The intelligent Content Completion Assistant (on page 2965) allows you to quickly identify and insert elements, attributes, and attribute values that are valid in the current editing context. All available proposals are listed in a pop-up menu displayed at the current cursor position.

The Content Completion Assistant is enabled by default. To disable it, open the Preferences dialog box (Options > Preferences) (on page 98), go to Editor > Content Completion, and deselect the Enable content completion option (on page 182).

When active, the Content Completion Assistant displays a list of context-sensitive proposals valid at the current cursor position. It can be manually activated with the Ctrl + Space (Command + Space on OS X) shortcut. You can navigate through the list of proposals by using the Up and Down keys on your keyboard. For each selected item in the list, the Content Completion Assistant displays a documentation window. You can customize the size of the documentation window by dragging its top, right, and bottom borders.

To insert the selected proposal in Text mode, do one of the following:

- Press Enter or Tab to insert both the start and end tags and position the cursor inside the start tag in a position suitable for inserting attributes.
- Press Ctrl + Enter (Command + Enter on OS X) to insert both the start and end tags and positions the cursor between the tags in a position where you can start typing content.

If you are using the concept of main files (on page 2968) to import/include modules, the Content Completion Assistant collects its components starting from the main files. The main files can be defined in the project or in the associated validation scenario. For more information about the Main Files support in Oxygen XML Editor, see Defining Main Files at Project Level (on page 383).

The Content Completion Assistant also offers additional information for the element and attribute proposals in the form of schema annotations that is displayed in a tooltip.
Syntax Highlighting in Relax NG Schemas

Oxygen XML Editor supports syntax highlighting in Text mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for Relax NG schemas, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98).
2. Go to Editor > Syntax Highlight (on page 195).
3. Select and expand the XML section in the top pane (for RELAX NG Compact Syntax schemas, select and expand the RNC section).
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.
5. Select the XML tab in the Preview pane to see the effects of your changes (for RELAX NG Compact Syntax schemas, the tab is RNC).

Tip:
Oxygen XML Editor also allows you to specify syntax highlighting colors for specific XML elements and attributes with specific namespace prefixes. This can be done in the Editor > Syntax Highlight > Elements/Attributes by Prefix preferences page (on page 195).

Related Information:
Syntax Highlight Preferences (on page 195)

Quick Fixes for DTD, XSD, and Relax NG Errors

Oxygen XML Editor offers Quick Fixes (on page 2970) for common errors that appear in XML documents that are validated against DTD, XSD, or Relax NG schemas.
Note: For XML documents validated against XSD schemas, the Quick Fixes are only available if you use the default Xerces validation engine.

Quick Fixes are available in Text mode and Author mode.

Oxygen XML Editor provides Quick Fixes for numerous types of problems, including the following:

<table>
<thead>
<tr>
<th>Problem Type</th>
<th>Available Quick Fixes</th>
</tr>
</thead>
<tbody>
<tr>
<td>A specific element is required in the current context</td>
<td>Insert the required element</td>
</tr>
<tr>
<td>An element is invalid in the current context</td>
<td>Remove the invalid element</td>
</tr>
<tr>
<td>The content of the element should be empty</td>
<td>Remove the element content</td>
</tr>
<tr>
<td>An element is not allowed to have child elements</td>
<td>Remove all child elements</td>
</tr>
<tr>
<td>Text is not allowed in the current element</td>
<td>Remove the text content</td>
</tr>
<tr>
<td>A required attribute is missing</td>
<td>Insert the required attribute</td>
</tr>
<tr>
<td>An attribute is not allowed to be set for the current element</td>
<td>Remove the attribute</td>
</tr>
<tr>
<td>The attribute value is invalid</td>
<td>Propose the correct attribute values</td>
</tr>
<tr>
<td>ID value is already defined</td>
<td>Generate a unique ID value</td>
</tr>
<tr>
<td>References to an invalid ID</td>
<td>Change the reference to an already defined ID</td>
</tr>
</tbody>
</table>

Ignoring/Unignoring Validation Problems (on page 755)

Relax NG Outline View
The Outline view for Relax NG schemas presents a list with the patterns that appear in the diagram in both the Full Model View (on page 1018) and Logical Model View (on page 1019) cases and it allows for quick access to a component by name. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.
This view has two modes, with the tree showing either the XML structure or the defined pattern (components) collected from the current document. By default, the Outline view presents the components.

When the Show components option is selected in the Settings menu on the Outline view toolbar, the following option is available:

Show XML structure

Shows the XML structure of the current document in a tree-like manner.

The following actions are available in the Settings menu on the Outline view toolbar when the Show XML structure option is selected:

Filter returns exact matches

The text filter of the Outline view returns only exact matches.

Selection update on cursor move

Allows a synchronization between Outline view and schema diagram. The selected view from the diagram will be also selected in the Outline view.

Show components

Shows the defined pattern collected from the current document.
Flat presentation mode of the filtered results
When active, the application flattens the filtered result elements to a single level.

Show comments and processing instructions
Show/hide comments and processing instructions in the Outline view.

Show element name
Show/hide element name.

Show text
Show/hide additional text content for the displayed elements.

Show attributes
Show/hide attribute values for the displayed elements. The displayed attribute values can be changed from the Outline preferences panel (on page 275).

Configure displayed attributes
Displays the XML Structured Outline preferences page (on page 275).

The following contextual menu actions are also available in the Outline view when the Show XML structure option is selected in the Settings menu:

Append Child
Displays a list of elements that you can insert as children of the current element.

Insert Before
Displays a list of elements that you can insert as siblings of the current element, before the current element.

Insert After
Displays a list of elements that you can insert as siblings of the current element, after the current element.

Edit Attributes
Opens a dialog box that allows you to edit the attributes of the currently selected component.

Toggle Comment
Comments/uncomments the currently selected element.

Search references
Searches for the references of the currently selected component.

Search references in
Searches for the references of the currently selected component in the context of a scope that you define.

Component dependencies
Opens the Component Dependencies view (on page 1031) that displays the dependencies of the currently selected component.

Rename Component in

Renames the currently selected component in the context of a scope that you define.

Cut

Cuts the currently selected component.

Copy

Copies the currently selected component.

Delete

Deletes the currently selected component.

Expand More

Expands the structure of a component in the Outline view.

Collapse All

Collapses the structure of all the component in the Outline view.

The upper part of the Outline view contains a filter box that allows you to focus on the relevant components. Type a text fragment in the filter box and only the components that match it are presented. For advanced usage you can use wildcard characters (such as * or ?) and separate multiple patterns with commas.

RNG Resource Hierarchy/Dependencies View

The Resource Hierarchy/Dependencies view displays the hierarchy or dependencies for resources included in an RNG schema. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

If you want to see the hierarchy or dependencies of an RNG schema, select the desired schema in the Project view (on page 368) and choose Resource Hierarchy or Resource Dependencies from the contextual menu.
The following actions are available on the toolbar of the **Resource Hierarchy/Dependencies** view:

- **Refresh**
  
  Refreshes the Hierarchy/Dependencies structure.

- **Stop**
  
  Stops the hierarchy/dependencies computing.

- **Show Hierarchy**
  
  Allows you to choose a resource to compute the hierarchy structure.

- **Show Dependencies**
  
  Allows you to choose a resource to compute the dependencies structure.

- **Configure dependencies search scope**
  
  Allows you to configure a scope to compute the dependencies structure. There is also an option for automatically using the defined scope for future operations.

- **History**
  
  Provides access to the list of previously computed dependencies. Use the **Clear history** button to remove all items from this list.

The contextual menu for a resource listed in the **Resource Hierarchy/Dependencies** view contains the following actions:

- **Open**
  
  Opens the resource. You can also double-click a resource in the Hierarchy/Dependencies structure to open it.
Go to reference
Opens the source document where the resource is referenced.

Copy location
Copies the location of the resource.

Move resource
Moves the selected resource.

Rename resource
Renames the selected resource.

Resource Hierarchy
Shows the hierarchy for the selected resource.

Resource Dependencies
Shows the dependencies for the selected resource.

Add to Main Files
Adds the currently selected resource in the Main Files directory (on page 383).

Expand More
Expands more of the children of the selected resource from the Hierarchy/Dependencies structure.

Collapse All
Collapses all children of the selected resource from the Hierarchy/Dependencies structure.

Tip:
When a recursive reference is encountered in the Hierarchy view, the reference is marked with a special icon 🏢.

Note:
The Move resource or Rename resource actions give you the option to update the references to the resource (on page 995).

Related Information:
Working with Modular XML Files in the Main Files Context (on page 772)
Search and Refactor Operations Scope (on page 774)

Moving/Renaming RNG Resources
You can move and rename a resource presented in the Resource/Hierarchy Dependencies view, using the Rename resource and Move resource refactoring actions from the contextual menu.
When you select the Rename action in the contextual menu of the Resource/Hierarchy Dependencies view, the Rename resource dialog box is displayed. The following fields are available:

- **New name** - Presents the current name of the edited resource and allows you to modify it.
- **Update references of the renamed resource(s)** - Select this option to update the references to the resource you are renaming. A Preview option is available that allows you to see what will be updated before selecting Rename to process the operation.

When you select the Move action from the contextual menu of the Resource/Hierarchy Dependencies view, the Move resource dialog box is displayed. The following fields are available:

- **Destination** - Presents the path to the current location of the resource you want to move and gives you the option to introduce a new location.
- **New name** - Presents the current name of the moved resource and gives you the option to change it.
- **Update references of the moved resource(s)** - Select this option to update the references to the resource you are moving, in accordance with the new location and name. A Preview option is available that allows you to see what will be updated before selecting Move to process the operation.

Note:
Updating the references of a resource that is resolved through a catalog is not supported. Also, the update references operation is not supported if the path to the renamed or moved resource contains entities.

Relax NG Schema Component Dependencies View

The Component Dependencies view allows you to see the dependencies for a selected component. This is helpful if you want to see where components are used in the entire hierarchy. For example, if you want to find all the references where a given component is used.

If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

To see the dependencies of a Relax NG component:

1. Right-click the desired component in the editor or Outline view.
2. Select the Component Dependencies action from the contextual menu.

The action is available for all named defines.

If a component contains multiple references, a small table is displayed at the bottom of the view that contains all the references. When a recursive reference is encountered, it is marked with a special icon §.
The **Component Dependencies** view includes the following toolbar actions:

**Refresh**

Refreshes the dependencies structure.

**Stop**

Stops the dependency computation.

**Configure**

Allows you to choose the search scope for computing the dependencies structure. This is helpful for making sure all imported/included resources are computed.

**History**

Allows you to select from a list of the most recently used dependency computations.

In addition, the following actions are available in the contextual menu:

**Go to First Reference**

Selects the first reference of the currently selected component in the dependencies tree.

**Go to Component**

Shows the definition of the currently selected component in the dependencies tree.

---

**Related Information:**

[Search and Refactor Operations Scope (on page 774)](#)

---

**Searching and Refactoring Actions in RNG Schemas**

**Search Actions**

The following search actions can be applied on named *defines* and are available from the **Search** submenu in the contextual menu of the current editor or from the **Document > References** menu:

**Search References**
Searches all references of the item found at current cursor position in the defined scope, if any. If a scope is defined, but the currently edited resource is not part of the range of resources determined by this, a warning dialog box is displayed and you have the possibility to define another search scope.

**Search References in**

Searches all references of the item found at current cursor position in the file or files that you specify when define a scope in the **Search References** dialog box.

**Search Declarations**

Searches all declarations of the item found at current cursor position in the defined scope if any. If a scope is defined, but the currently edited resource is not part of the range of resources determined by this, a warning dialog box will be displayed and you have the possibility to define another search scope.

**Search Declarations in**

Searches all declarations of the item found at current cursor position in the file or files that you specify when you define a scope for the search operation.

**Search Occurrences in File**

Searches all occurrences of the item at the cursor position in the currently edited file.

The following action is available from the contextual menu and the **Document > Schema** menu:

**Go to Definition**

Moves the cursor to the definition of the current element in the Relax NG (full syntax) schema.

**Note:**

You can also use the **Ctrl + Single-Click (Command + Single-Click on OS X)** shortcut on a reference to display its definition.

**Refactoring Actions**

The following refactoring actions can be applied on named *defines* and are available from the **Refactoring** submenu in the contextual menu of the current editor or from the **Document > Refactoring** menu:

**Rename Component**

Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the **Esc** or **Enter** key on your keyboard.

**Rename Component in**

Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the **Preview** button, you can view the files to be affected by the action.
Figure 381. Rename Identity Constraint Dialog Box

RNG Quick Assist Support

The *Quick Assist support (on page 2970)* improves the development work flow, offering fast access to the most commonly used actions when you edit schema documents.

The *Quick Assist feature (on page 2970)* is activated automatically when the cursor is positioned over the name of a component. It is accessible via a yellow bulb icon (💡) placed at the current line in the stripe on the left side of the editor. Also, you can invoke the quick assist menu by using the `Alt + 1` (*Meta + Alt + 1* on macOS) keyboard shortcuts.
The *Quick Assist* support offers direct access to the following actions:

- **Rename Component in**
  Renames the component and all its dependencies.

- **Search Declarations**
  Searches the declaration of the component in a predefined scope. It is available only when the context represents a component name reference.

- **Search References**
  Searches all references of the component in a predefined scope.

- **Component Dependencies**
  Searches the component dependencies in a predefined scope.

- **Change Scope**
  Configures the scope that will be used for future search or refactor operations.

- **Rename Component**
  Allows you to rename the current component in-place.

- **Search Occurrences**
  Searches all occurrences of the component within the current file.

**Related Information:**
- Component Dependencies View *(on page 1031)*
- Resource Hierarchy/Dependencies View *(on page 1028)*
- Searching and Refactoring Actions *(on page 1032)*
- Search and Refactor Operations Scope *(on page 774)*
Configuring a Custom Datatype Library for a RELAX NG Schema

A RELAX NG schema can declare a custom datatype library for the values of elements found in XML document instances. The datatype library must be developed in Java and it must implement the interface specified on the www.thaiopensource.com website.

The JAR (on page 2967) file containing the custom library and any other dependent JAR file must be added to the classpath of the application, that is the JAR files must be added to the folder  

\[\text{OXYGEN}\_\text{INSTALL}\_\text{DIR}/\text{lib} \].

To load the custom library, restart Oxygen XML Editor.

Editing NVDL Schemas

Some complex XML documents are composed by combining elements and attributes from namespaces. Furthermore, the schemas that define these namespaces are not even developed in the same schema language. In such cases, it is difficult to specify in the document all the schemas that must be taken into account for validation of the XML document or for content completion. An NVDL (Namespace Validation Definition Language) schema can be used. This schema allows the application to combine and interleave multiple schemas of different types (W3C XML Schema, RELAX NG schema, Schematron schema) in the same XML document.

Oxygen XML Editor offers support for editing NVDL schema files in the following editing modes:

- **Text editing mode (on page 926)** - Allows you to edit NVDL schema files in a source editing mode, along with a schema design pane with two tabs that offer a Full Model View (on page 1037) and Logical Model View (on page 1037).
- **Grid editing mode (on page 321)** - Displays NVDL schema files in a structured spreadsheet-like grid.
- **Author editing mode** - The visual Author mode is also available for Relax NG schema files, presenting them in a compact and easy to understand representation.

For information about applying and detecting schemas, see Associating a Schema to XML Documents (on page 759).

Related Information:

Associating a Schema to XML Documents (on page 759)

NVDL Schema Diagram

This section explains how to use the graphical diagram of a NVDL schema.

Introduction to NVDL Schema Diagram Editor

Oxygen XML Editor provides a simple, expressive, and easy-to-read schema diagram editor for NVDL schemas.
With this new feature you can easily develop complex schemas, print them on multiple pages or save them as JPEG, PNG, and BMP images. It helps both schema authors in developing the schema and content authors that are using the schema to understand it.

Oxygen XML Editor provides a side-by-side source and diagram presentation with real-time synchronization:

- The changes you make in the editor are immediately visible in the Diagram (no background parsing).
- Changing the selected element in the diagram selects the underlying code in the source editor.

**Full Model View**

When you create a schema document or open an existing one, the editor panel is divided in two sections: one containing the schema diagram and the second the source code. The diagram view has two tabbed panes offering a **Full Model View** and a **Logical Model View** (on page 1037).

**Figure 383. NVDL Schema Editor - Full Model View**

The **Full Model View** renders all the NVDL elements with intuitive icons. This representation coupled with the synchronization support makes the schema navigation easy.

Double-click any diagram component to edit its properties.
Logical Model View

The Logical Model View presents the compiled schema in the form of a single pattern. The patterns that form the element content are defined as top-level patterns with generated names. These names are generated depending on the elements name class.

Figure 384. Logical Model View for an NVDL Schema

Actions Available in the Diagram Editor

The contextual menu offers the following actions:

**Show only the selected component**

Depending on its state (selected/not selected), either the selected component or all the diagram components are shown.

**Show Annotations**

Depending on its state (selected/not selected), the documentation nodes are shown or hidden.

**Auto expand to references**

This option controls how the schema diagram is automatically expanded. For instance, if you select it and then edit a top-level element or you trigger a diagram refresh, the diagram will be expanded until it reaches the referenced components. If this option is left unchecked, only the first level of the diagram is expanded, showing the top-level elements. For large schemas, the editor disables this option automatically.

**Collapse Children**

Collapses the children of the selected view.

**Expand Children**

Expands the children of the selected view.
Print Selection

Prints the selected view.

Save as Image

Saves the current selection as image, in JPEG, BMP, SVG or PNG format.

Refresh

Refreshes the schema diagram according to the changes in your code (changes in your imported documents or those that are not reflected automatically in the compiled schema).

If the schema is not valid, you see only an error message in the Logical Model View (on page 1037) instead of the diagram.

Validating NVDL Schema Documents

By default, NVDL schema files are validated as you type. To change this, open the Preferences dialog box (Options > Preferences) (on page 98), go to Editor > Document Checking, and deselect the Enable automatic validation option (on page 197).

To validate an NVDL schema document manually, select the Validate action from the Validation toolbar drop-down menu or the Document > Validate menu. When Oxygen XML Editor validates an NVDL schema file, it expands all the included modules so the entire schema hierarchy is validated. The validation problems are highlighted directly in the editor, making it easy to locate and fix any issues.

Related Information:
Validating XML Documents Against a Schema (on page 728)
Presenting Validation Errors in Text Mode (on page 730)

Content Completion in NVDL Schemas

The intelligent Content Completion Assistant (on page 2965) allows you to quickly identify and insert elements, attributes, and attribute values that are valid in the current editing context. All available proposals are listed in a pop-up menu displayed at the current cursor position.

The Content Completion Assistant is enabled by default. To disable it, open the Preferences dialog box (Options > Preferences) (on page 98), go to Editor > Content Completion, and deselect the Enable content completion option (on page 182).

When active, the Content Completion Assistant displays a list of context-sensitive proposals valid at the current cursor position. It can be manually activated with the Ctrl + Space (Command + Space on OS X) shortcut. You can navigate through the list of proposals by using the Up and Down keys on your keyboard. For each selected item in the list, the Content Completion Assistant displays a documentation window. You can customize the size of the documentation window by dragging its top, right, and bottom borders.

To insert the selected proposal in Text mode, do one of the following:
• Press **Enter** or **Tab** to insert both the start and end tags and position the cursor inside the start tag in a position suitable for inserting attributes.

• Press **Ctrl + Enter (Command + Enter on OS X)** to insert both the start and end tags and positions the cursor between the tags in a position where you can start typing content.

If you are using the concept of *main files (on page 2968)* to import/include modules, the **Content Completion Assistant** collects its components starting from the *main files*. The *main files* can be defined in the project or in the associated validation scenario. For more information about the **Main Files** support in Oxygen XML Editor, see Defining Main Files at Project Level (on page 383).

The **Content Completion Assistant** also offers additional information for the element and attribute proposals in the form of schema annotations that is displayed in a tooltip.

![Figure 385. NVDL Content Completion Assistant](image)

**Syntax Highlighting in NVDL Schemas**

Oxygen XML Editor supports syntax highlighting in **Text** mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for NVDL schemas, follow these steps:

1. Open the **Preferences** dialog box (**Options > Preferences**) (on page 98).
2. Go to **Editor > Syntax Highlight** (on page 195).
3. Select and expand the **XML** section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.
5. Select the **XML** tab in the **Preview** pane to see the effects of your changes.

**Tip:**

Oxygen XML Editor also allows you to specify syntax highlighting colors for specific XML elements and attributes with specific namespace prefixes. This can be done in the **Editor > Syntax Highlight > Elements/Attributes by Prefix** preferences page (on page 195).
NVDL Outline View

The Outline view for NVDL schemas presents a list with the named or anonymous rules that appear in the diagram and it allows for quick access to a rule by name. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

NVDL Schema Component Dependencies View

The Component Dependencies view allows you to see the dependencies for a selected component. This is helpful if you want to see where components are used in the entire hierarchy. For example, if you want to find all the references where a given component is used.

If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

To see the dependencies of an NVDL component:

1. Right-click the desired component in the editor or Outline view.
2. Select the Component Dependencies action from the contextual menu.

The action is available for all named modes.

If a component contains multiple references, a small table is displayed at the bottom of the view that contains all the references. When a recursive reference is encountered, it is marked with a special icon 🍃.

![Component Dependencies View](image)

The Component Dependencies view includes the following toolbar actions:

- **Refresh**
  Refreshes the dependencies structure.

- **Stop**
  Stops the dependency computation.

- **Configure**
Allows you to choose the search scope for computing the dependencies structure. This is helpful for making sure all imported/included resources are computed.

History

Allows you to select from a list of the most recently used dependency computations.

In addition, the following actions are available in the contextual menu:

**Go to First Reference**

Selects the first reference of the currently selected component in the dependencies tree.

**Go to Component**

Shows the definition of the currently selected component in the dependencies tree.

**Searching and Refactoring Actions in NVDL Schemas**

**Search Actions**

The following search actions can be applied on `@name`, `@useMode`, and `@startMode` attributes and are available from the Search submenu in the contextual menu of the current editor or from the Document > References menu:

**Search References**

Searches all references of the item found at current cursor position in the defined scope, if any. If a scope is defined, but the currently edited resource is not part of the range of resources determined by this, a warning dialog box is displayed and you have the possibility to define another search scope.

**Search References in**

Searches all references of the item found at current cursor position in the file or files that you specify when define a scope in the Search References dialog box.

**Search Declarations**

Searches all declarations of the item found at current cursor position in the defined scope if any. If a scope is defined, but the currently edited resource is not part of the range of resources determined by this, a warning dialog box will be displayed and you have the possibility to define another search scope.

**Search Declarations in**

Searches all declarations of the item found at current cursor position in the file or files that you specify when you define a scope for the search operation.

**Search Occurrences in File**

Searches all occurrences of the item at the cursor position in the currently edited file.

The following action is available from the contextual menu and the Document > Schema menu:

**Go to Definition**

Moves the cursor to its definition in the schema used by the NVDL to validate it.
Refactoring Actions

The following refactoring actions can be applied on @name, @useMode, and @startMode attributes and are available from the Refactoring submenu in the contextual menu of the current editor or from the Document > Refactoring menu:

Rename Component

Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the Esc or Enter key on your keyboard.

Rename Component in

Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the Preview button, you can view the files to be affected by the action.

Figure 387. Rename Identity Constraint Dialog Box
Editing JSON Documents

This section explains the features of the Oxygen XML Editor JSON Editor and how to use them.

For more information about JSON editing support, watch this video demonstration:

https://www.youtube.com/embed/wglkagwSDrU

For more information about various JSON tools available in Oxygen XML Editor, watch this video demonstration:

https://www.youtube.com/embed/k3LHBU01GFI

JSON Editor

Oxygen XML Editor includes a specialized JSON editor with various editing features for files that have the json file extension. It also includes a document template to help you get started with JSON documents. The template is called JSON and it can be found in the New Document folder in the New document wizard (on page 335).

Tip:
You can experiment with a sample of a JSON file available at: [OXYGEN-INSTALL-DIR]/samples/json/personal.json.

Text Mode Editor

When editing JSON documents in the Text editing mode, the usual text editing actions (on page 480) are available, along with other editor-specific actions, including:

- Search and Find/Replace (on page 386)
- Drag and Drop (on page 488)
- Validation (on page 1047)
- Format and Indent (Pretty Print) (on page 514)

Note:
You can run XPath expressions on open JSON documents, but in Text mode the XPath results cannot be mapped in the document. However, they can be mapped in the Grid editing mode. You can use the Grid button at the bottom of the editor panel to switch to that editing mode.

Grid Mode Editor

Oxygen XML Editor allows you to view and edit the JSON documents in the Grid mode (on page 321). The JSON is represented in Grid mode as a compound layout of nested tables and the JSON data and structure can be easily manipulated with table-specific operations or drag and drop operations on the grid components.
You can also use the following JSON-specific contextual actions:

**Array**
Useful when you want to convert a JSON *value* to *array*.

**Insert value before**
Inserts a value before the currently selected one.

**Insert value after**
Inserts a value after the currently selected one.

**Append value as child**
Appends a value as a child of the currently selected value.

You can customize the JSON grid appearance *(on page 146)* according to your needs. For instance, you can change the font, the cell background, foreground, or even the colors from the table header gradients. The default width of the columns can also be changed.

**Author Visual Editor**
You can edit JSON files in the visual **Author** editing mode and you have access to the various features and actions that are available when editing XML documents in **Author mode** *(on page 547)*. When a JSON document is opened in **Author** mode, it is automatically converted to proper XML structure using the built-in **JSON to XML Converter** *(on page 1066)*. Additionally, for **Boolean**, **Number**, and **Null** types, an `oxy_Type={[symple_type]}` attribute structure is added in the XML to preserve the type of the value from the JSON document.
You can also create your own custom JSON framework, similar to the process for creating custom XML frameworks. For example, to create a document type association (framework) for JSON documents, you could:

- Add a rule to match the "JSON" as the root local name.
- Add a rule to match the `topProperties` attribute that contains a value that is the name of the properties from the first level of the JSON document.
- Add a rule to match the `schema` attribute that contains a value that is the associated schema from the `$schema` property.

**Note:**
The default JSON framework has the Lowest priority in the Document Type Association preferences page. If you create a custom JSON framework, you need to set it to a higher priority. Otherwise, the Author mode rendering will revert to the default JSON framework.

**Tip:**
You can experiment with some samples of custom JSON frameworks available in the `[OXYGEN-INSTALL-DIR]/samples/json/author/` directory. There is a sample application form called `residentCardForm.json` and a sample travel guide called `travel-guide.json`, along with referenced resources in the images folder.

For more information about the visual editing support for JSON, watch our video demonstration:
Navigating References in JSON Documents

When editing JSON documents (or JSON Schema), you can easily navigate JSON Pointer references and hyperlinks by using the CTRL + Click shortcut. Holding the CTRL key while hovering over a JSON Pointer references or hyperlink will change the reference to a clickable link.

Validating JSON Documents

Oxygen XML Editor includes a built-in JSON validator that is used to validate JSON documents against JSON Schemas, as well as a built-in JSON Well-Formedness validator (based on the free JAVA source code available at www.json.org). A built-in JSON Schematron Validator engine is also provided to validate JSON documents against a specified Schematron schema. Validation for JSON documents works in both Text mode and Author mode.

For more information, see the following video demonstration:

https://www.youtube.com/embed/3JEL6nFUozQ

Checking Well-Formedness in JSON Documents

A Well-formed JSON document is a sequence of Unicode code points that strictly conforms to the JSON grammar defined by the JSON Data Interchange Syntax specification. By default, Oxygen XML Editor automatically checks the document for Well-formedness as you type.

Check for Well-Formedness Manually

To manually check documents for Well-formedness:

- Select the ✔️ Check Well-Formedness (Ctrl + Shift + W (Command + Shift + W on OS X)) action from the ✔️ Validation drop-down menu on the toolbar or from the Document > Validate menu.
- A selection of files can be checked for well-formedness by selecting the ✔️ Check Well-Formedness action from the Validate submenu when invoking the contextual menu in the Project view (on page 368).

Result: If any errors are found, the result is displayed in the message panel at the bottom of the editor. Each error is displayed as one record in the result list and is accompanied by an error message. Clicking the record will open the document containing the error and highlight its approximate location.

Example: A non Well-formed JSON Document

```json
{"person": { "name": "John Doe" }}
```

This would result in the following error:

```
Expected a ',' or '}'
```
To resolve the error, click the record in the result list and it will locate and highlight the approximate position of the error. In this case, you would need to identify where the missing end bracket needs to be placed.

**Validating JSON Documents Against JSON Schema or Schematron**

A *valid* JSON document is a *well-formed* document that also conforms to the rules of a JSON Schema that defines the legal syntax of a JSON document. The purpose of the JSON schema is to define the legal properties and values of a JSON document.

This section contains topics that explain the automatic and manual validation possibilities in Oxygen XML Editor, how validation errors are presented, and information about built-in validation scenarios.

Oxygen XML Editor also includes a built-in JSON Schematron Validator engine to validate JSON documents against a Schematron schema specified in a custom validation scenario or using the Validate with action *(on page 1049).*

**Tip:**

Inside the samples folder, there are a few files you can use to see how Schematron validation can be done with JSON files. The path of the folder containing these sample files is:

```plaintext
[OXYGEN_INSTALL_DIR]/samples/json/schematron/.
```

For information about how to associate a schema for the purposes of validation, see Associating a Schema Through a Validation Scenario *(on page 1055).*

**Automatic Validation**

By default, Oxygen XML Editor is configured to automatically mark validation errors in the JSON document as you are editing. The Enable automatic validation option *(on page 197)* in the Document Checking preferences page *(on page 196)* controls whether or not all validation errors and warnings will automatically be highlighted in the editor pane.

The automatic validation starts parsing the document and marking the errors after a configurable delay *(on page 197)* from the last typed key. Errors are highlighted with underline markers in the main editor pane and small rectangles on the right side ruler. Hovering over a validation error presents a tooltip message with more details about the error.

If the error message is too long to be displayed completely in the error line at the bottom of the editing area, double-clicking the error icon at the left of the error line, or on the error line itself, displays an information dialog box with the full error message. You can use the arrow buttons in this dialog box to navigate through the errors issued by the automatic validation feature.

**Related Information:**

- Manual Validation Actions *(on page 1048)*
- Presenting Validation Errors in JSON Documents *(on page 1049)*
Manual Validation Actions

You can choose to validate JSON documents at any time by using the manual validation actions that are available in Oxygen XML Editor.

Manual Validation Actions

To manually validate the currently edited document, use one of the following actions:

- **Validate (Ctrl + Shift + V (Command + Shift + V on OS X))**
  Available from the * Validation drop-down menu on the toolbar, the Document > Validate menu, or from the Validate submenu when invoking the contextual menu in the Project view (on page 368).

- **Validate with**
  Available from the * Validation drop-down menu on the toolbar or the Document > Validate menu.
  This action opens a dialog box that allows you to specify a schema for validating the current document (on page 1056).

Note:
The Validate with action does not work for files loaded through a custom protocol plugin (on page 2266) developed independently and added to Oxygen XML Editor after installation.

- **Validate with Schema**
  Available from the Validate submenu when invoking the contextual menu in the Project view (on page 368).
  This action opens a dialog box that allows you to specify a JSON or Schematron schema for validating the current document (on page 1056).

Other Validation Options

Tip:
If a large number of validation errors are detected and the validation process takes too long, you can limit the maximum number of reported errors in the Document Checking preferences page (on page 196).

Related Information:
Automatic Validation (on page 1048)
Presenting Validation Errors in JSON Documents (on page 1049)
Presenting Validation Errors in JSON Documents

Validation errors and warnings in JSON documents are presented in various locations within the interface.

Validation Marker Locations

Validation issues are marked in the following locations:

- In the main editing pane, with the issue underlined in a color according to the type of issue.
- In the right-side vertical stripe, with a marker that is colored according to the type of issue.
- In the Outline view, with an icon that is colored according to the type of issue.

Validation Marker Colors

The colors for each type of issue are as follows:

- **Validation Errors** [Red] - By default, the underline in the editing pane, the marker in the right vertical stripe, and the foreground color of the attribute in the Attributes view are colored in red.
- **Validation Warnings** [Yellow] - By default, the underline in the editing pane, the marker in the right vertical stripe, and the foreground color of the attribute in the Attributes view are colored in yellow.
- **Validation Info** [Blue] - By default, the underline in the editing pane, the marker in the right vertical stripe, and the foreground color of the attribute in the Attributes view are colored in blue.

You can configure the color for each type in the Document Checking preferences page (on page 196).

Validation Markers in the Right-Side Stripe

Also, the stripe on the right side of the editor panel is designed to display the issues found during the validation process and to help you locate them in the document. The stripe contains the following:

**Upper Part of the Stripe**

A success indicator square will turn green if the validation is successful or only info messages are found, red if validation errors are found, or yellow if only validation warnings are found. More details about the issues are displayed in a tooltip when you hover over indicator square. If there are numerous problems, only the first three are presented in the tooltip.

**Middle Part of the Stripe**

Errors are presented with red markers, warnings with yellow markers, and info message with blue markers. If you want to limit the number of markers that are displayed, open the Preferences dialog box (Options > Preferences) (on page 98), go to Editor > Document checking, and specify the desired limit in the Maximum number of validation highlights option (on page 196).

Clicking a marker will highlight the corresponding text area in the editor. The validation message is also displayed both in a tooltip (when hovering over the marker) and in the message area on the bottom of the editor panel (clicking the Document checking options button opens the Document Checking preferences page (on page 196).

**Bottom Part of the Stripe**
Two navigation arrows (←) can be used to jump to the next or previous issue. The same actions can be triggered from Document > Automatic validation > Next Error/Highlight (Ctrl + Period (Command + Period on OS X)) and Document > Automatic validation > Previous Error/Highlight (Ctrl + Comma (Command + Comma on OS X)). Also, the Remove All button can be used to clear all the validation markers.

**Hovering Over Validation Issues**

Hovering over a validation issue presents a tooltip message with more details about the problem. Also, when hovering over an issue, pressing F2 will change the focus to the tooltip.

**Details About Validation Issues**

- Information about the issue is also displayed in the message area on the bottom of the editor panel (clicking the Document checking options button opens the Document Checking preferences page (on page 196) where you can configure some validation options (such as the colors used to present the validation issues). Some validation messages have an icon (⚠️) and clicking it opens a dialog box with additional information and a link to specifications.
- If you want to see all the validation messages grouped in the Results view (on page 508), use the Validate action from the toolbar or Document > Validate menu. To see more information about a validation message, right-click the item in the Results view and select Show message. Some validation messages have an icon (⚠️) in the Info column and clicking it opens a dialog box with additional information and a link to specifications.

**Creating a JSON Validation Scenario**

Validation scenarios can be used to associate one or more JSON Schemas with a JSON document (on page 1055). Oxygen XML Editor also includes a built-in JSON Schematron Validator engine that can be specified in the validation scenario to validate JSON documents against a specified Schematron schema.

**Creating a JSON Validation Scenario**

To create a validation scenario, follow these steps:

1. Select the Configure Validation Scenario(s) action in one of the following ways:
   - From the Validation toolbar drop-down menu.
   - From the Document > Validate menu.
   - From the Validate submenu, when invoking the contextual menu on a file in the Project view (on page 368).

   **Step Result:** The Configure Validation Scenario(s) dialog box is displayed.

2. Click the New button.

   **Step Result:** A validation scenario configuration dialog box is displayed.
This scenario configuration dialog box allows you to configure the following information and options:

**Name**

The name of the validation scenario.

**Storage**

You can choose between storing the scenario in the [Project Options](on page 2970) or [Global Options](on page 2967).

**URL of the file to validate**

The URL of the main module that includes the current module. It is also the entry module of the validation process when the current one is validated. To edit the URL, double-click its cell and specify the URL of the main module by doing one of the following:

- Enter the URL in the text field or select it from the drop-down list.
- Use the 🗄️ Browse drop-down button to browse for a local, remote, or archived file.
- Use the ✏️ Insert Editor Variable button to insert an [editor variable](on page 292) or a [custom editor variable](on page 301).
Figure 391. Insert an Editor Variable

```xml
${Desktop} - My Desktop
${start-dir} - Start directory of custom validator
${standard-params} - List of standard params for command line
${fn} - The current file name without extension
${currentFileURL} - The path of the currently edited file (URL)
${fdu} - The path of current file directory (URL)
${frameworks} - Oxygen frameworks directory (URL)
${pdu} - Project directory (URL)
${ oxygen-home} - Oxygen installation directory (URL)
${home} - The path to user home directory (URL)
${proj} - Project name
${env(VAR_NAME)} - Value of environment variable VAR_NAME
${system(var.name)} - Value of system variable var.name
```

File type

The type of the document that is validated in the current validation unit. Oxygen XML Editor automatically selects the file type depending on the value of the URL of the file to validate field.

Validation engine

You can choose between the following types of validation engines for validating JSON documents:

- **Default engine** - The built-in JSON Validator will be used. For JSON Schema documents, this type should not be chosen unless the document has a schema version specified.

- **JSON Schema Validator** - This type is for JSON Schema documents only. It will use the version specified in the JSON Schema, or if a version is not specified, the JSON Schema draft-04 will be used.

- **JSON Schematron Validator** - The built-in JSON Schematron Validator will be used to validation JSON documents against a specified Schematron schema.

**Note:**

For proper error localization, the root element of the Schematron schema should include the `@queryBinding` attribute with the value of `xslt2` after the Schematron namespace declaration:

```xml
<sch:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron" query Binding="xslt2">
```

Automatic validation
If this option is selected, the validation operation defined by this row is also applied by the automatic validation feature (on page 728). If the Automatic validation feature is disabled in the Document Checking preferences page (on page 196), then this option is ignored, as the preference setting has a higher priority.

**Schema**
Displays the specified schema.

**Specify Schema**
Opens the Specify Schema dialog box that allows you to set a schema to be used for validating JSON documents.

**Move Up**
Moves the selected scenario up one spot in the list.

**Move Down**
Moves the selected scenario down one spot in the list.

**Add**
Adds a new validation unit to the list.

**Remove**
Removes an existing validation unit from the list.

3. Configure any of the existing validation units according to the information above. You can use the buttons at the bottom of the table to add, remove, or move validation units.

4. Click OK.

**Result:** The newly created validation scenario will now be included in the list of scenarios in the Configure Validation Scenario(s) dialog box. You can select the scenario in this dialog box to associate it with the current document and click the Apply associated button to run the validation scenario.

**Sharing JSON Validation Scenarios**

The validation scenarios and their settings can be shared with other users by saving them at project level (on page 2970) or by exporting them to a specialized scenarios file (on page 292) that can then be imported. When you create a new validation scenario or edit an existing one, there is a Storage option to control whether the scenarios are stored in Project Options (on page 2970) or Global Options (on page 2967).

**Storage:**
- Project Options
- Global Options

Selecting Project Options (on page 2970) stores the scenario in the project file and can be shared with other users that have access to the project. If your project is saved on a source versioning/sharing system (CVS,
SVN, Source Safe, etc.) then your team will have access to the scenarios that you define. When you create a scenario at the project level, the URLs from the scenario become relative to the project URL.

Selecting Global Options (on page 2967) stores the scenario in the global options that are stored in the user home directory.

You can also change the storage options of existing validation scenarios by using the Change storage action from the contextual menu of the list of scenarios in the Configure Validation Scenario(s) dialog box.

Resolving References with an XML Catalog

If a reference to a remote JSON schema must be used but a local copy of the schema should actually be preferred for performance reasons, the reference can be resolved to the local copy with an XML Catalog (on page 2972).

For example, if the JSON schema contains a reference to a remote schema such as:

```
{"$ref": "http://json-schema.org/example/geo.json"}
```

the reference can be resolved to a local copy of the schema by inserting the following catalog entry:

```
<uri name="http://json-schema.org/example/geo.json" uri="schemas/geo.json"/>
```

Related Information:

Working with XML Catalogs (on page 769)

Associating a Schema to JSON Documents

To provide as-you-type validation and to compute valid proposals for the Content Completion Assistant (on page 2965), Oxygen XML Editor requires a schema to be associated with the JSON document. The schema specifies how the internal structure is defined.

Detecting the Schema(s) for Validation and Content Completion

For validation, Oxygen XML Editor tries to detect the JSON Schema by searching in the following order:

1. The schema referenced in validation stages from the validation scenario(s) (on page 1055) associated with the current JSON document.
2. If a schema is not detected, then it falls back to the schema associated directly in the JSON document (on page 1058).

Tip:

To quickly open the schema used for validating the current document, select the Open Associated Schema action from the toolbar (or Document > Schema menu).
Associating a Schema Through a Validation Scenario

Oxygen XML Editor uses the rules defined in the detected schema to report errors and warnings during automatic and manual validations that help maintain the structural integrity of your JSON documents. Oxygen XML Editor includes built-in validation engines for validating JSON documents against a JSON Schema or Schematron schema. There are several methods that can be used to validate JSON document with a schema.

Configure a Validation Scenario and Specify the Schema

You can specify the schema to be used for validation directly in the JSON validation scenario (on page 1051). To associate a schema to a validation scenario to be used whenever the scenario is invoked, follow these steps:

1. Select the Configure Validation Scenario(s) from the Validation toolbar drop-down menu, from the Document > Validate menu, or from the Validate submenu when invoking the contextual menu on a JSON file in the Project view (on page 368).
2. Click the New button to create a new validation scenario (on page 1051) or the Edit button to modify an existing one.
3. Add or configure validation units according to your needs. For details about all of the configuration options, see Creating a JSON Validation Scenario (on page 1051).
4. Click the Specify Schema button to select the schema to be associated with the validation unit.
5. Click OK on both dialog boxes.

Result: The schema is now associated with that validation scenario whenever it is invoked.

Use the Validate with Action to Specify a Schema for Validating the Current Document

To validate the current document using a specified schema, follow these steps:

1. Select the Validation with action from the Validation drop-down menu on the toolbar (or Document > Validate menu).

Step Result: The Validate with dialog box is displayed:

![Figure 392. Validate with Dialog Box](image)

This dialog box contains the following options:
• **URL** - Allows you to specify or select a URL for the schema. It also keeps a history of the last used schemas. The URL must point to the schema file that can be loaded from the local disk or from a remote server through HTTP(S), FTP(S) or a custom protocol (on page 2281). You can specify the URL by using the text field, the history drop-down, the Insert Editor Variables (on page 292) button, or the browsing actions in the Browse drop-down list.

• **Schema type** - You can select one of the following two types (other types of schema will not work with JSON documents):
  - **JSON** - Used for validating JSON documents against a specified JSON Schema.
  - **Schematron** - Used for validating JSON documents against a specified Schematron schema. You can also select a Schematron phase that you want to use for the validation.

**Note:** For proper error localization, the root element of the Schematron schema should include the `@queryBinding` attribute with the value of `xslt2` after the Schematron namespace declaration:

```
<sch:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron" queryBinding="xslt2">
```

2. Select the schema to be associated with the manual validation.
3. Click **OK**.

**Result:** The current document is validated using the schema you specified.

**Use the Validate with Schema Action to Specify a Schema for Validating all Selected JSON Documents**

To validate multiple JSON documents using a specified schema, follow these steps:

1. Select all the JSON documents you want to validate in the **Project** view.
2. Invoke the contextual menu (right-click) and select the **Validate with Schema** action from the Validate submenu.

**Step Result:** The **Validate with** dialog box is displayed:

**Figure 393. Validate with Dialog Box**
This dialog box contains the following options:

- **URL** - Allows you to specify or select a URL for the schema. It also keeps a history of the last used schemas. The URL must point to the schema file that can be loaded from the local disk or from a remote server through HTTP(S), FTP(S) or a custom protocol ([on page 2281](#)). You can specify the URL by using the text field, the history drop-down, the ✖️ Insert Editor Variables ([on page 292](#)) button, or the browsing actions in the 🌐 Browse drop-down list.

- **Schema type** - You can select one of the following two types (other types of schema will not work with JSON documents):
  - **JSON** - Used for validating JSON documents against a specified JSON Schema.
  - **Schematron** - Used for validating JSON documents against a specified Schematron schema. You can also select a Schematron phase that you want to use for the validation.

**Note:** For proper error localization, the root element of the Schematron schema should include the `@queryBinding` attribute with the value of `xslt2` after the Schematron namespace declaration:

```xml
<sch:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron" queryBinding="xslt2"/>
```

3. Select the JSON schema that you want to use to validate all selected JSON documents.
4. Click OK.

**Result:** The selected JSON documents are validated using the JSON schema you specified.

### Associating a Schema Directly in JSON Documents

#### Associate Schema Action

The schema used by the [Content Completion Assistant ([on page 2965](#))] and document validation engine can be associated with the current document by using the ✖️ Associate Schema action. The association can specify a relative file path or a URL of the schema.

To associate a JSON Schema to the current JSON document, follow these steps:

1. Select the ✖️ Associate Schema action from the toolbar (or Document > Schema menu).

**Step Result:** The Associate Schema dialog box is displayed:
Figure 394. Associate Schema Dialog Box

This dialog box contains the following options for JSON documents:

- **URL** - Allows you to specify or select a URL for the schema. It also keeps a history of the last used schemas. The URL must point to the schema file that can be loaded from the local disk or from a remote server through HTTP(S), FTP(S) or a custom protocol (on page 2281).
- **Use path relative to file location** - Select this option if the JSON instance document and the associated schema contain relative paths. The location of the schema file is inserted in the JSON instance document as a relative file path. This practice allows you, for example, to share these documents with other users without running into problems caused by multiple project locations on physical disk.

2. Select the JSON Schema that will be associated with the JSON document.
3. Click **OK**.

**Result:** A `$schema` property is added at the beginning of the document with its value set to the specified URL. If the document already contained a schema association, the old association will be replaced with the new one.

**Tip:**
To quickly open the schema used for validating the current document, select the Open Associated Schema action from the toolbar (or Document > Schema menu).

### Content Completion Assistant in JSON

Oxygen XML Editor includes an intelligent Content Completion Assistant (on page 2965) that offers proposals for inserting JSON structures that are valid at the current editing location.

The Content Completion Assistant is enabled by default. To disable it, open the Preferences dialog box (Options > Preferences) (on page 98), go to Editor > Content Completion, and deselect the Enable content completion option (on page 182).

Figure 395. Content Completion Assistant in JSON

- `email` - Specifies who is the manager and who are the subordinates for this person.
- `id`
- `link`
- `name`
Content Completion and the Associated Schema

The Content Completion Assistant feature is schema-driven and the list of proposals in the Content Completion Assistant (on page 2965) depend on the associated JSON Schema. For information about ways to associate a schema to a JSON document, see the Associating a Schema to JSON Documents (on page 1055) section.

Using the Content Completion Assistant in JSON

The feature is activated in Text mode for JSON documents by:

- Typing a quote symbol (" ) to insert a property or value.
- Pressing Ctrl + Space (Command + Space on OS X) or Alt + ForwardSlash (Command + Alt + ForwardSlash on OS X).

The feature is activated in Author mode by using the Enter key.

You can navigate through the list of proposals by using the Up and Down keys on your keyboard. In some cases, the Content Completion Assistant displays a documentation window with information about the particular proposal (on page 1060). You can also change the size of the documentation window by dragging its top, right, and bottom borders.

To insert the selected proposal, press Enter or Tab.

Types of Proposals Listed in the Content Completion Assistant for JSON

The proposals that populate the Content Completion Assistant for JSON documents depend on the structure defined in the associated JSON Schema. The types of structure proposed in the content completion window include:

- JSON properties
- JSON values
- JSON arrays
- JSON objects

The number and type of proposals displayed by the Content Completion Assistant is dependent on the cursor’s current position in the JSON document and the child items displayed within a given context are defined by the structure of the specified JSON Schema.

Code Templates in the Content Completion

Oxygen XML Editor includes a set of built-in code templates for JSON documents that can be selected from the Content Completion Assistant. The code templates are displayed with a🎍 symbol in the content completion list. You can also define your own code templates and share them with others. For more information, see Code Templates (on page 496).
Schema Annotations in JSON Content Completion

A schema annotation is a documentation snippet that appears in the Content Completion Assistant (on page 2965) offering more information about the current proposal.

This feature is enabled by default, but you can disable it by deselecting the Show annotations in Content Completion Assistant (on page 187) option in the Annotations preferences page.

