topics and tutorials in the Creating and Configuring Custom Frameworks (on page 2322) section. Make sure that you save any resources you reference in your framework configuration (CSS files, new document templates, schemas used for validation, catalogs, etc.) in your custom framework directory you created in step 1.

6. Click OK to close the configuration dialog box and then OK or Apply to save your changes.

   **Results:** You now have a fully functional framework that can be shared with others (on page 2371).

---

Configuring Actions, Menus, Toolbars, Content Completion for a Framework

You can configure actions, menus, toolbars, icons, and content completion proposals specifically for a particular framework (on page 3282) (document type) to customize your editing experience in Author.
mode by using the Document Type configuration dialog box (on page 95). Advanced users who are familiar with API development can also create custom Author mode operations for a particular framework.

Configuring Actions for a Framework

To add or configure actions for a framework (on page 3282) (document type), follow this procedure:

1. Open the Preferences dialog box (Options > Preferences) (on page 79), go to Document Types Association, and select the framework for which you want to create an action.
2. Click Edit and in the Document Type configuration dialog box (on page 95) go to the Author tab, then go to the Actions subtab.
3. To create a new action, click the New button. To edit an existing action, select the action and click the Edit button.

Result: In either case, this opens the Action configuration dialog box (on page 102) where you can configure numerous aspects of the action.

Example: Configure the Insert Section Action for a Framework

This topic describes the procedure for defining the Insert Section action for a custom framework (on page 3282). It is assumed that the icon files, § (Section16.gif) for the menu item and § (Section20.gif) for the toolbar, are already available. Although you could use the same icon size for both the menu and toolbar, usually the icons from the toolbars are larger than the ones found in the menus. These files should be placed in your custom framework directory (/OXYGEN_INSTALL_DIR/frameworks/[CUSTOM_FRAMEWORK_DIR]).

Figure 700. Action Dialog Box
1. Set the ID field to `insert_section`. This is a unique action identifier.

2. Set the Name field to `Insert Section`. This will be the action's name, displayed as a tooltip when the action is placed in the toolbar, or as the menu item name.

3. Set the Menu access key to `i`. On Windows, the menu items can be accessed using `Alt+letter` keys combination, when the menu is visible. The letter is visually represented by underlining the first letter from the menu item name having the same value.

4. Add a Description.

5. Set the Large icon (20x20) field to `${frameworks}/sdf/Section20.gif`. A good practice is to store the image files inside the framework directory and use editor variable (on page 276) `${framework}` to make the image relative to the framework location.
   If the images are bundled in a JAR (on page 3283) archive together with some Java operations implementation, for instance, it might be convenient for you to reference the images not by the file name, but by their relative path location in the class-path.
   
   If the image file `Section20.gif` is located in the images directory inside the JAR archive, you can reference it by using `/images/Section20.gif`. The JAR file must be added into the Classpath list.

6. Set the Small icon (16x16) field to `${frameworks}/sdf/Section16.gif`.

7. Click the text field next to Shortcut key and set it to `Ctrl+Shift+S` (Meta+Shift+S on Mac OS). This will be the key combination to trigger the action using the keyboard only.
The shortcut is enabled only by adding the action to the main menu of Author mode (on page 2327), which contains all the actions that the author will have in a menu for the current document type.

8. At this time the action has no functionality added to it. Next you must define how this action operates. An action can have multiple operation modes. The first action mode enabled by the evaluation of its associated XPath expression will be executed when the action is triggered by the user. The XPath expression needs to be version 2.0 and its scope must be only element and attribute nodes of the edited document. Otherwise, the expression will not return a match and will not trigger the action. If the expression is left empty, the action will be enabled anywhere in the scope of the root element. For this example, suppose you want the action to add a section only if the current element is either a book, article, or another section.

   a. Set the XPath expression field to:

   ```
   local-name()='section' or local-name()='book' or local-name()='article'
   ```

   b. Set the invoke operation field to InsertFragmentOperation built-in operation, designed to insert an XML fragment at cursor position. This belongs to a set of built-in operations, a complete list of which can be found in the Author Default Operations (on page 2451) section. This set can be expanded with your own Java operation implementations.

   c. Configure the arguments section as follows:

   ```
   <section xmlns="http://www.oxygenxml.com/sample/documentation">
   <title/>
   </section>
   ```

   insertLocation - leave it empty. This means the location will be at the cursor position.

   insertPosition - select "Inside".