Collecting Annotations from the JSON Schema

In a JSON Schema, the annotations are specified in the value of the title and description properties like this:

```
"idType": {
   "title": "The 'id' property",
   "description": "Specifies a required ID for this person.",
   "type": "string",
   "maxLength": 20
}
```

Syntax Highlighting in JSON Documents

Oxygen XML Editor supports syntax highlighting in Text mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for JSON files, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98).
2. Go to Editor > Syntax Highlight (on page 195).
3. Select and expand the JSON section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

You can see the effects of your changes in the Preview pane.

Related Information:

Syntax Highlight Preferences (on page 195)

Folding in JSON

In a large JSON document, the data enclosed in the curly bracket characters {} can be collapsed so that only the needed data remains in focus. The folding features available for XML documents (on page 487) are also available in JSON documents.

JSON Outline View

The Outline view for JSON documents displays the list of all the components of the JSON document you are editing. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.
Outline View Features

The **Outline** view allows you to:

- Quickly navigate through the document by selecting nodes in the **Outline** tree.
- Move elements by dragging them to a new position in the tree structure.
- Highlight elements in the editor area. It is synchronized with the editor area, so when you make a selection in the editor area, the corresponding nodes are highlighted in the **Outline** view, and vice versa.
- View document errors, as they are highlighted in the **Outline** view. A tooltip also provides more information about the nature of the error when you hover over the faulted element.

Outline View Interface

By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

The upper part of the **Outline** view contains a filter box that allows you to focus on the relevant components. Type a text fragment in the filter box and only the components that match it are presented. For advanced usage you can use wildcard characters (such as `*` or `?`) and separate multiple patterns with commas.

It also includes a **Settings** menu in the top-right corner that presents the following options to help you filter the view even further.

**Filter returns exact matches**

The text filter of the **Outline** view returns only exact matches.

**Selection update on cursor move**

Controls the synchronization between **Outline** view and source document. The selection in the **Outline** view can be synchronized with the cursor moves or the changes in the editor. Selecting
one of the components from the **Outline** view also selects the corresponding item in the source document.

**Flat presentation mode of the filtered results**

When active, the application flattens the filtered result elements to a single level.

**Drag and Drop Actions in the Outline View**

Entire JSON properties, objects, and arrays can be moved or copied in the edited document using only the mouse in the **Outline** view with drag-and-drop operations. Several drag and drop actions are possible:

- If you drag a JSON node in the **Outline** view and drop it on another node, then the dragged node will be moved after the drop target.
- If you hold the mouse pointer over the drop target for a short time before the drop then the drop target node will be expanded first and the dragged node will be moved inside the drop target.
- You can also drop a node before or after another node if you hold the mouse pointer towards the upper or lower part of the target. A marker will indicate whether the drop will be performed before or after the target node.
- If you hold down the **Ctrl (Command on OS X)** key after dragging, a copy operation will be performed instead of a move.

**Contextual Menu Actions**

The following actions are available in the contextual menu of the JSON **Outline** view:

- **Cut**
  
  Cuts the currently selected component.

- **Copy**
  
  Copies the currently selected component.

- **Paste**
  
  Pastes the copied component.

- **Delete**
  
  Deletes the currently selected component.

- **Expand More**
  
  Expands the structure of a component in the **Outline** view.

- **Collapse All**
  
  Collapses the structure of all the component in the **Outline** view.

**XSD to JSON Schema Converter**

Oxygen XML Editor includes a tool for converting an XML Schema file (XSD) to a JSON Schema file. The **XSD to JSON Schema** action for invoking the tool can be found in the **Tools > JSON Tools** menu. It requires an
additional add-on to be installed, so the first time you invoke the action, Oxygen XML Editor will present a dialog box asking if you want to install it. Once installed, you need to restart Oxygen XML Editor and the XSD to JSON Schema action will invoke the tool.

To convert an XML Schema (XSD) to a JSON Schema, follow these steps:

1. Select the XSD to JSON Schema action from the Tools > JSON Tools menu.

   **Step Result:** The XSD to JSON Schema dialog box is displayed:

   ![Figure 397. XSD to JSON Schema Dialog Box](image)

2. In the XSD URL field, choose or enter the URL of the XML Schema document. The conversion supports XSD versions 1.0 and 1.1.

3. In the Output file field, choose the path for the resulting output file.

4. For the JSON Schema version option, choose the version of the resulting JSON schema. The possible choices are: Draft 4, Draft 6, Draft 7, and Draft 2019-09.

5. [Optional] If you select the Restrict additional content option, then additionalProperties (for objects) and additionalItems (for arrays) will be set to false in the resulting schema. By default, these keys are not in the schema, meaning that providing additional content (according to the schema) is allowed.

6. [Optional] You can select the Preserve case of names from the XSD option if you want the names from the XSD to remain unchanged in the resulting JSON Schema. Otherwise, the default JAXB naming algorithm will be applied (for example, "some.nAMe" is changed to "SomeNAMe", or "Some_oth3r_name" is changed to "SomeOth3RName").

7. [Optional] You can select the Open in Editor option to open the resulting JSON Schema document in the main editing pane.

8. Click the Convert button.

   **Result:** The original XSD document is now converted to a JSON Schema document. The resulting JSON Schema will be the specified draft and will contain:

   - The $id of the schema, generated from XSD targetNamespace.
   - The $definitions section, which declares complex and enum types.
   - The anyOf section, which lists possible top-level elements as an array of objects.
Other Possible Results:

- If an XSD type extends another type, then its schema is combined with the schema of the base type using the `allOf` keyword.
- If an extension in XSD defines an element with the same name as an attribute in the base, a property named `rest` is generated to avoid name conflicts in JSON.
- If a property of a complex type is a collection property, the schema of the collection items will be wrapped in the JSON array schema.

Conversion Mappings

The following table lists the specific conversion mapping details.

<table>
<thead>
<tr>
<th>XML Schema Type</th>
<th>JSON Schema Representation</th>
</tr>
</thead>
<tbody>
<tr>
<td>anySimpleType</td>

</tbody>
</table>

**Conversion Limitations**

In most cases, the conversion creates an equivalent schema, but there are some limitations:

- Restrictions/facets are not taken into consideration when converting (*fractionDigits*, *pattern*, *totalDigits*, *whiteSpace*, *minInclusive*, *maxInclusive*, and the restrictions for length, except *enumeration*). However, extensions and indicators are properly converted (*minOccurs*, *maxOccurs*, *group*, *sequence*, *choice*).
- The `<documentation>` element is not converted into `<description>`.
- The `@substitutionGroup` attribute for an element that has no declared type becomes a reference to the element that can substitute it.
- The `@block` attribute is not taken into consideration during the conversion.
Online JSON to XML Converter

Attention:

For a simple ONLINE tool for converting a single JSON file to XML, or vice versa, go to: https://www.oxygenxml.com/xml_json_converter.html.

Converting JSON to XML in Oxygen

Oxygen XML Editor includes a useful and simple tool for converting JSON files to XML. The JSON to XML action for invoking the tool can be found in the Tools > JSON Tools menu.

To convert a JSON document to XML, follow these steps:

1. Select the JSON to XML action from the Tools > JSON Tools menu.

   The JSON to XML dialog box is displayed:

   ![Figure 398. JSON to XML Dialog Box](image)

   - Choose or enter the Input URL of the JSON document.
   - Choose the path of the Output file that will contain the resulting XML document.
   - Select the Open in Editor option to open the resulting XML document in the main editing pane.
   - Click the Convert button.

Result: The original JSON document is now converted to an XML document.
Conversion Details

- If the JSON document has more than one property on the first level, the converted XML document will have an additional root element called `<JSON>`.

For example, the following JSON document:

```json
{
  "personnel": {
    "person": [
      {
        "name": "Boss"
      },
      {
        "name": "Worker"
      }
    ],
    "id": "personnel-id"
  }
}
```

it is converted to:

```xml
<?xml version="1.0" encoding="UTF-8"?>

<JSON>
  <personnel>
    <person>
      <name>Boss</name>
    </person>
  </personnel>
</JSON>
```
• If the JSON document is an array, the converted XML document will have a root element called `<array>` and for each item within the array, another `<array>` is created.

```json
[
  {
    "name": "Boss",
  },
  {
    "name": "Worker"
  }
]
```

it is converted to:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<array>
  <array>
    <name>Boss</name>
  </array>
  <array>
    <name>Worker</name>
  </array>
</array>
```

• If the name of a JSON property contains characters that are not valid in XML element names (for example, `$`), then the invalid characters will be escaped as its hexadecimal equivalent in the converted XML.

```json
{"$id": "personnel-id"}
```

is converted to:

```xml
<_X24_id>personnel-id/_X24_id
```

Related Information:

**XML to JSON Converter**

**Online XML to JSON Converter**

**Attention:**

For a simple ONLINE tool for converting a single XML file to JSON, or vice versa, go to: [https://www.oxygenxml.com/xml_json_converter.html](https://www.oxygenxml.com/xml_json_converter.html).
Converting XML to JSON in Oxygen

Oxygen XML Editor includes a useful and simple tool for converting XML files to JSON. The XML to JSON action for invoking the tool can be found in the Tools > JSON Tools menu.

To convert an XML document to JSON, follow these steps:

1. Select the XML to JSON action from the Tools > JSON Tools menu.
   
   **Step Result:** The XML to JSON dialog box is displayed:

   ![XML to JSON Dialog Box](image)

2. Choose or enter the Input URL of the XML document.
3. Choose the path of the Output file that will contain the resulting JSON document.
4. Select the Open in Editor option to open the resulting JSON document in the main editing pane.
5. Click the Convert button.

**Result:** The original XML document is now converted to a JSON document.
Conversion Details

- Some XML components are ignored (e.g. comments and processing instructions).
- If any elements contain attributes in the XML document, the attributes are converted to properties in the converted JSON document. If the XML document contains more than one element with the same name, they will be converted into an array of object in the converted JSON document.

For example, the following XML document:

```xml
<personnel>
    <person id="person.one">
        <name>Boss</name>
    </person>

    <person id="person.two">
        <name>Worker</name>
    </person>
</personnel>
```

it is converted to:

```json
{
    "personnel": {
        "person": [
            {
                "id": "person.one",
                "name": "Boss"
            },
            {
                "id": "person.two",
                "name": "Worker"
            }
        ]
    }
}
```
• If the XML document contains elements with mixed content (text plus elements), the converted JSON document will contain a `#text` property with its value set as the text content. If there are multiple text nodes, the subsequent `#text` properties will contain a number (e.g. `#text1`, `#text2`). If there are multiple elements with the same name, the first property will have the element name and the subsequent properties will contain a number (e.g. `b`, `b#1`, `b#2`).

```xml
<p>This <b>is</b> an <b>example</b>!</p>
```

is converted to:

```json
{  "p": {    "#text": "This ",    "b": "is",    "#text1": " an ",    "b#1": "example",    "#text2": "!"  }
}
```

• If the XML document contains element names that contains hexadecimal codes (for example, if they were escaped during a JSON to XML conversion (on page 1066)), it will be converted to the normal character value in the converted JSON document.

```xml
<_X24_id>personnel-id</_X24_id>
```

is converted to:

```json
{"$id": "personnel-id"}
```

**JSON to YAML Converter**

**Converting JSON to YAML in Oxygen**

Oxygen XML Editor includes a useful and simple tool for converting JSON files to YAML. The **JSON to YAML** action for invoking the tool can be found in the **Tools > JSON Tools** menu.
To convert a JSON document to YAML, follow these steps:

1. Select the **JSON to YAML** action from the **Tools > JSON Tools** menu. The **JSON to YAML** dialog box is displayed:

   ![JSON to YAML Dialog Box](image)

2. Choose or enter the **JSON URL** for the document you want to convert.
3. Choose the path of the **Output file** that will contain the resulting YAML document.
4. [Optional] Select the **Open in Editor** option to open the resulting YAML document in the main editing pane.
5. Click the **Convert** button.

**Result:** The original JSON document is now converted to a YAML document.

**Related Information:**

- YAML to JSON Converter *(on page 1073)*

---

**YAML to JSON Converter**

**Converting YAML to JSON in Oxygen**

Oxygen XML Editor includes a useful and simple tool for converting YAML files to JSON. It even works on files that consist of multiple YAML documents, each separated by three dashes (---), in which case the conversion creates multiple JSON files with a number in the name.

The **YAML to JSON** action for invoking the tool can be found in the **Tools > JSON Tools** menu.

To convert a YAML document to JSON, follow these steps:

1. Select the **YAML to JSON** action from the **Tools > JSON Tools** menu. The **YAML to JSON** dialog box is displayed:
2. Choose or enter the YAML URL for the document you want to convert.
3. Choose the path of the Output file that will contain the resulting JSON document.
4. [Optional] Select the Open in Editor option to open the resulting JSON document in the main editing pane.
5. Click the Convert button.

Result: The original YAML document is now converted to a JSON document.

Related Information:
JSON to YAML Converter (on page 1072)

Generating Sample JSON Files
Oxygen XML Editor includes a tool for generating sample JSON files. To generate sample JSON files from a JSON Schema, select Generate Sample JSON Files from the Tools > JSON Tools menu. The action opens a dialog box where you can configure a variety of options for generating the files.
The **Generate Sample JSON Files** dialog box includes the following fields and options:

**Schema URL**

The URL of the Schema location. You can specify the path by using the text field, the history drop-down menu, or the browsing actions in the **Browse** drop-down list.

**Associate schema in the document**

If enabled, the specified schema will be associated with the generated files.

**Output folder**

Path to the folder where the generated JSON instances will be saved.

**File name**

The name of the instance(s) that will be generated. By default, `instance.json` is used.

**Number of instances**

The desired number of JSON instances to be generated. When more than one instance is generated, the index of the instance will be added to its file name.

**Property value**

You can specify the way the values of the properties are generated. The following options are available:
- **None** - Assigns empty values for properties (a template file will be generated). This is the default value.
- **Default** - Assigns the name of the property as the value (for strings) or assigns the specified minimum value (for numbers).
- **Random** - Assigns random values according to schema restrictions.

### Generate optional properties

If selected, the JSON instance will be generated with optional properties that are defined in the JSON schema. Otherwise, only the required properties will be generated.

### Generate additional content

If selected, the JSON instance will be generated with additional properties that are defined in the JSON schema as `additionalProperties` and additional items that are defined as `additionalItems` (in the case of an Array).

### Choice strategy

You can specify the way an instance will be generated from a schema that contains a `CombinedSchema` (with either `oneOf` or `anyOf`). The following options are available:

- **First** - The first defined schema in `oneOf` or `anyOf` will be used.
- **Random** - A random schema defined in `oneOf` or `anyOf` will be used.

### Recursion level

This option controls the maximum allowed depth (must be a number), in case the selected schema contains recursive calls of `$ref` schemas referencing one another. By default, it is set to 1, meaning that the generation for the recursive calls will stop after the first iteration.

### Open first instance in editor

If selected, the first generated instance is opened in the editor.

You can click **OK** at any point to generate the sample JSON files.

### Contextual Menu Actions in JSON Documents

When editing JSON documents, Oxygen XML Editor provides the following actions in the contextual menu:

- **Cut, Copy, Paste**

  Executes the typical editing actions on the currently selected content.

- **Copy JSON Pointer**

  Creates a *JSON Pointer* at the current cursor location and copies the expression that denotes the JSON pointer to the system clipboard.

- **Copy XPath**

  Copies the XPath expression of the current property from the current editor to the clipboard.

- **Go to Matching Bracket** (*Ctrl + Shift + G* (Command + Shift + G on OS X))
Moves the cursor to the end bracket that matches the start bracket, or vice versa.

Source submenu

This submenu includes the following actions:

**To Lower Case**

Converts the content selection to lower case characters. This works with contiguous and multiple selections.

**To Upper Case**

Converts the selected content to upper case characters. This works with contiguous and multiple selections.

**Capitalize Lines**

It capitalizes the first letter found on every new line that is selected. Only the first letter is affected, the rest of the line remains the same. If the first character on the new line is not a letter then no changes are made.

**Convert Hexadecimal Sequence to Character (Ctrl + Shift + X (Command + Shift + X on OS X))**

Converts a sequence of hexadecimal characters to the corresponding Unicode character (on page 427). The action can be invoked if there is a selection containing a valid hexadecimal sequence or if the cursor is placed at the right side of a valid hexadecimal sequence. A valid hexadecimal sequence can be composed of 2 to 4 hexadecimal characters and may or may not be preceded by the 0x or 0X prefix. Examples of valid sequences and the characters they will be converted to:

- \(0x0045\) will be converted to \(E\)
- \(0X0125\) to \(ĥ\)
- 265 to \(ɥ\)
- 2190 to \(←\)

**Note:**

For more information about finding the hexadecimal value of a character, see Finding the Decimal, Hexadecimal, or Character Entity Equivalent (on page 430).

**Base64 Encode/Decode submenu**

This submenu include the following actions for encoding or decoding base 64 schemes:

**Import File to Encode and Insert**

Encodes a file and then inserts the encoded content into the current document at the cursor position.
Decode Selection and Export to File

Decodes a selection of text from the current document and then exports (saves) the result to another file.

Encode Selection

Replaces a selection of text with the result of encoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the Encoding for Base64, Base32, Hex conversions option in the Encoding preferences page (on page 141) will be used. Likewise, the same is true if the Show the dialog box for choosing the encoding for Base64, Base32, Hex conversions option is not selected in the Messages preference page (on page 277).

Decode Selection

Replaces a selection of text with the result of decoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the Encoding for Base64, Base32, Hex conversions option in the Encoding preferences page (on page 141) will be used. Likewise, the same is true if the Show the dialog box for choosing the encoding for Base64, Base32, Hex conversions option is not selected in the Messages preference page (on page 277).

Modify All Matches

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

Base32 Encode/Decode submenu

This submenu include the following actions for encoding or decoding base32 schemes:

Import File to Encode and Insert

Encodes a file and then inserts the encoded content into the current document at the cursor position.

Decode Selection and Export to File
Decodes a selection of text from the current document and then exports (saves) the result to another file.

**Encode Selection**

Replaces a selection of text with the result of encoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the **Encoding for Base64, Base32, Hex conversions** option in the Encoding preferences page (on page 141) will be used. Likewise, the same is true if the **Show the dialog box for choosing the encoding for Base64, Base32, Hex conversions** option is not selected in the Messages preference page (on page 277).

**Decode Selection**

Replaces a selection of text with the result of decoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the **Encoding for Base64, Base32, Hex conversions** option in the Encoding preferences page (on page 141) will be used. Likewise, the same is true if the **Show the dialog box for choosing the encoding for Base64, Base32, Hex conversions** option is not selected in the Messages preference page (on page 277).

**Modify All Matches**

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

**Hex Encode/Decode submenu**

This submenu includes the following actions for encoding or decoding hex schemes:

**Import File to Encode and Insert**

Encodes a file and then inserts the encoded content into the current document at the cursor position.

**Decode Selection and Export to File**

Decodes a selection of text from the current document and then exports (saves) the result to another file.
Encode Selection

Replaces a selection of text with the result of encoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the Encoding for Base64, Base32, Hex conversions option in the Encoding preferences page (on page 141) will be used. Likewise, the same is true if the Show the dialog box for choosing the encoding for Base64, Base32, Hex conversions option is not selected in the Messages preference page (on page 277).

Decode Selection

Replaces a selection of text with the result of decoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the Encoding for Base64, Base32, Hex conversions option in the Encoding preferences page (on page 141) will be used. Likewise, the same is true if the Show the dialog box for choosing the encoding for Base64, Base32, Hex conversions option is not selected in the Messages preference page (on page 277).

Modify All Matches

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

Join and Normalize Lines (Ctrl + J (Command + J on OS X))

For the current selection, this action joins the lines by replacing the line separator with a single space character. It also normalizes the whitespaces by replacing a sequence of such characters with a single space.

Insert new line after (Ctrl + Alt + Enter (Command + Alt + Enter on OS X))

This action has the same result as moving the cursor to the end of the current line and pressing the ENTER key.

Modify All Matches

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are
found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

Go to Definition

Navigates to the definition of the current property.

Open submenu

The following actions are available in this submenu:

Open File at Cursor

Opens the file at the cursor position in a new panel. If the file path represents a directory path, it will be opened in system file browser. If the file at the specified location does not exist, an error dialog box is displayed and it includes a Create new file button that starts the New document wizard. This allows you to choose the type or the template for the file. If the action succeeds, the file is created with the referenced location and name and is opened in a new editor panel. If the file is an image file, it will be opened in the Image Preview pane (on page 432).

Open File at Cursor in System Application

Opens the file (identified by its link) or web page (identified by a web link) found at the cursor position. The target is opened in the default system application associated with that file type.

Compare

Opens the current file in the Compare Files tool (on page 437).

Transforming and Querying JSON Documents

Oxygen XML Editor provides the ability to transform JSON documents to XML or HTML through XSLT or XQuery processing. You also have access to some powerful tools for querying JSON through XPath expressions or XQuery.

For more information about transforming and querying in JSON, watch our video demonstration:

https://www.youtube.com/embed/1LHoMhEFagA

Transforming JSON Documents with XSLT

It is possible to transform JSON documents through XSLT processing. To do so, follow these steps:

1. Create an XSLT 3.0 stylesheet that has the xsl:initial-template. You can use one of the following two templates available in the New Document Wizard.
   - **XSLT Stylesheet for JSON** - Processes a JSON document by using a json-doc() function and matches the JSON properties from the JSON map.
   - **XSLT Stylesheet for JSON to XML** - Processes a JSON document by using a json-to-xml() function and matches the converted XML content.

2. Create a new XSLT transformation scenario for your stylesheet.
3. Reference the JSON document that you want to transform using one of these two methods:
   - In the transformation scenario, click the **Parameters** button in the **XSLT** tab and add a parameter that specifies the URL to your JSON document in its value. For example, if you are transforming one of the built-in templates mentioned above, the `input` parameter is added by default and you could specify the URL in its value.
   - Specify the URL to your JSON document in the stylesheet you created. For example, if you use one of the built-in templates mentioned above, you would specify the URL in the value of the `input` parameter (in the `xsl:param` element).

4. Run the transformation.

**Tip:**
There are some sample files in the `[OXYGEN_INSTALL_DIR]/samples/json/transform` folder that can be used to transform a JSON document to XML or HTML.

**Related Information:**
- Blog: Transforming JSON
- XSLT Functions on JSON Data

**Transforming JSON Documents with XQuery**

It is possible to transform JSON documents through XQuery processing. To do so, follow these steps:

2. Create a new **XQuery transformation** scenario for your XQuery file.
3. Reference the JSON document that you want to transform using one of these two methods:
   - In the transformation scenario, click the **Parameters** button in the **XQuery** tab and add a parameter that specifies the URL to your JSON document in its value.
   - Specify the URL to your JSON document in the XQuery file you created.

4. Run the transformation.

**Tip:**
There is a sample XQuery file in the `[OXYGEN_INSTALL_DIR]/samples/json/transform` folder that can be used to transform a JSON document.

**Querying JSON Documents with XPath or XQuery**

Oxygen XML Editor provides an XPath toolbar that makes it easy to quickly query JSON documents using XPath expressions. You can also use the dedicated **XPath/XQuery Builder** view that allows you to compose more complex XPath or XQuery expressions and execute them over JSON documents in **Text** or **Author** mode.
XPath Toolbar

When an XPath expression is run over a JSON document, the document is converted to XML and the XPath is executed over the converted XML document. For more information about this toolbar, see XPath Toolbar (on page 1852).

Figure 405. XPath Toolbar for JSON

XPath/XQuery Builder View

You can also use the XPath/XQuery view to run XPath and XQuery expressions over a JSON document. For XQuery, you need to reference the JSON document in your XQuery content. For more information about this view, see XPath Builder View (on page 1854).

Figure 406. XPath/XQuery Builder View for JSON
Details About Querying JSON Documents Using XPath Expressions

To execute XPath expressions over a JSON document, the document is converted to XML and the XPath is executed over the converted XML document. For this conversion, Oxygen XML Editor uses the built-in JSON to XML Converter tool (on page 1066). The results are mapped back to the original JSON document.

For example, if you have the following JSON document:

```json
{
    "personnel": {
        "person": [
            {
                "name": "Boss"
            },
            {
                "name": "Worker"
            }
        ],
        "id": "personnel-id"
    }
}
```

and you want to match the name of the second person, the XPath expression would look like this:

```
/JSON/personnel/person[2]/name
```

The reason why the first element is `JSON` is because if the JSON document contains more than one property on the first level, the converted XML document will have an additional root element called `<JSON>`. For more information, see JSON to XML Conversion Details (on page 1068).

The `[2]` in the expression represents the index of the `person` in the array and in this case, it matches the second `person` because the index counting starts with 1.

Editing JSON Schema Documents

The purpose of the JSON schema is to define the legal properties and values of a JSON document to keep it valid and well-formed. When editing JSON Schema, all of the same features in the JSON editor (on page 1044) are available.

Text Mode Editor

When editing JSON Schema documents in Text editing mode, the usual text editing actions (on page 480) are available, along with other editor-specific actions, including:

- Search and Find/Replace (on page 386)
- Drag and Drop (on page 488)
- Validation (on page 1047)
- Format and Indent (Pretty Print) (on page 514)

Author Visual Editor

It is also possible to edit JSON files in the visual Author editing mode. Oxygen XML Editor uses a specific CSS for rendering JSON Schema documents in Author mode and you have access to the various features and actions that are available when editing XML documents in Author mode (on page 547).
New Document Templates
Oxygen XML Editor includes a new document template to help you get started creating a JSON Schema document. The template is called JSON Schema and it can be found in the New Document folder in the New document wizard (on page 335). You can also customize your own JSON Schema templates (on page 344) and specify other versions (draft 04, 06, or 07).

Tip:
You can experiment with a sample of a JSON Schema file available at: [OXYGEN-INSTALL-DIR]/samples/json/personal-schema.json.

JSON Schema Validation
For information about using a JSON Schema to validate documents, see Validating JSON Documents Against JSON Schema or Schematron (on page 1048).
For information about how to associate a JSON schema for the purposes of validation, see Associating a Schema Through a Validation Scenario (on page 1055).

Validating JSON Schema Documents
A valid JSON Schema document is a well-formed document that also conforms to the JSON meta-schema rules that defines the legal syntax of a JSON Schema document.

If a JSON document includes a meta-schema URL in the document root with the "$schema" key, the file will be validated as a JSON Schema against the specified meta-schema.

Quick Reference

• If there is a "$schema": "http://json-schema.org/draft-04/schema" property in the schema root, then Draft 4 will be used.
• If there is a "$schema": "http://json-schema.org/draft-06/schema" property in the schema root, then Draft 6 will be used.
• If there is a "$schema": "http://json-schema.org/draft-07/schema" property in the schema root, then Draft 7 will be used.
• If there is a "$schema": "http://json-schema.org/draft/2019-09/schema" property in the schema root, then a Draft 7 compatibility mode will be used.
• If there is a "$schema" property in the schema root, but with a different draft value, then an error will be displayed ("no meta-schema is known with URI").
• If none of these are found, then it is validated as a simple JSON instance.
• You could also select the JSON Schema Validator in a JSON validation scenario (on page 1051) and it will use the version specified in the JSON Schema, or if a version is not specified, the JSON Schema draft-04 will be used.

For information about how to associate a JSON schema for the purposes of validation, see Associating a Schema Through a Validation Scenario (on page 1055).
Generating JSON Schema from a JSON File

Oxygen XML Editor includes a tool for generating a sample JSON Schema from a JSON file. To generate a sample JSON Schema, select Generate JSON Schema from the Tools > JSON Tools menu. The action opens a dialog box where you can configure some options for generating the JSON Schema.

**Figure 407. Generate JSON Schema Dialog Box**

The Generate JSON Schema dialog box includes the following fields and options:

**JSON Document URL**

The URL of the JSON file. You can specify the path by using the text field, the history drop-down menu, or the browsing actions in the Browse drop-down list.

**Output JSON Schema**

The path to the folder where the generated JSON Schema will be saved.

**JSON Schema version**

The version of the resulting JSON schema. The possible choices are: Draft 4, Draft 6, Draft 7, and Draft 2019-09.

**Extract matching format for strings**

If selected, the generator will attempt to find a format that matches the string values from the JSON Document.

**Add default values for simple types**

If selected, the default values (0 for number, "" for string, false for boolean) and examples for strings will be added.

**Restrict additional content**

If selected, additionalProperties (for objects) and additionalItems (for arrays) will be set to false in the resulting schema. By default, these keys are not in the schema, meaning that providing additional content (according to the schema) is allowed.
Open in Editor

If selected, the generated JSON Schema is opened in the editor.

You can click **Generate** at any point to generate the JSON Schema.

**Generating JSON Schema Documentation**

Oxygen XML Editor includes a tool for generating documentation for a JSON Schema file in HTML format. To generate JSON Schema documentation, select **JSON Schema Documentation** from the **Tools > Generate Documentation** menu. You can also open the tool by using the **Generate Documentation** toolbar button. This opens a dialog box where you can specify the location of the JSON Schema file and HTML output file.

This tool requires an additional add-on to be installed, so the first time you invoke the action, Oxygen XML Editor presents a dialog box asking if you want to install it. Once installed, you need to restart Oxygen XML Editor and the **JSON Schema Documentation** action will invoke the tool.

![Figure 408. JSON Schema Documentation Dialog Box](image)

The **JSON Schema Documentation** dialog box includes the following fields and options:

**JSON Schema URL**

The URL of the JSON Schema file. You can specify the path by using the text field, the history drop-down menu, or the browsing actions in the **Browse** drop-down list.

**Output file**

The path to the folder where the generated HTML file will be saved.

**Split output into multiple files**

If selected, the application splits the output into multiple files. You can choose between splitting them by **component** name or **location**.

**Open in Browser/System Application**
If selected, the generated result is opened in the system application associated with the output file type (HTML).

**Included component details**

This section can be used to specify whether or not the following components are shown in the generated documentation:

- **Annotations** - Displays the annotations (title, description) for each component (property or definition).
- **Constraints** - Displays the schema constraints for each component, according to its type.
- **Source** - Displays the text schema source for each component.
- **Location** - Displays the schema location for each component.
- **Used By** - Displays the list of all the components that reference the current definition.
- **Properties** - Displays the `properties` of an Object Schema.
- **Pattern Properties** - Displays the `patternProperties` of an Object Schema.
- **Enumerations** - Displays the enumerated values, if specified in the schema.

You can click **Generate** at any point to generate the JSON Schema documentation.

**Generated JSON Schema Documentation in HTML Format**

After generating the JSON Schema documentation, it is presented in a visual diagram style with various sections, hyperlinks, and options.
The generated documentation includes a Table of Contents on the left pane with links to particular sections in the right pane. You can collapse or expand details by using the Showing options or the Collapse or Expand buttons.

### Editing YAML Documents

Oxygen XML Editor includes a specialized YAML editor with various editing features for files that have the yaml/yml file extension. It includes the usual text editing actions (on page 480), syntax highlighting (on page 1091), automatic validation (on page 1090), and formatting and indenting (on page 1090). Oxygen XML Editor also includes a document template to help you get started with YAML documents. The template is called YAML and it can be found in the New Document folder in the New document wizard (on page 335).

**Tip:**

You can experiment with a sample of a YAML file available at: [OXYGEN-INSTALL-DIR]/samples/yaml/personal.yaml.
Format and Indent YAML Documents

Oxygen XML Editor includes support for formatting and indenting YAML documents. You can trigger a format and indent operation for your YAML document using the `Format and Indent` toolbar button.

Some of the formatting actions that are performed include:

- Indents the document with the indent size specified in the Editor > Format preferences page (on page 173).
- Removes empty lines and extra spaces between keys and values.
- Compacts the string values (for example, `description`) and limits it to 80 characters on a row.

To batch format/indent multiple YAML files, select and right-click the files in the Project view, then select `Format and Indent Files`.

Validating YAML Documents

Automatic Validation

Oxygen XML Editor includes built-in validation engine for YAML documents to help you keep them well-formed. YAML documents are validated automatically as you type and the validation engine detects syntax errors (such as improper indentation or duplicate keys), based upon the YAML specification. The built-in validation also works on files that consist of multiple YAML documents.

Manual Validation Actions

To manually validate the currently edited YAML document, use one of the following actions:

- **Validate** (Ctrl + Shift + V (Command + Shift + V on OS X))
  Available from the **Validation** drop-down menu on the toolbar, the Document > Validate menu, or from the Validate submenu when invoking the contextual menu in the Project view (on page 368). This action validates the document based upon the YAML specification.

- **Check Well-Formedness** (Ctrl + Shift + W (Command + Shift + W on OS X))
  Available from the **Validation** drop-down menu on the toolbar, the Document > Validate menu, or from the Validate submenu when invoking the contextual menu in the Project view (on page 368). This action checks the document for syntax errors to make sure it is well-formed.

Batch Validation

The built-in validation engine can also be used to batch validation multiple YAML files at once. This can be done by selecting multiple files in the Project view, right-click, and select Validate > **Check Well-
**Formedness or Validate > Validate.** This will automatically validate the selected files using the built-in YAML validation engine, based upon the YAML specification.

**Syntax Highlighting in YAML Documents**

Oxygen XML Editor supports syntax highlighting in **Text** mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for YAML files, follow these steps:

1. Open the Preferences dialog box (**Options > Preferences**) (*on page 98*).
2. Go to **Editor > Syntax Highlight** (*on page 195*).
3. Select and expand the **YAML** section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

You can see the effects of your changes in the **Preview** pane.

**Related Information:**

Syntax Highlight Preferences (*on page 195*)

**Editing StratML Documents**

Strategy Markup Language (StratML) is an XML vocabulary and schema for strategic plans. Oxygen XML Editor supports StratML Part 1 (Strategic Plan) and StratML Part 2 (Performance Plans and Reports) and provides templates for the following documents:

- **Strategic Plan** (StratML Part 1)
- **Performance Plan** (StratML Part 2)
- **Performance Report** - (StratML Part 2)
- **Strategic Plan** - (StratML Part 2)

You can view the components of a StratML document in the **Outline view** (*on page 498*). Oxygen XML Editor implements a default XML with XSLT transformation scenario for this document type, called StratML to HTML.

**Editing XLIFF Documents**

XLIFF (XML Localization Interchange File Format) is an XML-based format that was designed to standardize the way multilingual data is passed between tools during a localization process. Oxygen XML Editor provides the following support for editing XLIFF documents:

- **XLIFF Version 1.2, 2.0, and 2.1 Support:**
  - New document templates for XLIFF documents.
  - A default CSS file (**xliff.css**) used for rendering XLIFF content in **Author** mode is stored in 
    \[OXYGEN\_INSTALL\_DIR]/frameworks/xliff/css/.
• Validation and content completion support using local catalogs. The default catalog (catalog.xml) for version 1.2 is stored in \[OXYGEN_INSTALL_DIR\]/frameworks/xliff/schemas/1.2, for version 2.0 in \[OXYGEN_INSTALL_DIR\]/frameworks/xliff/schemas/2.0, and for version 2.1 in \[OXYGEN_INSTALL_DIR\]/frameworks/xliff/schemas/2.1.

**XLIFF Version 2.0 and 2.1 Enhanced Support:**

Support for validating XLIFF 2.0 and 2.1 documents using modules. For version 2.0, the default modules are stored in \[OXYGEN_INSTALL_DIR\]/frameworks/xliff/schemas/2.0/modules and for version 2.1, they are stored in \[OXYGEN_INSTALL_DIR\]/frameworks/xliff/schemas/2.1.

**Editing XLIFF Documents in Author Mode**

By default, when you create a new XLIFF document from a template (on page 335), Oxygen XML Editor opens it in Text mode. Aside from the normal editing features found in Text mode, you can also switch to Author mode where Oxygen XML Editor offers some special form controls specifically for XLIFF documents. These form controls simply allow you to add or edit XLIFF attribute values and content in a visual mode.

For XLIFF version 2.0 and 2.1 documents, you can also change the style of the visual editing mode. The Styles drop-down menu on the toolbar offers the following styles that are specifically designed to render XLIFF 2.0 and 2.1 documents in Author mode:

- Default
- Classic
- Translate

**Editing JavaScript Documents**

This section explains the features of the Oxygen XML Editor JavaScript Editor and how you can use them.

**JavaScript Editing Actions**

Oxygen XML Editor allows you to create and edit JavaScript files and assists you with useful features such as syntax highlight, content completion, and outline view. To enhance your editing experience, you can select entire blocks (parts of text delimited by brackets) by double-clicking somewhere inside the brackets.
Figure 410. JavaScript Editor Text Mode

```javascript
function change_sides(front) {
    switch ($('#version-switch').text()) {
        case 'Original':
            $('#holder').html($('#div .original[id]').html());
            make_clickable();
            $('#version-switch').text('Translation 1');
            break;
        case 'Translation 1':
            $('#holder').html($('#div .translation[id]').filter(':first').html());
            $('#version-switch').text('Translation 2');
            break;
        case 'Translation 2':
            $('#holder').html($('#div .translation[id]').filter(':last').html());
            $('#version-switch').text('Original');
            break;
    }
}
```

The contextual menu of the JavaScript editor offers the following actions:

**Cut**

Allows you to cut fragments of text from the editing area.

**Copy**

Allows you to copy fragments of text from the editing area.

**Paste**

Allows you to paste fragments of text in the editing area.

**Toggle Comment**

Allows you to comment a line or a fragment of the JavaScript document you are editing. This option inserts a single comment for the entire fragment you want to comment.

**Toggle Line Comment**

Allows you to comment a line or a fragment of the JavaScript document you are editing. This option inserts a comment for each line of the fragment you want to comment.

**Go to Matching Bracket**

Use this option to find the closing, or opening bracket, matching the bracket at the cursor position. When you select this option, Oxygen XML Editor moves the cursor to the matching bracket, highlights its row, and decorates the initial bracket with a rectangle.

**Note:**

A rectangle decorates the opening or closing bracket that matches the current one, at all times.

Source
Allows you to select one of the following actions:

**To Lower Case**
Converts the selection content to lower case characters.

**To Upper Case**
Converts the selection content to upper case characters.

**Capitalize Lines**
Converts to upper case the first character of every selected line.

**Join and Normalize Lines**
Joins all the rows you select to one row and normalizes the content.

**Insert new line after**
Inserts a new line after the line at the cursor position.

**Modify all matches**
Use this option to modify (in-place) all the occurrences of the selected content. When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

**Open**
Allows you to select one of the following actions:

- **Open File at Cursor** - select this action to open the source of the file located at the cursor position
- **Open File at Cursor in System Application** - select this action to open the source of the file located at the cursor position with the application that the system associates with the file

**Compare**
Select this option to open the **Compare Files** tool to compare the file you are editing with a file you choose in the dialog box.

**Folding**
When you invoke the contextual menu from the folding (on page 2966) triangles in the stripe on the left side of the editor, the following actions are available:

- **Collapse Other Folds** *(Ctrl + NumPad/ (Command + NumPad/ on OS X))*
  Folds all the elements except the current element.

- **Collapse Child Folds** *(Ctrl + NumPad. (Command + NumPad. on OS X))*
  Folds the elements indented with one level inside the current element.

- **Expand Child Folds**
Unfolds all child elements of the currently selected element.

**Expand All (Ctrl + NumPad* (Command + NumPad* on OS X))**

Unfolds all elements in the current document.

### Validating JavaScript Files

You have the possibility to validate the JavaScript document you are editing. Oxygen XML Editor uses the Mozilla Rhino library for validation. For more information about this library, go to [http://www.mozilla.org/rhino/doc.html](http://www.mozilla.org/rhino/doc.html). The JavaScript validation process checks for errors in the syntax. Calling a function that is not defined is not treated as an error by the validation process. The interpreter discovers this error when executing the faulted line. Oxygen XML Editor can validate a JavaScript document both on-request and automatically.

### Content Completion in JavaScript Documents

When you edit a JavaScript document, the *Content Completion Assistant (on page 2965)* presents you a list of the elements you can insert at the cursor position. It can be manually activated with the **Ctrl + Space (Command + Space on OS X)** shortcut.

For an enhanced assistance, JQuery methods are also presented. The following icons decorate the elements in the content completion list of proposals depending on their type:

- • f - function
- • v - variable
- • O - object
- • ø - property
- • f - method

**Note:**

These icons decorate both the elements from the content completion list of proposals and from the **Outline view (on page 1097)**.
The **Content Completion Assistant** collects:

- Method names from the current file and from the library files.
- Functions and variables defined in the current file.

If you edit the content of a function, the content completion list of proposals contains all the local variables defined in the current function, or in the functions that contain the current one.

**Syntax Highlighting in JavaScript Documents**

Oxygen XML Editor supports syntax highlighting in Text mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for JavaScript files, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98).
2. Go to Editor > Syntax Highlight (on page 195).
3. Select and expand the JavaScript section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.
You can see the effects of your changes in the **Preview** pane.

Related Information:
* Syntax Highlight Preferences (on page 195)

### JavaScript Outline View

Oxygen XML Editor present a list of all the components of the JavaScript document you are editing in the **Outline** view. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

![JavaScript Outline View](image)

The following icons decorate the elements in the **Outline** view depending on their type:

- f - function
- v - variable
- □ - object
- ◆ - property
- f - method

The contextual menu of the JavaScript **Outline** view contains the usual **Cut**, **Copy**, **Paste**, and **Delete** actions. From the **Settings** menu, you can select the **Update selection on cursor move** option to synchronize the **Outline** view with the editing area.
Editing XProc Scripts

XProc is an XML pipeline language that can be used to script transformations. An XProc script is edited as an XML document that is validated against a RELAX NG schema, or if the script has an associated transformation scenario, then the XProc engine selected in the scenario is used as the validating engine (if the XProc engine supports validation). The default engine for XProc scenarios is a version of the Calabash engine that comes bundled with Oxygen XML Editor version 23.1.

XProc Content Completion

Oxygen XML Editor helps you edit a XProc scripts through the Content Completion Assistant (on page 2965), offering proposals that are valid at the cursor position. It can be manually activated with the Ctrl + Space (Command + Space on OS X) shortcut.

The content completion inside the `<input:inline>` element from the XProc namespace http://www.w3.org/ns/xproc offers elements from the following schemas depending both on the `@port` attribute and the parent of the `<input>` element. When invoking the content completion inside the `<inline>` XProc element, the list of content completion proposals is populated as follows:

- If the value of the `@port` attribute is `stylesheet` and the `<xslt>` element is the parent of the `<input>` elements, the Content Completion Assistant offers XSLT elements.
- If the value of the `@port` attribute is `schema` and the `<validate-with-relax-ng>` element is the parent of the `<input>` element, the Content Completion Assistant offers RELAX NG schema elements.
- If the value of the `@port` attribute is `schema` and the `<validate-with-xml-schema>` element is the parent of the `<input>` element, the Content Completion Assistant offers XML Schema schema elements.
- If the value of the `@port` attribute is `schema` and the `<validate-with-schematron>` element is the parent of the `<input>` element, the Content Completion Assistant offers either ISO Schematron elements or Schematron 1.5 schema elements.
- If the above cases do not apply, then the Content Completion Assistant offers elements from all the schemas from the above cases.

**Figure 413. XProc Content Completion**
XProc Syntax Highlighting

The XProc editor assists you in writing XPath expressions by offering dedicated coloring schemes for syntax highlighting.

To customize the colors or styles used for the syntax highlighting colors for XProc, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98).
2. Go to Editor > Syntax Highlight (on page 195).
3. Select and expand the XML section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.
5. Select the XML tab in the Preview pane to see the effects of your changes.

Enabling Extensions in Calabash

If you are using the default Calabash engine, it is possible to configure extensions (for a list of the valid extensions, see http://xmlcalabash.com/docs/reference/cfg.extension.html).

To configure an extension:

1. Edit the following file: OXYGEN_INSTALL_DIR/lib/xproc/calabash/engine.xml.
2. Add the extension and its value as a system-property, as in the following example:

   ```xml
   <system-property name="com.xmlcalabash.allow-text-results" value="true"/>
   ```

Related Information:
Creating an XProc Transformation Scenario (on page 1425)
Integrating an External XProc Engine (on page 1430)
XProc Preferences (on page 214)

Editing Schematron Schemas

Schematron is a simple and powerful Structural Schema Language for making assertions about patterns found in XML documents. It relies almost entirely on XPath query patterns for defining rules and checks. Schematron validation rules allow you to specify a meaningful error message. This error message is provided to you if an error is encountered during the validation stage.

There are numerous online resources out there to help you get started with writing Schematron rules. Here are just a few that might help you:

- Guide to Schema Writing with Schematron
- Presentation: Schematron Development with Oxygen

Oxygen XML Editor assists you in editing Schematron documents with schema-based content completion, syntax highlight, search and refactor actions, and dedicated icons for the Outline view (on page 1118). You.
can create a new Schematron schema using one of the Schematron templates available in the New document wizard (on page 335).

For information about applying and detecting Schematron schemas, see Associating a Schema to XML Documents (on page 759).

**Validating XML Documents Against Schematron**

The Skeleton XSLT processor is used for validation and conforms with ISO Schematron or Schematron 1.5. It allows you to validate XML documents against Schematron schemas (on page 1112) or against combined RELAX NG / W3C XML Schema and Schematron.

**How to Specify the Query Language Binding**

You can specify the query language binding to be used in the Schematron schema by doing the following:

- For embedded ISO Schematron, open the Preferences dialog box (Options > Preferences) (on page 98), go to XML > XML Parser > Schematron, and select it in the Embedded rules query language binding option (on page 211).
- For standalone ISO Schematron, specify the version by setting the query language to be used in a @queryBinding attribute on the schema root element. For more information, see the Query Language Binding section of the Schematron specifications.
- For Schematron 1.5 (standalone and embedded), open the Preferences dialog box (Options > Preferences) (on page 98), go to XML > XML Parser > Schematron, and select the version in the XPath Version option (on page 212).

**Multi-Lingual Support in Schematron Messages**

You can specify the desired language for the validation messages in the Schematron Preferences page (on page 210). The Schematron validation messages can be presented in multiple languages by defining the language for each message using the Schematron `<diagnostics>` element. For more information, see the Use of Schematron for Multi-Lingual Schemas specification.

**How to Customize Color Schemes in Schematron**

The Schematron editor renders the XPath expressions with dedicated color schemes. To customize the coloring schemes, open the Preferences dialog box (Options > Preferences) (on page 98) and go to Editor > Syntax Highlight.

**Schematron Transformation Scenario**

When you create a Schematron document, Oxygen XML Editor provides a built-in transformation scenario. You can use this scenario to obtain the XSLT style-sheet corresponding to the Schematron schema. You can apply this XSLT stylesheet to XML documents to obtain the Schematron validation results.

For more information about the Schematron support in Oxygen XML Editor, watch our video demonstrations:

https://www.youtube.com/embed/HdcZA3DjI7E

https://www.youtube.com/embed/y3u3wl092e4
Examples of Schematron Rules and Quick Fixes

This topic is meant to provide some basic examples of Schematron Rules and Schematron Quick Fixes (SQF) to help you create and impose your own rules and quick fixes.

Other examples and ideas can also be found at:

- Public GitHub project with the Schematron file used for Oxygen's User Guide
- Public GitHub project with sample Schematron Quick Fixes

Schematron Examples

Schematron Use Case 1: Impose a Relax NG Schema Declaration

**Description:** The following sample rule is useful if, for example, you need to enforce the use of Relax NG schema declarations in all of your documents (i.e. instead of using DTD schemas).

**Sample Code:**

```xml
<?xml version="1.0" encoding="UTF-8"?>
<sch:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron"
    queryBinding="xslt2" xmlns:saxon="http://saxon.sf.net/">
    <sch:let name="rngDeclaration" value="processing-instruction('xml-model')
        [saxon:get-pseudo-attribute('schematypens')='http://relaxng.org/ns/structure/1.0']"/>
    <sch:pattern>
        <sch:rule context="/element()">
            <sch:assert test="exists($rngDeclaration)">You must define a Relax NG schema declaration in the document (DTD schemas are not supported).</sch:assert>
        </sch:rule>
    </sch:pattern>
</sch:schema>
```

**Result:** The engine checks for a Relax NG schema declaration in the document and displays an error if it is missing. The error is reported on the document's root element (/element()).

Schematron Use Case 2: Check for Missing IDs

**Description:** The following sample rule checks for missing or undefined IDs in a TEI document. Specifically, it looks for IDs from the tei:rs/@ref attribute defined in the document named persons.xml (as xml:id of a TEI person element).

**Sample Code:**

```xml
<?xml version="1.0" encoding="UTF-8"?>
<sch:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron"
    queryBinding="xslt2" xmlns:saxon="http://saxon.sf.net/">
    <sch:let name="rngDeclaration" value="processing-instruction('xml-model')
        [saxon:get-pseudo-attribute('schematypens')='http://relaxng.org/ns/structure/1.0']"/>
    <sch:pattern>
        <sch:rule context="/element()">
            <sch:assert test="exists($rngDeclaration)">You must define a Relax NG schema declaration in the document (DTD schemas are not supported).</sch:assert>
        </sch:rule>
    </sch:pattern>
</sch:schema>
```
<sch:rule context="tei:rs">
  <sch:let name="refIds" value="for $id in tokenize(@ref, ' ') return substring-after($id, '#')"/>
  <sch:let name="missingIds" value="for $id in $refIds return (if($id = $personIds) then '' else $id)"/>
  <sch:report test="$missingIds != ''">
    The following ids "<sch:value-of select="$missingIds"/>
    are not defined in "<sch:value-of select="$personIds"/>
  </sch:report>
</sch:rule>
</sch:pattern>
</sch:schema>

where the XML document looks something like this:

```xml
<tei xmlns="http://www.tei-c.org/ns/1.0">
  <rs ref="../SomePerson/persons.xml#EDP ../personography/HAMpersons.xml#SD">text</rs>
  <rs ref="../SomePerson/persons.xml#EDP">text</rs>
</tei>
```

**Result:** The engine displays an error message listing the missing/undefined IDs.

### Schematron Use Case 3: Check for Broken Links

**Description:** The following sample rule detects broken links in DITA `<xref>` or `<link>` elements. The first example only checks links that do not contain an anchor (#).

#### Sample Code:

```xml
<rule context="*[contains(@class, ' topic/xref ') or contains(@class, ' topic/link ')]
[@href][not(contains(@href, '#'))][not(@scope = 'external')][not(@type) or @type='dita']">
  <assert test="doc-available(resolve-uri(@href, base-uri(.)))">
    The document linked by `<value-of select="local-name()"/>
    "<value-of select="@href="/" does not exist!</assert>
</rule>
```

For links that contain an anchor, the Schematron rule must look something like this:
Result: The engine displays an error message when a broken link or cross reference is detected.

Schematron Use Case 4: Check for Duplicate IDs

Description: The following sample rule detects if there are two sibling `<step>` elements with the same `@id` value in a DITA Task document.

Sample Code:

```sch
<sch:rule context="*[contains(@class, ' task/step ')]">
    <sch:let name="id" value="@id"/>
    <sch:report
        test="preceding-sibling::element{}[contains(@class, ' task/step ')][@id = $id]">
        Element with duplicate ID "<sch:value-of select="$id"/>" detected.
    </sch:report>
</sch:rule>
```

Result: The engine displays an error message when a duplicate ID is detected in sibling `<step>` elements within a DITA Task document.

Schematron Use Case 5: Check for Duplicate DITA Topic References

Description: The following sample rule checks a DITA map for duplicate `<topicref>` elements with the same `@href` value.

Sample Code:
Schematron Use Case 6: Restrict Certain Words from the Title

**Description:** The following sample rule checks for instances of specified words to be restricted from a `<title>` element (in this example, the words *test* and *hello* are restricted).

**Sample Code:**

```xml
<sch:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron"
    queryBinding="xslt2">
    <sch:let name="words" value="'test,hello'"/>
    <sch:let name="wordsToMatch" value="replace($words, ',', '|')"/>
    <sch:pattern>
        <sch:rule context="title">
            <sch:report test="matches(text(), $wordsToMatch)" role="warn">
                The following words should not be added in the title:
                <sch:value-of select="$words"/>
            </sch:report>
        </sch:rule>
    </sch:pattern>
</sch:schema>
```

**Result:** The engine displays an error message if one of the specified restricted words appear in a title.

Schematron Use Case 7: Check the Location of a Resource

**Description:** The following sample rule checks if the path to a resource (in this case, an image) is specified correctly. Specifically, this sample rule reports that the image must be located in the current project (the images location must be relative to the parent folder and no more than one `../` in the path).

**Sample Code:**

```xml
<sch:rule context="image">
    <sch:report test="count(tokenize(@href, '\\./')) > 2">
        The image must be located in the current project. It is currently located in: <sch:value-of select="@href"/>
    </sch:report>
</sch:rule>
```
**Result:** The engine displays an error message if an image is detected in a location other than the current project, relative to the parent folder.

**Schematron Use Case 8: Check for Extra Spaces at Beginning/End of Elements**

**Description:** The following sample rule checks for spaces at the beginning and end of elements.

**Tip:** You could specify a list of elements to check to make the rule context-sensitive.

**Sample Code:**

```xml
<rule context="p|ph|codeph|filename|indexterm|xref|user-defined|user-input">
  <let name="firstNodeIsElement" value="node()[1] instance of element()"/>
  <let name="lastNodeIsElement" value="node()[last()] instance of element()"/>
  <report test="(not($firstNodeIsElement) and matches(.,'^\s',';j'))
           or (not($lastNodeIsElement) and matches(.,'\s$',';j'))"
           role="warning">
    Textual elements should not begin or end with whitespace.</report>
</rule>
```

**Result:** The engine displays an error message if a whitespace is detected at the beginning or end of a textual element.

**Schematron Use Case 9: Impose Capitalizing the First Letter**

**Description:** The following sample rule detects if elements start with a capital letter or a number. The rule is implemented using abstract patterns. The abstract pattern `starts-with-capital` has one argument representing the element to be checked. There are two implementations of the abstract pattern, one that specifies the `<tittle>` element as the element to verify, and one that specifies the `<li>` element.

**Sample Code:**

```xml
<sch:pattern abstract="true" id="starts-with-capital">
  <sch:rule context="$element" role="information">
    <sch:let name="firstNodeIsElement" value="node()[1] instance of element()"/>
    <sch:report test="(not($firstNodeIsElement) and (not(matches(.,'^[A-Z|0-9]'))))">
      Start the element &lt;$element&gt; with a capital letter.</sch:report>
  </sch:rule>
</sch:pattern>

<sch:pattern is-a="starts-with-capital">
  <sch:param name="element" value="title"/>
</sch:pattern>

<sch:pattern is-a="starts-with-capital">
  <sch:param name="element" value="li"/>
</sch:pattern>
```
**Result:** The engine displays an error message if a title begins with a word that does not contain a capital letter or number as its first character.

**Schematron Use Case 10: Check for Specified Terms in a Paragraph**

**Description:** The following sample rule checks if any DITA `<p>` elements contain certain keywords defined in an external document.

**Sample Code:**

```xml
<sch:pattern>
  <sch:let name="keys" value="document('keys-common.ditamap')//keyword"/>
  <sch:rule context="p">
    <sch:let name="text" value="."/>
    <sch:let name="matchedKeys" value="$keys[contains($text, normalize-space(.))]]"/>
    <sch:report id="now001" test="count($matchedKeys) > 0" role="error">
      The paragraph text contains the keywords: <sch:value-of select="$matchedKeys"/>
    </sch:report>
  </sch:rule>
</sch:pattern>
```

**Result:** The engine displays an error message if any of the keywords listed in an external document are detected within a DITA `<p>` element.

**Schematron Use Case 11: Impose a Minimum Value**

**Description:** The following sample rule determines the `<type>` element value with the minimum version specified by the `@version` attribute and then verifies that they are all equal to the determined value.

**Sample Code:**

```xml
<sch:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron" queryBinding="xslt2">
  <sch:let name="typeValue" value="/Node1[not(@version > 1)]/Node1/@version]1]//Type/text()"/>
  <sch:pattern>
    <sch:rule context="Type">
      <sch:assert test="text() = $typeValue">
        The Type value must be "<sch:value-of select="$typeValue"/>"
      </sch:assert>
    </sch:rule>
  </sch:pattern>
</sch:schema>
```

where the XML file would look something like this:

```xml
<root>
  <Node1 version="1">
    <Element1>Value1</Element1>
  </Node1>
</root>
```
Result: The engine displays an error message if a `<type>` element value does not equal the minimum version specified by the `@version` attribute.

**SQF (Schematron Quick Fix) Examples**

**SQF Use Case 1: Impose a DITA Prolog**

**Description:** The following sample Schematron rule checks a DITA topic to make sure it contains `<prolog>`, `<critdates>`, `<revised>` elements and the sample Quick Fix proposes options for inserting the missing elements.

**Sample Code:**

```xml
<sch:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron" queryBinding="xslt2"
xmlns:sqf="http://www.schematron-quickfix.com/validator/process"/>
<sch:rule context="*[contains(@class, ' topic/topic ')]">
    <sch:assert sqf:fix="add_prolog" test="prolog" role="warn">Every topic must contain prolog/critdates/revised elements where the revised modified date is in YYYY-MM-DD format.</sch:assert>
    <sqf:fix id="add_prolog">
        <sqf:description>
            Add prolog/critdates/revised elements, where the revised element's @modified attribute value is the current date in YYYY-MM-DD format.
        </sqf:description>
        <sqf:title>Add prolog/critdates/revised elements if the revised element's @modified attribute value is the current date in YYYY-MM-DD format.</sqf:title>
        <sqf:add match="*[contains(@class, ' topic/body ')]" node-type="element" position="before" target="prolog">
            <critdates>
                <revised modified=""></revised>
            </critdates>
        </sqf:add>
    </sqf:fix>
</sch:rule>
```
Result: The engine displays an error message if the `<prolog>`, `<critdates>`, or `<revised>` elements are missing from a DITA topic and the Quick Fix mechanism proposes options for inserting the missing elements.

**SQF Use Case 2: Impose an ID for all DITA Section Elements**

**Description:** The following sample Schematron rule checks if each DITA `<section>` element has a specified ID and the sample Quick Fix proposes options for inserting the missing IDs.

**Sample Code:**

```xml
<\sch:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron"
queryBinding="xslt2"
 xmlns:sqf="http://www.schematron-quickfix.com/validator/process">
<sch:pattern>
<!-- Add IDs to all sections to impose link targets -->
<sch:rule context="section">
  <sch:assert test="@id" sqf:fix="addId addIds" [Bug] All sections should have an @id attribute </sch:assert>
</sch:rule>
</sch:pattern>
</sch:schema>
```
<sqf:fix id="addId">
  <sqf:description>
    <sqf:title>Add @id to the current section</sqf:title>
    <sqf:p>Add an @id attribute to the current section. The ID is generated from the section title.</sqf:p>
  </sqf:description>
  <!-- Generate an id based on the section title. If there is no title then generate a random id. -->
  <sqf:add target="id" node-type="attribute" select="
    concat('section_',
    if (exists(title) and string-length(title) > 0)
    then
      substring(lower-case(replace(replace(normalize-space(string(title)), '\s', '_'), '[^a-zA-Z0-9_]', '')), 0, 50)
    else
generate-id())"/>
</sqf:fix>

<sqf:fix id="addIds">
  <sqf:description>
    <sqf:title>Add @id to all sections</sqf:title>
    <sqf:p>Add an @id attribute to each section from the document. The ID is generated from the section title.</sqf:p>
  </sqf:description>
  <!-- Generate an id based on the section title. If there is no title then generate a random id. -->
  <sqf:add match="/section[not(@id)]" target="id" node-type="attribute" select="
    concat('section_',
    if (exists(title) and string-length(title) > 0)
    then
      substring(lower-case(replace(replace(normalize-space(string(title)), '\s', '_'), '[^a-zA-Z0-9_]', '')), 0, 50)
    else
generate-id())"/>
</sqf:fix>
</sch:rule>
</sch:pattern>
</sch:schema>

Result: The engine displays an error message if an @id attribute is missing for any <section> element in a DITA topic and the Quick Fix mechanism proposes options for inserting the missing ID.
SQF Use Case 3: Impose a Short Description in an Abstract Element

**Description:** The following sample Schematron rule checks a DITA topic to make sure it contains a `<shortdesc>` element inside an `<abstract>` element and the sample Quick Fix proposes options for correcting the missing structure.

**Sample Code:**

```xml
<sch:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron" queryBinding="xslt2"
    xmlns:sqf="http://www.schematron-quickfix.com/validator/process"
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
  <sch:pattern>
    <sch:rule context="shortdesc">
      <sch:assert test="parent::abstract" sqf:fix="moveToAbstract moveToExistingAbstract">
        The short description must be added in an abstract element
      </sch:assert>
      <!-- Check if there is an abstract element -->
      <sch:let name="abstractElem" value="preceding-sibling::abstract | following-sibling::abstract"/>
      <!-- Create an abstract element and add the short description -->
      <sqf:fix id="moveToAbstract" use-when="not($abstractElem)">
        <sqf:description>
          <sqf:title>Move short description in an abstract element</sqf:title>
        </sqf:description>
        <abstract>
          <xsl:apply-templates mode="copyExceptClass" select="."/>
        </abstract>
      </sqf:fix>
      <!-- Move the short description in the abstract element -->
      <sqf:fix id="moveToExistingAbstract" use-when="$abstractElem">
        <sqf:description>
          <sqf:title>Move short description in the abstract element</sqf:title>
        </sqf:description>
        <sch:let name="shortDesc">
          <xsl:apply-templates mode="copyExceptClass" select="."/>
        </sch:let>
        <sqf:add match="$abstractElem" select="$shortDesc"/>
        <sqf:delete/>
      </sqf:fix>
    </sch:rule>
  </sch:pattern>
</sch:schema>
```
Result: The engine displays an error message if an `<abstract>` element does not contain a `<shortdesc>` element and the Quick Fix mechanism proposes options for inserting the missing structure or to move the `<shortdesc>` element inside the `<abstract>` element.

SQF Use Case 4: Impose a Certain Article Type

Description: The following sample Schematron rule checks the `@article-type` attribute to make sure its value is one of the specified allowed values (abstract, addendum, announcement, article-commentary) and the sample Quick Fix proposes options for replacing any other detected value with one of the allowed values.

Sample Code:

```
<!-- Template used to copy the current node -->
<xsl:template match="node() | @*" mode="copyExceptClass">
  <xsl:copy copy-namespaces="no">
    <xsl:apply-templates select="node() | @*" mode="copyExceptClass"/>
  </xsl:copy>
</xsl:template>

<!-- Template used to skip the @class attribute from being copied -->
<xsl:template match="@class" mode="copyExceptClass"/>
</xsl:schema>

Result: The engine displays an error message if an `<abstract>` element does not contain a `<shortdesc>` element and the Quick Fix mechanism proposes options for inserting the missing structure or to move the `<shortdesc>` element inside the `<abstract>` element.

SQF Use Case 4: Impose a Certain Article Type

Description: The following sample Schematron rule checks the `@article-type` attribute to make sure its value is one of the specified allowed values (abstract, addendum, announcement, article-commentary) and the sample Quick Fix proposes options for replacing any other detected value with one of the allowed values.

Sample Code:

```
<x:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron" queryBinding="xslt2"
  xmlns:sqf="http://www.schematron-quickfix.com/validator/process">
  <sch:let name="articleTypes" value="('abstract', 'addendum', 'announcement',
    'article-commentary')"/>
  <sch:pattern>
    <sch:rule context="article/@article-type">
      <sch:assert test=". = $articleTypes" sqf:fix="setArticleType">
        Should be one of the article types:
        <sch:value-of select="$articleTypes"/>
      </sch:assert>
      <sqf:fix id="setArticleType" use-for-each="$articleTypes">
        <sqf:description>
          Set article type to '<sch:value-of select="$sqf:current"/>
        </sqf:description>
      </sqf:fix>
      <sqf:replace node-type="attribute" target="article-type" select="$sqf:current"/>
    </sch:rule>
  </sch:pattern>
</x:schema>
```
Result: The engine displays an error message if an @article-type attribute has any other value other than abstract, addendum, announcement, or article-commentary and the Quick Fix mechanism proposes options for replacing the disallowed value with one of those four allowed values (using the use-for-each construct).

Editing Schematron Schema in the Main Files Context

Smaller interrelated modules that define a complex Schematron cannot be correctly edited or validated individually, due to their interdependency with other modules. For example, a diagnostic defined in a main schema document is not visible when you edit an included module. Oxygen XML Editor provides the support for defining the main module (or modules), thus allowing you to edit any of the imported/included schema files in the context of the larger schema structure.

You can set a main Schematron document either using the main files support from the Project view (on page 383), or using a validation scenario.

To set a main file using a validation scenario, add validation units that point to the main schemas. Oxygen XML Editor warns you if the current module is not part of the dependencies graph computed for the main schema. In this case, it considers the current module as the main schema.

The advantages of editing in the context of main file include:

- Correct validation of a module in the context of a larger schema structure.
- Content Completion Assistant (on page 2965) displays all the referable components valid in the current context. This include components defined in modules other than the currently edited one.

Presenting Schematron Validation Issues

The possible issues that might occur during the validation process when validating XML documents against Schematron are presented with colored underlines in the editing pane, colored markers in the right vertical stripe, and details about the issues are presented in the Errors panel at the bottom area of the Oxygen XML Editor window. Each error is flagged with a severity level that can be: warning, error, fatal or info.

To set a severity level, Oxygen XML Editor looks for the following information:

- The role attribute, which can have one of the following values:
  - warn or warning - Sets the severity level to warning. By default, underlined with a yellow squiggly line in the editing pane and a yellow marker in the right vertical stripe.
  - error - Sets the severity level to error. By default, underlined with a red squiggly line in the editing pane and a red marker in the right vertical stripe.
  - fatal - Sets the severity level to fatal. By default, underlined with a red squiggly line in the editing pane and a red marker in the right vertical stripe.
  - info or information - Sets the severity level to information. By default, underlined with a blue squiggly line in the editing pane and a blue marker in the right vertical stripe.
• The start of the message, after trimming leading white-spaces. Oxygen XML Editor looks to match the following exact string of characters (case-sensitive):
  ◦ **Warning**: - Sets the severity level to *warning*. By default, underlined with a yellow squiggly line in the editing pane and a yellow marker in the right vertical stripe.
  ◦ **Error**: - Sets the severity level to *error*. By default, underlined with a red squiggly line in the editing pane and a red marker in the right vertical stripe.
  ◦ **Fatal**: - Sets the severity level to *fatal*. By default, underlined with a red squiggly line in the editing pane and a red marker in the right vertical stripe.
  ◦ **Info**: - Sets the severity level to *info*. By default, underlined with a blue squiggly line in the editing pane and a blue marker in the right vertical stripe.
  ◦ If none of the previous rules match, Oxygen XML Editor sets the severity level to *error*. By default, underlined with a red squiggly line in the editing pane and a red marker in the right vertical stripe.

**Tip:**
You can configure the color for each type in the [Document Checking preferences page](on page 196).

### Integrating Schematron Rules in a Framework and Sharing Them

Custom **Schematron** rules are a great way to ensure consistency for XML authoring, especially when there is a large team working on the same set of documents. You can use **Schematron** for numerous use cases. For example, to restrict certain elements from being used, to impose restrictions on the amount of text for an element, or to impose restrictions on certain elements based on various attribute values or text content set in other elements. Furthermore, you can define quick fixes for each **Schematron** rule *(on page 1139)* to offer technical writers proposed solutions for reported problems.

Once you define the **Schematron** rules, they can be shared with the other members of your team by integrating them in a framework *(on page 2967)* (document type) configuration.

#### How to Integrate Schematron Rules in a Framework

To integrate a Schematron rule in an existing framework bundled with the application, follow these steps:

1. Create a folder structure for an extended framework and save it somewhere on disk where you have full write access (for example, `custom_frameworks/dita-extension`).
2. In that new folder structure, create another folder that will contain all of your custom Schematron files (for example, `custom_frameworks/dita-extension/rules`).
3. Define the Schematron rules in an existing or new Schematron file and save it in the folder you created in step 2. There are numerous online resources out there to help you get started with writing Schematron rules. Here are just a few that might help you:
   - Guide to Schema Writing with Schematron
   - Presentation: Schematron Development with Oxygen

4. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Document Type Association > Locations (on page 113). In this preferences page, add the path to your custom_frameworks folder in the Additional frameworks directories list, then click OK or Apply to save your changes.

5. Go to the Document Type Association preferences page (on page 111) and select a framework configuration (for example, DITA) and use the Extend button to create an extension for it.

6. Give the extension an appropriate name (for example, DITA - Custom), select External for the Storage option, and specify an appropriate path to your framework configuration file (for example, path/to/.../custom_frameworks/dita-extension/dita-extension.framework).

7. Make whatever changes you desire to the extension, then go to the Validation tab, edit the default validation scenario (select the scenario and click the Edit button), and add an extra validation unit to it (one that uses your custom Schematron file). For more details about editing validation scenarios, see Configuring Validation Scenarios for a Framework (on page 2067).

8. Click OK to close the dialog box and then OK or Apply to save the changes to the Document Type Association preferences page (on page 111).

9. Open an XML document that matches your framework configuration and test the new rule.

10. You can continue to refine the Schematron and develop additional rules as needed.

Sharing Schematron Rules

To share Schematron rules with other members of your team, you simply need to share the framework where you integrated the Schematron rules. There are several methods for sharing frameworks and you can find details here: Sharing a Framework (on page 2131).

Related Information:

- Defining Schematron Quick Fixes (on page 1139)
- Associating a Schema in Validation Scenarios Defined in the Document Type (on page 764)
- Sharing a Framework (on page 2131)

Validating Schematron Documents

By default, a Schematron schema is validated as you type. To change this, open the Preferences dialog box (Options > Preferences) (on page 98), go to Editor > Document Checking, and deselect the Enable automatic validation option (on page 197).

To validate a Schematron document manually, select the Validate action from the Validation toolbar drop-down menu or the Document > Validate menu. When Oxygen XML Editor validates a Schematron
schema, it expands all the included modules so the entire schema hierarchy is validated. The validation problems are highlighted directly in the editor, making it easy to locate and fix any issues.

Oxygen XML Editor offers an error management mechanism capable of pinpointing errors in XPath expressions and in the included schema modules.

Related Information:
Presenting Schematron Validation Issues (on page 1112)

Content Completion in Schematron Documents

Oxygen XML Editor helps you edit a Schematron schema through the Content Completion Assistant (on page 2965), offering proposals that are valid at the cursor position. It can be manually activated with the Ctrl + Space (Command + Space on OS X) shortcut.

When you edit the value of an attribute that refers a component, the proposed components are collected from the entire schema hierarchy. For example, if the editing context is phase/active/@pattern, the Content Completion Assistant proposes all the defined patterns.

Note:
For Schematron resources, the Content Completion Assistant collects its components starting from the main files (on page 2968). The main files can be defined in the project or in the associated validation scenario. For further details about the Main Files support go to Defining Main Files at Project Level (on page 383).

If the editing context is an attribute value that is an XPath expression (such as assert/@test or report/@test), the Content Completion Assistant offers the names of XPath functions, the XPath axes, and user-defined variables.

The Content Completion Assistant displays XSLT 1.0 functions and optionally XSLT 2.0 / 3.0 functions in the attributes path, select, context, subject, test depending on the Schematron options (on page 210) that are set in Preferences pages. If the Saxon 6.5.5 namespace (xmlns:saxon="http://icl.com/saxon") or the Saxon 9.9.1.5 namespace is declared in the Schematron schema (xmlns:saxon="http://saxon.sf.net/*") the content completion also displays the XSLT Saxon extension functions as in the following figure:
The Content Completion Assistant also includes code templates that can be used to quickly insert code fragments (on page 496) into Schematron documents.

Syntax Highlighting in Schematron

Oxygen XML Editor supports syntax highlighting in Text mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for Schematron schemas, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98).
2. Go to Editor > Syntax Highlight (on page 195).
3. Select and expand the XML section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.
5. Select the XML tab in the Preview pane to see the effects of your changes.

Tip:

Oxygen XML Editor also allows you to specify syntax highlighting colors for specific XML elements and attributes with specific namespace prefixes. This can be done in the Editor > Syntax Highlight > Elements/Attributes by Prefix preferences page (on page 195).
Embedding Schematron Rules in XML Schema or RELAX NG

Schematron rules can be embedded into an XML Schema through annotations (using the `<appinfo>` element), or in any element on any level of a RELAX NG Schema (taking into account that the RELAX NG validator ignores all elements that are not in the RELAX NG namespace).

Oxygen XML Editor supports Schematron validation schemas and it is able to extract and use the embedded rules.

Validating XML Documents with XML Schema and Embedded Schematron

To validate an XML document with XML Schema and its embedded Schematron, you can associate the document like this:

```xml
<?xml-model href="percent.xsd" type="application/xml" schematypens="http://purl.oclc.org/dsdl/schematron"?>
```

Validating XML Documents with Relax NG and Embedded Schematron

To validate an XML document with RELAX NG schema and its embedded Schematron rules, you need to associate the document with both schemas like this:

```xml
<?xml-model href="percent.rng" type="application/xml" schematypens="http://relaxng.org/ns/structure/1.0"?>
<?xml-model href="percent.rng" type="application/xml" schematypens="http://purl.oclc.org/dsdl/schematron"?>
```

The second association validates your document with Schematron rules extracted from the RELAX NG Schema.

Note:

When you work with XML Schema or Relax NG documents that have embedded Schematron rules Oxygen XML Editor provides two built-in validation scenarios: Validate XML Schema with embedded Schematron for XML schema, and Validate Relax NG with embedded Schematron for Relax NG. You can use one of these scenarios to validate the embedded Schematron rules.

Example: Embedded Schematron in XML Schema

```xml
<xsd:appinfo>
  <sch:pattern>
    <sch:rule context="...">
      <sch:assert test="...">Message.</sch:assert>
    </sch:rule>
  </sch:pattern>
</xsd:appinfo>
```
Example: Embedded Schematron in Relax NG Schema

```xml
<grammar
    xmlns="http://relaxng.org/ns/structure/1.0"
    xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <sch:pattern>
    <sch:rule context="...">
      <sch:assert test="...">Message.</sch:assert>
    </sch:rule>
  </sch:pattern>
  <start>
    ..............
  </start>
</grammar>
```

Embedding Schematron Quick Fixes in Relax NG or XML Schema (on page 1153)

Schematron Outline View

The Outline view for Schematron schemas presents a list of components in a tree-like structure and it allows for quick access to a component by name. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

![Schematron Outline View](image.png)

The following actions are available in the Settings menu on the Outline view toolbar:

- Filter returns exact matches
  - The text filter of the Outline view returns only exact matches.
- Selection update on cursor move
Controls the synchronization between Outline view and source document. The selection in the Outline view can be synchronized with the cursor moves or the changes in the editor. Selecting one of the components from the Outline view also selects the corresponding item in the source document.

Flat presentation mode of the filtered results
When active, the application flattens the filtered result elements to a single level.

Show comments and processing instructions
Show/hide comments and processing instructions in the Outline view.

Show element name
Show/hide element name.

Show text
Show/hide additional text content for the displayed elements.

Show attributes
Show/hide attribute values for the displayed elements. The displayed attribute values can be changed from the Outline preferences panel (on page 275).

Configure displayed attributes
Displays the XML Structured Outline preferences page (on page 275).

The following contextual menu actions are also available in the Outline view:

Append Child
Displays a list of elements that you can insert as children of the current element.

Insert Before
Displays a list of elements that you can insert as siblings of the current element, before the current element.

Insert After
Displays a list of elements that you can insert as siblings of the current element, after the current element.

Edit Attributes
Opens a dialog box that allows you to edit the attributes of the currently selected component.

Toggle Comment
Comments/uncomments the currently selected element.

Cut
Cuts the currently selected component.

Copy
Copies the currently selected component.

**Delete**

Deletes the currently selected component.

**Expand More**

Expands the structure of a component in the **Outline** view.

**Collapse All**

Collapses the structure of all the component in the **Outline** view.

The upper part of the **Outline** view contains a filter box that allows you to focus on the relevant components. Type a text fragment in the filter box and only the components that match it are presented. For advanced usage you can use wildcard characters (such as `*` or `?`) and separate multiple patterns with commas.

### Schematron Resource Hierarchy/Dependencies View

The **Resource Hierarchy/Dependencies** view displays the hierarchy or dependencies for resources included in a Schematron schema. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

If you want to see the hierarchy of a schema, select the desired schema in the **Project view (on page 368)** and choose **Resource Hierarchy** from the contextual menu.

![Figure 416. Resource Hierarchy](image)

If you want to see the dependencies of a schema, select the desired schema in the **Project view (on page 368)** and choose **Resource Dependencies** from the contextual menu.

![Figure 417. Resource Dependencies](image)
The following actions are available on the toolbar of the **Resource Hierarchy/Dependencies** view:

- **Refresh**
  Refreshes the Hierarchy/Dependencies structure.

- **Stop**
  Stops the hierarchy/dependencies computing.

- **Show Hierarchy**
  Allows you to choose a resource to compute the hierarchy structure.

- **Show Dependencies**
  Allows you to choose a resource to compute the dependencies structure.

- **Configure dependencies search scope**
  Allows you to configure a scope to compute the dependencies structure. There is also an option for automatically using the defined scope for future operations.

- **History**
  Provides access to the list of previously computed dependencies. Use the ✂️ Clear history button to remove all items from this list.

The contextual menu for a resource listed in the **Resource Hierarchy/Dependencies** view contains the following actions:

- **Open**
  Opens the resource. You can also double-click a resource in the Hierarchy/Dependencies structure to open it.

- **Go to reference**
  Opens the source document where the resource is referenced.

- **Copy location**
  Copies the location of the resource.

- **Move resource**
  Moves the selected resource.

- **Rename resource**
  Renames the selected resource.

- **Resource Hierarchy**
  Shows the hierarchy for the selected resource.

- **Resource Dependencies**
  Shows the dependencies for the selected resource.

- **Add to Main Files**
Adds the currently selected resource in the Main Files directory (on page 383).

Expand More

Expands more of the children of the selected resource from the Hierarchy/Dependencies structure.

Collapse All

Collapses all children of the selected resource from the Hierarchy/Dependencies structure.

Tip:

When a recursive reference is encountered in the Hierarchy view, the reference is marked with a special icon ்.

Note:

The Move resource or Rename resource actions give you the option to update the references to the resource (on page 1122).

Moving/Renaming Schematron Resources

You can move and rename a resource presented in the Resource/Hierarchy Dependencies view, using the Rename resource and Move resource refactoring actions from the contextual menu.

When you select the Rename action in the contextual menu of the Resource/Hierarchy Dependencies view, the Rename resource dialog box is displayed. The following fields are available:

- **New name** - Presents the current name of the edited resource and allows you to modify it.
- **Update references of the renamed resource(s)** - Select this option to update the references to the resource you are renaming. A Preview option is available that allows you to see what will be updated before selecting Rename to process the operation.

When you select the Move action from the contextual menu of the Resource/Hierarchy Dependencies view, the Move resource dialog box is displayed. The following fields are available:

- **Destination** - Presents the path to the current location of the resource you want to move and gives you the option to introduce a new location.
- **New name** - Presents the current name of the moved resource and gives you the option to change it.
- **Update references of the moved resource(s)** - Select this option to update the references to the resource you are moving, in accordance with the new location and name. A Preview option is available that allows you to see what will be updated before selecting Move to process the operation.

Highlight Component Occurrences in Schematron Documents

When you position your mouse cursor over a component in a Schematron document, Oxygen XML Editor searches for the component declaration and all its references and highlights them automatically.
Customizable colors are used: one for the component definition and another one for component references. Occurrences are displayed until another component is selected.

To change the default behavior of Highlight Component Occurrences, open the Preferences dialog box (Options > Preferences) (on page 98) and go to Editor > Mark Occurrences. You can also trigger a search using the Search > Search Occurrences in File Ctrl + Shift + U (Command + Shift + U on OS X) action from contextual menu. Matches are displayed in separate tabs of the Results view (on page 508).

Searching and Refactoring Operations in Schematron Documents

Search Actions

The following search actions can be applied on pattern, phase, or diagnostic types and are available from the Search submenu in the contextual menu of the current editor or from the Document > References menu:

- **Search References**
  Searches all references of the item found at current cursor position in the defined scope, if any. If a scope is defined, but the currently edited resource is not part of the range of resources determined by this, a warning dialog box is displayed and you have the possibility to define another search scope.

- **Search References in**
  Searches all references of the item found at current cursor position in the file or files that you specify when define a scope in the Search References dialog box.

- **Search Declarations**
  Searches all declarations of the item found at current cursor position in the defined scope if any. If a scope is defined, but the currently edited resource is not part of the range of resources determined by this, a warning dialog box will be displayed and you have the possibility to define another search scope.

- **Search Declarations in**
  Searches all declarations of the item found at current cursor position in the file or files that you specify when you define a scope for the search operation.

- **Search Occurrences in File**
  Searches all occurrences of the item at the cursor position in the currently edited file.

Refactoring Actions

The following refactoring actions can be applied on pattern, phase, or diagnostic types and are available from the Refactoring submenu in the contextual menu of the current editor or from the Document > Refactoring menu:

- **Rename Component**
  Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at
the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the Esc or Enter key on your keyboard.

**Rename Component in**

Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the Preview button, you can view the files to be affected by the action.

![Rename Identity Constraint Dialog Box](image)

**Figure 418. Rename Identity Constraint Dialog Box**

**Searching and Refactoring Operations Scope in Schematron Documents**

The scope is a collection of documents that define the context of a search and refactor operation. To control it you can use the ![Change scope] operation, available in the Quick Assist action set or on the Resource Hierarchy/Dependency View toolbar. You can restrict the scope to the current project or to one or multiple working sets (on page 2972). The Use only Main Files, if enabled checkbox allows you to restrict the scope of the search and refactor operations to the resources from the Main Files directory. Click read more for details about the Main Files support (on page 383).
The scope you define is applied to all future search and refactor operations until you modify it. Contextual menu actions allow you to add or delete files, folders, and other resources to the working set (on page 2972) structure.

**Quick Assist Support in Schematron Documents**

The *Quick Assist support* (on page 2970) improves the development work flow, offering fast access to the most commonly used actions when you edit schema documents.

The *Quick Assist feature* (on page 2970) is activated automatically when the cursor is positioned over the name of a component. It is accessible via a yellow bulb icon (💡) placed at the current line in the stripe on the left side of the editor. Also, you can invoke the quick assist menu by using the Alt + 1 (Meta + Alt + 1 on macOS) keyboard shortcuts.

**Figure 420. Schematron Quick Assist Support**

The *Quick Assist* support offers direct access to the following actions:

- Rename Component in
Renames the component and all its dependencies.

**Search Declarations**

Searches the declaration of the component in a predefined scope. It is available only when the context represents a component name reference.

**Search References**

Searches all references of the component in a predefined scope.

**Component Dependencies**

Searches the component dependencies in a predefined scope.

**Change Scope**

Configures the scope that will be used for future search or refactor operations.

**Rename Component**

Allows you to rename the current component in-place.

**Search Occurrences**

Searches all occurrences of the component within the current file.

---

**Schematron Unit Test (XSpec)**

XSpec is a behavior driven development (BDD) framework for XSLT, XQuery, and Schematron. XSpec consists of syntax for describing the behavior of your XSLT, XQuery, or Schematron code, and some code that enables you to test your code against those descriptions.

**Creating a Schematron Unit Test**

To create a Schematron Unit Test, go to File > New > Schematron Unit Test. This is simple document template to help you get started.

**Running a Schematron Unit Test**

To run a Unit Test, open the XSpec file in an editor and click **Apply Transformation Scenario(s)** on the main toolbar. This will run the built-in **Run XSpec Test** transformation scenario that is defined in the XSpec framework (on page 2967).

**Testing a Stylesheet**

An XSpec file contains one or more test scenarios.

**Example**

Suppose you have this Schematron rule that says sections should have a title:

```xml
<sch:pattern>
  <sch:rule context="section">
    <sch:assert test="title" id="a002">
      section should have a title
    </sch:assert>
  </sch:rule>
</sch:pattern>
```
The XSpec test could look like this:

```xml
<description xmlns:x="http://www.jenitennison.com/xslt/xspec" schematron="demo-01.sch">
  <scenario label="section should have a title">
    <context>
      <article>
        <section>
          <title>Introduction</title>
          <p>This is an example.</p>
        </section>
        <section>
          <p>This is an example.</p>
        </section>
      </article>
    </context>
    <expect-not-assert id="a002" location="/article[1]/section[1]"/>
    <expect-assert id="a002" location="/article[1]/section[2]"/>
  </scenario>
</description>
```

The `<sch:assert>` with the id="a002" is not expected to be triggered on the first section since it includes a title. This requirement is expressed with the `<x:expect-not-assert>` element.

Since the second section does not have a title, you would expect the Schematron rule to be triggered and this requirement is expressed with the `<x:expect-assert>` element.

For more details about how to write Schematron tests and various samples, see [https://github.com/xspec/xspec/wiki/Writing-Scenarios-for-Schematron#writing-tests](https://github.com/xspec/xspec/wiki/Writing-Scenarios-for-Schematron#writing-tests).

**Adding a Catalog to an XSpec Transformation**

If your Schematron needs a catalog, you can add one to the XSpec transformation by doing one of the following:

- If you are using a project (on page 365) in Oxygen XML Editor, create a `catalog.xml` file in the project directory. This catalog will then be loaded automatically.
- Edit (on page 1440) the Run XSpec Test transformation scenario, go to the Parameters tab (on page 1404), and set the value of the catalog parameter to the location of your catalog file.
Editing Schematron Quick Fixes

Oxygen XML Editor provides support for editing the Schematron Quick Fixes (on page 758) (SQF). They help you resolve issues that appear in XML documents that are validated against Schematron schemas by offering you solution proposals. The Schematron Quick Fixes are an extension of the Schematron language and they allow you to define fixes for Schematron validation messages. Specifically, they are associated with `assert` or `report` messages. You can define a library of Quick Fixes by editing them directly in the current Schematron file or in a separate file. Oxygen XML Editor assists you in editing Schematron Quick Fixes with schema-based content completion, syntax highlighting, and validation as you type.

A typical use case is using Schematron Quick Fixes to assist content authors with common editing tasks. For example, you can use Schematron rules to automatically report certain validation warnings (or errors) when performing regular editing tasks, such as inserting specific elements or changing IDs to match specific naming conventions.

For information about applying and detecting the Schematron schemas that include SQF, see Associating a Schema to XML Documents (on page 759).

Displaying the Schematron Quick Fix Proposals

The defined Schematron Quick Fixes are displayed on validation errors in Text mode and Author mode.

**Figure 421. Example of a Schematron Quick Fix**

Examples of Schematron Rules and Quick Fixes

This topic is meant to provide some basic examples of Schematron Rules and Schematron Quick Fixes (SQF) to help you create and impose your own rules and quick fixes.

Other examples and ideas can also be found at:

- Public GitHub project with the Schematron file used for Oxygen's User Guide
- Public GitHub project with sample Schematron Quick Fixes
Schematron Examples

Schematron Use Case 1: Impose a Relax NG Schema Declaration

Description: The following sample rule is useful if, for example, you need to enforce the use of Relax NG schema declarations in all of your documents (i.e. instead of using DTD schemas).

Sample Code:

```xml
<?xml version="1.0" encoding="UTF-8"?>
    <sch:let name="rngDeclaration" value="processing-instruction('xml-model')
        [saxon:get-pseudo-attribute('schematypens')='http://relaxng.org/ns/structure/1.0']"/>
    <sch:pattern>
        <sch:rule context="/element()">
            <sch:assert test="exists($rngDeclaration)">
                You must define a Relax NG schema declaration in the document (DTD schemas are not supported).</sch:assert>
        </sch:rule>
    </sch:pattern>
</sch:schema>
```

Result: The engine checks for a Relax NG schema declaration in the document and displays an error if it is missing. The error is reported on the document's root element (/element()).

Schematron Use Case 2: Check for Missing IDs

Description: The following sample rule checks for missing or undefined IDs in a TEI document. Specifically, it looks for IDs from the `tei:rs/@ref` attribute defined in the document named `persons.xml` (as `xml:id` of a TEI `person` element).

Sample Code:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<sch:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron" queryBinding="xslt2">
    <sch:ns uri="http://www.tei-c.org/ns/1.0" prefix="tei"/>
    <sch:let name="personIds" value="document('..//persons.xml')/tei:TEI//tei:person/@xml:id"/>
    <sch:pattern>
        <sch:rule context="tei:rs">
            <sch:let name="refIds" value="for $id in tokenize(@ref, ' ') return substring-after($id, '#')"/>
            <sch:let name="missingIds" value="for $id in $refIds return (if($id = $personIds) then '' else $id)"/>
            <sch:report test="$missingIds != ''">
                The following ids "<sch:value-of select="$missingIds"/>
            </sch:report>
        </sch:rule>
    </sch:pattern>
</sch:schema>
```
are not defined in "<sch:value-of select="$personIds"/>
</sch:report>
</sch:rule>
</sch:pattern>
</sch:schema>

where the XML document looks something like this:

```xml
<tei xmlns="http://www.tei-c.org/ns/1.0">
  <rs ref="../SomePerson/persons.xml#EDP ../personography/HAMpersons.xml#SD">text</rs>
  <rs ref="../SomePerson/persons.xml#EDP">text</rs>
</tei>
```

**Result:** The engine displays an error message listing the missing/undefined IDs.

**Schematron Use Case 3: Check for Broken Links**

**Description:** The following sample rule detects broken links in DITA `<xref>` or `<link>` elements. The first example only checks links that do not contain an anchor (#).

**Sample Code:**

```xml
<rule
  context="*[contains(@class, ' topic/xref ') or contains(@class, ' topic/link ')]
  [@href][not(contains(@href, '#'))][not(@scope = 'external')]
  [not(@type) or @type='dita']">
  <assert test="doc-available(resolve-uri(@href, base-uri(.)))">
    The document linked by <value-of select="local-name()"/>
    "<value-of select="@href"/>" does not exist!</assert>
</rule>
```

For links that contain an anchor, the Schematron rule must look something like this:

```xml
<rule
  context="*[contains(@class, ' topic/xref ') or contains(@class, ' topic/link ')]
  [@href][contains(@href, '#')][not(@scope = 'external')]
  [not(@type) or @type='dita']">
  <let name="file" value="substring-before(@href, '#')"/>
  <let name="idPart" value="substring-after(@href, '#')"/>
  <let name="topicId"
    value="if (contains($idPart, '/') then substring-before($idPart, '/') else $idPart")/>
  <let name="id"
    value="substring-after($idPart, '/')"/>

  <assert test="document($file, .)//*[@id=$topicId]">
    Invalid topic id "<value-of select="$topicId"/>" </assert>
  <assert test="$id ='' or document($file, .)//*[@id=$id]">
    No such id "<value-of select="$id"/>" is defined! </assert>
  <assert test="$id='' or document($file, .)//*[@id=$id]"/>
```

```xml
</rule>
```
The id "<value-of select="$id"/>" is not in the scope of the referenced topic id "<value-of select="$topicId"/>". </assert>
</rule>

Result: The engine displays an error message when a broken link or cross reference is detected.

**Schematron Use Case 4: Check for Duplicate IDs**

**Description:** The following sample rule detects if there are two sibling `<step>` elements with the same `id` value in a DITA Task document.

**Sample Code:**

```xml
<sch:rule context="*[contains(@class, ' task/step ')]">
  <sch:let name="id" value="@id"/>
  <sch:report
    test="preceding-sibling::element()[contains(@class, ' task/step ')][@id = $id]">
    Element with duplicate ID "<sch:value-of select="$id"/>" detected.
  </sch:report>
</sch:rule>
```

Result: The engine displays an error message when a duplicate ID is detected in sibling `<step>` elements within a DITA Task document.

**Schematron Use Case 5: Check for Duplicate DITA Topic References**

**Description:** The following sample rule checks a DITA map for duplicate `<topicref>` elements with the same `href` value.

**Sample Code:**

```xml
<sch:rule context="*[contains(@class, ' map/topicref ')]">
  <sch:let name="href" value="@href"/>
  <sch:report
    test="preceding::element()[contains(@class, ' map/topicref ')][@href = $href]">
    Duplicate topicref "<sch:value-of select="$href"/>" detected in map.
  </sch:report>
</sch:rule>
```

Result: The engine displays an error message when multiple `<topicref>` elements with the same `href` value are detected in a DITA map.

**Schematron Use Case 6: Restrict Certain Words from the Title**

**Description:** The following sample rule checks for instances of specified words to be restricted from a `<title>` element (in this example, the words `test` and `hello` are restricted).

**Sample Code:**
Result: The engine displays an error message if one of the specified restricted words appear in a title.

Schematron Use Case 7: Check the Location of a Resource

Description: The following sample rule checks if the path to a resource (in this case, an image) is specified correctly. Specifically, this sample rule reports that the image must be located in the current project (the images location must be relative to the parent folder and no more than one ".../" in the path.

Sample Code:

```
<sch:rule context="image">
    <sch:report test="count(tokenize(@href, '\./\')) > 2">
        The image must be located in the current project. It is currently located in: <sch:value-of select="@href"/>
    </sch:report>
</sch:rule>
```

Result: The engine displays an error message if an image is detected in a location other than the current project, relative to the parent folder.

Schematron Use Case 8: Check for Extra Spaces at Beginning/End of Elements

Description: The following sample rule checks for spaces at the beginning and end of elements.

Tip: You could specify a list of elements to check to make the rule context-sensitive.

Sample Code:

```
<rule context="p|ph|codeph|filename|indexterm|xref|user-defined|user-input">
    <let name="firstNodeIsElement" value="node()[1] instance of element()"/>
    <let name="lastNodeIsElement" value="node()[last()] instance of element()"/>
    <report test="(not($firstNodeIsElement) and matches(., '\s', ';j')) or (not($lastNodeIsElement) and matches(., '\s$', ';j'))"
```
Result: The engine displays an error message if a whitespace is detected at the beginning or end of a textual element.

Schematron Use Case 9: Impose Capitalizing the First Letter

Description: The following sample rule detects if elements start with a capital letter or a number. The rule is implemented using abstract patterns. The abstract pattern `starts-with-capital` has one argument representing the element to be checked. There are two implementations of the abstract pattern, one that specifies the `<title>` element as the element to verify, and one that specifies the `<li>` element.

Sample Code:

```xml
<sch:pattern abstract="true" id="starts-with-capital">
  <sch:rule context="$element" role="information">
    <sch:let name="firstNodeIsElement" value="node()[1] instance of element()"/>
    <sch:report test="(not($firstNodeIsElement) and (not(matches(., '^[A-Z|0-9]')))">
      Start the element <$element&gt; with a capital letter.</sch:report>
  </sch:rule>
</sch:pattern>

<sch:pattern is-a="starts-with-capital">
  <sch:param name="element" value="title"/>
</sch:pattern>

<sch:pattern is-a="starts-with-capital">
  <sch:param name="element" value="li"/>
</sch:pattern>
```

Result: The engine displays an error message if a title begins with a word that does not contain a capital letter or number as its first character.

Schematron Use Case 10: Check for Specified Terms in a Paragraph

Description: The following sample rule checks if any DITA `<p>` elements contain certain keywords defined in an external document.

Sample Code:

```xml
<sch:pattern>
  <sch:let name="keys" value="document('keys-common.ditamap')//keyword"/>
  <sch:rule context="p">
    <sch:let name="text" value="."/>
    <sch:let name="matchedKeys" value="keys[contains($text, normalize-space(.))]"/>
    <sch:report id="now001" test="count($matchedKeys) > 0" role="error">
      The paragraph text contains the keywords: <sch:value-of select="$matchedKeys"/>
    </sch:report>
  </sch:rule>
</sch:pattern>
```
Result: The engine displays an error message if any of the keywords listed in an external document are detected within a DITA `<px>` element.

**Schematron Use Case 11: Impose a Minimum Value**

**Description:** The following sample rule determines the `<type>` element value with the minimum version specified by the @version attribute and then verifies that they are all equal to the determined value.

**Sample Code:**

```xml
<sch:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron" queryBinding="xslt2">
  <sch:let name="typeValue" value="/Node1[not(@version > ../Node1/@version)][1]/Type/text()"/>

  <sch:pattern>
    <sch:rule context="Type">
      <sch:assert test="text() = $typeValue">
        The Type value must be "<sch:value-of select="$typeValue"/>"
      </sch:assert>
    </sch:rule>
  </sch:pattern>
</sch:schema>
```

where the XML file would look something like this:

```xml
<root>
  <Node1 version="1">
    <Element1>Value1</Element1>
    <Type>123456</Type>
  </Node1>
  <Node1 version="2">
    <Element1>Value1</Element1>
    <Type>123456</Type>
  </Node1>
  <Node1 version="3">
    <Element1>Value1</Element1>
    <Type>1234567</Type>
  </Node1>
</root>
```

Result: The engine displays an error message if a `<type>` element value does not equal the minimum version specified by the @version attribute.
SQF (Schematron Quick Fix) Examples

SQF Use Case 1: Impose a DITA Prolog

**Description:** The following sample Schematron rule checks a DITA topic to make sure it contains `<prolog>`, `<critdates>`, `<revised>` elements and the sample Quick Fix proposes options for inserting the missing elements.

**Sample Code:**

```
<sch:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron" queryBinding="xslt2"
            xmlns:sqf="http://www.schematron-quickfix.com/validator/process">
  <sch:rule context="*[contains(@class, ' topic/topic ')]">
    <sch:assert sqf:fix="add_prolog" test="prolog" role="warn">Every topic must contain prolog/critdates/revised elements where the revised modified date is in YYYY-MM-DD format.</sch:assert>
    <sqf:fix id="add_prolog">
      <sqf:description>
        <sqf:title>Add prolog/critdates/revised elements, where the revised element's @modified attribute value is the current date in YYYY-MM-DD format.</sqf:title>
      </sqf:description>
      <sqf:add match="*[contains(@class, ' topic/body ')]" node-type="element" position="before" target="prolog">
        <critdates>
          <revised modified=""></revised>
        </critdates>
      </sqf:add>
    </sqf:fix>
  </sch:rule>

  <sch:rule context="*[contains(@class, ' topic/prolog ')]" role="warn">
    <sch:report test="not(critdates)" sqf:fix="add_critdates">The prolog element must have critdates/revised elements with the @modified attribute value in YYYY-MM-DD format.</sch:report>
    <sqf:fix id="add_critdates">
      <sqf:description>
        <sqf:title>Add the critdates element.</sqf:title>
      </sqf:description>
      <sqf:add node-type="element" target="critdates">
        <revised modified=""></revised>
      </sqf:add>
    </sqf:fix>
  </sch:rule>
</sch:schema>
```
The critdates element must have revised @modified in YYYY-MM-DD format.

Add the revised element.

Add @id attribute to the current section. The ID is generated from the section title.

Generate an id based on the section title. If there is no title then generate a random id.
The short description must be added in an abstract element
<sch:assert>
<!-- Check if there is an abstract element -->
<sch:let name="abstractElem" value="preceding-sibling::abstract | following-sibling::abstract"/>

<!-- Create an abstract element and add the short description -->
<sqf:fix id="moveToAbstract" use-when="not($abstractElem)"
  
  <sqf:title>Move short description in an abstract element</sqf:title>
</sqf:fix>

<!-- Move the short description in the abstract element-->
sqf:fix id="moveToExistingAbstract" use-when="$abstractElem"
  
  <sqf:title>Move short description in the abstract element</sqf:title>
</sqf:fix>

<!-- Template used to copy the current node -->
<xsl:template match="node() | @*" mode="copyExceptClass">
  
  <xsl:copy copy-namespaces="no">
    <xsl:apply-templates select="node() | @*" mode="copyExceptClass"/>
  </xsl:copy>
</xsl:template>

<!-- Template used to skip the @class attribute from being copied -->
<xsl:template match="@class" mode="copyExceptClass"/>
</sch:schema>
**Result:** The engine displays an error message if an `<abstract>` element does not contain a `<shortdesc>` element and the Quick Fix mechanism proposes options for inserting the missing structure or to move the `<shortdesc>` element inside the `<abstract>` element.

**SQF Use Case 4: Impose a Certain Article Type**

**Description:** The following sample Schematron rule checks the `@article-type` attribute to make sure its value is one of the specified allowed values (`abstract`, `addendum`, `announcement`, `article-commentary`) and the sample Quick Fix proposes options for replacing any other detected value with one of the allowed values.

**Sample Code:**

```xml
<sch:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron" queryBinding="xslt2"
xmlns:sqf="http://www.schematron-quickfix.com/validator/process">

<sch:let name="articleTypes" value="('abstract', 'addendum', 'announcement', 'article-commentary')"/>

<sch:pattern>
  <sch:rule context="article/@article-type">
    <sch:assert test=". = $articleTypes" sqf:fix="setArticleType">
      Should be one of the article types:
      <sch:value-of select="$articleTypes"/>
    </sch:assert>

    <sqf:fix id="setArticleType" use-for-each="$articleTypes">
      <sqf:description>
        <sqf:title>Set article type to '<sch:value-of select="$sqf:current" />'
      </sqf:title>
      <sqf:replace node-type="attribute" target="article-type" select="$sqf:current"/>
    </sqf:fix>
  </sch:rule>
</sch:pattern>
</sch:schema>
```

**Result:** The engine displays an error message if an `@article-type` attribute has any other value other than `abstract`, `addendum`, `announcement`, or `article-commentary` and the Quick Fix mechanism proposes options for replacing the disallowed value with one of those four allowed values (using the `use-for-each` construct).

**Defining Schematron Quick Fixes**

You can define and customize Schematron Quick Fixes (on page 2970) directly in the current Schematron file or in a separate Schematron file. The Schematron Quick Fixes are an extension of the Schematron language and they allow you to define fixes for Schematron error messages. You can reference the Quick Fixes using the `@sqf:fix` attribute inside the `<assert>` or `<report>` elements (for example: `<assert test="title" sqf:fix="removeComments">Remove comments</assert>`).
Defining a Schematron Quick Fix
The basics of a Schematron Quick Fix is defined by an ID, name, description, and the operations to be executed.

- **ID** - Defined by the `@id` attribute from the `<sqf:fix>` element and must be unique in the current context. It is used to refer the Quick Fix from a `<report>` or `<assert>` element.
- **Name** - The name of the Quick Fix is defined by the `<sqf:title>` element.
- **Description** - Defined by the text in the paragraphs (`<sqf:p>`) of the `<sqf:description>` element.
- **Operations** - The following basic types of operations (elements) *on page 1141* are supported:
  - `<sqf:add>` Element - To add a new node or fragment in the document.
  - `<sqf:delete>` Element - To remove a node from the document.
  - `<sqf:replace>` Element - To replace a node with another node or fragment.
  - `<sqf:stringReplace>` Element - To replace text content with other text or a fragment.

Figure 422. Schematron Quick Fix Components

The assertion message that generates the Quick Fix is added as the `<sqf:description>` of the problem to be fixed. The `<sqf:title>` is presented as the name of the Quick Fix. The content of the paragraphs (`<sqf:p>`) within the `<sqf:description>` element are presented in the tooltip message when the Quick Fix is selected.

Additional Elements Supported in the Schematron Quick Fixes

- `<sqf:user-entry>`
  This element defines a value that must be set manually by the user. For more information, see User Entry SQF Operation *(on page 1145).*

- `<sqf:call-fix>`
  This element calls another Quick Fix within a Quick Fix. The called Quick Fix must be defined globally or in the same Schematron rule as the calling Quick Fix. A calling Quick Fix adopts the activity elements of the called Quick Fix and should not include other activity elements. You can also specify which parameters are sent by using the `<sqf:with-param>` child element.
<sqf:group>

Allows you to group multiple Quick Fixes and refer them from an `<assert>` or `<report>` element.

<sqf:fixes>

Is defined globally and contains global fixes and groups of fixes.

<sqf:copy-of>

Used to copy the selected nodes that are specified by the `<select>` attribute. The element with its attribute is treated as an `xsl:copy-of` with a `<select>` attribute, as defined in the XSLT specification.

<sqf:param>

Defines a parameter for a Quick Fix. If the parameter is defined as `abstract` then the `type` and default value should not be specified and the fix can be called from an abstract pattern that defines this parameter.

Other SQF Notes

Note: The `<sqf:default-fix>` attribute is ignored in Oxygen XML Editor.

For more details on editing Schematron Quick Fixes, go to: Schematron Quick Fix Specifications

Basic Schematron Quick Fix Operations

There are four basic operations that can be executed in a Schematron Quick Fix (on page 2970): Add, Delete, Replace, and String Replace.

Add

The `<sqf:add>` element allows you to add a node to the instance. An anchor node is required to select the position for the new node. The anchor node can be selected by the `<match>` attribute. Otherwise, it is selected by the `<context>` attribute of the rule.

The `<target>` attribute defines the name of the node to be added. It is required if the value of the `<node-type>` attribute is set to anything other than "comment".

The `<sqf:add>` element has a `<position>` attribute and it determines the position relative to the anchor node. The new node could be specified as the first child of the anchor node, the last child of the anchor node, before the anchor node, or after the anchor node (`first-child` is the default value). If you want to add an attribute to the anchor node, do not use the `<position>` attribute.

Note:
If you insert an element and its content is empty, Oxygen XML Editor will insert the required element content.

An Example of the `<sqf:add>` Element:
<schema xmlns="http://purl.oclc.org/dsdl/schematron"
                xmlns:sqf="http://www.schematron-quickfix.com/validator/process"
                queryBinding="xslt2">
  <pattern>
    <rule context="head">
      <assert test="title" sqf:fix="addTitle">title element missing.</assert>
      <sqf:fix id="addTitle">
        <sqf:description>
          <sqf:title>Insert title element.</sqf:title>
        </sqf:description>
        <sqf:add target="title" node-type="element">Title text</sqf:add>
      </sqf:fix>
    </rule>
  </pattern>
</schema>

Specific Add Operations:

- **Insert Element** - To insert an element, use the `<sqf:add>` element, set the value of the `@node-type` attribute as "element", and specify the element QName (on page 2970) with the `@target` attribute. If the element has a prefix, it must be defined in the Schematron using a namespace declaration (`<ns uri="namespace" prefix="prefix"/>`).

- **Insert Attribute** - To insert an attribute, use the `<sqf:add>` element, set the value of the `@node-type` attribute as "attribute", and specify the attribute QName (on page 2970) with the `@target` attribute. If the attribute has a prefix, it must be defined in the Schematron using a namespace declaration (`<ns uri="namespace" prefix="prefix"/>`).

- **Insert Fragment** - If the `@node-type` attribute is not specified, the `<sqf:add>` element will insert an XML fragment. The XML fragment must be well-formed. You can specify the fragment in the `<sqf:add>` element or by using the `@select` attribute.

- **Insert Comment** - To insert a comment, use the `<sqf:add>` element and set the value of the `@node-type` attribute as "comment".

- **Insert Processing Instruction** - To insert a processing instruction, use the `<sqf:add>` element, set the value of the `@node-type` attribute as "pi" or "processing-instruction", and specify the name of the processing instruction in the `@target` attribute.

Delete

The `<sqf:delete>` element allows you to remove any type of node (such as elements, attributes, text, comments, or processing instructions). To specify nodes for deletion, the `<sqf:delete>` element can include a `@match` attribute that is an XPath expression (the default value is `.`). If the `@match` attribute is not included, it deletes the context node of the Schematron rule.

An Example of the `<sqf:delete>` Element:
Replace

The `sqf:replace` element allows you to replace nodes. Similar to the `sqf:delete` element, it can include a `match` attribute. Otherwise, it replaces the context node of the rule. The `sqf:replace` element has three tasks. It identifies the nodes to be replaced, defines the replacing nodes, and defines their content.

An Example of the `sqf:replace` Element:

```xml
<schema xmlns="http://purl.oclc.org/dsdl/schematron"
        xmlns:sqf="http://www.schematron-quickfix.com/validator/process"
        queryBinding="xs1t2">
  <pattern>
    <rule context="title">
      <report test="exists(ph)" sqf:fix="resolvePh" role="warn">
        ph element is not allowed in title.</report>
      <sqf:fix id="resolvePh">
        <sqf:replace match="ph">
          <value-of select="."/>
        </sqf:replace>
      </sqf:fix>
    </rule>
  </pattern>
</schema>
```

Other Attributes for Replace Operations:
• **node-type** - Determines the type of the replacing node. The permitted values include:
  - **keep** - Keeps the node type of the node to be replaced.
  - **element** - Replaces the node with an element.
  - **attribute** - Replaces the node with an attribute.
  - **pi** - Replaces the node with a processing instruction.
  - **comment** - Replaces the node with a comment.

• **target** - By using a *QName (on page 2970)* it gives the replacing node a name. This is necessary when the value of the `@node-type` attribute is anything other than "comment".

• **select** - Allows you to choose the content of the replacing nodes. You can use XPath expressions with the `@select` attribute. If the `@select` attribute is not specified then the content of the `<sqf:replace>` element is used instead.

### String Replace

The `<sqf:stringReplace>` element is different from the others. It can be used to find a sub-string of text content and replace it with nodes or other strings.

**Attributes for the String Replace Operation:**

• **match** - Allows you to select text nodes that contain the sub-strings you want to replace.

• **select** - Allows you to select the replacing fragment, in case you do not want to set it in the content of the `<stringReplace>` element.

• **regex** - Matches the sub-strings using a regular expression.

---

**Note:**

Consider the following information about using regular expressions in the `<stringReplace>` element:

- The regular expressions from this operation are compiled as Java regular expressions. For more information, see [https://docs.oracle.com/javase/7/docs/api/java/util/regex/Pattern.html](https://docs.oracle.com/javase/7/docs/api/java/util/regex/Pattern.html).
- The *j flag* allows you to use the standard Java regular expression engine, which allows native Java regular expression syntax. This allows, for example, the use of `\b` in a regular expression to match word boundaries. For more information, see [http://www.saxonica.com/html/documentation/functions/fn/matches.html](http://www.saxonica.com/html/documentation/functions/fn/matches.html).
- Regular expressions in the `<sqf:stringReplace>` element always have the *dot matches all* flag set to "true". Therefore, the line terminator will also be matched by the regular expression.

• **flags** - Specifies flags to control the interpretation of the regular expression (given in the `@regex` attribute).
Attention:
The context of the content within the `<sqf:stringReplace>` element is set to the whole text node, rather than the current sub-string.

An Example of the `<sqf:stringReplace>` Element:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<sch:schema
    xmlns:sch="http://purl.oclc.org/dsdl/schematron"
    xmlns:sqf="http://www.schematron-quickfix.com/validator/process"
    queryBinding="xslt2">

    <sch:pattern>
        <sch:rule context="text()">
            <sch:report test="matches(., 'Oxygen', 'i')">
                sqf:fix="changeWord">The oXygen word is not allowed</sch:report>
            </sch:report>
            <sqf:fix id="changeWord">
                <sqf:description>
                    <sqf:title>Replace word with product</sqf:title>
                </sqf:description>
                <sqf:stringReplace regex="Oxygen" flags="i">\ph keyref="product"/></sqf:stringReplace>
            </sqf:fix>
        </sch:rule>
    </sch:pattern>
</sch:schema>
```

Related Information:
User Entry SQF Operation (on page 1145)
Restricting Quick Fix Operations (on page 1146)
Examples of Schematron Rules and Quick Fixes (on page 1101)

User Entry SQF Operation

The `<sqf:user-entry>` element defines a value that must be set manually by the user. If multiple `<user-entry>` elements are defined, Oxygen XML Editor will display a dialog box for each one where the user can specify values. Also, the `<user-entry>` element can be used as an XPath variable where the XPath variable is the name of the `<user-entry>`. Note that the `@default` attribute defines a default value for the operation by using an XPath expression (as in the example below) and its value will be presented in the user entry dialog box.

An Example of the `<sqf:user-entry>` Element:

```xml
<sqf:fix id="editTitle">
    <sqf:description>
        <sqf:title>Edit the journal title</sqf:title>
    </sqf:description>
</sqf:fix>
```
<sqf:user-entry name="newTitle" default="@title">
  <sqf:description>
    <sqf:title>Edit the title:</sqf:title>
  </sqf:description>
</sqf:user-entry>

<sqf:replace match="@title" target="title" node-type="keep" select="$newTitle/>
</sqf:fix>

Related Information:
Basic Schematron Quick Fix Operations (on page 1141)
Examples of Schematron Rules and Quick Fixes (on page 1101)

Restricting Quick Fix Operations
To restrict a Quick Fix (on page 2970) or a specific operation to only be available if certain conditions are met, the @use-when attribute can be included in the <sqf:fix> element or any of the SQF operation elements. The condition of the @use-when attribute is an XPath expression and the fix or operation will be performed only if the condition is satisfied. In the following example, the use-when condition is applied to the <sqf:fix> element:

<sqf:fix id="last" use-when="$colWidthSummarized - 100 lt $lastWidth"
  role="replace">
  <sqf:title>Subtract excessive width from the last element.</sqf:title>
</sqf:fix>

Related Information:
Basic Schematron Quick Fix Operations (on page 1141)

Formatting/Indenting Content Inserted by SQF Operations
Content that is inserted by the Add, Replace, or String Replace Schematron Quick Fix (on page 2970) operations is automatically indented unless you set the value of the @xml:space attribute to preserve on the operation element. There are several methods available to format the content that is inserted:

- **xsl:text** - You can use an <xsl:text> element to format the inserted content and keep the automatic indentation, as in the following example:

  <sqf:add position="last-child">
    <xsl:text>
• **xml:space** - Use the `@xml:space` attribute and set its value to `preserve` to format the content and specify the spacing between elements, as in the following example:

```xml
<sqf:add node-type="element" target="codeblock" xml:space="preserve">
/* a long sample program */
Do forever
    Say "Hello, World"
End</sqf:add>
```

Related Information:
Basic Schematron Quick Fix Operations *(on page 1141)*

**Executing Schematron Quick Fixes in Other Documents**

You can apply Schematron Quick Fixes *(on page 2970)* over nodes from referenced documents (using XInclude or external entities), and you can access them as nodes in your current document.

Also, you can apply the Quick Fixes over other documents using the `doc()` function in the value of the `@match` attribute. For example, you can add a new key in the `keylist.xml` file using the following operation:

```xml
<sqf:add match="doc('keylist.xml')/KeyList" target="Key" node-type="element" select="Key2">
```

**Generate Multiple Similar Quick Fixes**

You can generate the same Schematron Quick Fix *(on page 2970)* for multiple matches. To do this, you can add the `@use-for-each` attribute inside the `<sqf:fix>` element and for each match of the XPath expression in the value of the `@use-for-each` attribute, a Quick Fix will be presented to the user. The XPath expression does not change the context of the Quick Fix. If you want to access the current match from the XPath expression, you can use the `$sqf:current` variable.

**Example:**

Suppose you want to restrict the user from entering more than 4 list items in a list. The following example presents an error on any list that has more than 4 list items and offers a Quick Fix with multiple proposals where the user would specify which list item to remove.

```xml
<sch:rule context="ul">
    <sch:report test="count(li) gt 4" sqf:fix="removeAnyItem">
```
The list cannot contain more than 4 entries.

```xml
<sch:report>
  <sqf:fix id="removeAnyItem" use-for-each="1 to count(li)"
    <sqf:description>
      <sqf:title>Remove item #<sch:value-of select="$sqf:current"/></sqf:title>
      <sqf:delete match="li[$sqf:current]"/>
    </sqf:fix>
  </sch:rule>
</sch:report>
```

**Localizing SQF Messages**

Oxygen XML Editor provides support for presenting Schematron Quick Fix messages in multiple languages. The language used for the SQF messages is the language specified in the 'Message Language' option in the Schematron preferences page (on page 211). If you want to provide an alternative message for a specific language, you can reference IDs or key values for the specific alternate text phrase. In Oxygen XML Editor, the alternate text phrase is defined in a `<sch:diagnostic>` element and it can be used in conjunction with `<sch:assert>` or `<sch:report>` elements.

**Example:**

The following example presents a quick fix with a different message depending on whether the user's language is English or German.

```xml
<sch:rule context="dog">
  <sch:assert test="bone" diagnostics="d_en d_de" sqf:fix="addBone">
    A dog should have a bone.</sch:assert>

  <sqf:fix id="addBone">
    <sqf:description>
      <sqf:title ref="fix_en fix_de" xml:lang="en">Add a bone</sqf:title>
      <sqf:p ref="fix_desc_en fix_desc_de" xml:lang="en">Add bone element as child</sqf:p>
    </sqf:description>
    <sqf:add node-type="element" target="bone"/>
  </sqf:fix>
</sch:rule>
```

```xml
<sch:diagnostics xml:lang="en">
  <sch:diagnostic id="d_en"> A dog should have a bone. </sch:diagnostic>
  <sch:diagnostic id="fix_en"> Add a bone </sch:diagnostic>
  <sch:diagnostic id="fix_desc_en"> Add a bone element as child </sch:diagnostic>
</sch:diagnostics>
```

```xml
<sch:diagnostics xml:lang="de">
  <sch:diagnostic id="d_de"> Ein Hund sollte ein Bein haben. </sch:diagnostic>
  <sch:diagnostic id="fix_de"> Fügen Sie einen Knochen hinzu </sch:diagnostic>
```
Integrating SQF in a Framework and Sharing Them

You can use Schematron Quick Fixes (on page 2970) to assist your content authors by imposing rules for an entire framework (on page 2967) (document type) and offering fixes when a rule violation is detected.

For example, if you are using DITA, you may want your contributors to avoid inserting a figure ( `<fig>` element) inside a paragraph ( `<p>` element) that contains other content since it may result in undesirable placement or spacing in the output. The Schematron rule and its Quick Fix for this particular use-case could look like this:

```xml
<schema xmlns="http://purl.oclc.org/dsdl/schematron"
  xmlns:sqf="http://www.schematron-quickfix.com/validator/process"
  queryBinding="xslt2">
  <pattern id="check.figure.location">
    <rule context="p/fig">
      <report test="true()" role="warn" sqf:fix="moveAfter">
        A figure inside a paragraph doesn't transform well into PDF. </report>
        <sqf:fix id="moveAfter">
          <sqf:title>Move after the paragraph.</sqf:title>
          <sqf:description>
            Move after the paragraph. </sqf:description>
          <let name="figToMove" value="."/>
          <sqf:add match="parent::p" select="$figToMove" position="after"/>
          <sqf:delete match="."/>
        </sqf:fix>
      </rule>
    </pattern>
  </schema>
```

The result of this example would be that the user will see a warning if they insert a `<fig>` element inside a `<p>` element and they are presented with the option of selecting the Quick Fix that would move the figure outside the paragraph.

How to Integrate SQF in a Framework

To integrate a Schematron Quick Fix in a framework (on page 2967), follow these steps:

1. Create a folder structure for an extended framework and save it somewhere on disk where you have full write access (for example, `<custom_frameworks/dita-extension>`).
2. In that new folder structure, create another folder that will contain all of your custom Schematron files (for example, `<custom_frameworks/dita-extension/rules>`).
3. Define the Schematron Quick Fix for a rule (on page 1139) in an existing or new Schematron file and save it in the folder you created in step 2.
4. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Document Type Association > Locations (on page 113). In this preferences page, add the path to your custom_frameworks folder in the Additional frameworks directories list, then click OK or Apply to save your changes.

5. Go to the Document Type Association preferences page (on page 111) and select a framework configuration (for example, DITA) and use the Extend button to create an extension for it.

6. Give the extension an appropriate name (for example, DITA - Custom), select External for the Storage option, and specify an appropriate path to your framework configuration file (for example, path/to/.../custom_frameworks/dita-extension/dita-extension.framework).

7. Make whatever changes you desire to the extension, then go to the Validation tab, edit the default validation scenario (select the scenario and click the Edit button), and add an extra validation unit to it (one that uses your custom Schematron file that includes the SQF). For more details about editing validation scenarios, see Configuring Validation Scenarios for a Framework (on page 2067).

8. Click OK to close the dialog box and then OK or Apply to save the changes to the Document Type Association preferences page (on page 111).

9. Add a reference to the Schematron file that includes the SQF in your framework by following the procedure in Associating a Schema in Validation Scenarios Defined in the Document Type (on page 764).

10. Open a document in your framework and test the new rule and Quick Fix.

11. You can continue to refine the Schematron and develop additional rules as needed.

Sharing Schematron Quick Fixes

To share Schematron Quick Fixes with other members of your team, you simply need to share the framework where you integrated the SQF. There are several methods for sharing frameworks and you can find details here: Sharing a Framework (on page 2131).

Related Information:
- Defining Schematron Quick Fixes (on page 1139)
- Basic Schematron Quick Fix Operations (on page 1141)
- Associating a Schema in Validation Scenarios Defined in the Document Type (on page 764)
- Sharing a Framework (on page 2131)

Validating Schematron Quick Fixes

By default, Schematron Quick Fixes (on page 2970) are validated as you edit them within the Schematron file or while editing them in a separate file. To change this, open the Preferences dialog box (Options > Preferences) (on page 98), go to Editor > Document Checking, and deselect the Enable automatic validation option (on page 197).

To validate Schematron Quick Fixes manually, select the Validate action from the Validation toolbar drop-down menu or the Document > Validate menu. The validation problems are highlighted directly in the editor, making it easy to locate and fix any issues.
Content Completion in SQF

Oxygen XML Editor helps you edit Schematron Quick Fixes (on page 2970) embedded in a Schematron document by offering proposals that are valid at the cursor position in a Content Completion Assistant (on page 2965). It can be manually activated with the Ctrl + Space (Command + Space on OS X) shortcut.

When you edit the value of an attribute that references a Quick Fix ID, the ids are collected from the entire definition scope. For example, if the editing context is assert/@sqf:fix, the Content Completion Assistant proposes all fixes defined locally and globally.

If the editing context is an attribute value that is an XPath expression (such as sqf:add/@match or replace/@select), the Content Completion Assistant offers the names of XPath functions, the XPath axes, and user-defined variables and parameters.

The Content Completion Assistant displays XSLT 1.0 functions (and optionally XSLT 2.0 / 3.0 functions) in the @path, @select, @context, @subject, and @test attributes, depending on the Schematron options (on page 210) that are set in Preferences pages. If the Saxon namespace (xmlns:saxon="http://icl.com/saxon") or the Saxon namespace is declared in the Schematron schema (xmlns:saxon="http://saxon.sf.net/") the content completion also displays the XSLT Saxon extension functions.

Highlight Quick Fix Occurrences in SQF

When you position your mouse cursor over a Quick Fix (on page 2970) ID in a Schematron document, Oxygen XML Editor searches for the Quick Fix declaration and all its references and highlights them automatically.

Customizable colors are used: one for the Quick Fix definition and another one for its references. Occurrences are displayed until another Quick Fix is selected.

To change the default behavior of Highlight Component Occurrences, open the Preferences dialog box (Options > Preferences) (on page 98) and go to Editor > Mark Occurrences. You can also trigger a search using the Search > Search Occurrences in File (Ctrl + Shift + U (Command + Shift + U on OS X)) action from contextual menu. Matches are displayed in separate tabs of the Results view (on page 508).

Searching and Refactoring Operations in SQF

Search Actions

The following search actions can be applied on Quick Fix (on page 2970) IDs and are available from the Search submenu in the contextual menu of the current editor or from the Document > References menu:
Search References in

Searches all references of the item found at current cursor position in the defined scope, if any. If a scope is defined, but the currently edited resource is not part of the range of resources determined by this, a warning dialog box is displayed and you have the possibility to define another search scope.

Search References in

Searches all references of the item found at current cursor position in the file or files that you specify when you define a scope in the Search References dialog box.

Search Declarations

Searches all declarations of the item found at current cursor position in the defined scope if any. If a scope is defined, but the currently edited resource is not part of the range of resources determined by this, a warning dialog box will be displayed and you have the possibility to define another search scope.

Search Declarations in

Searches all declarations of the item found at current cursor position in the file or files that you specify when you define a scope for the search operation.

Search Occurrences in File

Searches all occurrences of the item at the cursor position in the currently edited file.

Refactoring Actions

The following refactoring actions can be applied on Quick Fix IDs and are available from the Refactoring submenu in the contextual menu of the current editor or from the Document > Refactoring menu:

Rename Component

Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the Esc or Enter key on your keyboard.

Rename Component in

Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the Preview button, you can view the files to be affected by the action.
Embedding Schematron Quick Fixes in Relax NG or XML Schema

Schematron Quick Fixes (on page 2970) can be embedded into an XML Schema through annotations (using the `<appinfo>` element), or in a Schematron rule embedded in the RELAX NG Schema. For more information about embedding Schematron in XML Schema or Relax NG, see Embedding Schematron Rules in XML Schema or RELAX NG (on page 1117).

Oxygen XML Editor is able to extract and use the embedded Schematron Quick Fixes. To make the embedded Schematron Quick Fixes available, follow these steps:

1. Define a validation against a schema (on page 728).
2. For the Schema type, choose XML Schema Or Relax NG.
3. Select the Embedded Schematron rules option.

Example: Embedded Schematron Quick Fix in XML Schema

```xml
<xsd:appinfo>
  <sch:pattern>
    <sch:rule context="...">
      <sch:assert test="..." sqf:fix="fixId">Message.</sch:assert>
      <sqf:fix id="fixId">
```

Figure 423. Rename Identity Constraint Dialog Box

![Rename Identity Constraint Dialog Box](image)
Example: Embedded Schematron Quick Fix in Relax NG

```xml
<grammar
   xmlns="http://relaxng.org/ns/structure/1.0"
   xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <sch:pattern>
    <sch:rule context="...">
      <sch:assert test="..." sqf:fix="fixId">Message.</sch:assert>
    </sch:rule>
  </sch:pattern>
</grammar>
```

Tip:
For more extensive examples, see the samples in the `[OXYGEN_INSTALL_DIR]/samples/schematron` folder.

- Embedding Schematron Rules in XML Schema or RELAX NG (on page 1117)
- Defining Schematron Quick Fixes (on page 1139)

Editing SVG Files

SVG (Scalable Vector Graphics) is a platform for two-dimensional graphics. It has two parts: an XML-based file format and a programming API for graphical applications. Some of the key features include support for shapes, text, and embedded raster graphics with many painting styles, scripting through languages such as ECMAScript, and support for animation.

SVG is a vendor-neutral, open standard that has important industry support. Companies such as Adobe, Apple, and IBM have contributed to its W3C specifications. Many documentation frameworks (on page 2967) (including DocBook) have support for SVG by defining the graphics directly in the document.
Oxygen XML Editor adds SVG support by using the Batik distribution package (an open source project developed by the Apache Software Foundation) and the default XML Catalog (on page 769) resolves the SVG DTD.

Note: Batik partially supports SVG 1.1. For a detailed list of supported elements, attributes, and properties, see the Batik Implementation Status page.

How to Render SVG Images that Use Java Scripting

1. Copy the js.jar library from the Batik distribution into the Oxygen XML Editor lib folder.
2. Restart the application.

SVG 1.2 Rendering Issues

Oxygen XML Editor uses the Apache Batik open source library to render SVG images and it only has partial support for SVG 1.2. For more information, see http://xmlgraphics.apache.org/batik/dev/svg12.html.

This partial support could lead to some rendering issues in Oxygen XML Editor. For example, if you are using the Inkscape SVG editor, it is possible for it to save the SVG as 1.1, while using SVG 1.2 elements (such as <flowRoot>) inside it. This means that the image will not be properly rendered inside the application.

Note: SVG images shown in the Author visual editing mode are rendered as static images, without support for animations and JavaScript.

Standalone SVG Viewer

Oxygen XML Editor includes a simple SVG Viewer that allows you to work with SVG images.

To open the viewer, select SVG Viewer from the Tools menu.
You can browse for and open any SVG file that has the `.svg` or `.svgz` extension.

If the file is included in the current project, you can open it in the viewer by right-clicking the image file in the Project view (on page 368) and selecting Open with > SVG Viewer.

**Actions Available in the SVG Viewer**

The following actions are available in the SVG Viewer:

**Zoom in**

To zoom in on an image, use any of the following methods:

- Scroll forward with the mouse wheel.
- Select **Zoom in** from the contextual menu.
- Use the **Ctrl + I (Command + I on OS X)** keyboard shortcut.

**Zoom out**

To zoom in on an image, use any of the following methods:

- Scroll backward with the mouse wheel.
- Use the **Ctrl + O (Command + O on OS X)** keyboard shortcut.
- Select **Zoom out** from the contextual menu.

**Rotate**

To rotate an image, use either of the following methods:

- Use the **Ctrl + Right-Click + Drag (Command + Right-Click + Drag on OS X)** shortcut.
- Select **Rotate** from the contextual menu. This rotates the image exactly 90 degrees clockwise.
Refresh

To refresh (or reset) an image, use either of the following methods:

- Use the **Ctrl + T (Command + T on OS X)** keyboard shortcut.
- Select **Refresh** from the contextual menu.

Move

To move an image, use either of the following methods:

- Use the **Arrow Keys** on your keyboard.
- Use the **Shift + Left-Click + Drag** shortcut.

Pan

To pan an image, **click and drag** the image with your mouse.

Related Information:

- [Editing SVG Files](on page 1154)

Integrated SVG Viewer in the Results Panel

Oxygen XML Editor includes an integrated **SVG Viewer** that can render the results of an XSLT transformation scenario that generates SVG images in the **Results panel** *at the bottom of the editor*. This is useful for developing XSL stylesheets with the capability of producing SVG graphics.

To enable this feature, select **Show in results view as > SVG** in the **Output** tab of the XSLT transformation scenario configuration dialog box *at the bottom of the editor*. When you run the transformation, the SVG result is then rendered in an integrated SVG viewer in the **Results panel** *at the bottom of the editor*.

Example of a Use-Case

Suppose you have an XML document that describes the evolution of your sales over a time period and you want to create a graphic for it. You could use the following steps to accomplish this task:

1. Start with a static SVG image, written directly in Oxygen XML Editor or exported from a external graphics tool.
2. Extract the parts that are dependent upon the data from the XML document and create an XSL template to produce the image.
3. Create an **XML transformation with XSLT scenario** *at the bottom of the editor*.
4. While configuring the transformation scenario, select **Show in results view as > SVG** in the **Output** tab *at the bottom of the editor* of the configuration dialog box.
5. Run the transformation.

The SVG image is rendered in an integrated SVG viewer in the **Results panel** *at the bottom of the editor*. 
Editing HTML Documents

Oxygen XML Editor provides a special framework for editing HTML files (html or htm file extensions) with a variety of specialized editing features, including validation, content completion, syntax highlighting, HTML-specific actions, and more. You can edit HTML documents in Text or Author mode.

Oxygen XML Editor also includes a built-in XHTML framework (on page 1273) (files with the http://www.w3.org/1999/xhtml namespace or with the xhtml or xht file extension) that has a full set of features (full editing support, document templates, enhanced CSS rendering, specific actions, validation, content completion, transformation scenarios, and more). Oxygen XML Editor also includes support for importing HTML files as an XML document (on page 1952).

For more information about HTML editing support, watch our video demonstration:

https://www.youtube.com/embed/-GObGytf8eY

Related Information:

XHTML Document Type (Framework) (on page 1273)

HTML Editor

Oxygen XML Editor includes a specialized HTML editor and various editing features for files that have the html or htm file extensions. The encoding is detected automatically based on the value specified in the @charset attribute of the <meta> element.

Note:

If an HTML document has an XHTML namespace, or there is an XSD schema declared, or there is a PUBLIC ID specified in a DOCTYPE, or there is a SYSTEM ID with a value other than "about:legacy-compat", then the document will be opened as an XHTML file.
New Document Template

Oxygen XML Editor includes a new document template to help you get started creating HTML content. It is available when creating new documents from templates (on page 335) and can be found in the New Document folder or by typing html in the search field.

Text Mode Editor

You can edit HTML files in the Text editing mode (on page 476) using all of its useful features (on page 476). It includes content completion (on page 1161) based on a special HTML schema, syntax highlighting (on page 1162), a specialized Outline view (on page 1163) that presents the structure, folding support (on page 1163), and more.

HTML documents support formatting and indenting single or multiple documents to make them more readable. The formatting works even if the document is not XML well-formed and it also works on embedded CSS or JavaScript code. The HTML formatting details are similar to those for XML documents. For details, see Formatting and Indenting XML Documents (on page 514).

Author Mode Editor

You can edit HTML files in the visual Author editing mode (on page 547), but when opening an HTML document in Author mode, if it is not considered well-formed according to XML standards, you will see a warning message at the top of the editor explaining that once you make a modification, the document will be automatically converted to proper XML structure. For more details, see XML Well-Formedness Details for HTML Documents (on page 1160).

When editing HTML documents in Author mode, you have access to many of the same authoring features and actions as you have with XHTML documents (on page 1275). You also have the benefit of CSS rendering and you can specify a CSS file to be associated with an HTML document (on page 1165).

HTML-Specific Contextual Menu Actions

There are some specialized actions (available in the contextual menu when you right-click anywhere in the current HTML document) that invoke features unique to HTML documents. These contextual menu actions include:

- **View in Browser/System Application**
  - Opens the HTML document in your default browser.

- **Minify HTML**
  - Compresses the HTML document by removing unnecessary white spaces, without affecting the functionality of the document, but significantly reducing the loading time in Web browsers.

- **HTML to XML Well-formed (Available in both Text and Author modes)**
  - Converts the currently edited HTML document to be XML well-formed. This means that unclosed tags will be properly closed, unquoted attribute values will be quoted, and more. This is helpful if, for example, you use XSLT stylesheets while applying transformations on HTML documents (since the transformation will require the HTML document to be XML well-formed).
XML Well-Formedness Details for HTML Documents

When opening an HTML document in Author mode, if it is not XML well-formed, you will see a warning message at the top of the editor explaining that once you make a modification, the document will be automatically converted to proper XML structure. Examples of things that are automatically converted include:

- Missing end tags are added to applicable elements.
- Empty tags are closed.
- Missing quote characters are added to applicable attributes.
- Entity references that are allowed in the HTML5 specification are converted to the corresponding character.

Tip:
It is also possible to manually convert HTML documents to be XML well-formed. There are two ways to do this, depending on whether you want to convert a single document or batch convert multiple documents at once:

- **Single Document** - To convert a single HTML document, right-click anywhere in the currently open HTML document (in the main editor) and select HTML to XML Well-formed.
- **Multiple Documents** - To batch convert multiple HTML documents at once, go to the Project view, select the documents you want to convert, then right-click and select HTML to XML Well-formed.

Notes:
- All selected HTML files are backed up before being processed (same path/name but with the ".bak" extension added at the end).
- Any detected conversion errors are grouped and listed in a dedicated tab in the Results pane at the bottom of the application.
- A brief report is displayed at the end of the operation.

HTML Validation

Oxygen XML Editor includes a built-in default validator used for validating HTML documents. It is based upon the W3C HTML Validator and the HTML documents are validated against the W3C HTML5 specification. The validator in Oxygen XML Editor only supports HTML5 structure. It presents the [errors in the editor similar to XML documents][1] (on page 730). It also checks the embedded CSS content and the warnings and errors are presented similar to the CSS editor (on page 1010).

Validating HTML Against a Schematron

It is also possible to validate HTML documents against a Schematron schema. Besides the default HTML validator, Oxygen XML Editor also includes a built-in [HTML Schematron Validator][1] engine. There are several ways to validate an HTML document against a Schematron:
• **Configure a Validation Scenario** - You can create or edit a validation scenario *(on page 740)*, change the **File type** column to *HTML Document*, change the **Validation engine** column to *HTML Schematron Validator*, and specify the Schematron document in the **Schema** column.

• **Manually Validate a Single Document** - You can use the Validate with action from the **Validation** drop-down menu on the toolbar. This opens a dialog box where you can specify the Schematron document to validate the current document against.

• **Batch Validate Multiple Documents** - You can select multiple HTML documents in the **Project** view, right-click, and use the Validate with schema action from the Validate submenu. This opens a dialog box where you can specify the Schematron document to validate the selected documents against.

---

**Notes:**

• The Schematron must use the HTML5 namespace to reference the elements from the instance.

• Implicit HTML elements (i.e. `<html>`, `<body>`, `<tbody>`) must be included in an XPath expression in the Schematron document, even if they are missing from the HTML document.

---

**Tip:**

The Oxygen XML Editor installation directory includes a samples folder that contains numerous sample files to help you learn about features, certain file types, and XML technologies. For example, inside the samples folder, there is an html folder with a schematron subfolder where you can find some samples that illustrate HTML validation against a Schematron schema.

---

**Validating HTML Against Other Types of Schema**

If your HTML document is XML well-formed, you could also configure a validation scenario to validate it as an XML document against other types of schemas. You would create or edit a validation scenario *(on page 740)*, make sure the **File type** column is set to *XML Document*, select the appropriate **Validation engine**, and specify the schema document in the **Schema** column.

---

**HTML Content Completion Assistant**

Oxygen XML Editor includes an intelligent *Content Completion Assistant* *(on page 2965)* that offers proposals for inserting HTML structures that are valid at the current editing location. Content completion is even available for CSS and JavaScript code that is embedded in an HTML document.

The *Content Completion Assistant* is enabled by default. To disable it, open the Preferences dialog box (Options > Preferences) *(on page 98)*, go to Editor > Content Completion, and deselect the Enable content completion option *(on page 182).*
Using the Content Completion in HTML

For HTML documents, the Content Completion Assistant uses a built-in schema and the list of proposals depend on the RELAX NG schema specified in the HTML framework. Using the content completion feature is the same as with any other XML document. For more details, see:

- Using the Content Completion Assistant in Text Mode (on page 492)
- Using the Content Completion Assistant in Author Mode (on page 573)

Code Templates in the Content Completion

Oxygen XML Editor includes a set of built-in code templates for HTML documents that can be selected from the Content Completion Assistant. The code templates are displayed with a symbol in the content completion list. You can also define your own code templates and share them with others. For more information, see Code Templates (on page 496).

Content Completion for XPath Expressions

When entering XPath expressions in the XPath toolbar or XPath Builder view, the Content Completion Assistant is available as you type to help you compose query patterns.

Syntax Highlighting in HTML Documents

Oxygen XML Editor supports syntax highlighting in Text mode to make it easier to read the semantics of the structured content by displaying each type of code in different colors and fonts.

For HTML documents, it handles attributes without quotes, unclosed or void elements, and it also offers highlighting for embedded CSS or JavaScript content.

To customize the colors or styles used for the syntax highlighting colors for HTML files, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98).
2. Go to Editor > Syntax Highlight (on page 195).
3. Select and expand the XHTML section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

You can see the effects of your changes in the Preview pane.
Folding in HTML

In a large HTML document, elements can be collapsed so that only the needed data remains in focus. The folding features available for XML documents (on page 487) are also available in HTML documents, but it also provides folding for nested elements that are not closed.

Minifying HTML Documents

*Minification* (or compression) of an HTML document is the practice of removing unnecessary white spaces, without affecting the functionality of the document, but significantly reducing the loading time in Web browsers. While a minified HTML document gains in terms of execution performance, it is more difficult to read.

To minify an HTML document, right-click anywhere in the editor for an HTML document that is open in Text mode (or right-click an HTML document in the Project view and select the *Minify HTML* action. This opens a dialog box with the following options:

**Output file**

Use this option to set the name and location of the resulting compressed/minified HTML document.

**Remove comments**

If selected (default), all the HTML comments and also the comments from embedded CSS or JavaScript code blocks will be removed from the resulting output file.

**Compress on a single line**

If selected (default), the resulting output file will consist of a single line, as all the ‘new line’ characters from the source document are removed.

**Open output file in editor**

If selected (default), the resulting output file will be opened in Oxygen XML Editor.

When you click **OK**, the resulting HTML document is a compressed version of the original file for the purpose of enhanced performance, while losing some readability. The source HTML document is not affected.

HTML Outline View

The *Outline* view for HTML documents displays the structure of the HTML document you are editing. By default, it is displayed on the left side of the editor. In addition to the normal features available in the *Outline view for XML documents* (on page 498), the HTML *Outline* view also handles void elements, elements that are not closed, or attributes without quotes, and presents the tree structure of the HTML document correctly.
Querying HTML Documents with XPath

Oxygen XML Editor provides an XPath toolbar that makes it easy to quickly query HTML documents using XPath expressions. You can also use the dedicated XPath Builder view (on page 1854) that allows you to compose more complex XPath expressions and execute them over HTML documents (even if they are not well-formed according to XML standards). Both the XPath toolbar and XPath Builder view offer content completion as you type to help you compose expressions.

XPath Toolbar

You can run an XPath expression over an HTML document or on an entire project. For more information about this toolbar, see XPath Toolbar (on page 1852).

Note:

Implicit HTML elements (i.e. `<html>`, `<body>`, `<tbody>`) must be included in the XPath expression, even if they are missing from the HTML document.
Associating a CSS with an HTML Document

The rendering of an HTML document in the Author mode is driven by a CSS stylesheet that conforms to the version 2.1 of the CSS specification from the W3C consortium. Oxygen XML Editor also supports stylesheets coded with the LESS dynamic stylesheet language.

To associate a CSS with an HTML document:

1. Use the Associate XSLT/CSS Stylesheet action that is available on the toolbar or in the Document > XML Document menu.
2. In the resulting dialog box, specify the URL for the CSS file and optionally a title, and click OK.

Result: A CSS association is added in the HTML document in a `<link>` element, as specified in the W3C stylesheet specification.

Editing Markdown Documents

Markdown was created as a lightweight markup language with plain text formatting syntax designed to provide syntax that is very easy to read and write, and to convert it to HTML and other formats. It is often used by content contributors who want a quick and easy way to write content without having to take their fingers off the keyboard and without having to learn numerous codes or shortcuts, and it can easily be shared interchangeably between virtually any types of contributor and system.

Oxygen XML Editor provides a built-in Markdown editor that allows you to convert Markdown syntax to HTML or DITA and it includes a preview panel to help you visualize the final output. Aside from the plain text syntax that is common among most Markdown applications, the editor in Oxygen XML Editor also integrates many
other powerful features that content authors are accustomed to using for other types of documents. Some of these additional unique features include:

- Additional toolbar and contextual menu actions.
- Automatic validation to help keep the syntax valid.
- Dedicated syntax highlighting to make Markdown documents even easier to read and write.
- Unique features for creating Markdown documents directly in DITA maps (on page 2966) and converting Markdown documents to DITA topics.
- Specialized syntax rules to combine popular syntax features from several specifications.

Markdown Editor

Oxygen XML Editor provides an intuitive, dynamic, and easy-to-use Markdown editor. It is a split-screen editor with two panels that are synchronized in real time. The left side is a simple text editor that is specially designed for writing Markdown syntax. The right side is a WYSIWYG style preview of how changes will look in the output.

Markdown Text Editor Pane (Left Side)

The left pane is a simple text editor that is refined to accept Markdown syntax. At the same time, you still have many of the actions, options, and features that you are used to when editing any other type of document in Oxygen XML Editor.

The features of this special editor that are unique for Markdown documents include:

- **Unique Markdown Syntax Rules** - The Markdown editor in Oxygen XML Editor uses an integration of rules (on page 1180) that combine rules from common default Markdown syntax along with many of the rules used in the GitHub Flavored Markdown syntax.

- **Syntax Highlighting** - The Oxygen XML Editor syntax highlighting feature is integrated into the Markdown text editor to make it easier to read and write Markdown syntax. You can even customize the colors and styles for the syntax highlighting (on page 1176).

- **Automatic Spell Checking** - The Markdown editor supports the Oxygen XML Editor automatic spell checking feature (on page 420) that reports possible misspelled words as you type. You simply need to select the Automatic spell check option in the Spell Check preferences page (on page 200), then click the Select editors button and select Markdown Editor.

- **Helpful Toolbar and Contextual Menu Actions** - A variety of unique actions (on page 1168) are available from the toolbar to help you insert proper Markdown syntax. The contextual menu also includes some common editing actions, as well as unique actions to export (convert) Markdown documents to HTML or DITA.

- **Shortcut Keys** - Many of the shortcut keys that are most commonly used (on page 26) in Oxygen XML Editor also work in the Markdown editor.
WYSIWYG Preview Pane (Right Side)

The right pane is a WYSIWYG Preview pane that shows a visual representation of how changes made in the left-side text editor will be converted to HTML, XDITA (Lightweight DITA XML), or DITA output. The changes you make in the text editor are parsed continually and they are immediately visible in the Preview pane. There are two tabs available in the Preview pane, one for visualizing DITA output and one for visualizing HTML output. You can switch between the two tabs at the bottom of the pane.

The Preview pane includes the following features:

- **WYSIWYG Visualization** - This pane presents the Markdown syntax from the left-side text editor in a visual WYSIWYG style interface that is automatically synchronized as you type.

- **Synchronous caret and scroll synchronization** - Moving the cursor in the editor area will display the corresponding move in the Preview area. In addition, moving the cursor in the Preview area will display the corresponding move in the editor area.