Example: Configure the Insert Table Action for a Framework

This topic describes the procedure for defining the Insert Table action for a custom framework (on page 3282). Suppose that you want to create an action that inserts a table with three rows and three columns into a document and the first row is the table header. As with the insert section action (on page 2324), you will use the InsertFragmentOperation built-in operation.

Place the icon files for the menu item, and for the toolbar, in your custom framework directory (`{OXYGEN_INSTALL_DIR}\frameworks\{CUSTOM_FRAMEWORK_DIR}\`).
1. Set **ID** field to **insert_table**.
2. Set **Name** field to **Insert table**.
3. Set **Menu access key** field to **t**.
4. Set **Description** field to **Adds a table element**.
5. Set **Toolbar icon** to **${framework} / toolbarIcon.png**.
6. Set **Menu icon** to **${framework} / menuIcon.png**.
7. Set **Shortcut key** to **Ctrl + Shift + T (Command + Shift + T on OS X)**.
8. Set up the action's functionality:
   a. Set **XPath expression** field to **true()**. **true()** is equivalent with leaving this field empty.
   b. Set **Invoke operation** to use **InsertFragmentOperation** built-in operation that inserts an XML fragment to the cursor position.
   c. Configure operation's arguments as follows:
      - **fragment** - set it to:

```
<table xmlns="http://www.oxygenxml.com/sample/documentation">
  <header>
    <td/> <td/> <td/>
  </header>
  <tr>
    <td/> <td/> <td/>
  </tr>
  <tr>
    <td/> <td/> <td/>
  </tr>
</table>
```

- **insertLocation** - to add tables at the end of the section use the following code:

```
ancestor::section/*[last()]
```

- **insertPosition** - Select **After**.

**Configure the Main Menu for a Framework**

Defined actions can be grouped into customized menus in the Oxygen XML Editor menu bar.

1. Open the **Document Type** configuration dialog box (**on page 95**), select your custom **framework** (**on page 3282**), and go to the **Author** tab.

2. Go to the **Menu** subtab. In the left side you have the list of actions and some special entries:
   - **Submenu** - Creates a submenu. You can nest an unlimited number of menus.
   - **Separator** - Creates a separator into a menu. This way you can logically separate the menu entries.
3. The right side of the panel displays the current actions for that menu tree. To change its name, click this label to select it, then press the Edit button.

4. Select the Submenu label in the left panel section and the appropriate label in the right panel section, then press the Add as child button. Change the submenu name to Table, using the Edit button.

5. Select the Insert section action in the left panel section and the Table label in the right panel section, then press the Add as sibling button.

6. Now select the Insert table action in the left panel section and the Table in the right panel section. Press the Add as child button.

Figure 701. Configuring the Menu

When opening a test document for a custom framework in Author mode, the menu you created is displayed in the editor menu bar, between the Tools and the Document menus. The upper part of the menu contains generic Author mode actions (common to all document types) and the two actions created previously (with Insert table under the Table submenu).

Figure 702. Author Mode Menu
Configure the Contextual Menu for a Framework

The contextual menu is displayed when you right-click in the Author editing area. You can only configure the bottom part of the menu, since the top part is reserved for a list of generic actions (such as Copy, Paste, Undo, etc.)

1. Open the Document Type configuration dialog box (on page 95) for the particular framework (on page 3282) and go to the Author tab. Next, go to the Contextual Menu subtab.

2. Follow the same steps as explained in the Configuring the Main Menu (on page 2327), except changing the menu name because the contextual menu does not have a name.

   Note: You can choose to reuse a submenu that contains general authoring actions. In this case, all actions (both general and framework-specific ones) are grouped together under the same submenu.

Figure 703. Configuring the Contextual Menu
To test it, open the test file, and open the contextual menu. In the lower part there is shown the **Table** sub-menu and the **Insert section** action.

### Configure the Toolbars for a Framework

This procedure describes how to add defined actions to a toolbar for a custom [framework (on page 3282)](#). You can also create additional custom toolbars with existing or custom actions.