- **Export Options** - The DITA tab includes a contextual menu action to export (convert) the current Markdown document to a DITA topic (on page 1176). The XDITA tab includes a contextual menu action to export (convert) the current Markdown document to a Lightweight DITA topic (on page 1176). Similarly, the HTML tab includes a contextual menu action to export (convert) it to an XHTML document (on page 1176).

- **Automatic Validation** - As you edit Markdown documents, they are validated automatically (on page 1177). The conversion engine constantly tries to parse your changes and if a change results in an error that prevents the parser from converting the syntax, an error message will be displayed in the Preview pane or Results view (on page 508) at the bottom of the editor.

- **Print Feature** - The Markdown editor includes a Print action that is available in the contextual menu and it allows you to configure options for printing the current document as you see it in the Preview pane.

- **Preview Markup** - The Markdown editor includes a Tags Display Mode drop-down menu (on page 1171) that is available on the toolbar and it allows you to control the amount of markup that is displayed in the Preview pane.

- **Specialized DITA Features** - The Markdown editor includes some unique, specialized features to integrate it with the powerful DITA support (on page 2787) in Oxygen XML Editor.
Creating New Markdown Documents

To create a new Markdown document in Oxygen XML Editor, follow these steps:

1. Click the New button on the toolbar or select File > New.
3. Click the Create button.

Result: A new Markdown document is created and it is opened in the specialized Markdown Editor (on page 1166).
Actions Available in the Markdown Editor

Aside from the actions that are available in Oxygen XML Editor for any type of document (such as the actions in the various menus and the common sections of the toolbar), a variety of unique actions are also available in the Markdown editor, from the toolbar and contextual menu.

Toolbar Actions

The following default actions are available on the Markdown toolbar when editing Markdown documents:

- **Header (1st Level)**
  - Inserts an *atx-style first-level header (on page 1180)* at the cursor position.

- **Header (2st Level)**
  - Inserts an *atx-style second-level header (on page 1180)* at the cursor position.

- **Header (3rd Level)**
  - Inserts an *atx-style third-level header (on page 1180)* at the cursor position.

- **Horizontal Rule**
  - Inserts a *horizontal rule (on page 1181)* at the cursor position.

- **Bold (Strong)**
  - Marks the selected text with *bold (on page 1182).*

- **Italic (Emphasis)**
  - Marks the selected text with *italics (on page 1181).*

- **Strikethrough**
  - Marks the selected text with a *strikethrough (on page 1182).*

- **Code Block**
  - Inserts (or surrounds selected text in) a *codeblock (on page 1185).*

- **Blockquote**
  - Inserts a *blockquote (on page 1184)* at the cursor position.

- **Insert Link**
  - Opens the *Insert Link* dialog box that allows you to define a *link (on page 1182)* to insert at the cursor position.
Figure 430. Insert Link Dialog Box

<table>
<thead>
<tr>
<th>Insert link</th>
</tr>
</thead>
<tbody>
<tr>
<td>URL: <a href="http://www.example.com/path">http://www.example.com/path</a></td>
</tr>
<tr>
<td>Text (optional): Link Text</td>
</tr>
<tr>
<td>Title (optional): Title</td>
</tr>
<tr>
<td>ID (optional): ID1</td>
</tr>
</tbody>
</table>

Insert Image

Opens the Insert Image dialog box that allows you to define an image (on page 1184) to insert at the cursor position. You can type the URL of the image you want to insert or use browsing actions in the Browse drop-down menu.

Figure 431. Insert Link Dialog Box

<table>
<thead>
<tr>
<th>Insert Image</th>
</tr>
</thead>
<tbody>
<tr>
<td>URL: file:C:/pictures/example.png</td>
</tr>
<tr>
<td>Alternate text (optional): Alt Text</td>
</tr>
<tr>
<td>Title (optional): Title</td>
</tr>
<tr>
<td>ID (optional): ID1</td>
</tr>
</tbody>
</table>

Insert Ordered List

Inserts an ordered list (on page 1187) at the cursor position. Three child list items are also automatically inserted by default. You can also use this action to convert selected content to an ordered list.

Insert Unordered List

Inserts an unordered list (on page 1187) at the cursor position. Three child list items are also automatically inserted by default. You can also use this action to convert selected content to an unordered list.

Insert Task List

Inserts a task list (on page 1188) at the cursor position. Three child list items are also automatically inserted by default. You can also use this action to convert selected content to a task list.

Insert Table

Inserts a table (on page 1189) at the cursor position.
Tags Display Mode drop-down menu

Allows you to control the amount of markup that is displayed in the Preview pane and offers the following choices:

- **Full Tags with Attributes**
  Displays full tag names with attributes for both block and inline elements.

- **Full Tags**
  Displays full tag names without attributes for both block and inline elements.

- **Block Tags**
  Displays full tag names for block elements and simple tags without names for inline elements.

- **Inline Tags**
  Displays full tag names for inline elements, while block elements are not displayed.

- **Partial Tags**
  Displays simple tags without names for inline elements, while block elements are not displayed.

- **No Tags**
  No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

Configure Tags Display Mode

Opens the Author preferences page (on page 148) where you can configure options regarding tags, such as the default Tags Display Mode, Tags Background Color, Tags Foreground Color, and Tags Font.

Contextual Menu Actions

The following default actions are available in the contextual menu when editing Markdown documents:

- **Cut**, **Copy**, **Paste**
  Use these actions to execute the typical editing actions on the currently selected content.

Source submenu

This submenu includes the following actions:

- **To Upper Case**
  Converts the content selection to upper case characters.

- **To Lower Case**
  Converts the content selection to lower case characters.

- **Capitalize Lines**
It capitalizes the first letter found on every new line that is selected. Only the first letter is affected, the rest of the line remains the same. If the first character on the new line is not a letter then no changes are made.

**Convert Hexadecimal Sequence to Character (Ctrl + Shift + X (Command + Shift + X on OS X))**

Converts a sequence of hexadecimal characters to the corresponding Unicode character (see page 427). The action can be invoked if there is a selection containing a valid hexadecimal sequence or if the cursor is placed at the right side of a valid hexadecimal sequence. A valid hexadecimal sequence can be composed of 2 to 4 hexadecimal characters and may or may not be preceded by the \(0x\) or \(0X\) prefix. Examples of valid sequences and the characters they will be converted to:

- \(0x0045\) will be converted to E
- \(0x0125\) to ĥ
- 265 to ɥ
- 2190 to ←

**Note:**

For more information about finding the hexadecimal value of a character, see Finding the Decimal, Hexadecimal, or Character Entity Equivalent (see page 430).

**Base64 Encode/Decode submenu**

This submenu includes the following actions for encoding or decoding base 64 schemes:

**Import File to Encode and Insert**

Encodes a file and then inserts the encoded content into the current document at the cursor position.

**Decode Selection and Export to File**

Decodes a selection of text from the current document and then exports (saves) the result to another file.

**Encode Selection**

Replaces a selection of text with the result of encoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the Encoding for Base64, Base32, Hex conversions option in the Encoding preferences page (see page 141) will be used. Likewise, the same is true if the Show the dialog box for choosing
the encoding for Base64, Base 32, Hex conversions option is not selected in the Messages preference page (on page 277).

**Decode Selection**

Replaces a selection of text with the result of decoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the Encoding for Base64, Base32, Hex conversions option in the Encoding preferences page (on page 141) will be used. Likewise, the same is true if the Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions option is not selected in the Messages preference page (on page 277).

**Modify All Matches**

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

**Base32 Encode/Decode submenu**

This submenu includes the following actions for encoding or decoding base32 schemes:

- **Import File to Encode and Insert**
  
  Encodes a file and then inserts the encoded content into the current document at the cursor position.

- **Decode Selection and Export to File**
  
  Decodes a selection of text from the current document and then exports (saves) the result to another file.

**Encode Selection**

Replaces a selection of text with the result of encoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the Encoding for Base64, Base32, Hex conversions option in the Encoding preferences page (on page 141) will be used. Likewise, the same is true if the Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions option is not selected in the Messages preference page (on page 277).
Decode Selection

Replacing a selection of text with the result of decoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the Encoding for Base64, Base32, Hex conversions option in the Encoding preferences page (on page 141) will be used. Likewise, the same is true if the Show the dialog box for choosing the encoding for Base64, Base32, Hex conversions option is not selected in the Messages preference page (on page 277).

Modify All Matches

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

Hex Encode/Decode submenu

This submenu includes the following actions for encoding or decoding hex schemes:

Import File to Encode and Insert

Encodes a file and then inserts the encoded content into the current document at the cursor position.

Decode Selection and Export to File

Decodes a selection of text from the current document and then exports (saves) the result to another file.

Encode Selection

Replacing a selection of text with the result of encoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the Encoding for Base64, Base32, Hex conversions option in the Encoding preferences page (on page 141) will be used. Likewise, the same is true if the Show the dialog box for choosing the encoding for Base64, Base32, Hex conversions option is not selected in the Messages preference page (on page 277).
Replaces a selection of text with the result of decoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the Encoding for Base64, Base32, Hex conversions option in the Encoding preferences page (on page 141) will be used. Likewise, the same is true if the Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions option is not selected in the Messages preference page (on page 277).

Modify All Matches

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

Join and Normalize Lines (Ctrl + J (Command + J on OS X))

For the current selection, this action joins the lines by replacing the line separator with a single space character. It also normalizes the whitespaces by replacing a sequence of such characters with a single space.

Insert new line after (Ctrl + Alt + Enter (Command + Alt + Enter on OS X))

This action has the same result as moving the cursor to the end of the current line and pressing the ENTER key.

Modify All Matches

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

Open submenu

The following actions are available in this submenu:

Open File at Cursor

Opens the file at the cursor position in a new panel. If the file path represents a directory path, it will be opened in system file browser. If the file at the specified location does not exist, an error dialog box is displayed and it includes a Create new file button that starts the New document wizard. This allows you to choose the type or the template for the file. If the action succeeds, the file is created with
the referenced location and name and is opened in a new editor panel. If the file is an image file, it will be opened in the Image Preview pane (on page 432).

**Open File at Cursor in System Application**

Opens the file (identified by its link) or web page (identified by a web link) found at the cursor position. The target is opened in the default system application associated with that file type.

**Compare**

Opens the current file in the Compare Files tool (on page 437).

**Show/Hide Preview**

A toggle action that shows or hides the Preview pane.

**Export as DITA Topic**

Converts the current Markdown document into a DITA topic.

**Export as XDITA Topic**

Converts the current Markdown document into a Lightweight DITA XML topic.

**Export as HTML**

Converts the current Markdown document into an XHTML document.

**Print (Available in the Preview pane)**

Opens a page setup dialog box that allows you to configure printing options for the current document.

**Related Information:**

Markdown Editor (on page 1166)

Working with Markdown Documents in DITA (on page 2787)

Markdown Editor Syntax Rules and Specifications (on page 1180)

**Syntax Highlighting in the Markdown Editor**

Oxygen XML Editor supports syntax highlighting in the Markdown editor to make it easier to read the semantics of the structured content by displaying each type of XML code in different colors and fonts.

To customize the colors or styles used for the syntax highlighting colors for Markdown documents, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98).
2. Go to Editor > Syntax Highlight (on page 195).
3. Select and expand the Markdown section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.
You can see the effects of your changes in the Preview pane.

Related Information:
- Syntax Highlight Preferences (on page 195)
- Markdown Editor (on page 1166)

Automatic Validation in Markdown Documents

Markdown documents are validated automatically as you type. The conversion engine constantly tries to parse your changes to display the results in the Preview pane. If a change results in an error that prevents the parser from converting the syntax, an error message will be displayed in the DITA tab or in the Results view (on page 508) at the bottom of the editor.

Examples of the type of errors that will be reported include headers being in the wrong order or the syntax of a document begins with something other than a 1st level header.

Validating Markdown Documents with Schematron

It is possible to validate Markdown documents with Schematron rules. There are two ways to create an association between Markdown documents and Schematron files:

- You can configure an association using the Markdown preferences page (on page 246). You can specify a Schematron file to validate converted HTML content, as well as one to validate converted DITA content.
- You can create a Schematron association for Markdown documents by adding a catalog mapping (on page 769) for one of the following URIs:
  - http://www.oxygenxml.com/schematron/validation/markdown-as-html - The obtained Schematron will be applied over HTML conversions.
  - http://www.oxygenxml.com/schematron/validation/markdown-as-dita - The obtained Schematron will be applied over DITA conversions.

The catalog mapping is a fallback in case the Schematron validation is disabled in the Markdown preferences page (on page 246) or the path to the Schematron file is empty.

⚠️ Warning:

If you are using a custom version of DITA-OT (on page 239), the mapping information might not be generated properly, causing issues with the Schematron validation. For example, error locations may not be accurate or synchronization may fail.

ℹ️ Tip:

Inside the samples folder, there is a schematron-validation folder with some files you can use to see how Schematron validation can be done with Markdown files. The path of the folder is: [OXYGEN_INSTALL_DIR]/samples/markdown/schematron-validation/.
Working with Markdown Documents in DITA

Oxygen XML Editor includes some unique features that allow you to easily integrate Markdown documents in a DITA project. This is especially helpful for teams that have contributors who are familiar with the Markdown syntax, but they want their output to be generated from DITA projects. The integration between the Markdown editor and DITA includes actions to export or convert Markdown documents to DITA topics and the DITA tab in the Preview pane provides a visualization of how the DITA topic will look after conversion. Likewise, the XDITA tab in the Preview pane provides a visualization of how a Lightweight DITA topic will look after conversion. Keys that are defined in the root map are also resolved in the Preview pane.

Export Markdown as a DITA Topic

The Markdown editor includes an option to quickly convert the current Markdown document into a DITA topic. The Export as DITA Topic action is available in the contextual menu.

The conversion creates a new XML file that is defined as a DITA topic and opens it in the Text editing mode. You can then work with the document as you would with any other DITA topic, although you may need to manually correct some issues where the parser could not properly map Markdown syntax to DITA markup.

Working with Markdown Documents in the DITA Maps Manager

Oxygen XML Editor has some specialized features that allow you to integrate Markdown documents directly into your DITA project using the DITA Maps Manager (on page 2662). The following features are available for Markdown documents in the DITA Maps Manager view:

- **Insert Reference to Markdown Document** - You can use the New, Reference, and Reference to the currently edited file actions from the Append Child, Insert Before, or Insert After submenu when invoking the contextual menu in the DITA Maps Manager to insert a reference to a Markdown document at the selected location in the map. Markdown documents will be inserted as a topic reference (topicref element) with the format attribute set to markdown.

- **Validate Markdown Documents in DITA Maps** - When you use the Validate and Check for Completeness action from the DITA Maps Manager toolbar to check the integrity of the structure of a DITA map, Markdown documents that are referenced in the DITA map will be converted to DITA topics in the background and validated the same as any other DITA topic.

- **Transforming DITA Maps with Markdown Documents** - When transforming DITA maps that have Markdown documents referenced, the transformation will convert the Markdown documents to normal DITA output without you needing to manually convert the Markdown documents to DITA topics.

- **Manually Convert Markdown Documents to DITA Topics** - If you need to use DITA semantics that are not possible in Markdown syntax (such as content references, related links, and other DITA-specific syntax), you can manually convert the Markdown document into a DITA topic. To do so, right-click the Markdown document in the DITA Maps Manager and select Refactoring > Convert Markdown to DITA.
**Topic.** This will open a dialog box that allows you to configure options for converting the document to an XML file that is defined as a DITA topic.

**Figure 432. Convert Markdown to DITA Topic Dialog Box**

This dialog box includes the following options:

- **Destination**
  
  The destination path for the new DITA topic.

- **File Name**
  
  Presents the current name and allows you to change it.

- **Update references**
  
  Select this option to update all references of the file in the DITA map and in the files referenced from the DITA map.

- **Delete Markdown file**
  
  If selected, the Markdown version of the file is deleted when the document is converted into a DITA file. If deselected (default value), when the document is converted into a DITA file, the original Markdown file is also preserved in its current location.

- **Preview**
  
  Select this button to display a preview of the changes Oxygen XML Editor is about to make.

- **Convert**
  
  Select this button to perform the conversion. If the Markdown file has `format="markdown"`, it will be converted to a DITA topic. If it has `format="mdita"`, it will be converted to a LightWeight DITA topic.

**Tip:**

Oxygen XML Editor comes with a sample ditamap project for converting Markdown to DITA. Go to the Project view (on page 368), open the sample.xpr project, and navigate to the dita/markdown-dita folder.
Converting Multiple Markdown Documents to DITA

Oxygen XML Editor offers an add-on that contributes actions in the Tools menu and contextual menu to enable batch conversion between various formats, including Markdown to DITA. For more information and instructions for installing the add-on, see Batch Documents Converter Add-on (on page 2351).

- Markdown Editor Syntax Rules and Specifications (on page 1180)
- Automatic Validation in Markdown Documents (on page 1177)
- Markdown DITA Syntax Reference

Markdown Editor Syntax Rules and Specifications

The Markdown editor in Oxygen XML Editor uses rules that were integrated from the most common set of default Markdown syntax rules along with many of the GitHub Flavored Markdown rules.

This topic lists the Oxygen XML Editor implementation of the most commonly used syntax rules.

Headers

The Markdown editor supports two styles of headers, Setext and Atx.

- **Setext Style**
  
  Setext-style headers are underlined using equal signs (for first-level headers) and dashes (for second-level headers). Any number of equal signs or dashes will result in the same output.

  **Example: Setext Style Headers**

  
  First-Level Header (H1)
  
  ===========
  
  Second-Level Header (H2)
  
  ===========

- **Atx Style**
  
  Atx-style headers use 1-6 hash characters at the start of the line, corresponding to header levels 1-6. Optionally, you may close atx-style headers. This is purely cosmetic and the closing hashes do not need to match the number of hashes used to open the header. It is the number of opening hashes that determines the header level.

  **Example: Atx Style Headers**

  
  # H1 text #
  
  ## H2 text
  
  ### H3 text ######
Horizontal Rules (for HTML output only)

You can produce a horizontal rule tag (<hr>) by placing three or more hyphens, asterisks, or underscores on a line by themselves (they also need to be preceded and followed by a blank line). Optionally, they can be separated by spaces.

Example: Horizontal Rules

```
* * *
*****
---------------------------------------
_ _ _ _
```

Paragraphs and Line Breaks

A paragraph is simply one or more consecutive lines of text, separated by one or more blank lines. The text at the beginning of a paragraph should not be indented with spaces or tabs. To create a new paragraph, simply insert a blank line in between them.

Important:

When converting to HTML, if you break a paragraph on multiple lines (without a blank line in between them), it will create a break tag (<br>). When converting to DITA, the text is kept in a single paragraph in this case and a blank line is required to break a paragraph. This behavior differs slightly from the default Markdown rules.

Example: Paragraphs

This is a paragraph that contains two lines of text. (In HTML, a break tag is created in between the two lines)

This is a new paragraph.

Styling Text

The Markdown editor supports some syntax rules for styling text (such as bold, italic, or strikethrough).

- **Italic (Emphasis)**

  Text wrapped with one asterisk or underscore produces an italic (emphasis) tag.
**Italic**

_italic_

- **Bold (Strong)**

Text wrapped with two asterisks or underscores produces a bold (strong) tag.

**bold**

__bold__

- **Strikethrough**

In HTML only, text wrapped with two tildes (~~) produces a strikethrough tag.

~~strikethrough~~

Tip:

You can also combine these styling rules. For example, **BoldText _ItalicText_ BoldText** would produce italicized text within bold text. Also, if you surround an asterisk or underscore with spaces, it will be treated as a literal asterisk or underscore. To produce a literal asterisk or underscore at a position where it would otherwise be used as a styling delimiter, you can escape it with a backslash (for example, \*literal asterisks\*).

---

**Links**

The Markdown editor supports two types of links, *inline* and *reference*. In both cases, it begins with link text that is delimited by [square brackets].

- **Inline Links**

  To create an inline link, use a set of regular parentheses immediately after the closing square bracket for the link text. Inside the parentheses, put the URL where you want the link to point, and optionally a title surrounded in quotes. Also, if you reference a local resource on the same server, you can use relative paths.

  **Examples: Inline Link**

  With a title:

  Text with [example link text](http://www.example.com/path "Title") inline link and title.

  Without a title:

  Text with [example link text](http://www.example.com/path) inline link without a title.

  Relative path:

  Text with [example link text](/relative_path/) inline link with relative path.

- **Reference Links**

  Reference-type links use a second set of square brackets that include a label (link identifier) to reference the target for the link (link identifier may consist of letters, numbers, spaces, and punctuation...
and it is not case-sensitive). You can optionally use a space to separate the sets of brackets. The labels
(link identifiers) are only used for creating the links and do not appear in the output.

Text with [link text1][id 1] a reference-type link and [link text2][id_2] another one.

Then, somewhere in the document, you need to define your link label on a line by itself. The link
identifier must be within square brackets followed by a colon, then after one or more spaces the URL
for the link. Optionally this can be followed by a title enclosed in single quotes, double quotes, or
parentheses. Also, the link may optionally be enclosed in angle brackets (< >).

[id 1]: http://example1.com/ "Optional Title"
[id_2]: <http://example2.com/> "Optional Title2"

Other notes about Reference Links:
- You can put the title on a second line and use extra spaces or tabs for padding. This is useful for
  aesthetics when the URL is long.

[id]: http://example.com/long/path/to/resource/here
  "Optional Title Here"

- The label (link identifier) can be missing, in which case the link text (in square brackets) is used
  as the name.

[My Link] []

and then defined as:

[My Link]: http://example.com/

Automatic Links
The Markdown editor supports a shortcut style for creating automatic links for URLs and email addresses.
You simply surround the URL or email address with angle brackets.

Note:
These automatic links only work properly in HTML conversions. The Preview pane may display them
properly in the DITA tab, but the DITA output will not properly recognize the format.

- URLs

By surrounding a URL with angle brackets, you can show the actual text of the URL while also making it
clickable in the output.

<http://example.com/>

For example, in HTML it is converted to:

<a href=“http://example.com/”>http://example.com/</a>

- Email Addresses

Automatic links for email addresses work similarly, except that Markdown will also perform a bit of
randomized decimal and hex entity-encoding to help obscure your address from address-harvesting
spambots.
In HTML, it is converted to something like:

```html
<a href="mailto:address@example.com">address@example.com</a>
```

**Images**

The Markdown editor uses an image syntax that is intended to resemble the syntax for two types of links *(inline and reference)*. In both cases, the syntax for images begins with an exclamation mark, followed by **Alt** attribute text surrounded by square brackets, and then followed by a set of parentheses that contain the URL or path to the image.

- **Inline Images**
  
  For inline images, use a set of regular parentheses immediately after the closing square bracket for the **Alt** attribute text. Inside the parentheses, put the URL or path of the image, and optionally a title surrounded in quotes.

  **Examples: Inline Images**

  With a title:

  ```markdown
  Text with ![Alt text](/path/to/img.jpg "Optional title") inline image and a title.
  ```

  Without a title:

  ```markdown
  Text with ![Alt text](/path/to/img.jpg) inline link without a title.
  ```

- **Reference Images**
  
  For reference-type images, use a second set of square brackets that include a label (image identifier) to identify the image (it may consist of letters, numbers, spaces, and punctuation and it is not case-sensitive). You can optionally use a space to separate the sets of brackets. The labels (image identifiers) do not appear in the output.

  ```markdown
  Text with ![Alt text1][id] a reference-type image.
  ```

  Then, somewhere in the document, you need to define your image label on a line by itself. The image identifier must be within square brackets followed by a colon, then after one or more spaces the URL or path of the image. Optionally this can be followed by a title enclosed in single quotes, double quotes, or parentheses.

  ```markdown
  [id]: url/to/image "Optional Title"
  ```

**Blockquotes**

The Markdown editor uses email-style greater than characters (>) for *blockquotes*. You only need to put the > before the first line of a hard-wrapped paragraph, but it looks better (and is clearer) if you put a > before every line.
• **Example: Blockquotes**

> This is a blockquote with two paragraphs. Lorem ipsum dolor sit amet, consectetur adipiscing elit. Aliquam hendrerit mi posuere lectus. Vestibulum enim wisi, viverra nec, fringilla in, laoreet vitae, risus. 
> 
> Donec sit amet nisl. Aliquam semper ipsum sit amet velit. Suspendisse id sem consectetur libero luctus adipiscing.

• **Example: Nested Blockquotes**

Blockquotes can be nested by adding additional levels of > characters.

> This is the first level of quoting.
> 
> > This is nested blockquote.
> 
> > Back to the first level.

• **Example: Blockquotes with Other Markdown Elements**

Blockquotes can also contain other Markdown elements (such as headers, lists, and code blocks).

> ## This is a header.
> 
> 1. This is the first list item.
> 2. This is the second list item.
> 
> Here's some example code:
> 
> return shell_exec("echo $input | $markdown_script")

**Quoting Code (Inline and Code Blocks)**

The Markdown editor supports quoting code or commands inline within a sentence or in distinct blocks.

• **Inline**

You can quote or emphasize code within a sentence (inline) with single backticks (`). The text within the backticks will not be formatted.

**Example: Inline Code Emphasis**

This is a normal sentence with a `code` in the middle.

• **Code Blocks**

You can format code or text into its own distinct block by inserting a blank line before and after the content and using at least 4 spaces (or 1 tab), or by using opening and closing triple backticks (```) on separate lines.

**Example: Code Block**
This is a normal paragraph:

This is a code block

This is a normal paragraph:

...

This is a code block

...

One level of indentation is removed from each line of a codeblock and it continues until it reaches a line that is not indented (or until the closing backticks).

**Example: Code Block with Indentation**

```plaintext
tell application "something"
  beep
end tell
```

For example, in HTML the result would look like this:

```html
<pre><code>tell application "Foo"
  beep
end tell
</code></pre>

You can also add an optional language identifier to enable syntax highlighting in your code blocks. The Oxygen XML Editor Markdown editor supports the following languages: **Java**, **JavaScript**, **CSS**, and **Python**.

**Example: Syntax Highlighting in Code Block**

```css
input[type="submit"] {
  color: white;
  font-weight: bold;
}
```

**Inline XHTML (for HTML output only)**

The Markdown editor supports writing inline XHTML. Since Markdown is just a writing format, it requires a conversion for publishing purposes. If you are using the HTML conversion, for any markup that is not covered by Markdown syntax, you can simply use XHTML syntax.

**Example: Inline XHTML**

```html
This is a regular paragraph.

<table>
  <tr>
```

This is a code block

```html
```
Lists

The Markdown editor supports ordered and unordered lists. You can also insert *blockquotes* (on page 1184) and *code blocks* (on page 1185) inside list items. List markers typically start at the left margin, but may be indented by up to three spaces.

**Unordered Lists**

For unordered lists, you can use asterisks (*) plus signs (+), and hyphens (−) interchangeably.

* List item 1
+ List item 2
− List item 3

**Ordered Lists**

For ordered lists, use numbers followed by periods. The actual numbers you use have no effect on the output. It simply converts them to list items within an ordered list and the actual number of list items will determine the numbers in the output.

1. List item 1
8. List item 2
5. List item 3

**Nested Lists**

You can create nested lists by indenting lines by three spaces.

1. Ordered list item 1
   1. Nested ordered list item 1
   2. Nested ordered list item 2
      * 2nd level nested unordered list item 1
      * 2nd level nested unordered list item 2
         * 3rd level nested unordered list item 1
   2. Ordered list item 2

**Paragraphs Inside Lists**

If list items are separated by blank lines, Markdown will wrap the items in a paragraph in the output.

* List item 1

* List item 2

For both DITA and HTML output, this would result in:
• **Multiple Paragraphs Inside Lists**

List items may consist of multiple paragraphs. Each subsequent paragraph in a list item must be indented by either 4 spaces or one tab. Optionally, you can also indent each line of a paragraph to make it look nicer.

1. This is a list item with two paragraphs. *Lorem ipsum dolor sit amet, consectetuer adipiscing elit. Aliquam hendrerit mi posuere lectus.*
   
   Vestibulum enim wisi, viverra nec, fringilla in, laoreet vitae, risus. *Donec sit amet nisl. Aliquam semper ipsum sit amet velit.*

2. Suspendisse id sem consectetuer libero luctus adipiscing.

• **Blockquotes Inside Lists**

To put a *blockquote* within a list item, the blockquote delimiters (`>` need to be indented so that it is under the first letter of the text after the list item marker.

  * A list item with a blockquote:
    
    > This is a blockquote
    
    > inside a list item.

• **Code Blocks Inside Lists**

To put a code block within a list item, insert an empty line in between the list item and the code block, and the code block needs to be indented twice (with 8 spaces or 2 tabs), or if you are using the triple backticks method, the opening triple backtick needs to be indented with 4 spaces or 1 tab.

  * A list item with a code block:
    
    ```
    This is a code block inside a list item
    ...
    This is a code block inside a list item using the backticks method
    ...
    ```

**Task Lists**

You can create task lists by prefacing list items with a hyphen followed by a space followed by square brackets (`- [ ]`). To mark a task as complete, use `- [x]`.

**Example: Task Lists**
Definition Lists

You can create definition lists by using a colon plus a space for each list item.

**Example: Definition Lists**

| Term 1 | Definition A | Definition B |

Tables

You can create tables in the Markdown editor by using pipes (|) and hyphens (-).

- **Creating a Table**

  Pipes are used to separate each column, while hyphens are used to create column headers. The pipes on either end of the table are optional. Cells can vary in width and do not need to be perfectly aligned within columns, but there must be at least three hyphens in each column of the header row.

<table>
<thead>
<tr>
<th>First Header</th>
<th>Second Header</th>
</tr>
</thead>
<tbody>
<tr>
<td>Column 1 Row 1 Cell</td>
<td>Column 2 Row 1 Cell</td>
</tr>
<tr>
<td>Column 1 Row 2 Cell</td>
<td>Column 2 Row 2 Cell</td>
</tr>
</tbody>
</table>

- **Formatting Rules in Table Cells**

  You can use formatting rules inside the cells of the table (such as links, inline code blocks, and text styling).

<table>
<thead>
<tr>
<th>First Header</th>
<th>Second Header</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>inline code</code></td>
<td>Content with <strong>bold text</strong> inside cell</td>
</tr>
</tbody>
</table>

- **Aligning Text in Tables**

  You can align text to the left, right, or center of a column by including colons (:) to the left, right, or on both sides of the hyphens within the header row.

<table>
<thead>
<tr>
<th align="left">Left-aligned</th>
<th align="center">Center-aligned</th>
<th align="right">Right-aligned</th>
</tr>
</thead>
<tbody>
<tr>
<td align="left">Content Cell</td>
<td align="center">Content Cell</td>
<td align="right">Content Cell</td>
</tr>
</tbody>
</table>

- **Joining Cells (Span a Cell Over Multiple Columns)**

  You can join cells horizontally (span a cell over multiple columns) by using multiple consecutive pipe characters (|) to the right of the particular cell. The number of consecutive pipes indicate the number of columns the cell will span (|| for two, ||| for three, and so on).
Emoji

You can add *emoji* in the Markdown editor by surrounding the EMOJICODE with colons (:EMOJICODE:).

**Example: Emoji**

```markdown
:smile:
:laughing:
```

The resulting emoticons will appear in the output, but they are not displayed in the *Preview* pane.

For a full list of available emoji codes, see [Emoji Cheat Sheet](#).

Backslash Escapes

You can ignore Markdown formatting by using backslash escapes (\) to generate literal characters that would otherwise have special meaning in the Markdown syntax. For example, if you want to surround a word with literal asterisks (instead of an italic or emphasis tag), you can use backslashes to escape the asterisks.

```
\*literal asterisks\*
```

The Markdown editor provides backslash escapes for the following characters:

<table>
<thead>
<tr>
<th>Literal Character</th>
<th>Escaping Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>\</td>
<td><code>\</code></td>
</tr>
<tr>
<td>`</td>
<td>``</td>
</tr>
<tr>
<td>*</td>
<td><code>*</code></td>
</tr>
<tr>
<td>_</td>
<td><code>_</code></td>
</tr>
<tr>
<td>{}</td>
<td><code>{}</code></td>
</tr>
<tr>
<td>[]</td>
<td><code>[]</code></td>
</tr>
<tr>
<td>()</td>
<td><code>()</code></td>
</tr>
<tr>
<td>#</td>
<td><code>#</code></td>
</tr>
<tr>
<td>+</td>
<td><code>+</code></td>
</tr>
<tr>
<td>-</td>
<td><code>-</code></td>
</tr>
<tr>
<td>.</td>
<td><code>.</code></td>
</tr>
<tr>
<td>!</td>
<td><code>!</code></td>
</tr>
</tbody>
</table>

Automatic Escaping for Special Characters

The Markdown editor includes support for automatically escaping special characters such as angle brackets (< >) and ampersands (&). If you want to use them as literal characters, you must escape them as entities, as in the table below. The exception to this is in HTML output, if the special characters for a valid tag (for example, `<b>`), they are treated as literal characters and escaping is not necessary.

<table>
<thead>
<tr>
<th>Literal Character</th>
<th>Escaping Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;</td>
<td>&lt;</td>
</tr>
<tr>
<td>Literal Character</td>
<td>Escaping Code</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>&gt;</td>
<td>&gt;</td>
</tr>
<tr>
<td>&amp;</td>
<td>&amp;</td>
</tr>
</tbody>
</table>

### Footnotes

The Markdown editor in Oxygen XML Editor supports normal and inline footnotes. The following examples show the required syntax.

- **Example: Normal Footnote**

  Here is a footnote reference,[^1]

[^1]: Here is the footnote.

- **Example: Normal Footnote with Multiple Blocks**

  Here is a footnote reference,[^longnote]

[^longnote]: Here is the footnote with multiple blocks.

  Subsequent paragraphs are indented with 4 spaces or 1 tab to show that they belong to the previous footnote.

- **Example: Inline Footnote**

  Here is an inline note.[^Inlines notes are easier to write, since you don't have to pick an identifier and move down to type the note.]
Built-in XML Frameworks (Document Types)

Oxygen XML Editor includes a variety of specialized editors, views, and features that are dynamic according to the type of document that you open or create. Oxygen XML Editor includes fully supported built-in frameworks (on page 2967) for the most popular XML document types (DITA, DocBook, TEI, XHTML, JATS) with a full set of features, as well as support for other document types with more generic features (on page 476).

The built-in frameworks (on page 2967) are defined according to a set of rules and a variety of settings that improve editing capabilities for its particular file type. These settings include:

- A default grammar used for validation and content completion in both Author mode and Text mode.
- CSS stylesheets for rendering XML documents in Author mode.
- User actions invoked from toolbars or menus in Author mode.
- Built-in transformation scenarios used for publishing XML documents.
- XML Catalogs (on page 2972) used for mapping resources.
- New document templates to make it easy to create XML documents.
- User-defined extensions for customizing the interaction with the content author in Author mode.

It is also possible to create and configure your own custom frameworks (document types). For more information, see the Creating and Configuring Custom Frameworks (on page 1987) section.

For extensive details about the DITA editing features included in Oxygen XML Editor, see the DITA Authoring chapter (on page 2653).

DocBook 4 Document Type (Framework)

DocBook is a very popular set of tags for describing books, articles, and other prose documents, particularly technical documentation. DocBook provides a vast number of semantic element tags, divided into three broad categories: structural, block-level, and inline. DocBook content can then be published in a variety of formats, including HTML, PDF, WebHelp, and EPUB.

File Definition

A file is considered to be a DocBook 4 document when one of the following conditions are true:

- The root element name is <book> or <article>.
- The PUBLIC ID of the document contains the string -//OASIS//DTD DocBook XML.

Default Document Templates

There are a variety of default DocBook 4 templates available when creating new documents from templates (on page 335) and they can be found in: Framework Templates > DocBook 4.
The default templates for DocBook 4 documents are located in the 
\[\text{OXYGEN_INSTALL_DIR}/\text{frameworks/docbook/templates/Docbook 4}\] folder.

**Default Schema for Validation and Content Completion**

The default schema that is used if one is not detected in the DocBook 4 file is `docbookxi.dtd` and it is stored in \[\text{OXYGEN_INSTALL_DIR}/\text{frameworks/docbook/4.5/dtd/}\].

**Default CSS**

The default CSS files used for rendering DocBook content in Author mode are stored in \[\text{OXYGEN_INSTALL_DIR}/\text{frameworks/docbook/css/}\].

By default, these default CSS files are merged with any that are specified in the document. For more information, see Configuring and Managing Multiple CSS Styles for a Framework (on page 1998).

**Default XML Catalog**

The default XML Catalog (on page 2972), `catalog.xml`, is stored in \[\text{OXYGEN_INSTALL_DIR}/\text{frameworks/docbook/}\].

**Transformation Scenarios**

Oxygen XML Editor includes numerous built-in DocBook transformation scenarios that allow you to transform DocBook 4 documents to a variety of outputs, such as WebHelp, PDF, HTML, HTML Chunk, XHTML, XHTML Chunk, and EPUB. All of them are listed in the DocBook 4 section in the Configure Transformation Scenario(s) dialog box (on page 1443).

For more information, see the DocBook Transformation Scenarios (on page 1355) section.

**Resources**

- Editing XML Documents in Text Mode (on page 476)
- Adding Tables in DocBook (on page 640)

**DocBook 4 Author Mode Actions**

A variety of actions are available for DocBook 4 documents in the DocBook4 menu, toolbar, contextual menu, and the Content Completion Assistant (on page 2965).

**DocBook 4 Toolbar Actions**

The following default actions are available on the DocBook toolbar when editing in Author mode (by default, most of them are also available in the DocBook4 menu and in various submenus of the contextual menu):
**Bold**
Emphasizes the selected text by surrounding it with a *bold* tag. You can use this action on multiple non-contiguous selections.

**Italic**
Emphasizes the selected text by surrounding it with an *italic* tag. You can use this action on multiple non-contiguous selections.

**Underline**
Emphasizes the selected text by surrounding it with an *underline* tag. You can use this action on multiple non-contiguous selections.

**Link Actions Drop-Down Menu**
The following link actions are available from this menu:

- **Cross reference (link)**
  Opens a dialog box that allows you to select a target to insert as a hypertext link.

- **Cross reference (xref)**
  Inserts a cross reference to other parts of the document.

- **Web Link (ulink)**
  Inserts a link that addresses its target with a URL (Universal Resource Locator).

- **Insert OLink**
  Opens an **OLink** dialog box that allows you to insert a link that addresses its target indirectly, using the values of the **@targetdoc** and **@targetptr** attributes that are present in a **Targetset (on page 1236)** file.
After you choose the **Targetset URL**, the structure of the target documents is presented. For each target document (`@targetdoc`), its content is displayed allowing you to easily identify the `@targetptr` for the `<olink>` element that will be inserted. You can also use the search fields to quickly identify a target. If you already know the values for `targetdoc` and `targetptr`, you can insert them directly in the corresponding fields. You can also edit an `<olink>` using the **Edit OLink** action that is available on the contextual menu. The last used **Targetset** URL will be used to identify the edited target.

To insert XREF text into the `<olink>`, enter the text in the `xreftext` field and make sure the **Insert xreftext in the OLink** option is selected.

**Insert URI**

Inserts a URI element. The URI identifies a Uniform Resource Identifier (URI) in content.

**Edit OLink**

Opens a dialog box that allows you edit an existing OLink. See the **Insert OLink** action for more information.

**Insert Image**

Opens a dialog box that allows you to select the path of an image to insert at the cursor position ([on page 672](#)). Depending on the current location, an image-type element is inserted. If the action is invoked between two block elements (such as paragraphs), the dialog box also allows you to provide a title.
Opens a **Choose Media** dialog box *(on page 701)* that allows you to select the URL of a media object to be inserted into a document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted and rendered in **Author** mode so that it can be played directly from there.

**Insert XInclude**

Opens a dialog box that allows you to browse and select content to be included and automatically generates the corresponding XInclude instruction.

**Section Drop-Down Menu**

The following actions are available from this menu:

**Section Drop-Down Menu**

- **Insert Section**
  - Inserts a new section or subsection in the document, depending on the current context. For example, if the current context is `<sect1>`, then a `<sect2>` is inserted. By default, this action also inserts a `<para>` element as a child node. The `<para>` element can be deleted if it is not needed.
  - **Promote Section** *(Ctrl + Alt + LeftArrow (Command + Alt + LeftArrow on OS X))*
    - Promotes the current node as a sibling of the parent node.
  - **Demote Section** *(Ctrl + Alt + RightArrow (Command + Alt + RightArrow on OS X))*
    - Demotes the current node a child of the previous node.

- **Insert Paragraph**
  - Insert a new paragraph element at current cursor position.

- **Insert Equation**
  - Opens the **XML Fragment Editor** that allows you to insert and **edit MathML notations** *(on page 703)*.

- **Insert List Item**
  - Inserts a list item in the current list type.

- **Insert Ordered List**
  - Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

- **Insert Itemized List**
  - Inserts an itemized list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an itemized list.

- **Insert Variable List**
Inserts a DocBook variable list. A child list item is also inserted automatically by default. You can also use this action to convert selected paragraphs or other types of lists to a variable list.

**Insert Procedure List**

Inserts a DocBook `<procedure>` element. A `<step>` child element is also inserted automatically. You can also use this action to convert selected paragraphs or other types of lists to a procedure list.

**Sort**

Sorts cells or list items in a table.

**Insert Table**

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a block element (on page 2964)) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

**Note:**

If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that Only lists, paragraphs, or inline content can be converted to tables.

**Insert Row**

Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

**Delete Row(s)**

Deletes the table row located at the cursor position or multiple rows in a selection.

**Insert Column**

Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

**Delete Column(s)**

Deletes the table column located at the cursor position or multiple columns in a selection.

**Table Properties**

Opens the Table properties dialog box that allows you to configure properties of a table (such as frame borders).

**Join Cells**

Joins the content of the selected cells (both horizontally and vertically).

**Split Cell**
Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

**DocBook4 Contextual Menu Actions**

The following actions are available in the contextual menu when editing in Author mode (most of them are also available in the DocBook4 menu at the top of the interface):

- **Add File to Review Task**
  
  This action can be used to add the current document to a task in the Content Fusion Tasks Manager view. Oxygen Content Fusion is a flexible, intuitive collaboration platform designed to adapt to any type of documentation review workflow. This functionality is available through a pre-installed connector add-on (on page 2353). To fully take advantage of all of the benefits and features of Content Fusion, your organization will need an Oxygen Content Fusion Enterprise Server. For more information, see the Oxygen Content Fusion website.

- **Edit Attributes**
  
  Displays an in-place attributes editor (on page 586) that allows you to manage the attributes of an element.

- **Edit Profiling Attributes**
  
  Allows you to change the profiling attributes (on page 623) defined on all selected elements.

- **Cut (Ctrl + X (Command + X on OS X))**
  
  Removes the currently selected content from the document and places it in the clipboard.

- **Copy (Ctrl + C (Command + C on OS X))**
  
  Places a copy of the currently selected content in the clipboard.

- **Paste (Ctrl + V (Command + V on OS X))**
  
  Inserts the current clipboard content into the document at the cursor position.

- **Paste special submenu**
  
  This submenu includes the following special paste actions:

  - **Paste As XInclude**
    
    Allows you to create a `<xi:include>` element that references a DocBook element copied from Author mode. The operation fails if the copied element does not have a declared ID.

  - **Paste as link**
    
    Allows you to create a `<link>` element that references a DocBook element copied from Author mode. The operation fails if the copied element does not have a declared ID.

  - **Paste as xref**
Allows you to create an `<xref>` element that references a DocBook element copied from Author mode. The operation fails if the copied element does not have a declared ID.

**Image Map Editor**

This action is available in the contextual menu when it is invoked on an image. This action applies an *image map* to the current image (if one does not already exist) and opens the *Image Map Editor* dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

**Insert submenu**

This submenu includes the following insert actions that are specific to the DocBook framework:

- **Insert Table**
  
  Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a *block element* (on page 2964)) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

  **Note:**
  
  If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that *Only lists, paragraphs, or inline content can be converted to tables*.

- **Insert Image**
  
  Inserts an image reference (on page 672) at the cursor position. Depending on the current location, an image-type element is inserted.

- **Insert Media Resource**
  
  Opens a *Choose Media* dialog box (on page 701) that allows you to select the URL of a media object to be inserted into a document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted and rendered in Author mode so that it can be played directly from there.

- **Insert Equation**
  
  Opens the *XML Fragment Editor* that allows you to insert and edit MathML notations (on page 703).

- **Insert Paragraph**
  
  Inserts a new *paragraph* element at current cursor position.
§ Insert Section

Inserts a new *section* element in the document, depending on the current context.

 pó Insert XInclude

Opens a dialog box that allows you to browse and select content to be included and automatically generates the corresponding XInclude instruction.

Insert Entity

Allows you to insert a predefined entity or character entity. Surrogate character entities (range #x10000 to #x10FFFF) are also accepted. Character entities can be entered in one of the following forms:

- `#<decimal value>` - e.g. #65
- `&#<decimal value>` - e.g. &#65
- `#<hexadecimal value>` - e.g. #x41
- `&#x<hexadecimal value>` - e.g. &#x41

§ Section submenu

The following actions are available in this submenu:

← Promote Section (Ctrl + Alt + LeftArrow (Command + Alt + LeftArrow on OS X))

Promotes the current node as a sibling of the parent node.

→ Demote Section (Ctrl + Alt + RightArrow (Command + Alt + RightArrow on OS X))

Demotes the current node a child of the previous node.

🔗 Link submenu

The following actions are available in this submenu:

Cross reference (link)

Opens a dialog box that allows you to select a target to insert as a hypertext link.

Cross reference (xref)

Inserts a cross reference to other parts of the document.

Web Link (ulink)

Inserts a link that addresses its target with a URL (Universal Resource Locator).

Insert OLink

Opens an OLink dialog box that allows you to insert a link that addresses its target indirectly, using the values of the `@targetdoc` and `@targetptr` attributes that are present in a Targetset (on page 1236) file.
After you choose the **Targetset URL**, the structure of the target documents is presented. For each target document (@targetdoc), its content is displayed allowing you to easily identify the @targetptr for the `<olink>` element that will be inserted. You can also use the search fields to quickly identify a target. If you already know the values for targetdoc and targetptr, you can insert them directly in the corresponding fields. You can also edit an `<olink>` using the **Edit OLink** action that is available on the contextual menu. The last used Targetset URL will be used to identify the edited target.

To insert XREF text into the `<olink>`, enter the text in the xreftext field and make sure the **Insert xreftext in the OLink** option is selected.

**Insert URI**

Inserts a URI element. The URI identifies a Uniform Resource Identifier (URI) in content.

**Edit OLink**

Opens a dialog box that allows you edit an existing OLink. See the **Insert OLink** action for more information.

**Table actions**

The following table editing actions are available in the contextual menu when it is invoked on a table:

**Insert Rows**

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (Above or Below the current row).
Delete Row(s)

Deletes the table row located at the cursor position or multiple rows in a selection.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (Above or Below the current column).

Delete Column(s)

Deletes the table column located at the cursor position or multiple columns in a selection.

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

Sort

Sorts cells or list items in a table.

Table Properties

Opens the Table properties dialog box that allows you to configure properties of a table (such as frame borders).

Other Actions submenu

This submenu give you access to all the usual contextual menu actions.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

• When invoked on a single selection, an ID is generated for the selected element at the cursor position.
• When invoked on a block of selected content, IDs are generated for all top-level elements and elements listed in the ID Options dialog box that are found in the current selection.

Note:
The Generate IDs action does not overwrite existing ID values. It only affects elements that do not already have an @id attribute.

Select submenu

This submenu allows you to select the following:
Element

Selects the entire element at the current cursor position.

Content

Selects the entire content of the element at the current cursor position, excluding
the start and end tag. Performing this action repeatedly will result in the selection
of the content of the ancestor of the currently selected element content.

Parent

Selects the entire parent element at the current cursor position.

Text submenu

This submenu contains the following actions:

To Lower Case

Converts the selected content to lower case characters.

To Upper Case

Converts the selected content to upper case characters.

Capitalize Sentences

Converts to upper case the first character of every selected sentence.

Capitalize Words

Converts to upper case the first character of every selected word.

Count Words

Counts the number of words and characters (no spaces) in the entire document or
in the selection for regular content and read-only content.

Note:

The content marked as deleted with change tracking (on page 2971) is
ignored when counting words.

Convert Hexadecimal Sequence to Character (Ctrl + Shift + X (Command + Shift + X on OS
X))

Converts a sequence of hexadecimal characters to the corresponding Unicode
character (on page 427). The action can be invoked if there is a selection
containing a valid hexadecimal sequence or if the cursor is placed at the right side
of a valid hexadecimal sequence. A valid hexadecimal sequence can be composed
of 2 to 4 hexadecimal characters and may or may not be preceded by the \texttt{0x} or \texttt{0X}
prefix. Examples of valid sequences and the characters they will be converted to:

- \texttt{0x0045} will be converted to $E$
- \texttt{0X0125} to $ĥ$
Refactoring submenu

Contains a series of actions designed to alter the XML structure of the document:

- **Toggle Comment**
  - Encloses the currently selected text in an XML comment, or removes the comment if it is commented.

- **Move Up (Alt + UpArrow)**
  - Moves the current node or selected nodes in front of the previous node.

- **Move Down (Alt + DownArrow)**
  - Moves the current node or selected nodes after the subsequent node.

- **Split Element (Alt + Shift + D (Ctrl + Alt + D on OS X))**
  - Splits the content of the closest element that contains the position of the cursor. Thus, if the cursor is positioned at the beginning or at the end of the element, the newly created sibling will be empty.

- **Join Elements**
  - Joins two adjacent block elements (on page 2964) that have the same name. The action is available only when the cursor position is between the two adjacent block elements. Also, joining two block elements can be done by pressing the Delete or Backspace keys and the cursor is positioned between the boundaries of these two elements.

- **Surround with Tags (Ctrl + E (Command + E on OS X))**
  - Allows you to choose a tag to enclose a selected portion of content. If there is no selection, the start and end tags are inserted at the cursor position.
    - If the Position cursor between tags option (on page 183) is selected in the Content Completion preferences page, the cursor is placed between the start and end tag.
    - If the Position cursor between tags option (on page 183) is not selected in the Content Completion preferences page, the cursor is placed at the end of the start tag, in an insert-attribute position.
**Surround with [tag]** (Ctrl + ForwardSlash (Command + ForwardSlash on OS X))

Surround the selected content with the last tag used.

**Rename Element**

The element from the cursor position, and any elements with the same name, can be renamed according with the options from the **Rename** dialog box.

**Delete Element Tags**

Deletes the tags of the closest element that contains the position of the cursor. This operation is also executed if the start or end tags of an element are deleted by pressing the **Delete** or **Backspace** keys.

**Remove All Markup**

Removes all the XML markup inside the selected block of content and keeps only the text content.

**Remove Text**

Removes the text content of the selected block of content and keeps the markup intact with empty elements.

**Attributes Refactoring Actions**

Contains built-in XML refactoring operations that pertain to attributes with some of the information preconfigured based upon the current context.

- **Add/Change attribute**
  
  Allows you to change the value of an attribute or insert a new one.

- **Convert attribute to element**

  Allows you to change an attribute into an element.

- **Delete attribute**

  Allows you to remove one or more attributes.

- **Rename attribute**

  Allows you to rename an attribute.

- **Replace in attribute value**

  Allows you to search for a text fragment inside an attribute value and change the fragment to a new value.

**Comments Refactoring Actions**

Contains built-in XML refactoring operations that pertain to comments with some of the information preconfigured based upon the current context.

- **Delete comments**

  Allows you to delete comments found inside one or more elements.
Elements Refactoring Actions

Contains built-in XML refactoring operations that pertain to elements with some of the information preconfigured based upon the current context.

**Delete element**

Allows you to delete elements.

**Delete element content**

Allows you to delete the content of elements.

**Insert element**

Allows you to insert new elements.

**Rename element**

Allows you to rename elements.

**Unwrap element**

Allows you to remove the surrounding tags of elements, while keeping the content unchanged.

**Wrap element**

Allows you to surround elements with element tags.

**Wrap element content**

Allows you to surround the content of elements with element tags.

Fragments Refactoring Actions

Contains built-in XML refactoring operations that pertain to XML fragments with some of the information preconfigured based upon the current context.

**Insert XML fragment**

Allows you to insert an XML fragment.

**Replace element content with XML fragment**

Allows you to replace the content of elements with an XML fragment.

**Replace element with XML fragment**

Allows you to replace elements with an XML fragment.

Review submenu

This submenu includes the following actions:

- **Track Changes**
  
  Enables or disables the *Track Changes (on page 2971)* support for the current document.

- **Accept Change(s) and Move to Next**
Accepts the Tracked Change (on page 2971) located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a deletion or insertion change, only the selected content is accepted.

☑️ Accept All Changes

Accepts all Tracked Changes (on page 2971) in the current document.

❌ Reject Change(s) and Move to Next

Rejects the Tracked Change (on page 2971) located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a deletion or insertion change, only the selected content is rejected.

❌ Reject All Changes

Rejects all Tracked Changes (on page 2971) in the current document.

💬 Comment Change

Opens a dialog box that allows you to add a comment to an existing Tracked Change (on page 2971). The comment will appear in a callout and a tooltip when hovering over the change. If the action is selected on an existing commented change, the dialog box will allow you to edit the comment.

🌈 Highlight

Enables the highlighting tool that allows you to mark text in your document.

Colors

Allows you to select the color for highlighting text.

Stop highlighting

Use this action to deactivate the highlighting tool.

Remove highlight(s)

Use this action to remove highlighting from the document.

📝 Add Comment

Inserts a comment at the cursor position. The comment appears in a callout box and a tooltip (when hovering over the change).

📝 Show/Edit Comment

Opens a dialog box that displays the discussion thread and allows the current user to edit comments that do not have replies. If you are not the author who inserted the original comment, the dialog box just displays the comment without the possibility of editing it.

📝 Remove Comment

Removes a selected comment. If you remove a comment that contains replies, all of the replies will also be removed.
Manage Reviews

Opens the **Review view** *(on page 619).*

**Folding submenu**

This submenu includes the following actions:

- **Toggle Fold**
  Toggles the state of the current fold.

- **Collapse Other Folds (Ctrl + NumPad/ (Command + NumPad/ on OS X))**
  Folds all the elements except the current element.

- **Collapse Child Folds (Ctrl + NumPad. (Command + NumPad. on OS X))**
  Folds the elements indented with one level inside the current element.

- **Expand Child Folds**
  Unfolds all child elements of the currently selected element.

- **Expand All (Ctrl + NumPad* (Command + NumPad* on OS X))**
  Unfolds all elements in the current document.

**About Element >** **Go to Definition**

Moves the cursor to the definition of the current element.

**Inspect Styles**

Opens the **CSS Inspector view** *(on page 597)* that allows you to examine the CSS rules that match the currently selected element.

**Options**

Opens the **Author mode preferences page** *(on page 148)* where you can configure various options with regard to the **Author** editing mode.

**Floating Contextual Toolbar for DocBook**

Oxygen XML Editor includes a dynamic feature where certain editing contexts will trigger a floating toolbar with common actions that are available in the current editing context.

**Figure 435. DocBook Floating Contextual Toolbar**

![DocBook Floating Contextual Toolbar](image)

The **floating contextual toolbar** is automatically displayed when editing DocBook documents in the following situations:
• When a `<para>` or `<listitem>` element has a selection inside, the floating toolbar includes actions such as **Bold**, *Italic*, _Underline_, `T` _Subscript_, and `T²` _Superscript_.

• When an `<imagedata>` or `<videodata>` element is selected, the floating toolbar includes a URL chooser where you can select the appropriate target.

• When an `<olink>` element is selected, the floating toolbar includes an **Edit OLink** action.

• When a `<link>` or `<include>` element is selected, the floating toolbar includes a URL chooser where you can select the appropriate target.

• When a `<programlisting>` element is selected, the floating toolbar includes a drop-down control where you can select the value of the `@language` attribute.

• When an `<itemizedlist>`, `<orderdlist>`, `<variablelist>`, or `<procedure>` element is selected, the floating toolbar includes actions for converting it to a different type of list or sorting the list.

• When a `<listitem>`, `<varlistentry>`, or `<step>` element is selected, the floating toolbar includes actions for moving the item up or down in the list/procedure.

• When a `<row>` or `<tr>` element is selected in a table, the floating toolbar includes various table-related actions (such as actions for editing table properties, inserting rows, or deleting rows).

• When an `<entry>` or `<td>` element is selected in a table, the floating toolbar includes various table-related actions (such as actions for editing table properties, inserting/deleting rows, or inserting/deleting columns).

• When a `<table>` element is selected, the floating toolbar includes actions for editing table properties or sorting the table.

**DocBook 4 Drag/Drop (or Copy/Paste) Actions**

Dragging a file from the [Project view (on page 368)](on page 368) or [DITA Maps Manager view (on page 2662)](on page 2662) and dropping it into a DocBook 4 document that is edited in **Author** mode, creates a link to the dragged file (the `<ulink>` DocBook element) at the drop location. Copy and paste actions work the same.

You can also drag images or media files from your system explorer or the [Project view (on page 368)](on page 368) and drop them into a DocBook 4 document (or copy and paste). This will insert the appropriate element at the drop or paste location (for example, dropping/pasting an image will insert the `<inlinegraphic>` DocBook element with a `@fileref` attribute).

**Tip:**

For information about customizing **Author** mode actions for a particular framework [(on page 2967)](on page 2967) (document type), see the [Customizing the Author Editing Experience for a Framework (on page 1998)](on page 1998) section.

**Related Information:**

Customizing the Author Editing Experience for a Framework (on page 1998)
Inserting an Olink in DocBook Documents

The `<olink>` element is used for linking to resources outside the current DocBook document. The `@targetdoc` attribute is used for the document ID that contains the target element and the `@targetptr` attribute for the ID of the target element (the value of an `@id` or `@xml:id` attribute). The combination of those two attributes provides a unique identifier to locate cross references.

For example, a *Mail Administrator Guide* with the document ID `MailAdminGuide` might contain a chapter about user accounts, like this:

```xml
<chapter id="user_accounts">
  <title>Administering User Accounts</title>
  <para>blah blah</para>
</chapter>
```

You can form a cross reference to that chapter by adding an `<olink>`, as in the following example:

```xml
<olink targetdoc="MailAdminGuide" targetptr="user_accounts">user accounts</olink>
```

When you get a new machine.

To use an `<olink>` to create links between documents, follow these steps:

1. Decide which documents are to be included in the domain for cross referencing.
   A unique ID must be assigned to each document that will be referenced with an `<olink>`. It is usually added as an `@id` (or `@xml:id` for DocBook5) attribute to the root element of the document.

2. Decide on your output hierarchy.
   For creating links between documents, the relative locations of the output documents must be known. Before going further you must decide the names and locations of the output directories for all the documents from the domain. Each directory will be represented by an element: `<dir name="directory_name"`, in the target database document.

3. Create the target database document.
   Each collection of documents has a main target database document that is used to resolve all `<olink>`s from that collection. The target database document is an XML file that is created once. It provides a means for pulling in the target data for each document. The database document is static and all the document data is pulled in dynamically.

**Tip:**

Oxygen XML Editor includes a built-in new document template called **DocBook Targetset Map** available in the **New document wizard (on page 335)** that will help you get started.

**Example:** The following is an example of a target database document. It structures a collection of documents in a `<sitemap>` element that provides the relative locations of the outputs (HTML in this example). Then it pulls in the individual target data using system entity references to target data files that will be created in the next step.
4. Generate the target data files by executing a DocBook transformation scenario. Before applying the transformation, you need to edit the transformation scenario, go to the Parameters tab, and make sure the value of the collect.xref.targets parameter is set to yes. The default name
of a target data file is `target.db`, but it can be changed by setting an absolute file path in the `targets.filename` parameter.

**Example:** An example of a `target.db` file:

```xml
<book href="#MailAdminGuide" number="1" targetptr="user_accounts">
  <ttl>Administering User Accounts</ttl>

  <xref href="#d5e4" number="I">Part I</xref>

  <chapter href="#d5e6" number="1">
    <ttl>Chapter Title</ttl>
  </chapter>

  <sect1 href="#src_chapter" number="1" targetptr="src_chapter">
    <xrefhref="xreflabel_here"></xrefhref>
  </sect1>
</book>
```

When editing a DocBook XML document in **Author** mode, the **Insert OLink** action is available in the ![Link](link.png) drop-down menu from the toolbar. This action opens the **Insert OLink** dialog box that allows you to select the target of an `<olink>` from the list of all possible targets from a specified target database document (specified in the **Targetset URL** field). Once a **Targetset URL** is selected, the structure of the target documents is presented. For each target document (`@targetdoc`), its content is displayed, allowing you to easily identify the appropriate `@targetptr`. You can also use the search fields to quickly identify a target. If you already know the values for the `@targetdoc` and `@targetptr` attributes, you can insert them directly in the corresponding fields.

**Example:** In the following image, the target database document is called `target.xml`, `dbadmin` is selected for the target document (`@targetdoc`), and `bldinit` is selected as the value for the `@targetptr` attribute. Notice that you can also add XREF text into the `<olink>` by using the `<xreftext>` field.
6. Process a DocBook transformation for each document to generate the output.
   a. Edit the transformation scenario and set the value of the `target.database.document` parameter to be the URL of the target database document.
   b. Apply the transformation scenario.

**DocBook 5 Document Type (Framework)**

*DocBook* is a very popular set of tags for describing books, articles, and other prose documents, particularly technical documentation. DocBook provides a vast number of semantic element tags, divided into three broad categories: structural, *block-level*, and *inline*. DocBook content can then be published in a variety of formats, including HTML, PDF, WebHelp, and EPUB.

**File Definition**

A file is considered to be a DocBook 5 document when the namespace is [http://docbook.org/ns/docbook](http://docbook.org/ns/docbook).

**Default Document Templates**

There are a variety of default *DocBook 5* templates available when creating new documents from templates (on page 335) and they can be found in: Framework Templates > DocBook 5 > DocBook 5.0 and Framework Templates > DocBook 5 > DocBook 5.1.
New document templates for both DocBook 5 documents are located in the \[OXYGEN_INSTALL_DIR]/frameworks/docbook/templates/Docbook5.0 folder.

New document templates for both DocBook 5.1 documents are located in the \[OXYGEN_INSTALL_DIR]/frameworks/docbook/templates/Docbook5.1 folder.

**Default Schema for Validation and Content Completion**

The default schema that is used if one is not detected is `docbookxi.rng` and it is stored in \[OXYGEN_INSTALL_DIR]/frameworks/docbook/5.0/rng/ (or for DocBook 5.1 in \[OXYGEN_INSTALL_DIR]/frameworks/docbook/5.1/rng/). Other types of schemas for various DocBook versions are also located in various folders inside the \[OXYGEN_INSTALL_DIR]/frameworks/docbook/ directory.

**Default CSS**

The default CSS files used for rendering DocBook content in **Author** mode is stored in \[OXYGEN_INSTALL_DIR]/frameworks/docbook/css/.

By default, these default CSS files are merged with any that are specified in the document. For more information, see Configuring and Managing Multiple CSS Styles for a Framework *(on page 1998)*.

**Transformation Scenarios**

Oxygen XML Editor includes numerous built-in DocBook transformation scenarios that allow you to transform DocBook 5 documents to a variety of outputs, such as WebHelp, PDF, HTML, HTML Chunk, XHTML, XHTML Chunk, and EPUB. Oxygen XML Editor also includes a DocBook 5.1 transformation scenario for **Assembly** documents *(on page 1234)*. All of them are listed in the **DocBook 5** section in the Configure Transformation Scenario(s) dialog box *(on page 1443)*.

For more information, see the DocBook Transformation Scenarios *(on page 1355)* section.

DocBook 5 Author Mode Actions

A variety of actions are available for DocBook 5 documents in the DocBook5 menu, toolbar, contextual menu, and the Content Completion Assistant (on page 2965).

DocBook 5 Toolbar Actions

The following default actions are available on the DocBook toolbar when editing in Author mode (by default, most of them are also available in the DocBook5 menu and in various submenus of the contextual menu):

- **Bold**
  Emphasizes the selected text by surrounding it with a *bold* tag. You can use this action on multiple non-contiguous selections.

- **Italic**
  Emphasizes the selected text by surrounding it with an *italic* tag. You can use this action on multiple non-contiguous selections.

- **Underline**
  Emphasizes the selected text by surrounding it with an *underline* tag. You can use this action on multiple non-contiguous selections.

- **Link Actions Drop-Down Menu**
  The following link actions are available from this menu:

  - **Cross reference (link)**
    Opens a dialog box that allows you to select a target to insert as a hypertext link.

  - **Cross reference (xref)**
    Inserts a cross reference to other parts of the document.

  - **Web Link (ulink)**
    Inserts a link that addresses its target with a URL (Universal Resource Locator).

  - **Insert OLink**
    Opens an OLink dialog box that allows you to insert a link that addresses its target indirectly, using the values of the @targetdoc and @targetptr attributes that are present in a Targetset (on page 1236) file.
After you choose the **Targetset URL**, the structure of the target documents is presented. For each target document (@targetdoc), its content is displayed allowing you to easily identify the @targetptr for the `<olink>` element that will be inserted. You can also use the search fields to quickly identify a target. If you already know the values for `targetdoc` and `targetptr`, you can insert them directly in the corresponding fields. You can also edit an `<olink>` using the Edit OLink action that is available on the contextual menu. The last used Targetset URL will be used to identify the edited target.

To insert XREF text into the `<olink>`, enter the text in the `xreftext` field and make sure the **Insert xreftext in the OLink** option is selected.

**Insert URI**

Inserts a URI element. The URI identifies a Uniform Resource Identifier (URI) in content.

**Edit OLink**

Opens a dialog box that allows you edit an existing OLink. See the **Insert OLink** action for more information.

**Insert Image**

Opens a dialog box that allows you to select the path of an image to insert at the cursor position (on page 672). Depending on the current location, an image-type element is inserted. If the action is invoked between two block elements (such as paragraphs), the dialog box also allows you to provide a title.

**Insert Media Resource**
Opens a Choose Media dialog box (on page 701) that allows you to select the URL of a media object to be inserted into a document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted and rendered in Author mode so that it can be played directly from there.

Insert XInclude

Opens a dialog box that allows you to browse and select content to be included and automatically generates the corresponding XInclude instruction.

Section Drop-Down Menu

The following actions are available from this menu:

- **Insert Section**
  
  Inserts a new section or subsection in the document, depending on the current context. For example, if the current context is `<sect1>`, then a `<sect2>` is inserted. By default, this action also inserts a `<para>` element as a child node. The `<para>` element can be deleted if it is not needed.

- **Promote Section (Ctrl + Alt + LeftArrow (Command + Alt + LeftArrow on OS X))**
  
  Promotes the current node as a sibling of the parent node.

- **Demote Section (Ctrl + Alt + RightArrow (Command + Alt + RightArrow on OS X))**
  
  Demotes the current node a child of the previous node.

- **Insert Paragraph**
  
  Insert a new paragraph element at current cursor position.

- **Insert Equation**
  
  Opens the XML Fragment Editor that allows you to insert and edit MathML notations (on page 703).

- **Insert List Item**
  
  Inserts a list item in the current list type.

- **Insert Ordered List**
  
  Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

- **Insert Itemized List**
  
  Inserts an itemized list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an itemized list.

- **Insert Variable List**
Inserts a DocBook variable list. A child list item is also inserted automatically by default. You can also use this action to convert selected paragraphs or other types of lists to a variable list.

Insert Procedure List

Inserts a DocBook <procedure> element. A <step> child element is also inserted automatically. You can also use this action to convert selected paragraphs or other types of lists to a procedure list.

Sort

Sorts cells or list items in a table.

Insert Table

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a block element (on page 2964)) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

Note:

If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that Only lists, paragraphs, or inline content can be converted to tables.

Insert Row

Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

Delete Row(s)

Deletes the table row located at the cursor position or multiple rows in a selection.

Insert Column

Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

Delete Column(s)

Deletes the table column located at the cursor position or multiple columns in a selection.

Table Properties

Opens the Table properties dialog box that allows you to configure properties of a table (such as frame borders).

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell
Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split
the cell, a dialog box will be displayed that allows you to select the number of rows or columns
to split the cell into.

**DocBook5 Contextual Menu Actions**

The following actions are available in the contextual menu when editing in **Author** mode (most of them are
also available in the **DocBook5** menu at the top of the interface):

- **Add File to Review Task**
  
  This action can be used to add the current document to a task in the **Content Fusion Tasks**
  Manager view. **Oxygen Content Fusion** is a flexible, intuitive collaboration platform designed to
  adapt to any type of documentation review workflow. This functionality is available through a
  pre-installed connector add-on *(on page 2353)*. To fully take advantage of all of the benefits and
  features of **Content Fusion**, your organization will need an **Oxygen Content Fusion Enterprise**
  Server. For more information, see the **Oxygen Content Fusion** website.

- **Edit Attributes**
  
  Displays an in-place attributes editor *(on page 586)* that allows you to manage the attributes of
  an element.

- **Edit Profiling Attributes**
  
  Allows you to change the profiling attributes *(on page 623)* defined on all selected elements.

- **Cut (Ctrl + X (Command + X on OS X))**
  
  Removes the currently selected content from the document and places it in the clipboard.

- **Copy (Ctrl + C (Command + C on OS X))**
  
  Places a copy of the currently selected content in the clipboard.

- **Paste (Ctrl + V (Command + V on OS X))**
  
  Inserts the current clipboard content into the document at the cursor position.

- **Paste special submenu**
  
  This submenu includes the following special paste actions:

  - **Paste As XInclude**
    
    Allows you to create an `<xi:include>` element that references a DocBook element
copied from **Author** mode. The operation fails if the copied element does not have
a declared ID.

  - **Paste as link**
    
    Allows you to create a `<link>` element that references a DocBook element copied
from **Author** mode. The operation fails if the copied element does not have a
declared ID.

  - **Paste as xref**
Allows you to create an `<xref>` element that references a DocBook element copied from Author mode. The operation fails if the copied element does not have a declared ID.

**Image Map Editor**

This action is available in the contextual menu when it is invoked on an image. This action applies an *image map* to the current image (if one does not already exist) and opens the Image Map Editor dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

**Insert submenu**

This submenu includes the following insert actions that are specific to the DocBook framework:

- **Insert Table**
  
  Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a *block element* [on page 2964]) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

  **Note:**
  
  If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that *Only lists, paragraphs, or inline content can be converted to tables.*

- **Insert Image**
  
  Inserts an *image reference* [on page 672] at the cursor position. Depending on the current location, an image-type element is inserted.

- **Insert Media Resource**
  
  Opens a Choose Media dialog box [on page 701] that allows you to select the URL of a media object to be inserted into a document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted and rendered in Author mode so that it can be played directly from there.

- **Insert Equation**
  
  Opens the XML Fragment Editor that allows you to insert and edit MathML notations [on page 703].

- **Insert Paragraph**
  
  Inserts a new *paragraph* element at current cursor position.
§ Insert Section

Inserts a new section element in the document, depending on the current context.

Insert XInclude

Opens a dialog box that allows you to browse and select content to be included and automatically generates the corresponding XInclude instruction.

Insert Entity

Allows you to insert a predefined entity or character entity. Surrogate character entities (range #x10000 to #x10FFFF) are also accepted. Character entities can be entered in one of the following forms:

- `#<decimal value>` - e.g. #65
- `&#<decimal value>` - e.g. &#65
- `#x<hexadecimal value>` - e.g. #x41
- `&#x<hexadecimal value>` - e.g. &#x41

Style submenu

This submenu includes the following text styling actions:

- **Bold**
  Emphasizes the selected text by surrounding it with a *bold* tag. You can use this action on multiple non-contiguous selections.

- **Italic**
  Emphasizes the selected text by surrounding it with an *italic* tag. You can use this action on multiple non-contiguous selections.

- **Underline**
  Emphasizes the selected text by surrounding it with an *underline* tag. You can use this action on multiple non-contiguous selections.

- **Subscript**
  Surrounds the selected text with a *subscript* tag, used for inserting a character (number, letter, or symbol) that will appear slightly below the baseline and slightly smaller than the rest of the text.

- **Superscript**
  Surrounds the selected text with a *superscript* tag, used for inserting a character (number, letter, or symbol) that will appear slightly above the baseline and slightly smaller than the rest of the text.

§ Section submenu

The following actions are available in this submenu:
Promote Section (Ctrl + Alt + LeftArrow (Command + Alt + LeftArrow on OS X))
Promotes the current node as a sibling of the parent node.

Demote Section (Ctrl + Alt + RightArrow (Command + Alt + RightArrow on OS X))
Demotes the current node a child of the previous node.

Link submenu
The following actions are available in this submenu:

Cross reference (link)
Opens a dialog box that allows you to select a target to insert as a hypertext link.

Cross reference (xref)
Inserts a cross reference to other parts of the document.

Web Link (ulink)
Inserts a link that addresses its target with a URL (Universal Resource Locator).

Insert OLink
Opens an OLink dialog box that allows you to insert a link that addresses its target indirectly, using the values of the @targetdoc and @targetptr attributes that are present in a Targetset (on page 1236) file.

Figure 438. Insert OLink Dialog Box

After you choose the Targetset URL, the structure of the target documents is presented. For each target document (@targetdoc), its content is displayed allowing you to easily identify the @targetptr for the <olink> element that will be inserted. You can also use the search fields to quickly identify a target. If you already
know the values for targetdoc and targetptr, you can insert them directly in the corresponding fields. You can also edit an <olink> using the Edit OLink action that is available on the contextual menu. The last used Targetset URL will be used to identify the edited target.

To insert XREF text into the <olink>, enter the text in the xreftext field and make sure the Insert xreftext in the OLink option is selected.

Insert URI

Inserts a URI element. The URI identifies a Uniform Resource Identifier (URI) in content.

Edit OLink

Opens a dialog box that allows you edit an existing OLink. See the Insert OLink action for more information.

Table actions

The following table editing actions are available in the contextual menu when it is invoked on a table:

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (Above or Below the current row).

Delete Row(s)

Deletes the table row located at the cursor position or multiple rows in a selection.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (Above or Below the current column).

Delete Column(s)

Deletes the table column located at the cursor position or multiple columns in a selection.

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

Sort

Sorts cells or list items in a table.

Table Properties
Opens the **Table properties** dialog box that allows you to configure properties of a table (such as frame borders).

**Other Actions submenu**

This submenu gives you access to all the usual contextual menu actions.

**Generate IDs**

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements listed in the **ID Options** dialog box that are found in the current selection.

**Note:**
The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `@id` attribute.

**Select submenu**

This submenu allows you to select the following:

- **Element**
  Selects the entire element at the current cursor position.

- **Content**
  Selects the entire content of the element at the current cursor position, excluding the start and end tag. Performing this action repeatedly will result in the selection of the content of the ancestor of the currently selected element content.

- **Parent**
  Selects the entire parent element at the current cursor position.

**Text submenu**

This submenu contains the following actions:

- **To Lower Case**
  Converts the selected content to lower case characters.

- **To Upper Case**
  Converts the selected content to upper case characters.

- **Capitalize Sentences**
  Converts to upper case the first character of every selected sentence.

- **Capitalize Words**
Converts to upper case the first character of every selected word.

**Count Words**

Counts the number of words and characters (no spaces) in the entire document or in the selection for regular content and read-only content.

**Note:**
The content marked as deleted with change tracking (on page 2971) is ignored when counting words.

**Convert Hexadecimal Sequence to Character (Ctrl + Shift + X (Command + Shift + X on OS X))**

Converts a sequence of hexadecimal characters to the corresponding Unicode character (on page 427). The action can be invoked if there is a selection containing a valid hexadecimal sequence or if the cursor is placed at the right side of a valid hexadecimal sequence. A valid hexadecimal sequence can be composed of 2 to 4 hexadecimal characters and may or may not be preceded by the 0x or 0X prefix. Examples of valid sequences and the characters they will be converted to:

- 0x0045 will be converted to E
- 0x0125 to ĥ
- 265 to ɥ
- 2190 to ←

**Note:**
For more information about finding the hexadecimal value of a character, see Finding the Decimal, Hexadecimal, or Character Entity Equivalent (on page 430).

**Refactoring submenu**

Contains a series of actions designed to alter the XML structure of the document:

- **Toggle Comment**
  Encloses the currently selected text in an XML comment, or removes the comment if it is commented.

- **Move Up (Alt + UpArrow)**
  Moves the current node or selected nodes in front of the previous node.

- **Move Down (Alt + DownArrow)**
  Moves the current node or selected nodes after the subsequent node.

- **Split Element (Alt + Shift + D (Ctrl + Alt + D on OS X))**
Splits the content of the closest element that contains the position of the cursor. Thus, if the cursor is positioned at the beginning or at the end of the element, the newly created sibling will be empty.

Join Elements

Joins two adjacent block elements that have the same name. The action is available only when the cursor position is between the two adjacent block elements. Also, joining two block elements can be done by pressing the Delete or Backspace keys and the cursor is positioned between the boundaries of these two elements.

Surround with Tags (Ctrl + E (Command + E on OS X))

Allows you to choose a tag to enclose a selected portion of content. If there is no selection, the start and end tags are inserted at the cursor position.

- If the Position cursor between tags option (on page 183) is selected in the Content Completion preferences page, the cursor is placed between the start and end tag.
- If the Position cursor between tags option (on page 183) is not selected in the Content Completion preferences page, the cursor is placed at the end of the start tag, in an insert-attribute position.

Surround with ‘[tag]’ (Ctrl + ForwardSlash (Command + ForwardSlash on OS X))

Surround the selected content with the last tag used.

Rename Element

The element from the cursor position, and any elements with the same name, can be renamed according with the options from the Rename dialog box.

Delete Element Tags

Deletes the tags of the closest element that contains the position of the cursor. This operation is also executed if the start or end tags of an element are deleted by pressing the Delete or Backspace keys.

Remove All Markup

Removes all the XML markup inside the selected block of content and keeps only the text content.

Remove Text

Removes the text content of the selected block of content and keeps the markup intact with empty elements.

Attributes Refactoring Actions

Contains built-in XML refactoring operations that pertain to attributes with some of the information preconfigured based upon the current context.
Add/Change attribute

Allows you to change the value of an attribute or insert a new one.

Convert attribute to element

Allows you to change an attribute into an element.

Delete attribute

Allows you to remove one or more attributes.

Rename attribute

Allows you to rename an attribute.

Replace in attribute value

Allows you to search for a text fragment inside an attribute value and change the fragment to a new value.

Comments Refactoring Actions

Contains built-in XML refactoring operations that pertain to comments with some of the information preconfigured based upon the current context.

Delete comments

Allows you to delete comments found inside one or more elements.

Elements Refactoring Actions

Contains built-in XML refactoring operations that pertain to elements with some of the information preconfigured based upon the current context.

Delete element

Allows you to delete elements.

Delete element content

Allows you to delete the content of elements.

Insert element

Allows you to insert new elements.

Rename element

Allows you to rename elements.

Unwrap element

Allows you to remove the surrounding tags of elements, while keeping the content unchanged.

Wrap element

Allows you to surround elements with element tags.

Wrap element content

Allows you to surround the content of elements with element tags.
Fragments Refactoring Actions

Contains built-in XML refactoring operations that pertain to XML fragments with some of the information preconfigured based upon the current context.

Insert XML fragment

Allows you to insert an XML fragment.

Replace element content with XML fragment

Allows you to replace the content of elements with an XML fragment.

Replace element with XML fragment

Allows you to replace elements with an XML fragment.

Review submenu

This submenu includes the following actions:

✔️ Track Changes

Enables or disables the Track Changes (on page 2971) support for the current document.

✔️ Accept Change(s) and Move to Next

Accepts the Tracked Change (on page 2971) located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a deletion or insertion change, only the selected content is accepted.

✔️ Accept All Changes

Accepts all Tracked Changes (on page 2971) in the current document.

❌ Reject Change(s) and Move to Next

Rejects the Tracked Change (on page 2971) located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a deletion or insertion change, only the selected content is rejected.

❌ Reject All Changes

Rejects all Tracked Changes (on page 2971) in the current document.

✍ Comment Change

Opens a dialog box that allows you to add a comment to an existing Tracked Change (on page 2971). The comment will appear in a callout and a tooltip when hovering over the change. If the action is selected on an existing commented change, the dialog box will allow you to edit the comment.

🖌 Highlight

Enables the highlighting tool that allows you to mark text in your document.

Colors
Allows you to select the color for highlighting text.

**Stop highlighting**

Use this action to deactivate the highlighting tool.

**Remove highlight(s)**

Use this action to remove highlighting from the document.

![Add Comment]

Inserts a comment at the cursor position. The comment appears in a callout box and a tooltip (when hovering over the change).

![Show/Edit Comment]

Opens a dialog box that displays the discussion thread and allows the current user to edit comments that do not have replies. If you are not the author who inserted the original comment, the dialog box just displays the comment without the possibility of editing it.

![Remove Comment]

Removes a selected comment. If you remove a comment that contains replies, all of the replies will also be removed.

![Manage Reviews]

Opens the Review view (on page 619).

**Folding submenu**

This submenu includes the following actions:

- **Toggle Fold**
  Toggles the state of the current fold.

- **Collapse Other Folds** *(Ctrl + NumPad/ (Command + NumPad/ on OS X))*
  Folds all the elements except the current element.

- **Collapse Child Folds** *(Ctrl + NumPad. (Command + NumPad. on OS X))*
  Folds the elements indented with one level inside the current element.

- **Expand Child Folds**
  Unfolds all child elements of the currently selected element.

- **Expand All** *(Ctrl + NumPad* (Command + NumPad* on OS X))
  Unfolds all elements in the current document.

**About Element > Go to Definition**

Moves the cursor to the definition of the current element.

**Inspect Styles**
Opens the **CSS Inspector view** *(on page 597)* that allows you to examine the CSS rules that match the currently selected element.

**Options**

Opens the *Author mode preferences page* *(on page 148)* where you can configure various options with regard to the *Author* editing mode.

### Floating Contextual Toolbar for DocBook

Oxygen XML Editor includes a dynamic feature where certain editing contexts will trigger a floating toolbar with common actions that are available in the current editing context.

**Figure 439. DocBook Floating Contextual Toolbar**

![Floating Contextual Toolbar](image)

The *floating contextual toolbar* is automatically displayed when editing DocBook documents in the following situations:

- When a `<para>` or `<listitem>` element has a selection inside, the floating toolbar includes actions such as **Bold**, **Italic**, **Underline**, **Subscript**, and **Superscript**.
- When an `<imagedata>` or `<videodata>` element is selected, the floating toolbar includes a URL chooser where you can select the appropriate target.
- When an `<olink>` element is selected, the floating toolbar includes an **Edit OLink** action.
- When a `<link>` or `<include>` element is selected, the floating toolbar includes a URL chooser where you can select the appropriate target.
- When a `<programlisting>` element is selected, the floating toolbar includes a drop-down control where you can select the value of the `@language` attribute.
- When an `<itemizedlist>`, `<orderdlist>`, `<variablelist>`, or `<procedure>` element is selected, the floating toolbar includes actions for converting it to a different type of list or sorting the list.
- When a `<listitem>`, `<varlistentry>`, or `<step>` element is selected, the floating toolbar includes actions for moving the item up or down in the list/procedure.
- When a `<row>` or `<tr>` element is selected in a table, the floating toolbar includes various table-related actions (such as actions for editing table properties, inserting rows, or deleting rows).
- When an `<entry>` or `<td>` element is selected in a table, the floating toolbar includes various table-related actions (such as actions for editing table properties, inserting/deleting rows, or inserting/deleting columns).
- When a `<table>` element is selected, the floating toolbar includes actions for editing table properties or sorting the table.
DocBook 5 Drag/Drop (or Copy/Paste) Actions

Dragging a file from the Project view (on page 368) and dropping it into a DocBook 5 document that is edited in Author mode, creates a link to the dragged file (the `<link>` DocBook element) at the drop location. Copy and paste actions work the same.

You can also drag images or media files from your system explorer or the Project view (on page 368) and drop them into a DocBook 5 document (or copy and paste). This will insert the appropriate element at the drop or paste location (for example, dropping/pasting an image will insert the `<imageobject>` DocBook element with an `<imagedata>` child element and a `@fileref` attribute).

**Tip:**
For information about customizing Author mode actions for a particular framework (on page 2967) (document type), see the Customizing the Author Editing Experience for a Framework (on page 1998) section.

Related Information:
Customizing the Author Editing Experience for a Framework (on page 1998)

Inserting an Olink in DocBook Documents

The `<olink>` element is used for linking to resources outside the current DocBook document. The `@targetdoc` attribute is used for the document ID that contains the target element and the `@targetptr` attribute for the ID of the target element (the value of an `@id` or `@xml:id` attribute). The combination of those two attributes provides a unique identifier to locate cross references.

For example, a Mail Administrator Guide with the document ID MailAdminGuide might contain a chapter about user accounts, like this:

```
<chapter id="user_accounts">
<title>Administering User Accounts</title>
<para>blah blah</para>
```

You can form a cross reference to that chapter by adding an `<olink>`, as in the following example:

```
<olink targetdoc="MailAdminGuide" targetptr="user_accounts">user accounts</olink>
```

You may need to update your
```
<olink targetdoc="MailAdminGuide" targetptr="user_accounts">user accounts</olink>
```

when you get a new machine.

To use an `<olinks>` to create links between documents, follow these steps:

1. Decide which documents are to be included in the domain for cross referencing.
   A unique ID must be assigned to each document that will be referenced with an `<olink>`. It is usually added as an `@id` (or `@xml:id` for DocBook5) attribute to the root element of the document.
2. Decide on your output hierarchy.
For creating links between documents, the relative locations of the output documents must be known. Before going further you must decide the names and locations of the output directories for all the documents from the domain. Each directory will be represented by an element `<dir name="directory_name">`, in the target database document.

3. Create the target database document.

Each collection of documents has a main target database document that is used to resolve all `olinks` from that collection. The target database document is an XML file that is created once. It provides a means for pulling in the target data for each document. The database document is static and all the document data is pulled in dynamically.

**Tip:**
Oxygen XML Editor includes a built-in new document template called **DocBook Targetset Map** available in the **New document wizard (on page 335)** that will help you get started.

**Example:** The following is an example of a target database document. It structures a collection of documents in a `<sitemap>` element that provides the relative locations of the outputs (HTML in this example). Then it pulls in the individual target data using system entity references to target data files that will be created in the next step.

```xml
<?xml version="1.0" encoding="utf-8"?>
<!DOCTYPE targetset [ 
<!ENTITY ugtargets SYSTEM "file:///doc/userguide/target.db"> 
<!ENTITY agtargets SYSTEM "file:///doc/adminguide/target.db"> 
<!ENTITY reftargets SYSTEM "file:///doc/man/target.db"> ]>
<targetset>
  <targetsetinfo>
    Description of this target database document, which is for the examples in olink doc.
  </targetsetinfo>

  <!-- Site map for generating relative paths between documents -->
  <sitemap>
    <dir name="documentation">
      <dir name="guides">
        <dir name="mailuser">
          <document targetdoc="MailUserGuide" baseuri="userguide.html">
            &ugtargets;
          </document>
        </dir>
      </dir>
    </dir>
    <dir name="mailadmin">
      <document targetdoc="MailAdminGuide">
        ...
      </document>
    </dir>
  </sitemap>
</targetset>
```
4. Generate the target data files by executing a DocBook transformation scenario.

Before applying the transformation, you need to edit the transformation scenario, go to the Parameters tab, and make sure the value of the `collect.xref.targets` parameter is set to `yes`. The default name of a target data file is `target.db`, but it can be changed by setting an absolute file path in the `targets.filename` parameter.

**Example:** An example of a `target.db` file:

```
<doc element="book" href="#MailAdminGuide" number="1" targetptr="user_accounts">
  <xref text="How to administer user accounts"/>
  <div element="part" href="#d5e4" number="I">
    <xref text="Part I, "First Part"/> <div element="chapter" href="#d5e6" number="1">
      <xref text="Chapter 1, Chapter Title"/>
      <div element="sect1" href="#src_chapter" number="1" targetptr="src_chapter">
        <xref text="Section1 Title"/>
        <xref text="xreflabel_here"/>
      </div>
    </div>
  </div>
</doc>
```

When editing a DocBook XML document in Author mode, the Insert OLink action is available in the Link drop-down menu from the toolbar. This action opens the Insert OLink dialog box that allows you to select the target of an `<olink>` from the list of all possible targets from a specified target database document (specified in the Targetset URL field). Once a Targetset URL is selected, the structure of the target documents is presented. For each target document (`@targetdoc`), its content is
displayed, allowing you to easily identify the appropriate @targetptr. You can also use the search fields to quickly identify a target. If you already know the values for the @targetdoc and @targetptr attributes, you can insert them directly in the corresponding fields.

**Example:** In the following image, the target database document is called target.xml, dbadmin is selected for the target document (@targetdoc), and bldinit is selected as the value for the @targetptr attribute. Notice that you can also add XREF text into the <olink> by using the xreftext field.

![Insert OLink Dialog Box](image)

6. Process a DocBook transformation for each document to generate the output.
   a. Edit the transformation scenario and set the value of the target.database.document parameter to be the URL of the target database document.
   b. Apply the transformation scenario.

**DocBook 5.1 Assembly**

The DocBook *Assembly* document type was introduced with DocBook 5.1 and it is used to define the hierarchy and relationships for a collection of resources. It is especially helpful for topic-oriented authoring scenarios since it assembles a set of resources (such as DocBook 5.1 topics (on page 1235)) to form a hierarchical structure for a larger publication.

An *Assembly* document usually has four major parts:
Oxygen XML Editor 23.1 | 9 - Built-in XML Frameworks (Document Types) | 1235

- **Resources** - Identifies a collection of resources (such as topics). An Assembly may identify one or more collections.
- **Structure** - Identifies an artifact to be assembled. A document in this case is the particular collection of resources (such as topics) that forms the documentation. Within the `<structure>` element, an `<output>` element can be used to identify the type of output to be generated and `<module>` elements can be used to identify the resources to be included. An Assembly may identify one or more structures.
- **Relationships** - Identifies relationships between resources. These relationships may be manifested in any number of structures during assembly. An Assembly may identify any number of relationships.
- **Transformations** - Identifies transformations that can be applied during assembly. An Assembly may identify any number of transformations.

For detailed information about the DocBook Assembly document type, see DocBook 5.1: The Definitive Guide - DocBook Assemblies.

**File Definition**

A file is considered to be an Assembly when the root name is `assembly`.

**Default Document Templates**

A default Assembly document template is available when creating new documents from templates (on page 335) and it can be found in: Framework Templates > DocBook 5 > DocBook 5.1.

The default template for DocBook Assembly documents is located in the `[OXYGEN_INSTALL_DIR]/frameworks/docbook/templates/Docbook5.1` folder.

**Default Schema for Validation and Content Completion**

The default schema that is used if one is not detected is `docbookxi.rng` and it is stored in `[OXYGEN_INSTALL_DIR]/frameworks/docbook/5.1/rng/`.

**Transformation Scenarios**

Oxygen XML Editor includes a built-in transformation scenario that can be applied on an Assembly file to generate an assembled (merged) DocBook file. The scenario is called DocBook Assembly and is found in the DocBook 5 section in the Configure Transformation Scenario(s) dialog box (on page 1443).

**Resources**

- DocBook 5.1: The Definitive Guide - DocBook Assemblies
- DocBook 5.1 Specifications
- Sample files: `[OXYGEN_INSTALL_DIR]/samples/docbook/v5/assembly`/

**DocBook 5.1 Topic**

The DocBook Topic document type was introduced with DocBook 5.1 and it is used as a modular unit of documentation. It is similar to the concept of the DITA Topic and can be used as modular resources in conjunction with DocBook 5.1 Assembly (on page 1234) documents.

File Definition
A DocBook file is considered to be a Topic when the root name is topic.

Default Document Templates
A default Topic document template is available when creating new documents from templates (on page 335) and it can be found in: Framework Templates > DocBook 5 > DocBook 5.1.

The default template for DocBook Assembly documents is located in the [OXYGEN_INSTALL_DIR]/frameworks/docbook/templates/Docbook5.1 folder.

Default Schema for Validation and Content Completion
The default schema that is used if one is not detected is docbookxi.rng and it is stored in [OXYGEN_INSTALL_DIR]/frameworks/docbook/5.1/rng/.

Transformation Scenarios
Since DocBook Topics are modular resources, they are assembled and transformed in the DocBook Assembly transformation process (on page 1235). You can also use any of the built-in DocBook transformation scenarios to transform individual DocBook Topics to a variety of outputs, such as PDF, HTML, EPUB, and more. They are found in the DocBook 5 section in the Configure Transformation Scenario(s) dialog box (on page 1443).

Resources
- DocBook 5.1: The Definitive Guide - Topic
- DocBook 5.1 Specifications
- Sample files: [OXYGEN_INSTALL_DIR]/samples/docbook/v5/assembly/

Related Information:
DocBook 5.1 Assembly (on page 1234)

DocBook Targetset Document Type (Framework)
DocBook Targetset documents are used to resolve cross references with the DocBook Olink.

File Definition
A file is considered to be a Targetset when the root name is targetset.

Default Document Templates
A default DocBook Targetset Map document template is available when creating new documents from templates (on page 335) and it can be found in: Framework Templates > DocBook Targetset.
The default template for DocBook Targetset documents is located in the \{OXYGEN_INSTALL_DIR\}/frameworks/docbook/templates/Targetset folder.

Default Schema for Validation and Content Completion

The default schema, targetdatabase.dtd, for this type of document is stored in \{OXYGEN_INSTALL_DIR\}/frameworks/docbook/xsl/common/.

Related Information:
DocBook Specifications

DITA Topics Document Type (Framework)

The Darwin Information Typing Architecture (DITA) is an XML-based architecture for authoring, producing, and delivering technical information. It divides content into small, self-contained topics that you can reuse in various deliverables. The extensibility of DITA permits organizations to define specific information structures while still using standard tools to work with them. DITA content is created as topics, each an individual XML file. Typically, each topic has a defined primary objective and structure, and DITA also includes several specialized topic types (task, concept, reference, glossary entry).

For much more detailed information, resources, and instructions, see the DITA Authoring (on page 2653) chapter.

File Definition

A file is considered to be a DITA topic document when one of the following conditions are true:

- The root element name is one of the following: <concept>, <task>, <reference>, <dita>, or <topic>.
- The PUBLIC ID of the document is a PUBLIC ID for the elements listed above.
- The root element of the file has a @DITAArchVersion attribute for the "http://dita.oasis-open.org/architecture/2005/" namespace. This enhanced case of matching is only applied when the Enable DTD/XML Schema processing in document type detection option (on page 112) is selected from the Document Type Association preferences page (on page 111).

Default Document Templates

There are a variety of default DITA topic templates available when creating new documents from templates (on page 335) and they can be found in various folders inside: Framework Templates > DITA.

The default templates for DITA topic documents are located in the \{OXYGEN_INSTALL_DIR\}/frameworks/dita/templates/topic folder.

Default Schema for Validation and Content Completion

Default schemas that are used if one is not detected in the DITA documents are stored in the various folders inside DITA-OT-DIR.dtd/ or DITA-OT-DIR/schema/.
Default CSS
The default CSS files used for rendering DITA content in Author mode are stored in the various folders inside: `<OXYGEN_INSTALL_DIR>/frameworks/dita/css/`.

By default, these default CSS files are merged with any that are specified in the document. For more information, see Configuring and Managing Multiple CSS Styles for a Framework (on page 1998).

Default XML Catalogs
The default XML Catalogs (on page 2972) for the DITA topic document type are as follows:

- `DITA-OT-DIR/catalog-dita.xml`
- `<OXYGEN_INSTALL_DIR>/frameworks/dita/catalog.xml`
- `<OXYGEN_INSTALL_DIR>/frameworks/dita/plugin/catalog.xml`
- `<OXYGEN_INSTALL_DIR>/frameworks/dita/styleguide/catalog.xml`

Transformation Scenarios
Oxygen XML Editor includes built-in transformation scenarios for transforming individual DITA Topics to HTML5, XHTML, or PDF output. They can be found in the DITA section in the Configure Transformation Scenario(s) dialog box (on page 1443).

Related Information:
DITA Authoring (on page 2653)
Getting Started with DITA (on page 2654)
Editing XML Documents in Author Mode (on page 547)
Editing XML Documents in Text Mode (on page 476)

DITA Topic Author Mode Actions
A variety of actions are available for DITA documents that can be found in DITA menu, toolbar, contextual menu, and the Content Completion Assistant (on page 2965).

DITA Toolbar Actions
The following default actions are available on the DITA toolbar when editing in Author mode (by default, most of them are also available in the DITA menu and in various submenus of the contextual menu):

- **Bold**
Surrounds the selected text with a `<b>` tag. You can use this action on multiple non-contiguous selections.

**Italic**

Surrounds the selected text with an `<i>` tag. You can use this action on multiple non-contiguous selections.

**Underline**

Surrounds the selected text with a `<u>` tag. You can use this action on multiple non-contiguous selections.

---

**Link Actions Drop-Down Menu**

The following link actions are available from this menu:

**Cross Reference**

Opens the Cross Reference (xref) dialog box (on page 2835) that allows you to insert a link to a target DITA resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your DITA map (on page 2966) structure. Once the target resource has been selected, you can also target specific elements within that resource. For more information, see Linking in DITA Topics (on page 2835).

**File Reference**

Opens the File Reference dialog box (on page 2836) that allows you to insert a link to a target non-DITA file resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your DITA map structure. For more information, see Linking in DITA Topics (on page 2835).

**Web Link**

Opens the Web Link dialog box (on page 2836) that allows you to insert a link to a target web-related resource at the current location within a document. The target resource can be a URL or a key that is already defined in your DITA map structure. For more information, see Linking in DITA Topics (on page 2835).

**Related Link to Topic**

Opens the Cross Reference (xref) dialog box (on page 2836) that allows you to insert a link to a target DITA resource in a related links section at the bottom of the current document. The target resource can be the location of a file or a key that is already defined in your DITA map structure. Once the target resource has been selected, you can also target specific elements within that resource. If a related links section does not already exist, this action creates one. For more information, see Linking in DITA Topics (on page 2835).
Tip:
You can use the Find Similar Topics action (available in the contextual menu or DITA menu) to quickly find related topics that can be added as related links. It opens the Open/Find Resource view and performs a search using text content from the <title>, <shortdesc>, <keyword>, and <indexterm> elements.

Related Link to File
Opens the File Reference dialog box (on page 2836) that allows you to insert a link to a target non-DITA file resource in a related links section at the bottom of the current document. The target resource can be the location of a file or a key that is already defined in your DITA map structure. If a related links section does not already exist, this action creates one. For more information, see Linking in DITA Topics (on page 2835).

Related Link to Web Page
Opens the Web Link dialog box (on page 2837) that allows you to insert a link to a target web-related resource in a related links section at the bottom of the current document. The target resource can be a URL or a key that is already defined in your DITA map structure. If a related links section does not already exist, this action creates one. For more information, see Linking in DITA Topics (on page 2835).

Insert Image
Opens the Insert Image dialog box (on page 2737) that allows you to configure the properties of an image to be inserted into a DITA document at the cursor position.

Insert Media Resource
Opens the Insert Media dialog box (on page 2740) that allows you to select and configure the properties of a media object to be inserted into a DITA document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted in an <object> element and it is rendered in Author mode so that it can be played directly from there.

Insert Section Drop-Down Menu
The following insert actions are available from this menu:

- Insert Section
  Inserts a new <section> element in the document, depending on the current context.

- Insert Concept
  Inserts a new <concept> element, depending on the current context. Concepts provide background information that users must know before they can successfully work with a product or interface.
**Insert Task**

Inserts a new `<task>` element, depending on the current context. Tasks are the main building blocks for task-oriented user assistance. They generally provide step-by-step instructions that will help a user to perform a task.

**Insert Topic**

Inserts a new `<topic>` element, depending on the current context. Topics are the basic units of DITA content and are usually organized around a single subject.

**Insert Reference**

Inserts a new `<reference>` element, depending on the current context. A reference is a top-level container for a reference topic.

**Insert Paragraph**

Inserts a new paragraph at current cursor position.

**Reuse Content**

This action provides a mechanism for reusing content fragments. It opens the Reuse Content dialog box (on page 2806) that allows you to insert several types of references to reusable content at the cursor position. The types of references that you can insert using this dialog box include content references (`@conref`) (on page 2807), content key references (`@conkeyref`) (on page 2809), or key references to metadata (`@keyref`) (on page 2812).

**Insert step or list item**

Inserts a new list or step item in the current list type.

**Insert Unordered List**

Inserts an unordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an unordered list.

**Insert Ordered List**

Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

**Sort**

Sorts cells or list items in a table.

**Insert Table**

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a block element (on page 2964)) into a table,
with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

**Note:**

If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that **Only lists, paragraphs, or inline content can be converted to tables.**

- **Insert Row**

  Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

- **Delete Row(s)**

  Deletes the table row located at the cursor position or multiple rows in a selection.

- **Insert Column**

  Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

- **Delete Column(s)**

  Deletes the table column located at the cursor position or multiple columns in a selection.

- **Table Properties**

  Opens the **Table properties** dialog box that allows you to configure properties of a table (such as frame borders).

- **Join Cells**

  Joins the content of the selected cells (both horizontally and vertically).

- **Split Cell**

  Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

### DITA Contextual Menu Actions

The following actions are available in the contextual menu when editing in **Author** mode (most of them are also available in the **DITA** menu at the top of the interface):

- **Add File to Review Task**

  This action can be used to add the current document to a task in the **Content Fusion Tasks Manager** view. **Oxygen Content Fusion** is a flexible, intuitive collaboration platform designed to adapt to any type of documentation review workflow. This functionality is available through a pre-installed **connector add-on (on page 2353)**. To fully take advantage of all of the benefits and
features of Content Fusion, your organization will need an Oxygen Content Fusion Enterprise Server. For more information, see the Oxygen Content Fusion website.

Edit Attributes

Displays an in-place attributes editor (on page 586) that allows you to manage the attributes of an element.

Edit Profiling Attributes

Allows you to change the profiling attributes (on page 623) defined on all selected elements.

Cut (Ctrl + X (Command + X on OS X))

Removes the currently selected content from the document and places it in the clipboard.

Copy (Ctrl + C (Command + C on OS X))

Places a copy of the currently selected content in the clipboard.

Paste (Ctrl + V (Command + V on OS X))

Inserts the current clipboard content into the document at the cursor position.

Paste special submenu

This submenu includes the following special paste actions that are specific to the DITA framework:

Paste as content reference

Inserts a content reference (a DITA element with a @conref attribute) to the DITA XML element from the clipboard. An entire DITA XML element with an ID attribute must be present in the clipboard when the action is invoked. The conref attribute will point to this ID value.

Paste as content key reference

Allows you to indirectly reference content using the @conkeyref attribute. When the DITA content is processed, the key references are resolved using key definitions from DITA maps (on page 2966). To use this action, you must first do the following:

1. Make sure the DITA element that contains the copied content has an ID attribute assigned to it.
2. In the DITA Maps Manager view, make sure that the Context combo box (on page 2667) points to the correct map that stores the keys.
3. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the DITA Maps Manager, select Edit Properties, and enter a value in the Keys field.

Paste as link
Looks for the first element with an ID value in the clipboard and inserts an `<xref>` that points to that element. If no elements with an ID value are found, a message will appear that informs you that to use this action, the clipboard contents must include at least one element with a declared ID.

**Paste as link (keyref)**

Inserts a link to the element that you want to reference. To use this action, you must first do the following:

1. Make sure the DITA element that contains the copied content has an ID attribute assigned to it.
2. In the DITA Maps Manager view, make sure that the **Context combo box** (on page 2667) points to the correct map that stores the keys.
3. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the DITA Maps Manager, select **Edit Properties**, and enter a value in the **Keys** field.

**Insert submenu**

This submenu includes the following insert actions that are specific to the DITA framework:

- **Insert Table**
  
  Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a **block element** (on page 2964)) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

  **Note:**
  
  If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that **Only lists, paragraphs, or inline content can be converted to tables**.

- **Insert Image**
  
  Inserts an image reference (on page 672) at the cursor position. Depending on the current location, an image-type element is inserted.

- **Insert Media Resource**
  
  Opens a Choose Media dialog box (on page 701) that allows you to select the URL of a media object to be inserted into a document at the cursor position. The result
will be that a reference to the specified video, audio, or embedded HTML frame is inserted and rendered in **Author** mode so that it can be played directly from there.

**Insert Equation**

Opens the **XML Fragment Editor** that allows you to insert and edit **MathML** notations (on page 703).

**Insert Note**

Inserts a new `<note>` element at the current cursor position.

**Insert Code Block**

Inserts a new `<codeblock>` element at current cursor position.

**Insert Menu Cascade**

Inserts a new `<menucascade>` element at current cursor position.

**Insert Paragraph**

Inserts a new `<p>` (paragraph) element at current cursor position.

**Insert Section**

Inserts a new `<section>` element in the document, depending on the current context.

**Insert Topic**

Inserts a new `<topic>` element, depending on the current context. Topics are the basic units of DITA content and are usually organized around a single subject.

**Insert Entity**

Allows you to insert a predefined entity or character entity. Surrogate character entities (range #x10000 to #x10FFFF) are also accepted. Character entities can be entered in one of the following forms:

- `#<decimal value>` - e.g. #65
- `&#<decimal value>` - e.g. &#65
- `#x<hexadecimal value>` - e.g. #x41
- `&#x<hexadecimal value>` - e.g. &#x41

**Style submenu**

This submenu includes the following text styling actions:

**Bold**

Emphasizes the selected text by surrounding it with a `<b>` (bold) tag. You can use this action on multiple non-contiguous selections.

**Italic**

Emphasizes the selected text by surrounding it with an `<i>` (italic) tag. You can use this action on multiple non-contiguous selections.
Underline

Emphasizes the selected text by surrounding it with a `<u>` (underline) tag. You can use this action on multiple non-contiguous selections.

Subscript

Surrounds the selected text with a `<sub>` (subscript) tag, used for inserting a character (number, letter, or symbol) that will appear slightly below the baseline and slightly smaller than the rest of the text.

Superscript

Surrounds the selected text with a `<sup>` (superscript) tag, used for inserting a character (number, letter, or symbol) that will appear slightly above the baseline and slightly smaller than the rest of the text.

Code

Surrounds the selected text with a `<codeph>` tag.

UI Control

Surrounds the selected text with a `<uicontrol>` tag, used to mark up names of buttons, entry fields, menu items, or other interface objects.

Filepath

Surrounds the selected text with a `<filepath>` tag, used to indicate the name, and optionally the location of a referenced file. You can specify the directory that contains the file and other directories that may precede it in the system hierarchy.

Image Map Editor

This action is available in the contextual menu when it is invoked on an image. This action applies an `image map` to the current image (if one does not already exist) and opens the Image Map Editor dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

Table Actions

A variety of table editing actions are available in the contextual menu when it is invoked on a table (depending on the context, the table-related actions are promoted to the top level of the contextual menu and the Other Actions submenu provides access to the other actions):

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (Above or Below the current row).

Delete Row(s)

Deletes the table row located at the cursor position or multiple rows in a selection.

Insert Columns
Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (Above or Below the current column).

### Delete Column(s)
Deletes the table column located at the cursor position or multiple columns in a selection.

### Join Cells
Joins the content of the selected cells (both horizontally and vertically).

### Split Cell
Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

### Sort
Sorts cells or list items in a table.

### Table Properties
Opens the Table properties dialog box that allows you to configure properties of a table (such as frame borders).

### Other Actions submenu
This submenu gives you access to all the usual contextual menu actions.

### Link submenu
The following link actions are available from this submenu:

#### Cross Reference
Opens the Cross Reference (xref) dialog box (on page 2835) that allows you to insert a link to a target DITA resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your DITA map (on page 2966) structure. Once the target resource has been selected, you can also target specific elements within that resource. For more information, see Linking in DITA Topics (on page 2835).

#### File Reference
Opens the File Reference dialog box (on page 2836) that allows you to insert a link to a target non-DITA file resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your DITA map structure. For more information, see Linking in DITA Topics (on page 2835).

#### Web Link
Opens the Web Link dialog box (on page 2836) that allows you to insert a link to a target web-related resource at the current location within a document. The target
resource can be a URL or a key that is already defined in your DITA map structure. For more information, see Linking in DITA Topics (on page 2835).

Related Link to Topic

Opens the Cross Reference (xref) dialog box (on page 2836) that allows you to insert a link to a target DITA resource in a related links section at the bottom of the current document. The target resource can be the location of a file or a key that is already defined in your DITA map structure. Once the target resource has been selected, you can also target specific elements within that resource. If a related links section does not already exist, this action creates one. For more information, see Linking in DITA Topics (on page 2835).

Tip:

You can use the Find Similar Topics action (available in the contextual menu or DITA menu) to quickly find related topics that can be added as related links. It opens the Open/Find Resource view and performs a search using text content from the <title>, <shortdesc>, <keyword>, and <indexterm> elements.

Related Link to File

Opens the File Reference dialog box (on page 2836) that allows you to insert a link to a target non-DITA file resource in a related links section at the bottom of the current document. The target resource can be the location of a file or a key that is already defined in your DITA map structure. If a related links section does not already exist, this action creates one. For more information, see Linking in DITA Topics (on page 2835).

Related Link to Web Page

Opens the Web Link dialog box (on page 2837) that allows you to insert a link to a target web-related resource in a related links section at the bottom of the current document. The target resource can be a URL or a key that is already defined in your DITA map structure. If a related links section does not already exist, this action creates one. For more information, see Linking in DITA Topics (on page 2835).

Sort

Available when invoked on a list, it opens a dialog box where you can configure a sorting operation for an entire list or a selection of list items.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:
• When invoked on a single selection, an ID is generated for the selected element at the cursor position.
• When invoked on a block of selected content, IDs are generated for all top-level elements and elements listed in the **ID Options** dialog box that are found in the current selection.

**Note:**
The *Generate IDs* action does not overwrite existing ID values. It only affects elements that do not already have an `@id` attribute.

**Reuse submenu**

This submenu includes the following actions regarding reusing content in DITA:

- **Reuse Content**
  
  This action provides a mechanism for reusing content fragments. It opens the **Reuse Content** dialog box (on page 2806) that allows you to insert several types of references to reusable content at the cursor position. The types of references that you can insert using this dialog box include content references (`@conref`) (on page 2807), content key references (`@conkeyref`) (on page 2809), or key references to metadata (`@keyref`) (on page 2812).

- **Push Current Element**
  
  Opens the **Push current element** dialog box (on page 2815) that allows content from a source topic to be inserted into another topic without any special coding in the topic where the content will be re-used.

- **Edit Content Reference**
  
  This action is available for elements with a `@conref` or `@conkeyref` attribute. It opens the **Edit Content Reference** dialog box that allows you to edit the source location (or key) and source element of a content reference (or content key reference), and the reference details (`@conref/@conkeyref` and `@conrefend` attributes). For more information, see **Reuse Content Dialog Box** (on page 2806).

- **Replace Reference with Content**
  
  Replaces the referenced fragment (`@conref` or `@conkeyref`) at the cursor position with its content from its source. This action is useful if you want to make changes to the content in the currently edited document without changing the referenced fragment in its source location. If the source content includes references to other topics/resources (hrefs), the operation also resolves those references relative to the new location. Attributes are preserved according to the following priority:
1. Attributes from the elements in the current document that reference other content are preserved except for attributes with a `-dita-use-conref-target` value.

2. Attributes from the referenced content are brought into the replaced elements in the current document except for `@id` attributes.

**Replace All References with Content**

Replaces all referenced fragments (@keyref, @conref, or @conkeyref) in the current document with the content. Attributes are preserved according to the following priority:

1. Attributes from the elements in the current document that reference other content are preserved except for attributes with a `-dita-use-conref-target` value.

2. Attributes from the referenced content are brought into the replaced elements in the current document except for `@id` attributes.

For `keyrefs` inside `<xref>` or `<link>` elements, the `@keyref` attribute is changed to an `@href` attribute, while the rest of the content for the `keyref` is replaced with its source content.

If the source content includes references to other topics/resources (`hrefs`), the operation also resolves those references relative to the new location.

**Remove Content Reference**

Removes the content reference (@conref or @conkeyref) inside the element at the cursor position.

**Create Reusable Component**

Opens a dialog box that helps you to create a reusable component from the current element or selection of elements. If the **Replace selection with content reference** option is selected in the dialog box, the selection will be replaced with a content reference (@conref). If multiple elements are selected (for example, multiple steps or list items), the selection will be replaced with a content reference range (@conref and @conrefend). For more information, see Creating a Reusable Content Component (on page 2817).

**Insert Reusable Component**

Inserts a reusable component at cursor location. For more information, see Inserting a Reusable Content Component (on page 2818).

**Search References (Ctrl + Shift + G (Command + Shift + G on OS X))**

Finds the references to the `@id` attribute value for the element at the current cursor position, in all the topics contained in the current DITA map (on page 2966) (opened in the DITA Maps...
Manager view (on page 2662). If no references are found for the current element, a dialog box will be displayed that offers you the option of searching for references to its ancestor elements.

Figure 441. Search References to Ancestors Dialog Box

Tip:
If you are invoking the action on an image, see Searching for References to Images (on page 2740) for details about what will be reported.

Find Similar Topics

Opens the Open/Find Resource view and performs a search using text content from the <title>, <shortdesc>, <keywords>, and <indexterm> elements. It is helpful for quickly finding related topics that can be added as related links.

Show Key Definition

Available for elements that have a @conkeyref or @keyref attribute set (or elements with an ancestor element that has a @conkeyref or @keyref attribute). It computes the key name and opens the DITA map (on page 2966) that contains the definition of the key with the element that defines that key selected.

About Element submenu

This submenu includes the following actions:

Style Guide

Opens the DITA Style Guide Best Practices for Authors in your browser and displays a topic that is relevant to the element at the cursor position. When editing DITA documents, this action is available in the contextual menu of the editing area (under the About Element sub-menu), in the DITA menu, and in some of the documentation tips that are displayed by the Content Completion Assistant (on page 2965).

Browse reference manual

Opens a reference to the documentation of the XML element closest to the cursor position in a web browser.

Go to Definition

Moves the cursor to the definition of the current element.
Select submenu

This submenu allows you to select the following:

- **Element**
  Selects the entire element at the current cursor position.

- **Content**
  Selects the entire content of the element at the current cursor position, excluding the start and end tag. Performing this action repeatedly will result in the selection of the content of the ancestor of the currently selected element content.

- **Parent**
  Selects the entire parent element at the current cursor position.

Text submenu

This submenu contains the following actions:

- **To Lower Case**
  Converts the selected content to lower case characters.

- **To Upper Case**
  Converts the selected content to upper case characters.

- **Capitalize Sentences**
  Converts to upper case the first character of every selected sentence.

- **Capitalize Words**
  Converts to upper case the first character of every selected word.

- **Count Words**
  Counts the number of words and characters (no spaces) in the entire document or in the selection for regular content and read-only content.

**Note:**
The content marked as deleted with change tracking (on page 2971) is ignored when counting words.

**Convert Hexadecimal Sequence to Character (Ctrl + Shift + X (Command + Shift + X on OS X))**

Converts a sequence of hexadecimal characters to the corresponding Unicode character (on page 427). The action can be invoked if there is a selection containing a valid hexadecimal sequence or if the cursor is placed at the right side of a valid hexadecimal sequence. A valid hexadecimal sequence can be composed of 2 to 4 hexadecimal characters and may or may not be preceded by the 0x or 0X prefix. Examples of valid sequences and the characters they will be converted to:
• \texttt{0x0045} will be converted to \texttt{E}
• \texttt{0x0125} to \texttt{ń}
• \texttt{265} to \texttt{ɥ}
• \texttt{2190} to \texttt{←}

\begin{quote}
\textbf{Note:}
For more information about finding the hexadecimal value of a character, see Finding the Decimal, Hexadecimal, or Character Entity Equivalent (on page 430).
\end{quote}

\textbf{Refactoring submenu}

Contains a series of actions designed to alter the XML structure of the document:

\begin{itemize}
\item \textbf{Toggle Comment} (Alt + UpArrow)
Encloses the currently selected text in an XML comment, or removes the comment if it is commented.

\item \textbf{Move Up} (Alt + DownArrow)
Moves the current node or selected nodes in front of the previous node.

\item \textbf{Move Down} (Alt + Shift + D (Ctrl + Alt + D on OS X))
Moves the current node or selected nodes after the subsequent node.

\item \textbf{Split Element} (Alt + Shift + D (Ctrl + Alt + D on OS X))
Splits the content of the closest element that contains the position of the cursor. Thus, if the cursor is positioned at the beginning or at the end of the element, the newly created sibling will be empty.

\item \textbf{Join Elements}
Joins two adjacent block elements (on page 2964) that have the same name. The action is available only when the cursor position is between the two adjacent block elements. Also, joining two block elements can be done by pressing the Delete or Backspace keys and the cursor is positioned between the boundaries of these two elements.

\item \textbf{Surround with Tags} (Ctrl + E (Command + E on OS X))
Allows you to choose a tag to enclose a selected portion of content. If there is no selection, the start and end tags are inserted at the cursor position.
• If the **Position cursor between tags** option *(on page 183)* is selected in the **Content Completion** preferences page, the cursor is placed between the start and end tag.

• If the **Position cursor between tags** option *(on page 183)* is not selected in the **Content Completion** preferences page, the cursor is placed at the end of the start tag, in an insert-attribute position.

**Surround with ‘[tag]’ (Ctrl + ForwardSlash (Command + ForwardSlash on OS X))**

Surround the selected content with the last tag used.

**Rename Element**

The element from the cursor position, and any elements with the same name, can be renamed according with the options from the **Rename** dialog box.

**Delete Element Tags**

Deletes the tags of the closest element that contains the position of the cursor. This operation is also executed if the start or end tags of an element are deleted by pressing the **Delete** or **Backspace** keys.

**Remove All Markup**

Removes all the XML markup inside the selected block of content and keeps only the text content.

**Remove Text**

Removes the text content of the selected block of content and keeps the markup intact with empty elements.

**DITA Refactoring Actions**

A variety of built-in XML refactoring operations that pertain to DITA documents with some of the information preconfigured based upon the current context.

**Change Topic ID to File Name**

Use this operation to change the ID of a topic to be the same as its file name.

**Convert CALS Tables to Simple Tables**

Use this operation to convert DITA CALS tables to simple tables. If you invoke this operation from a nested table (a table inside a table), only the nested table will be affected. If it is invoked on a parent table that contains nested tables, all of the contained tables will be converted.

**Convert conrefs to conkeyrefs**

Use this operation to convert `@conref` attributes to `@conkeyref` attributes.
Convert Simple Tables to CALS Tables
Use this operation to convert DITA simple tables to CALS tables. If you invoke this operation from a nested table (a table inside a table), only the nested table will be affected. If it is invoked on a parent table that contains nested tables, all of the contained tables will be converted.

Convert to Concept
Use this operation to convert a DITA topic (of any type) to a DITA Concept topic type (for example, Topic to Concept).

Convert to General Task
Use this operation to convert a DITA topic (of any type) to a DITA General Task topic type (for example, Task to General Task). A DITA General Task is a less restrictive alternative to the Strict Task information type.

Convert to Reference
Use this operation to convert a DITA topic (of any type) to a DITA Reference topic type (for example, Topic to Reference).

Convert to Task
Use this operation to convert a DITA topic (of any type) to a DITA Task topic type (for example, Topic to Task).

Convert to Topic
Use this operation to convert a DITA topic (of any type) to a DITA Topic (for example, Task to Topic).

Convert to Troubleshooting
Use this operation to convert a DITA topic (of any type) to a DITA Troubleshooting topic type (for example, Topic to Troubleshooting).

Rename Key
Available when invoked on a key, and can be used to quickly rename a key. It also updates all references to it. Note that it does not work on DITA 1.3 key scopes.

Generate IDs
Use this operation to automatically generate unique IDs for elements.

Attributes Refactoring Actions
Contains built-in XML refactoring operations that pertain to attributes with some of the information preconfigured based upon the current context.

Add/Change attribute
Allows you to change the value of an attribute or insert a new one.

**Convert attribute to element**

Allows you to change an attribute into an element.

**Delete attribute**

Allows you to remove one or more attributes.

**Rename attribute**

Allows you to rename an attribute.

**Replace in attribute value**

Allows you to search for a text fragment inside an attribute value and change the fragment to a new value.

**Comments Refactoring Actions**

Contains built-in XML refactoring operations that pertain to comments with some of the information preconfigured based upon the current context.

**Delete comments**

Allows you to delete comments found inside one or more elements.

**Elements Refactoring Actions**

Contains built-in XML refactoring operations that pertain to elements with some of the information preconfigured based upon the current context.

**Delete element**

Allows you to delete elements.

**Delete element content**

Allows you to delete the content of elements.

**Insert element**

Allows you to insert new elements.

**Rename element**

Allows you to rename elements.

**Unwrap element**

Allows you to remove the surrounding tags of elements, while keeping the content unchanged.

**Wrap element**

Allows you to surround elements with element tags.

**Wrap element content**

Allows you to surround the content of elements with element tags.

**Fragments Refactoring Actions**
Contains built-in XML refactoring operations that pertain to XML fragments with some of the information preconfigured based upon the current context.

**Insert XML fragment**

Allows you to insert an XML fragment.

**Replace element content with XML fragment**

Allows you to replace the content of elements with an XML fragment.

**Replace element with XML fragment**

Allows you to replace elements with an XML fragment.

**Review submenu**

This submenu includes the following actions:

- **Track Changes**
  Enables or disables the Track Changes (on page 2971) support for the current document.

- **Accept Change(s) and Move to Next**
  Accepts the Tracked Change (on page 2971) located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a deletion or insertion change, only the selected content is accepted.

- **Accept All Changes**
  Accepts all Tracked Changes (on page 2971) in the current document.

- **Reject Change(s) and Move to Next**
  Rejects the Tracked Change (on page 2971) located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a deletion or insertion change, only the selected content is rejected.

- **Reject All Changes**
  Rejects all Tracked Changes (on page 2971) in the current document.

- **Comment Change**
  Opens a dialog box that allows you to add a comment to an existing Tracked Change (on page 2971). The comment will appear in a callout and a tooltip when hovering over the change. If the action is selected on an existing commented change, the dialog box will allow you to edit the comment.

- **Highlight**
  Enables the highlighting tool that allows you to mark text in your document.

**Colors**

Allows you to select the color for highlighting text.
Stop highlighting

Use this action to deactivate the highlighting tool.

Remove highlight(s)

Use this action to remove highlighting from the document.

Add Comment

Inserts a comment at the cursor position. The comment appears in a callout box and a tooltip (when hovering over the change).

Show/Edit Comment

Opens a dialog box that displays the discussion thread and allows the current user to edit comments that do not have replies. If you are not the author who inserted the original comment, the dialog box just displays the comment without the possibility of editing it.

Remove Comment

Removes a selected comment. If you remove a comment that contains replies, all of the replies will also be removed.

Manage Reviews

Opens the Review view (on page 619).

Manage IDs submenu

This submenu is available for topics that have an associated DTD or schema. It includes the following actions:

Rename in

Renames the ID and all its occurrences. Selecting this action opens the Rename XML ID dialog box. This dialog box lets you insert the new ID value and choose the scope of the rename operation.

Search References

Searches for the references of the ID. By default, the scope of this action is the current project. If you configure a scope using the Select the scope for the Search and Refactor operations (on page 774) dialog box, this scope will be used instead.

Search References in

Searches for the references of the ID. Selecting this action opens the Select the scope for the Search and Refactor operations (on page 774).

Search Occurrences in file

Searches for the occurrences of the ID in the current document.

Folding submenu

This submenu includes the following actions:
Toggle Fold

Toggles the state of the current fold.

Collapse Other Folds (Ctrl + NumPad/ (Command + NumPad/ on OS X))

Folds all the elements except the current element.

Collapse Child Folds (Ctrl + NumPad. (Command + NumPad. on OS X))

Folds the elements indented with one level inside the current element.

Expand Child Folds

Unfolds all child elements of the currently selected element.

Expand All (Ctrl + NumPad* (Command + NumPad* on OS X))

Unfolds all elements in the current document.

Inspect Styles

Opens the CSS Inspector view (on page 597) that allows you to examine the CSS rules that match the currently selected element.

Options

Opens the Author mode preferences page (on page 148) where you can configure various options with regard to the Author editing mode.

Floating Contextual Toolbar for DITA

Oxygen XML Editor includes a dynamic feature where certain editing contexts will trigger a floating toolbar with common actions that are available in the current editing context.

Figure 442. DITA Floating Contextual Toolbar

![Floating Contextual Toolbar](image)

The floating contextual toolbar is automatically displayed when editing DITA documents in various situations, including:

- When a `<p>`, `<li>`, or `<shortdesc>` element has a selection inside, the floating toolbar includes actions such as **Bold**, *Italics*, _Underline_, a Link submenu, and more.

- When an `<image>` or `<xref>` element is selected:
  - If the element has an `@href` attribute, the floating toolbar includes a URL chooser where you can select the appropriate target.
  - If the element has a `@keyref` attribute, the floating toolbar includes a drop-down control where you can select the appropriate target key reference.

- When an `<object>` element is selected:
If the element has a `@data` attribute, the floating toolbar includes a URL chooser where you can select the appropriate target.

If the element has a `@datakeyref` attribute, the floating toolbar includes a drop-down control where you can select the appropriate target key reference.

- When an element with a `@conref` attribute is selected, the floating toolbar includes actions for editing, removing, or replacing content references.
- When a `<codeblock>` element is selected, the floating toolbar includes a drop-down control where you can select the value of the `@outputclass` attribute.
- When a `<ul>` element is selected, the floating toolbar includes actions for converting it to an ordered list or sorting the list.
- When an `<ol>` element is selected, the floating toolbar includes actions for converting it to an unordered list or sorting the list.
- When an `<li>` or `<step>` element is selected, the floating toolbar includes actions for moving the item up or down in the list/procedure.
- When a `<row>` or `<strow>` element is selected in a table, the floating toolbar includes various table-related actions (such as actions for editing table properties, inserting rows, or deleting rows).
- When an `<entry>` or `<stentry>` element is selected in a table, the floating toolbar includes various table-related actions (such as actions for editing table properties, inserting/deleting rows, or inserting/deleting columns).
- When a `<table>` or `<simpletable>` element is selected, the floating toolbar includes actions for editing table properties or sorting the table.

**DITA Drag/Drop (or Copy/Paste) Actions**

Dragging a file from the Project view (on page 368) or DITA Maps Manager view (on page 2662) and dropping it into a DITA document that is edited in Author mode, creates a link to the dragged file (the `xref` DITA element with the `@href` attribute) at the drop location. Copy and paste actions work the same.

You can also drag images or media files from your system explorer or the Project view (on page 368) and drop them into a DITA document (or copy and paste). This will insert the appropriate element at the drop or paste location (for example, dropping/pasting an image will insert the DITA `<image>` element with an `@href` attribute).

**Tip:**

For information about customizing Author mode actions for a particular framework (document type), see the Customizing the Author Editing Experience for a Framework (on page 1998) section.

**Related Information:**

Customizing the Author Editing Experience for a Framework (on page 1998)
DITA Map Document Type (Framework)

*DITA maps (on page 2966)* are documents that collect and organize references to DITA topics to indicate the relationships between the topics. They can be used as a container for topics used to transform a collection of content into a publication and they offer a sequence and structure to the topics. They can also serve as outlines or tables of contents for DITA deliverables and as build manifests for DITA projects. *DITA maps* allow scalable reuse of content across multiple contexts. Maps can reference topics or other maps, and can contain a variety of content types and metadata.

For much more detailed information, resources, and instructions, see the [DITA Authoring (on page 2653)](on page 2653) chapter.

**File Definition**

A file is considered to be a *DITA map* document when one of the following conditions are true:

- The root element name is one of the following: `<map>`, `<bookmap>`.
- The public ID of the document is `-//OASIS//DTD DITA Map` or `-//OASIS//DTD DITA BookMap`.
- The root element of the file has a `@class` attribute that contains the value `map/map` and a `@DITAArchVersion` attribute from the [http://dita.oasis-open.org/architecture/2005/](http://dita.oasis-open.org/architecture/2005/) namespace. This enhanced case of matching is only applied when the [Enable DTD/XML Schema processing in document type detection option (on page 112)](on page 112) from the Document Type Association preferences page (on page 111) is selected.

**Default Document Templates**

There are a variety of default *DITA map* templates available when creating new documents from templates (on page 335) and they can be found in various folders inside: [Framework Templates > DITA Map](on page 335).

The default templates for *DITA map* documents are located in the `{OXYGEN_INSTALL_DIR}/frameworks/sita/templates/map` folder.

**Default Schema for Validation and Content Completion**

Default schemas that are used if one is not detected in the *DITA map* document are stored in the various folders inside: `DITA-OT-DIR/dtd/` or `DITA-OT-DIR/schema/`.

**Default CSS**

The default CSS files used for rendering DITA content in Author mode are stored in the various folders inside: `{OXYGEN_INSTALL_DIR}/frameworks/dita/css/`.

By default, these default CSS files are merged with any that are specified in the document. For more information, see [Configuring and Managing Multiple CSS Styles for a Framework (on page 1998)](on page 1998).

**Default XML Catalogs**

The default *XML Catalogs (on page 2972)* for the *DITA map* document type are as follows:

- `{OXYGEN_INSTALL_DIR}/frameworks/dita/catalog.xml`
- `DITA-OT-DIR/catalog-dita.xml`
Transformation Scenarios
Oxygen XML Editor includes numerous built-in transformation scenarios that allow you to transform DITA maps to a variety of outputs, such as WebHelp, PDF, ODF, XHTML, EPUB, and CHM. All of them are listed in the DITA Map section in the Configure Transformation Scenario(s) dialog box (on page 1443).

For more information, see the DITA Map Transformation Scenarios (on page 2843) section.

DITA Map Author Mode Actions
A variety of actions are available for DITA map documents that can be found in DITA menu, toolbar, contextual menu, and the Content Completion Assistant (on page 2965).

DITA Map Toolbar and Menu Actions
When a DITA map is opened in Author mode, the following default actions are available on the DITA Map toolbar (by default, they are also available in the DITA menu and in various submenus of the contextual menu):

- **Insert New DITA Resource**
  Opens a New DITA file dialog box (on page 2725) where you can choose the type of DITA document to create and inserts a reference to it at the current position within the map.

- **Insert Topic Reference**
  Opens the Insert Reference dialog box (on page 2688) where you can configure a topic reference and inserts it at the current position within the map.

- **Insert Key Definition with Keyword**
  Opens a dialog box where you can choose the name of a key and its keyword value and inserts the key definition at the current position within the map.

- **Reuse Content**
Opens the Reuse Content dialog box (on page 2806) that allows you to insert and configure a content reference (@conref), or a content key reference (@conkeyref) at the cursor position.

Insert Topic Heading

Opens the Insert Reference dialog box (on page 2688) that allows you to insert a topic heading at the cursor position.

Insert Topic Group

Opens the Insert Reference dialog box (on page 2688) that allows you to insert a topic group at the cursor position.

Insert Relationship Table

Opens a dialog box that allows you to configure the relationship table to be inserted. The dialog box allows you to configure the number of rows and columns of the relationship table, if the header will be generated and if the title will be added.

Relationship Table Properties

Allows you to change the properties of rows in relationship tables.

Insert Relationship Row

Inserts a new table row with empty cells. The action is available when the cursor position is inside a table.

Insert Relationship Column

Inserts a new table column with empty cells after the current column. The action is available when the cursor position is inside a table.

Delete Relationship Column

Deletes the table column where the cursor is located.

Delete Relationship Row

Deletes the table row where the cursor is located.

Move Up

Moves the selected node up one position on its same level.

Move Down

Moves the selected node down one position on its same level.

Promote(Alt + LeftArrow)

Moves the selected node up one level to the level of its parent node.

Demote(Alt + RightArrow)

Moves the selected node down one level to the level of its child nodes.
**DITA Map Contextual Menu Actions**

The following actions are available in the contextual menu when editing in **Author** mode (most of them are also available in the **DITA** menu at the top of the interface):

- **Add File to Review Task**
  
  This action can be used to add the current document to a task in the **Content Fusion Tasks Manager** view. **Oxygen Content Fusion** is a flexible, intuitive collaboration platform designed to adapt to any type of documentation review workflow. This functionality is available through a pre-installed **connector add-on** (on page 2353). To fully take advantage of all of the benefits and features of **Content Fusion**, your organization will need an **Oxygen Content Fusion Enterprise Server**. For more information, see the **Oxygen Content Fusion** website.

- **Edit Properties**
  
  Opens the **Edit Properties** dialog box that allows you to configure the properties of a selected node. For more details about this dialog box, see **Edit Properties Dialog Box** (on page 2697).

- **Cut (Ctrl + X (Command + X on OS X))**

  Removes the currently selected content from the document and places it in the clipboard.

- **Copy (Ctrl + C (Command + C on OS X))**

  Places a copy of the currently selected content in the clipboard.

- **Paste (Ctrl + V (Command + V on OS X))**

  Inserts the current clipboard content into the document at the cursor position.

- **Paste special submenu**

  This submenu includes the following special paste actions that are specific to the DITA **framework**:

  - **Paste as content reference**
    
    Inserts a content reference (a DITA element with a @conref attribute) to the DITA XML element from the clipboard. An entire DITA XML element with an ID attribute must be present in the clipboard when the action is invoked. The `conref` attribute will point to this ID value.

  - **Paste as content key reference**
    
    Allows you to indirectly reference content using the @conkeyref attribute. When the DITA content is processed, the key references are resolved using key definitions from **DITA maps** (on page 2966). To use this action, you must first do the following:

    1. Make sure the DITA element that contains the copied content has an ID attribute assigned to it.
    2. In the **DITA Maps Manager** view, make sure that the **Context combo box** (on page 2667) points to the correct map that stores the keys.
3. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the **DITA Maps Manager**, select **Edit Properties**, and enter a value in the **Keys** field.

**Paste as link**

Looks for the first element with an ID value in the clipboard and inserts an `<xref>` that points to that element. If no elements with an ID value are found, a message will appear that informs you that to use this action, the clipboard contents must include at least one element with a declared ID.

**Paste as link (keyref)**

Inserts a link to the element that you want to reference. To use this action, you must first do the following:

1. Make sure the DITA element that contains the copied content has an ID attribute assigned to it.
2. In the **DITA Maps Manager** view, make sure that the **Context combo box** (on page 2667) points to the correct map that stores the keys.
3. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the **DITA Maps Manager**, select **Edit Properties**, and enter a value in the **Keys** field.

**Insert submenu**

This submenu includes the following insert actions that are specific to the DITA Map framework:

- **Insert New DITA Resource**
  
  Opens a **New DITA file dialog box** (on page 2725) where you can choose the type of DITA document to create and inserts a reference to it at the current position within the map.

- **Insert Topic Reference**
  
  Opens the **Insert Reference dialog box** (on page 2688) where you can configure a topic reference and inserts it at the current position within the map.

- **Insert Key Definition with Keyword**
  
  Opens a dialog box where you can choose the name of a key and its keyword value and inserts the key definition at the current position within the map.

- **Reuse Content**
Opens the **Reuse Content** dialog box *(on page 2806)* that allows you to insert and configure a content reference (@conref), or a content key reference (@conkeyref) at the cursor position.

**Insert Topic Heading**

Opens the **Insert Reference** dialog box *(on page 2688)* that allows you to insert a topic heading at the cursor position.

**Insert Topic Group**

Opens the **Insert Reference** dialog box *(on page 2688)* that allows you to insert a topic group at the cursor position.

**Insert Entity**

Allows you to insert a predefined entity or character entity. Surrogate character entities (range #x10000 to #x10FFFF) are also accepted. Character entities can be entered in one of the following forms:

- `#<decimal value>` - e.g. `#65`
- `&#<decimal value>` - e.g. `&#65`
- `#x<hexadecimal value>` - e.g. `#x41`
- `&#x<hexadecimal value>` - e.g. `&#x41`

**Relationship Table > Insert Relationship Table**

Opens a dialog box that allows you to configure the relationship table to be inserted. The dialog box allows you to configure the number of rows and columns of the relationship table, if the header will be generated and if the title will be added.

**Generate IDs**

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements listed in the **ID Options** dialog box that are found in the current selection.

**Note:**

The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `@id` attribute.

**Search References**

Finds the references to the `@href` or `@keys` attribute value of the topic/map reference element at the current cursor position, in all the topics from the current **DITA map** (opened in the **DITA Maps**...
Manager view (on page 2662)). The current topic/map reference element must have an `@href` or `@keys` attribute defined to complete the search.

**Show Key Definition**

Available for elements that have a `@conkeyref` or `@keyref` attribute set (or elements with an ancestor element that has a `@conkeyref` or `@keyref` attribute). It computes the key name and opens the DITA map (on page 2966) that contains the definition of the key with the element that defines that key selected.

**Select submenu**

This submenu allows you to select the following:

- **Element**
  Selects the entire element at the current cursor position.

- **Content**
  Selects the entire content of the element at the current cursor position, excluding the start and end tag. Performing this action repeatedly will result in the selection of the content of the ancestor of the currently selected element content.

- **Parent**
  Selects the entire parent element at the current cursor position.

**Text submenu**

This submenu contains the following actions:

- **To Lower Case**
  Converts the selected content to lower case characters.

- **To Upper Case**
  Converts the selected content to upper case characters.

- **Capitalize Sentences**
  Converts to upper case the first character of every selected sentence.

- **Capitalize Words**
  Converts to upper case the first character of every selected word.

- **Count Words**
  Counts the number of words and characters (no spaces) in the entire document or in the selection for regular content and read-only content.

**Note:**
The content marked as deleted with change tracking (on page 2971) is ignored when counting words.
Convert Hexadecimal Sequence to Character (Ctrl + Shift + X (Command + Shift + X on OS X))

Converts a sequence of hexadecimal characters to the corresponding Unicode character (on page 427). The action can be invoked if there is a selection containing a valid hexadecimal sequence or if the cursor is placed at the right side of a valid hexadecimal sequence. A valid hexadecimal sequence can be composed of 2 to 4 hexadecimal characters and may or may not be preceded by the 0x or 0X prefix. Examples of valid sequences and the characters they will be converted to:

- 0x0045 will be converted to Ê
- 0X0125 to ĥ
- 265 to ų
- 2190 to ←

Note:
For more information about finding the hexadecimal value of a character, see Finding the Decimal, Hexadecimal, or Character Entity Equivalent (on page 430).

Refactoring submenu

Contains a series of actions designed to alter the XML structure of the document:

- **Toggle Comment**
  Encloses the currently selected text in an XML comment, or removes the comment if it is commented.

- **Move Up (Alt + UpArrow)**
  Moves the current node or selected nodes in front of the previous node.

- **Move Down (Alt + DownArrow)**
  Moves the current node or selected nodes after the subsequent node.

- **Split Element (Alt + Shift + D (Ctrl + Alt + D on OS X))**
  Splits the content of the closest element that contains the position of the cursor. Thus, if the cursor is positioned at the beginning or at the end of the element, the newly created sibling will be empty.

- **Join Elements**
  Joins two adjacent block elements (on page 2964) that have the same name. The action is available only when the cursor position is between the two adjacent block elements. Also, joining two block elements can be done by pressing the Delete or Backspace keys and the cursor is positioned between the boundaries of these two elements.
Surround with Tags (Ctrl + E (Command + E on OS X))

Allows you to choose a tag to enclose a selected portion of content. If there is no selection, the start and end tags are inserted at the cursor position.

- If the **Position cursor between tags** option (on page 183) is selected in the **Content Completion** preferences page, the cursor is placed between the start and end tag.
- If the **Position cursor between tags** option (on page 183) is not selected in the **Content Completion** preferences page, the cursor is placed at the end of the start tag, in an insert-attribute position.