1. Open the **Document Type** configuration dialog box [on page 95](#) for your custom framework and select the **Author** tab.
2. Next, go to the **Toolbar** subtab.

![Figure 704. Configuring the Toolbar](#)

The panel is divided in two sections. The left side contains a list of actions, while the right side contains an action tree, displaying the list of actions added in the toolbar. The special entry called **Separator** allows you to visually separate the actions in the toolbar.

3. To add an action, select it in the left panel and select the particular toolbar label where you want it added in the right panel section, then click the **Add as child** or **Add as sibling** button.

**Result:** When opening a document for the particular framework in **Author** mode, the toolbar with the new buttons will be displayed in the toolbar area.

**Tip:** If you have many custom toolbar actions, or want to group actions according to their category, add more toolbars with custom names and split the actions to better suit your purpose. If your toolbar is not displayed when switching to the **Author** mode, right-click the main toolbar, select **Configure Toolbars**, and make sure the appropriate toolbar (such as the **Author Custom Actions** toolbar) is selected.
**Note:** A maximum of 16 toolbars can be added. If you add more, all extra toolbars will be automatically converted to sub-toolbars for the last added toolbar.

Configure Content Completion for a Framework

You can customize the content of the following **Author** controls, adding items (which, when invoked, perform custom actions) or filtering the default contributed ones:

- **Content Completion Assistant** ([on page 3280](#)) window
- **Elements** view ([on page 432](#))
- **Insert Element** menus (from the **Outline** view ([on page 347](#)) or breadcrumb ([on page 907](#)) contextual menus)

You can use the content completion customization support in a custom **framework** ([on page 3282](#)) by following this procedure:

1. Open the **Document type** configuration dialog box ([on page 95](#)) for your custom **framework** and select the **Author** tab. Next, go to the **Content Completion** tab.

The top side of the **Content Completion** section contains the list with all the actions defined within the custom **framework** and the list of actions that you decided to include in the **Content Completion Assistant** list of proposals. The bottom side contains the list with all the items that you decided to remove from the **Content Completion Assistant** list of proposals.
2. If you want to add a custom action to the list of current **Content Completion** proposals, select the action item from the **Available actions** list and press the **Add as child** or **Add as sibling** button to include it in the **Current actions** list. An **Insert Action** dialog box appears, giving you the possibility to select where to provide the selected action.

![Figure 706. Insert Action Dialog Box](image)

3. If you want to exclude a certain item from the **Content Completion** proposals, you can use the **Add** button from the **Filter - Remove content completion items** list. The **Remove item** dialog box is displayed, allowing you to input the item name and to choose the controls that filter it. The **Item name** combo box accepts wildcards.

![Figure 707. Remove Item Dialog Box](image)

**Adding Retina/HiDPI Icons in a Framework**

Higher resolution icons can also be included in customized frameworks (on page 3282) for rendering them in a Retina or HiDPI display. The icons can be referenced directly from the **Document Type Configuration** dialog box (on page 95) (from the **Action** dialog box (on page 102)) or from an API (ro.sync.exml.workspace.api.node.customizer.XMLNodeRendererCustomizer (on page 2431)).

As with any image, the higher resolution icons are stored in the same images folder as the normal resolution images and they are identified by a scaling factor that is included in the name of the image.
files. For instance, icons with a Retina scaling factor of 2 will include \( @2x \) in the name (for example, myIcon@2x.png).

Developers should not specify the path of the alternate icons (\( @2x \) or \( @3x \)) in the Action dialog box (on page 102) or the XMLNodeRendererCustomizer API (on page 2431). When using a Retina or HiDPI display, Oxygen XML Editor automatically searches the folder of the normal icon for a corresponding image file with a Retina scaling factor in the name. If the higher resolution icon file does not exist, the normal icon is scaled and used instead.

Related Information:
- Retina/HiDPI Images in Author Mode (on page 1028)

Localizing Frameworks

Oxygen XML Editor supports framework (on page 3282) localization (translating framework actions, buttons, and menu entries to various languages). This lets you develop and distribute a framework to users that speak other languages without changing the distributed framework. Changing the language used in Oxygen XML Editor in the Global preferences page is enough to set the right language for each framework.