Surround with ‘[tag]’ (Ctrl + ForwardSlash (Command + ForwardSlash on OS X))

Surround the selected content with the last tag used.

Rename Element

The element from the cursor position, and any elements with the same name, can be renamed according with the options from the **Rename** dialog box.

Delete Element Tags

Deletes the tags of the closest element that contains the position of the cursor. This operation is also executed if the start or end tags of an element are deleted by pressing the **Delete** or **Backspace** keys.

Remove All Markup

Removes all the XML markup inside the selected block of content and keeps only the text content.

Remove Text

Removes the text content of the selected block of content and keeps the markup intact with empty elements.

Attributes Refactoring Actions

Contains built-in XML refactoring operations that pertain to attributes with some of the information preconfigured based upon the current context.

Add/Change attribute

Allows you to change the value of an attribute or insert a new one.

Convert attribute to element

Allows you to change an attribute into an element.

Delete attribute

Allows you to remove one or more attributes.

Rename attribute
Allows you to rename an attribute.

Replace in attribute value

Allows you to search for a text fragment inside an attribute value and change the fragment to a new value.

Comments Refactoring Actions

Contains built-in XML refactoring operations that pertain to comments with some of the information preconfigured based upon the current context.

Delete comments

Allows you to delete comments found inside one or more elements.

Elements Refactoring Actions

Contains built-in XML refactoring operations that pertain to elements with some of the information preconfigured based upon the current context.

Delete element

Allows you to delete elements.

Delete element content

Allows you to delete the content of elements.

Insert element

Allows you to insert new elements.

Rename element

Allows you to rename elements.

Unwrap element

Allows you to remove the surrounding tags of elements, while keeping the content unchanged.

Wrap element

Allows you to surround elements with element tags.

Wrap element content

Allows you to surround the content of elements with element tags.

Fragments Refactoring Actions

Contains built-in XML refactoring operations that pertain to XML fragments with some of the information preconfigured based upon the current context.

Insert XML fragment

Allows you to insert an XML fragment.

Replace element content with XML fragment

Allows you to replace the content of elements with an XML fragment.
Replace element with XML fragment

Allows you to replace elements with an XML fragment.

Review submenu

This submenu includes the following actions:

✔️ Track Changes

Enables or disables the Track Changes (on page 2971) support for the current document.

✔️ Accept Change(s) and Move to Next

Accepts the Tracked Change (on page 2971) located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a deletion or insertion change, only the selected content is accepted.

✔️ Accept All Changes

Accepts all Tracked Changes (on page 2971) in the current document.

❌ Reject Change(s) and Move to Next

Rejects the Tracked Change (on page 2971) located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a deletion or insertion change, only the selected content is rejected.

❌ Reject All Changes

Rejects all Tracked Changes (on page 2971) in the current document.

💬 Comment Change

Opens a dialog box that allows you to add a comment to an existing Tracked Change (on page 2971). The comment will appear in a callout and a tooltip when hovering over the change. If the action is selected on an existing commented change, the dialog box will allow you to edit the comment.

🖌 Highlight

Enables the highlighting tool that allows you to mark text in your document.

Colors

Allows you to select the color for highlighting text.

Stop highlighting

Use this action to deactivate the highlighting tool.

Remove highlight(s)

Use this action to remove highlighting from the document.

✉️ Add Comment
Inserts a comment at the cursor position. The comment appears in a callout box and a tooltip (when hovering over the change).

Show/Edit Comment
Opens a dialog box that displays the discussion thread and allows the current user to edit comments that do not have replies. If you are not the author who inserted the original comment, the dialog box just displays the comment without the possibility of editing it.

Remove Comment
Removes a selected comment. If you remove a comment that contains replies, all of the replies will also be removed.

Manage Reviews
Opens the Review view (on page 619).

Folding submenu
This submenu includes the following actions:

Toggle Fold
Toggles the state of the current fold.

Collapse Other Folds (Ctrl + NumPad/ (Command + NumPad/ on OS X))
Folds all the elements except the current element.

Collapse Child Folds (Ctrl + NumPad. (Command + NumPad. on OS X))
Folds the elements indented with one level inside the current element.

Expand Child Folds
Unfolds all child elements of the currently selected element.

Expand All (Ctrl + NumPad* (Command + NumPad* on OS X))
Unfolds all elements in the current document.

About Element > Go to Definition
Moves the cursor to the definition of the current element.

Inspect Styles
Opens the CSS Inspector view (on page 597) that allows you to examine the CSS rules that match the currently selected element.

Options
Opens the Author mode preferences page (on page 148) where you can configure various options with regard to the Author editing mode.
Floating Contextual Toolbar for DITA

Oxygen XML Editor includes a dynamic feature where certain editing contexts will trigger a floating toolbar with common actions that are available in the current editing context.

The floating contextual toolbar is automatically displayed when editing DITA map documents when a `<topicref>` element is selected and it includes actions for moving the topic reference node up or down (or promoting/demoting the node).

DITA Map Drag/Drop Actions

Dragging a file from the Project view (on page 368) or DITA Maps Manager view (on page 2662) and dropping it into a DITA map document that is edited in Author mode creates a link to the dragged file (a `<topicref>` element, `<chapter>`, `<part>`, etc.) at the drop location.

Opening a Topic from a DITA Map in Author Mode

If a DITA map is open in the Author visual editing mode, you can open a referenced topic by clicking the icon to the left of the particular topic. The source topic is opened in a new tab in the main editor.

**Tip:**

For information about customizing Author mode actions for a particular framework (on page 2967) (document type), see the Customizing the Author Editing Experience for a Framework (on page 1998) section.

Related Information:

Customizing the Author Editing Experience for a Framework (on page 1998)

XHTML Document Type (Framework)

The Extensible HyperText Markup Language (XHTML), is a markup language that has the same depth of expression as HTML, but also conforms to XML syntax.

**File Definition**

A file is considered to be an XHTML document when the root element is `<html>`.

**Default Document Templates**

There are a variety of default XHTML templates available when creating new documents from templates (on page 335) and they can be found in: Framework Templates > XHTML.

The default templates for XHTML documents are located in the `OXYGEN_INSTALL_DIR/frameworks/xhtml/templates/` folder.

**Default Schema for Validation and Content Completion**

Default schemas that are used if one is not detected in the XHTML file are stored in the following locations:
• XHTML 1.0 - \{OXYGEN\_INSTALL\_DIR\}/frameworks/xhtml/dtd/ or \{OXYGEN\_INSTALL\_DIR\}/frameworks/xhtml/nvdl/.
• XHTML 1.1 - \{OXYGEN\_INSTALL\_DIR\}/frameworks/xhtml11/dtd/ or \{OXYGEN\_INSTALL\_DIR\}/frameworks/xhtml11/schema/.
• XHTML 5 - \{OXYGEN\_INSTALL\_DIR\}/frameworks/xhtml/xhtml5 (epub3)/.

Default CSS

The default CSS files used for rendering XHTML content in Author mode are stored in \{OXYGEN\_INSTALL\_DIR\}/frameworks/xhtml/css/.

By default, these default CSS files are merged with any that are specified in the document. For more information, see Configuring and Managing Multiple CSS Styles for a Framework (on page 1998).

Default XML Catalogs

The default XML Catalogs (on page 2972) for the XHTML document type are as follows:

• \{OXYGEN\_INSTALL\_DIR\}/frameworks/xhtml/dtd/xhtmlcatalog.xml
• \{OXYGEN\_INSTALL\_DIR\}/frameworks/relaxng/catalog.xml
• \{OXYGEN\_INSTALL\_DIR\}/frameworks/nvdl/catalog.xml
• \{OXYGEN\_INSTALL\_DIR\}/frameworks/xhtml11/dtd/xhtmlcatalog.xml
• \{OXYGEN\_INSTALL\_DIR\}/frameworks/xhtml11/schema/xhtmlcatalog.xml
• \{OXYGEN\_INSTALL\_DIR\}/xhtml5 (epub3)/catalog-compat.xml

Transformation Scenarios

Oxygen XML Editor includes built-in transformation scenarios that allow you to transform XHTML documents to several types of DITA document types (topic, task, concept, reference). They can be found in the XHTML section in the Configure Transformation Scenario(s) dialog box (on page 1443).

Related Information:
Editing HTML Documents (on page 1158)
Editing XML Documents in Text Mode (on page 476)
Editing XML Documents in Author Mode (on page 547)
Adding Tables in XHTML Documents (on page 664)
XHTML Specifications

XHTML Validation

XHTML documents can be validated in Oxygen XML Editor using the same validation features as with any other XML document (on page 726). In addition, Oxygen XML Editor includes a built-in validator engine (W3C XHTML Validator) based upon the W3C Nu HTML Checker that can be used to validate HTML or XHTML documents.

To use the W3C XHTML Validator engine:
1. Create or edit a validation scenario (on page 740) (e.g. select the Configure Validation Scenario(s) from the Validation toolbar drop-down menu).
2. Change the File type column to XML Document and select W3C XHTML Validator in the Validation engine column.
3. Click OK and Apply Associated to run the validation.

Related Information:
W3C Nu HTML Checker
Validating XML Documents (on page 726)
Batch Validation and Transformation (on page 379)

XHTML Author Mode Actions
A variety of actions are available for XHTML documents that can be found in XHTML menu, toolbar, contextual menu, and the Content Completion Assistant (on page 2965).

XHTML Toolbar Actions
The following default actions are available on the XHTML toolbar when editing in Author mode (by default, they are also available in the XHTML menu and some of them are in various submenus of the contextual menu):

**Bold**
Changes the style of the selected text to **bold** by surrounding it with the `<b>` tag. You can use this action on multiple non-contiguous selections.

**Italic**
Changes the style of the selected text to **italic** by surrounding it with `<i>` tag. You can use this action on multiple non-contiguous selections.

**Underline**
Changes the style of the selected text to **underline** by surrounding it with `<u>` tag. You can use this action on multiple non-contiguous selections.

**Link**
Inserts an `<a>` element with an `@href` attribute at the cursor position. You can type the URL of the reference you want to insert or use the browsing actions in the Browse drop-down menu.

**Insert Image**
Inserts a graphic object at the cursor position. This is done by inserting an `<img>` element regardless of the current context. The following graphical formats are supported: GIF, JPG, JPEG, BMP, PNG, SVG.

**Insert Media Resource**
Opens a **Choose Media** dialog box ([on page 701]) that allows you to select the URL of a media object to be inserted into a document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted and rendered in **Author** mode so that it can be played directly from there.

**Headings Drop-down Menu**

A drop-down menu that includes actions for inserting `<h1>`, `<h2>`, `<h3>`, `<h4>`, `<h5>`, `<h6>` elements.

- **Insert Paragraph**
  Insert a new paragraph element at current cursor position.

- **Insert Equation**
  Opens the **XML Fragment Editor** that allows you to insert and edit MathML notations ([on page 703]).

- **Insert List Item**
  Inserts a list item in the current list type.

- **Insert Unordered List**
  Inserts an unordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an unordered list.

- **Insert Ordered List**
  Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

- **Insert a definition list at the cursor position**
  Inserts a definition list (`<dl>` element) with one list item (a `<dt>` child element and a `<dd>` child element). You can also use this action to convert selected paragraphs or other types of lists to a definition list.

- **Sort**
  Sorts cells or list items in a table.

- **Insert Table**
  Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a **block element** ([on page 2964])) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).
Note:
If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that **Only lists, paragraphs, or inline content can be converted to tables.**

**Insert Row**

Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

**Insert Row Above**

Inserts a new table row with empty cells above the current row. This action is available when the cursor is positioned inside a table.

**Insert Column**

Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

**Insert Cell**

Inserts a new empty cell depending on the current context. If the cursor is positioned between two cells, Oxygen XML Editor a new cell at the cursor position. If the cursor is inside a cell, the new cell is created after the current cell.

**Delete Column(s)**

Deletes the table column located at the cursor position or multiple columns in a selection.

**Delete Row(s)**

Deletes the table row located at the cursor position or multiple rows in a selection.

**Join Cells**

Joins the content of the selected cells (both horizontally and vertically).

**Split Cell**

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

**XHTML Contextual Menu Actions**

The following actions are available in the contextual menu when editing in **Author** mode (most of them are also available in the **XHTML** menu at the top of the interface):

**Add File to Review Task**

This action can be used to add the current document to a task in the **Content Fusion Tasks Manager** view. **Oxygen Content Fusion** is a flexible, intuitive collaboration platform designed to adapt to any type of documentation review workflow. This functionality is available through a
pre-installed connector add-on (on page 2353). To fully take advantage of all of the benefits and features of Content Fusion, your organization will need an Oxygen Content Fusion Enterprise Server. For more information, see the Oxygen Content Fusion website.

Edit Attributes
Displays an in-place attributes editor (on page 586) that allows you to manage the attributes of an element.

Edit Profiling Attributes
Allows you to change the profiling attributes (on page 623) defined on all selected elements.

Cut (Ctrl + X (Command + X on OS X))
Removes the currently selected content from the document and places it in the clipboard.

Copy (Ctrl + C (Command + C on OS X))
Places a copy of the currently selected content in the clipboard.

Paste (Ctrl + V (Command + V on OS X))
Inserts the current clipboard content into the document at the cursor position.

Image Map Editor
This action is available in the contextual menu when it is invoked on an image. This action applies an image map to the current image (if one does not already exist) and opens the Image Map Editor dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

Insert submenu
This submenu includes the following insert actions:

Insert Table
Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a block element (on page 2964)) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

Note:
If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that Only lists, paragraphs, or inline content can be converted to tables.

Insert Link
Inserts an `<a>` element with an `@href` attribute at the cursor position. You can type the URL of the reference you want to insert or use the browsing actions in the `Browse` drop-down menu.

**Insert Image**

Inserts an image reference (on page 672) at the cursor position. Depending on the current location, an image-type element is inserted.

**Insert Media Resource**

Opens a Choose Media dialog box (on page 701) that allows you to select the URL of a media object to be inserted into a document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted and rendered in Author mode so that it can be played directly from there.

**Insert Equation**

Opens the XML Fragment Editor that allows you to insert and edit MathML notations (on page 703).

**Insert Paragraph**

Inserts a new paragraph element at current cursor position.

**Headings Drop-down Menu**

A drop-down menu that includes actions for inserting `<h1>`, `<h2>`, `<h3>`, `<h4>`, `<h5>`, `<h6>` elements.

**Insert Entity**

Allows you to insert a predefined entity or character entity. Surrogate character entities (range #x10000 to #x10FFFF) are also accepted. Character entities can be entered in one of the following forms:

- `#<decimal value>` - e.g. #65
- `&#<decimal value>` - e.g. &#65
- `#x<hexadecimal value>` - e.g. #x41
- `&#x<hexadecimal value>` - e.g. &#x41

**Style submenu**

This submenu includes the following text styling actions:

- **Bold**

  Emphasizes the selected text by surrounding it with a `bold` tag. You can use this action on multiple non-contiguous selections.

- **Italic**

  Emphasizes the selected text by surrounding it with an `italic` tag. You can use this action on multiple non-contiguous selections.
Underline

Emphasizes the selected text by surrounding it with an \textit{underline} tag. You can use this action on multiple non-contiguous selections.

Subscript

Surrounds the selected text with a \textit{subscript} tag, used for inserting a character (number, letter, or symbol) that will appear slightly below the baseline and slightly smaller than the rest of the text.

Superscript

Surrounds the selected text with a \textit{superscript} tag, used for inserting a character (number, letter, or symbol) that will appear slightly above the baseline and slightly smaller than the rest of the text.

Table actions

The following table editing actions are available in the contextual menu when it is invoked on a table:

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (\textit{Above} or \textit{Below} the current row).

Delete Row(s)

Deletes the table row located at the cursor position or multiple rows in a selection.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (\textit{Above} or \textit{Below} the current column).

Delete Column(s)

Deletes the table column located at the cursor position or multiple columns in a selection.

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

Sort

Sorts cells or list items in a table.

Table Properties
Opens the **Table properties** dialog box that allows you to configure properties of a table (such as frame borders).

**Other Actions submenu**

This submenu gives you access to all the usual contextual menu actions.

**Select submenu**

This submenu allows you to select the following:

- **Element**
  
  Selects the entire element at the current cursor position.

- **Content**
  
  Selects the entire content of the element at the current cursor position, excluding the start and end tag. Performing this action repeatedly will result in the selection of the content of the ancestor of the currently selected element content.

- **Parent**
  
  Selects the entire parent element at the current cursor position.

**Text submenu**

This submenu contains the following actions:

- **To Lower Case**
  
  Converts the selected content to lower case characters.

- **To Upper Case**
  
  Converts the selected content to upper case characters.

- **Capitalize Sentences**
  
  Converts to upper case the first character of every selected sentence.

- **Capitalize Words**
  
  Converts to upper case the first character of every selected word.

- **Count Words**
  
  Counts the number of words and characters (no spaces) in the entire document or in the selection for regular content and read-only content.

**Note:**

The content marked as deleted with change tracking (on page 2971) is ignored when counting words.

**Convert Hexadecimal Sequence to Character (Ctrl + Shift + X (Command + Shift + X on OS X))**
Converts a sequence of hexadecimal characters to the corresponding Unicode character (on page 427). The action can be invoked if there is a selection containing a valid hexadecimal sequence or if the cursor is placed at the right side of a valid hexadecimal sequence. A valid hexadecimal sequence can be composed of 2 to 4 hexadecimal characters and may or may not be preceded by the `0x` or `0x` prefix. Examples of valid sequences and the characters they will be converted to:

- `0x0045` will be converted to `E`
- `0x0125` to `ĥ`
- `265` to `ɥ`
- `2190` to `←`

Note:
For more information about finding the hexadecimal value of a character, see Finding the Decimal, Hexadecimal, or Character Entity Equivalent (on page 430).

Refactoring submenu

Contains a series of actions designed to alter the XML structure of the document:

- **Toggle Comment**
  
  Encloses the currently selected text in an XML comment, or removes the comment if it is commented.

- **Move Up (Alt + UpArrow)**
  
  Moves the current node or selected nodes in front of the previous node.

- **Move Down (Alt + DownArrow)**
  
  Moves the current node or selected nodes after the subsequent node.

- **Split Element (Alt + Shift + D (Ctrl + Alt + D on OS X))**
  
  Splits the content of the closest element that contains the position of the cursor. Thus, if the cursor is positioned at the beginning or at the end of the element, the newly created sibling will be empty.

- **Join Elements**
  
  Joins two adjacent block elements (on page 2964) that have the same name. The action is available only when the cursor position is between the two adjacent block elements. Also, joining two block elements can be done by pressing the Delete or Backspace keys and the cursor is positioned between the boundaries of these two elements.

- **Surround with Tags (Ctrl + E (Command + E on OS X))**
Allows you to choose a tag to enclose a selected portion of content. If there is no selection, the start and end tags are inserted at the cursor position.

- If the Position cursor between tags option (on page 183) is selected in the Content Completion preferences page, the cursor is placed between the start and end tag.
- If the Position cursor between tags option (on page 183) is not selected in the Content Completion preferences page, the cursor is placed at the end of the start tag, in an insert-attribute position.

Surround with '[tag]' (Ctrl + ForwardSlash (Command + ForwardSlash on OS X))
Surround the selected content with the last tag used.

Rename Element
The element from the cursor position, and any elements with the same name, can be renamed according with the options from the Rename dialog box.

Delete Element Tags
Deletes the tags of the closest element that contains the position of the cursor. This operation is also executed if the start or end tags of an element are deleted by pressing the Delete or Backspace keys.

Remove All Markup
Removes all the XML markup inside the selected block of content and keeps only the text content.

Remove Text
Removes the text content of the selected block of content and keeps the markup intact with empty elements.

Attributes Refactoring Actions
Contains built-in XML refactoring operations that pertain to attributes with some of the information preconfigured based upon the current context.

Add/Change attribute
Allows you to change the value of an attribute or insert a new one.

Convert attribute to element
Allows you to change an attribute into an element.

Delete attribute
Allows you to remove one or more attributes.

Rename attribute
Allows you to rename an attribute.
Replace in attribute value

Allows you to search for a text fragment inside an attribute value and change the fragment to a new value.

Comments Refactoring Actions

Contains built-in XML refactoring operations that pertain to comments with some of the information preconfigured based upon the current context.

Delete comments

Allows you to delete comments found inside one or more elements.

Elements Refactoring Actions

Contains built-in XML refactoring operations that pertain to elements with some of the information preconfigured based upon the current context.

Delete element

Allows you to delete elements.

Delete element content

Allows you to delete the content of elements.

Insert element

Allows you to insert new elements.

Rename element

Allows you to rename elements.

Unwrap element

Allows you to remove the surrounding tags of elements, while keeping the content unchanged.

Wrap element

Allows you to surround elements with element tags.

Wrap element content

Allows you to surround the content of elements with element tags.

Fragments Refactoring Actions

Contains built-in XML refactoring operations that pertain to XML fragments with some of the information preconfigured based upon the current context.

Insert XML fragment

Allows you to insert an XML fragment.

Replace element content with XML fragment

Allows you to replace the content of elements with an XML fragment.

Replace element with XML fragment
Allows you to replace elements with an XML fragment.

Review submenu

This submenu includes the following actions:

✔ Track Changes
   Enables or disables the Track Changes (on page 2971) support for the current document.

✔ Accept Change(s) and Move to Next
   Accepts the Tracked Change (on page 2971) located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a deletion or insertion change, only the selected content is accepted.

✔ Accept All Changes
   Accepts all Tracked Changes (on page 2971) in the current document.

✗ Reject Change(s) and Move to Next
   Rejects the Tracked Change (on page 2971) located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a deletion or insertion change, only the selected content is rejected.

✗ Reject All Changes
   Rejects all Tracked Changes (on page 2971) in the current document.

✔ Comment Change
   Opens a dialog box that allows you to add a comment to an existing Tracked Change (on page 2971). The comment will appear in a callout and a tooltip when hovering over the change. If the action is selected on an existing commented change, the dialog box will allow you to edit the comment.

_paint Highlight
   Enables the highlighting tool that allows you to mark text in your document.

Colors
   Allows you to select the color for highlighting text.

Stop highlighting
   Use this action to deactivate the highlighting tool.

Remove highlight(s)
   Use this action to remove highlighting from the document.

_paint Add Comment
   Inserts a comment at the cursor position. The comment appears in a callout box and a tooltip (when hovering over the change).
Show/Edit Comment

Opens a dialog box that displays the discussion thread and allows the current user to edit comments that do not have replies. If you are not the author who inserted the original comment, the dialog box just displays the comment without the possibility of editing it.

Remove Comment

Removes a selected comment. If you remove a comment that contains replies, all of the replies will also be removed.

Manage Reviews

Opens the Review view (on page 619).

Folding submenu

This submenu includes the following actions:

- **Toggle Fold**
  Toggles the state of the current fold.

- **Collapse Other Folds** *(Ctrl + NumPad/ (Command + NumPad/ on OS X))*
  Folds all the elements except the current element.

- **Collapse Child Folds** *(Ctrl + NumPad. (Command + NumPad. on OS X))*
  Folds the elements indented with one level inside the current element.

- **Expand Child Folds**
  Unfolds all child elements of the currently selected element.

- **Expand All** *(Ctrl + NumPad* (Command + NumPad* on OS X))*
  Unfolds all elements in the current document.

About Element > Go to Definition

Moves the cursor to the definition of the current element.

Inspect Styles

Opens the CSS Inspector view (on page 597) that allows you to examine the CSS rules that match the currently selected element.

Options

Opens the Author mode preferences page (on page 148) where you can configure various options with regard to the Author editing mode.

XHTML Drag/Drop (or Copy/Paste) Actions

Dragging a file from the Project view (on page 368) and dropping it into an XHTML document that is edited in Author mode, creates a link to the dragged file (the `a` element with the `href` attribute) at the drop location. Copy and paste actions work the same.
You can also drag images or media files from your system explorer or the Project view (on page 368) and drop them into an XHTML document (or copy and paste). This will insert the appropriate element at the drop or paste location (for example, dropping/pasting an image will insert the `<img>` element with the `@src` attribute).

**Tip:**
For information about customizing Author mode actions for a particular framework (on page 2967) (document type), see the Customizing the Author Editing Experience for a Framework (on page 1998) section.

Related Information:
Customizing the Author Editing Experience for a Framework (on page 1998)

**TEI P5 Document Type (Framework)**

The *TEI (Text Encoding Initiative)* document type is an international and interdisciplinary standard that enables libraries, museums, publishers, and individual scholars to represent a variety of literary and linguistic texts for online research, teaching, and preservation.

**File Definition**

A file is considered to be a TEI P5 document when one of the following conditions are true:

- The document namespace is `http://www.tei-c.org/ns/1.0`.
- The public ID of the document is `-//TEI P5`.

**Default Document Templates**

There are a variety of default TEI P5 templates available when creating new documents from templates (on page 335) and they can be found in: Framework Templates > TEI P5.

The default templates for TEI P5 documents are located in the `[/OXYGEN_INSTALL_DIR]/frameworks/tei/templates/TEI P5` folder.

**Default Schema for Validation and Content Completion**

The default schema that is used if one is not detected in the TEI P5 document is `tei_all.rng` and it is stored in `[/OXYGEN_INSTALL_DIR]/frameworks/tei/xml/tei/custom/schema/relaxng/`.

**Default CSS**

The default CSS files used for rendering TEI content in Author mode are stored in `[/OXYGEN_INSTALL_DIR]/frameworks/tei/xml/tei/css/`.

By default, these default CSS files are merged with any that are specified in the document. For more information, see Configuring and Managing Multiple CSS Styles for a Framework (on page 1998).
Default XML Catalogs

The default *XML Catalogs* (on page 2972) for the TEI P5 document type are as follows:

- `{OXYGEN_INSTALL_DIR}/frameworks/tei/xml/tei/schema/dtd/catalog.xml`
- `{OXYGEN_INSTALL_DIR}/frameworks/tei/xml/tei/custom/schema/dtd/catalog.xml`
- `{OXYGEN_INSTALL_DIR}/frameworks/tei/xml/tei/stylesheet/catalog.xml`

Transformation Scenarios

Oxygen XML Editor includes built-in transformation scenarios that allow you to transform TEI P5 documents to a variety of outputs, such as PDF, XHTML, EPUB, DOCX, and ODT. They can be found in the TEI P5 section in the *Configure Transformation Scenario(s)* dialog box (on page 1443).

- Adding Tables in TEI Documents (on page 667)

TEI P5 Author Mode Actions

A variety of actions are available for TEI P5 documents that can be found in TEI P5 menu, toolbar, contextual menu, and the *Content Completion Assistant* (on page 2965).

TEI P5 Toolbar Actions

The following default actions are available on the TEI P5 toolbar when editing in Author mode (by default, they are also available in the TEI P5 menu and some of them are in various submenus of the contextual menu):

- **Bold**
  
  Changes the style of the selected text to *bold* by surrounding it with the `<hi>` tag and setting the `@rend` attribute to *bold*. You can use this action on multiple non-contiguous selections.

- **Italic**
  
  Changes the style of the selected text to *italic* by surrounding it with the `<hi>` tag and setting the `@rend` attribute to *italic*. You can use this action on multiple non-contiguous selections.

- **Underline**
  
  Changes the style of the selected text to *underline* by surrounding it with the `<hi>` tag and setting the `@rend` attribute to *ul*. You can use this action on multiple non-contiguous selections.

- **Insert Section**
Inserts a new section or subsection, depending on the current context. For example, if the current context is `div1`, then a `div2` is inserted. By default, this action also inserts a paragraph element as a child node.

**Insert Paragraph**

Insert a new paragraph element at current cursor position.

**Insert Image**

Inserts an image reference (on page 672) at the cursor position. Depending on the current location, an image-type element is inserted.

**Insert List Item**

Inserts a list item in the current list type.

**Insert Ordered List**

Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

**Insert Itemized List**

Inserts an itemized list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an itemized list.

**Sort**

Sorts cells or list items in a table.

**Insert Table**

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a block element (on page 2964)) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

**Note:**

If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that Only lists, paragraphs, or inline content can be converted to tables.

**Insert Row**

Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.
Insert Column

Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

Insert Cell

Inserts a new empty cell depending on the current context. If the cursor is positioned between two cells, Oxygen XML Editor a new cell at the cursor position. If the cursor is inside a cell, the new cell is created after the current cell.

Delete Column(s)

Deletes the table column located at the cursor position or multiple columns in a selection.

Delete Row(s)

Deletes the table row located at the cursor position or multiple rows in a selection.

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

TEI Contextual Menu Actions

The following actions are available in the contextual menu when editing in Author mode (most of them are also available in the TEI P5 menu at the top of the interface):

Add File to Review Task

This action can be used to add the current document to a task in the Content Fusion Tasks Manager view. Oxygen Content Fusion is a flexible, intuitive collaboration platform designed to adapt to any type of documentation review workflow. This functionality is available through a pre-installed connector add-on (on page 2353). To fully take advantage of all of the benefits and features of Content Fusion, your organization will need an Oxygen Content Fusion Enterprise Server. For more information, see the Oxygen Content Fusion website.

Edit Attributes

Displays an in-place attributes editor (on page 586) that allows you to manage the attributes of an element.

Edit Profiling Attributes

Allows you to change the profiling attributes (on page 623) defined on all selected elements.

Cut (Ctrl + X (Command + X on OS X))

Removes the currently selected content from the document and places it in the clipboard.
Copy (Ctrl + C (Command + C on OS X))

Places a copy of the currently selected content in the clipboard.

Paste (Ctrl + V (Command + V on OS X))

Inserts the current clipboard content into the document at the cursor position.

Image Map Editor

This action is available in the contextual menu when it is invoked on an image. This action applies an image map to the current image (if one does not already exist) and opens the Image Map Editor dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

Insert submenu

This submenu includes the following insert actions:

- **Insert Table**
  
  Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a block element (on page 2964)) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

  **Note:**
  
  If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that Only lists, paragraphs, or inline content can be converted to tables.

- **Insert Image**
  
  Inserts an image reference (on page 672) at the cursor position. Depending on the current location, an image-type element is inserted.

- **Insert Paragraph**
  
  Inserts a new paragraph element at current cursor position.

- **Insert Section**
  
  Inserts a new section element in the document, depending on the current context.

- **Insert Entity**
  
  Allows you to insert a predefined entity or character entity. Surrogate character entities (range #x10000 to #x10FFFF) are also accepted. Character entities can be entered in one of the following forms:
• #<decimal value> - e.g. #65
• &#<decimal value> - e.g. &#65
• #x<hexadecimal value> - e.g. #x41
• &x<hexadecimal value> - e.g. &x41

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

• When invoked on a single selection, an ID is generated for the selected element at the cursor position.
• When invoked on a block of selected content, IDs are generated for all top-level elements and elements listed in the ID Options dialog box that are found in the current selection.

Note:
The Generate IDs action does not overwrite existing ID values. It only affects elements that do not already have an @id attribute.

Table actions

The following table editing actions are available in the contextual menu when it is invoked on a table:

Insert Rows
Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (Above or Below the current row).

Delete Row(s)
Deletes the table row located at the cursor position or multiple rows in a selection.

Insert Columns
Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (Above or Below the current column).

Delete Column(s)
Deletes the table column located at the cursor position or multiple columns in a selection.

Join Cells
Joins the content of the selected cells (both horizontally and vertically).

Split Cell
Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.
Sort
Sorts cells or list items in a table.

Table Properties
Opens the Table properties dialog box that allows you to configure properties of a table (such as frame borders).

Other Actions submenu
This submenu gives you access to all the usual contextual menu actions.

Select submenu
This submenu allows you to select the following:

Element
Selects the entire element at the current cursor position.

Content
Selects the entire content of the element at the current cursor position, excluding the start and end tag. Performing this action repeatedly will result in the selection of the content of the ancestor of the currently selected element content.

Parent
Selects the entire parent element at the current cursor position.

Text submenu
This submenu contains the following actions:

To Lower Case
Converts the selected content to lower case characters.

To Upper Case
Converts the selected content to upper case characters.

Capitalize Sentences
Converts to upper case the first character of every selected sentence.

Capitalize Words
Converts to upper case the first character of every selected word.

Count Words
Counts the number of words and characters (no spaces) in the entire document or in the selection for regular content and read-only content.

Note:
The content marked as deleted with change tracking (on page 2971) is ignored when counting words.
Convert Hexadecimal Sequence to Character (**Ctrl + Shift + X (Command + Shift + X on OS X)**)

Converts a sequence of hexadecimal characters to the corresponding Unicode character (**on page 427**). The action can be invoked if there is a selection containing a valid hexadecimal sequence or if the cursor is placed at the right side of a valid hexadecimal sequence. A valid hexadecimal sequence can be composed of 2 to 4 hexadecimal characters and may or may not be preceded by the \texttt{0x} or \texttt{0X} prefix. Examples of valid sequences and the characters they will be converted to:

- \texttt{0x0045} will be converted to \texttt{E}
- \texttt{0X0125} to \texttt{ĥ}
- \texttt{265} to \texttt{ɥ}
- \texttt{2190} to \texttt{←}

**Note:**
For more information about finding the hexadecimal value of a character, see **Finding the Decimal, Hexadecimal, or Character Entity Equivalent** (**on page 430**).

Refactoring submenu

Contains a series of actions designed to alter the XML structure of the document:

- **Toggle Comment**
  Encloses the currently selected text in an XML comment, or removes the comment if it is commented.

- **Move Up (Alt + UpArrow)**
  Moves the current node or selected nodes in front of the previous node.

- **Move Down (Alt + DownArrow)**
  Moves the current node or selected nodes after the subsequent node.

- **Split Element (Alt + Shift + D (Ctrl + Alt + D on OS X))**
  Splits the content of the closest element that contains the position of the cursor. Thus, if the cursor is positioned at the beginning or at the end of the element, the newly created sibling will be empty.

- **Join Elements**
  Joins two adjacent block elements (**on page 2964**) that have the same name. The action is available only when the cursor position is between the two adjacent block elements. Also, joining two block elements can be done by pressing the **Delete** or **Backspace** keys and the cursor is positioned between the boundaries of these two elements.
**Surround with Tags (Ctrl + E (Command + E on OS X))**

Allows you to choose a tag to enclose a selected portion of content. If there is no selection, the start and end tags are inserted at the cursor position.

- If the **Position cursor between tags** option (on page 183) is selected in the **Content Completion** preferences page, the cursor is placed between the start and end tag.
- If the **Position cursor between tags** option (on page 183) is not selected in the **Content Completion** preferences page, the cursor is placed at the end of the start tag, in an insert-attribute position.

**Surround with ‘[tag]’ (Ctrl + ForwardSlash (Command + ForwardSlash on OS X))**

Surround the selected content with the last tag used.

**Rename Element**

The element from the cursor position, and any elements with the same name, can be renamed according with the options from the **Rename** dialog box.

**Delete Element Tags**

Deletes the tags of the closest element that contains the position of the cursor. This operation is also executed if the start or end tags of an element are deleted by pressing the **Delete** or **Backspace** keys.

**Remove All Markup**

Removes all the XML markup inside the selected block of content and keeps only the text content.

**Remove Text**

Removes the text content of the selected block of content and keeps the markup intact with empty elements.

**Attributes Refactoring Actions**

Contains built-in XML refactoring operations that pertain to attributes with some of the information preconfigured based upon the current context.

- **Add/Change attribute**
  - Allows you to change the value of an attribute or insert a new one.

- **Convert attribute to element**
  - Allows you to change an attribute into an element.

- **Delete attribute**
  - Allows you to remove one or more attributes.

- **Rename attribute**
Allows you to rename an attribute.

Replace in attribute value

Allows you to search for a text fragment inside an attribute value and change the fragment to a new value.

Comments Refactoring Actions

Contains built-in XML refactoring operations that pertain to comments with some of the information preconfigured based upon the current context.

Delete comments

Allows you to delete comments found inside one or more elements.

Elements Refactoring Actions

Contains built-in XML refactoring operations that pertain to elements with some of the information preconfigured based upon the current context.

Delete element

Allows you to delete elements.

Delete element content

Allows you to delete the content of elements.

Insert element

Allows you to insert new elements.

Rename element

Allows you to rename elements.

Unwrap element

Allows you to remove the surrounding tags of elements, while keeping the content unchanged.

Wrap element

Allows you to surround elements with element tags.

Wrap element content

Allows you to surround the content of elements with element tags.

Fragments Refactoring Actions

Contains built-in XML refactoring operations that pertain to XML fragments with some of the information preconfigured based upon the current context.

Insert XML fragment

Allows you to insert an XML fragment.

Replace element content with XML fragment

Allows you to replace the content of elements with an XML fragment.
Replace element with XML fragment

Allows you to replace elements with an XML fragment.

Review submenu

This submenu includes the following actions:

- **Track Changes**
  Enables or disables the Track Changes (on page 2971) support for the current document.

- **Accept Change(s) and Move to Next**
  Accepts the Tracked Change (on page 2971) located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a deletion or insertion change, only the selected content is accepted.

- **Accept All Changes**
  Accepts all Tracked Changes (on page 2971) in the current document.

- **Reject Change(s) and Move to Next**
  Rejects the Tracked Change (on page 2971) located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a deletion or insertion change, only the selected content is rejected.

- **Reject All Changes**
  Rejects all Tracked Changes (on page 2971) in the current document.

- **Comment Change**
  Opens a dialog box that allows you to add a comment to an existing Tracked Change (on page 2971). The comment will appear in a callout and a tooltip when hovering over the change. If the action is selected on an existing commented change, the dialog box will allow you to edit the comment.

- **Highlight**
  Enables the highlighting tool that allows you to mark text in your document.

  **Colors**
  Allows you to select the color for highlighting text.

  **Stop highlighting**
  Use this action to deactivate the highlighting tool.

  **Remove highlight(s)**
  Use this action to remove highlighting from the document.

  **Add Comment**
Inserts a comment at the cursor position. The comment appears in a callout box and a tooltip (when hovering over the change).

Show/Edit Comment

Opens a dialog box that displays the discussion thread and allows the current user to edit comments that do not have replies. If you are not the author who inserted the original comment, the dialog box just displays the comment without the possibility of editing it.

Remove Comment

Removes a selected comment. If you remove a comment that contains replies, all of the replies will also be removed.

Manage Reviews

Opens the Review view (on page 619).

Folding submenu

This submenu includes the following actions:

Toggle Fold

Toggles the state of the current fold.

Collapse Other Folds (Ctrl + NumPad/ (Command + NumPad/ on OS X))

Folds all the elements except the current element.

Collapse Child Folds (Ctrl + NumPad. (Command + NumPad. on OS X))

Folds the elements indented with one level inside the current element.

Expand Child Folds

Unfolds all child elements of the currently selected element.

Expand All (Ctrl + NumPad* (Command + NumPad* on OS X))

Unfolds all elements in the current document.

About Element > Go to Definition

Moves the cursor to the definition of the current element.

Inspect Styles

Opens the CSS Inspector view (on page 597) that allows you to examine the CSS rules that match the currently selected element.

Options

Opens the Author mode preferences page (on page 148) where you can configure various options with regard to the Author editing mode.
TEI P5 Drag/Drop Actions

Dragging a file from the Project view (on page 368) and dropping it into a TEI P5 document that is edited in Author mode, creates a link to the dragged file (the element with the attribute) at the drop location. Dragging an image file from the default file system application (Windows Explorer on Windows or Finder on macOS, for example) and dropping it into a TEI P5 document inserts a graphic element (the element with the attribute) at the drop location, similar to the Insert Image toolbar action.

Tip:
For information about customizing Author mode actions for a particular framework (on page 2967) (document type), see the Customizing the Author Editing Experience for a Framework (on page 1998) section.

Related Information:
Customizing the Author Editing Experience for a Framework (on page 1998)

Customization of TEI Frameworks Using the Latest Sources

The TEI P5 (on page 1287) framework (on page 2967) is available as a public project at the following SVN repository: https://github.com/TEIC/oxygen-tei. This project is the base for customizing a TEI framework.

To customize a TEI framework, follow this procedure:

1. Check out the project on a local computer from the SVN repository.
   This action is done with an SVN client application that creates a working copy of the SVN repository on a local computer.
2. Customize the TEI framework in Oxygen XML Editor.

   a. Set the Oxygen XML Editor frameworks folder to the folder of the SVN working copy.
      Open the Preferences dialog box (Options > Preferences) (on page 98), go to Global, and set the path of the SVN working copy in the Use custom frameworks option.

   b. Open the Preferences dialog box (Options > Preferences) (on page 98), go to Document Type Association > Locations, and select Custom.

3. Build a JAR (on page 2967) file with the TEI framework.
   The SVN project includes a build.xml file that can be used for building a JAR file using the Ant tool.
   The command that should be used:

   ```
   ant -f build.xml
   ```

4. Distribute the JAR file to the users that need the customized TEI framework.
   The command from the above step creates a file tei.zip in the dist subfolder of the SVN project.
   Each user that needs the customized TEI framework will receive the tei.zip file and will unzip it in the frameworks folder of the Oxygen XML Editor install folder.
Customization of TEI Frameworks Using the Compiled Sources

The following procedure describes how to update to the latest stable version of TEI Schema and TEI XSL, already integrated in the TEI framework (on page 2967) for Oxygen XML Editor.

1. Go to https://code.google.com/p/oxygen-tei/;
2. Go to Downloads;
3. Download the latest uploaded .zip file;
4. Unpack the .zip file and copy its content in the Oxygen XML Editor frameworks folder.

TEI ODD Document Type (Framework)

The TEI ODD (Text Encoding Initiative - One Document Does it all) document type is a TEI XML-conformant specification format that allows you to create a custom TEI P5 schema in a literate programming fashion. A system of XSLT stylesheets called Roma was created by the TEI Consortium for manipulating the ODD files.

File Definition

A file is considered to be a TEI ODD document when the following conditions are true:

- The file extension is .odd.
- The document namespace is http://www.tei-c.org/ns/1.0.

Default Document Templates

There is a default TEI ODD document template available when creating new documents from templates (on page 335) and they can be found in: Framework Templates > TEI ODD.

The default template is located in the {OXYGEN_INSTALL_DIR}/frameworks/tei/templates/TEI ODD folder.

Default Schema for Validation and Content Completion

The default schema that is used if one is not detected in the TEI ODD document is tei_odds.rng and it is stored in {OXYGEN_INSTALL_DIR}/frameworks/tei/xml/tei/custom/schema/relaxng/.

Default CSS

The default CSS files used for rendering TEI ODD content in Author mode are stored in {OXYGEN_INSTALL_DIR}/frameworks/tei/xml/tei/css/.

By default, these default CSS files are merged with any that are specified in the document. For more information, see Configuring and Managing Multiple CSS Styles for a Framework (on page 1998).

Default XML Catalogs

The default XML Catalogs (on page 2972) for the TEI ODD document type are as follows:

- {OXYGEN_INSTALL_DIR}/frameworks/tei/xml/tei/custom/schema/catalog.xml
- {OXYGEN_INSTALL_DIR}/frameworks/tei/xml/tei/schema/catalog.xml
Transformation Scenarios

Oxygen XML Editor includes built-in transformation scenarios that allow you to transform TEI ODD documents to a variety of outputs, such as PDF, XHTML, EPUB, DOCX, ODT, RNG, DTD, and XML Schema. They can be found in the TEI ODD section in the Configure Transformation Scenario(s) dialog box (on page 1443).

Editing XML Documents in Text Mode (on page 476)

TEI ODD Author Mode Actions

A variety of actions are available for TEI ODD documents that can be found in TEI ODD menu, toolbar, contextual menu, and the Content Completion Assistant (on page 2965).

TEI ODD Toolbar Actions

The following default actions are available on the TEI ODD toolbar when editing in Author mode (by default, they are also available in the TEI ODD menu and some of them are in various submenus of the contextual menu):

- **Bold**
  Changes the style of the selected text to *bold* by surrounding it with the `<hi>` tag and setting the `@rend` attribute to `bold`. You can use this action on multiple non-contiguous selections.

- **Italic**
  Changes the style of the selected text to *italic* by surrounding it with the `<hi>` tag and setting the `@rend` attribute to `italic`. You can use this action on multiple non-contiguous selections.

- **Underline**
  Changes the style of the selected text to *underline* by surrounding it with the `<hi>` tag and setting the `@rend` attribute to `ul`. You can use this action on multiple non-contiguous selections.

- **Insert Section**
  Inserts a new section or subsection, depending on the current context. For example, if the current context is `div1`, then a `div2` is inserted. By default, this action also inserts a paragraph element as a child node.

- **Insert Paragraph**
  Insert a new paragraph element at current cursor position.
Insert Image

Inserts an image reference (on page 672) at the cursor position. Depending on the current location, an image-type element is inserted.

Insert List Item

Inserts a list item in the current list type.

Insert Ordered List

Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

Insert Itemized List

Inserts an itemized list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an itemized list.

Insert Table

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a block element (on page 2964)) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

Note:

If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that Only lists, paragraphs, or inline content can be converted to tables.

Insert Row

Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

Insert Column

Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

Insert Cell

Inserts a new empty cell depending on the current context. If the cursor is positioned between two cells, Oxygen XML Editor a new cell at the cursor position. If the cursor is inside a cell, the new cell is created after the current cell.

Delete Column(s)
Deletes the table column located at the cursor position or multiple columns in a selection.

**Delete Row(s)**

Deletes the table row located at the cursor position or multiple rows in a selection.

**Join Cells**

Joins the content of the selected cells (both horizontally and vertically).

**Split Cell**

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

**TEI Contextual Menu Actions**

The following actions are available in the contextual menu when editing in **Author** mode (most of them are also available in the **TEI ODD** menu at the top of the interface):

1. **Add File to Review Task**
   
   This action can be used to add the current document to a task in the **Content Fusion Tasks Manager** view. **Oxygen Content Fusion** is a flexible, intuitive collaboration platform designed to adapt to any type of documentation review workflow. This functionality is available through a pre-installed connector add-on on page 2353. To fully take advantage of all of the benefits and features of **Content Fusion**, your organization will need an **Oxygen Content Fusion Enterprise Server**. For more information, see the **Oxygen Content Fusion** website.

2. **Edit Attributes**

   Displays an in-place attributes editor on page 586 that allows you to manage the attributes of an element.

3. **Edit Profiling Attributes**

   Allows you to change the profiling attributes on page 623 defined on all selected elements.

4. **Cut (Ctrl + X (Command + X on OS X))**

   Removes the currently selected content from the document and places it in the clipboard.

5. **Copy (Ctrl + C (Command + C on OS X))**

   Places a copy of the currently selected content in the clipboard.

6. **Paste (Ctrl + V (Command + V on OS X))**

   Inserts the current clipboard content into the document at the cursor position.

**Image Map Editor**

This action is available in the contextual menu when it is invoked on an image. This action applies an image map to the current image (if one does not already exist) and opens the Image
Map Editor dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

Insert submenu

This submenu includes the following insert actions that are specific to the DocBook framework:

Insert Table

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a block element (on page 2964)) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

Note:

If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that Only lists, paragraphs, or inline content can be converted to tables.

Insert Image

Inserts an image reference (on page 672) at the cursor position. Depending on the current location, an image-type element is inserted.

Insert Paragraph

Inserts a new paragraph element at current cursor position.

Insert Section

Inserts a new section element in the document, depending on the current context.

Insert Entity

Allows you to insert a predefined entity or character entity. Surrogate character entities (range #x10000 to #x10FFFF) are also accepted. Character entities can be entered in one of the following forms:

- #<decimal value> - e.g. #65
- &#<decimal value> - e.g. &#65
- #x<hexadecimal value> - e.g. #x41
- &#x<hexadecimal value> - e.g. &#x41

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:
• When invoked on a single selection, an ID is generated for the selected element at the
cursor position.
• When invoked on a block of selected content, IDs are generated for all top-level elements
and elements listed in the ID Options dialog box that are found in the current selection.

Note:
The Generate IDs action does not overwrite existing ID values. It only affects elements
that do not already have an @id attribute.

Table actions

The following table editing actions are available in the contextual menu when it is invoked on a
table:

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the
position where they will be inserted (Above or Below the current row).

Delete Row(s)

Deletes the table row located at the cursor position or multiple rows in a selection.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify
the position where they will be inserted (Above or Below the current column).

Delete Column(s)

Deletes the table column located at the cursor position or multiple columns in a
selection.

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one
option to split the cell, a dialog box will be displayed that allows you to select the
number of rows or columns to split the cell into.

Sort

Sorts cells or list items in a table.

Table Properties

Opens the Table properties dialog box that allows you to configure properties of a
table (such as frame borders).

Other Actions submenu

This submenu give you access to all the usual contextual menu actions.
**Select submenu**

This submenu allows you to select the following:

**Element**

Selects the entire element at the current cursor position.

**Content**

Selects the entire content of the element at the current cursor position, excluding the start and end tag. Performing this action repeatedly will result in the selection of the content of the ancestor of the currently selected element content.

**Parent**

Selects the entire parent element at the current cursor position.

**Text submenu**

This submenu contains the following actions:

**To Lower Case**

Converts the selected content to lower case characters.

**To Upper Case**

Converts the selected content to upper case characters.

**Capitalize Sentences**

Converts to upper case the first character of every selected sentence.

**Capitalize Words**

Converts to upper case the first character of every selected word.

**Count Words**

Counts the number of words and characters (no spaces) in the entire document or in the selection for regular content and read-only content.

**Note:**

The content marked as deleted with change tracking (on page 2971) is ignored when counting words.

**Convert Hexadecimal Sequence to Character (Ctrl + Shift + X (Command + Shift + X on OS X))**

Converts a sequence of hexadecimal characters to the corresponding Unicode character (on page 427). The action can be invoked if there is a selection containing a valid hexadecimal sequence or if the cursor is placed at the right side of a valid hexadecimal sequence. A valid hexadecimal sequence can be composed of 2 to 4 hexadecimal characters and may or may not be preceded by the 0x or 0X prefix. Examples of valid sequences and the characters they will be converted to:
Refactoring submenu

Contains a series of actions designed to alter the XML structure of the document:

- **Toggle Comment**
  Encloses the currently selected text in an XML comment, or removes the comment if it is commented.

- **Move Up (Alt + UpArrow)**
  Moves the current node or selected nodes in front of the previous node.

- **Move Down (Alt + DownArrow)**
  Moves the current node or selected nodes after the subsequent node.

- **Split Element (Alt + Shift + D (Ctrl + Alt + D on OS X))**
  Splits the content of the closest element that contains the position of the cursor. Thus, if the cursor is positioned at the beginning or at the end of the element, the newly created sibling will be empty.

- **Join Elements**
  Joins two adjacent block elements (on page 2964) that have the same name. The action is available only when the cursor position is between the two adjacent block elements. Also, joining two block elements can be done by pressing the Delete or Backspace keys and the cursor is positioned between the boundaries of these two elements.

- **Surround with Tags (Ctrl + E (Command + E on OS X))**
  Allows you to choose a tag to enclose a selected portion of content. If there is no selection, the start and end tags are inserted at the cursor position.

Note:
For more information about finding the hexadecimal value of a character, see Finding the Decimal, Hexadecimal, or Character Entity Equivalent (on page 430).

- \( \text{x0045} \) will be converted to ง
- \( \text{x0125} \) to ꙯
- \( \text{265} \) to Ꙫ
- \( \text{2190} \) to ꩒
• If the **Position cursor between tags** option (*on page 183*) is selected in the **Content Completion** preferences page, the cursor is placed between the start and end tag.

• If the **Position cursor between tags** option (*on page 183*) is not selected in the **Content Completion** preferences page, the cursor is placed at the end of the start tag, in an insert-attribute position.

**Surround with ‘[tag]’** (*Ctrl + ForwardSlash (Command + ForwardSlash on OS X)*)

Surround the selected content with the last tag used.

**Rename Element**

The element from the cursor position, and any elements with the same name, can be renamed according with the options from the **Rename** dialog box.

**Delete Element Tags**

Deletes the tags of the closest element that contains the position of the cursor. This operation is also executed if the start or end tags of an element are deleted by pressing the **Delete** or **Backspace** keys.

**Remove All Markup**

Removes all the XML markup inside the selected block of content and keeps only the text content.

**Remove Text**

Removes the text content of the selected block of content and keeps the markup intact with empty elements.

**Attributes Refactoring Actions**

Contains built-in XML refactoring operations that pertain to attributes with some of the information preconfigured based upon the current context.

**Add/Change attribute**

Allows you to change the value of an attribute or insert a new one.

**Convert attribute to element**

Allows you to change an attribute into an element.

**Delete attribute**

Allows you to remove one or more attributes.

**Rename attribute**

Allows you to rename an attribute.

**Replace in attribute value**

Allows you to search for a text fragment inside an attribute value and change the fragment to a new value.
Comments Refactoring Actions
Contains built-in XML refactoring operations that pertain to comments with some of the information preconfigured based upon the current context.

Delete comments
Allows you to delete comments found inside one or more elements.

Elements Refactoring Actions
Contains built-in XML refactoring operations that pertain to elements with some of the information preconfigured based upon the current context.

Delete element
Allows you to delete elements.

Delete element content
Allows you to delete the content of elements.

Insert element
Allows you to insert new elements.

Rename element
Allows you to rename elements.

Unwrap element
Allows you to remove the surrounding tags of elements, while keeping the content unchanged.

Wrap element
Allows you to surround elements with element tags.

Wrap element content
Allows you to surround the content of elements with element tags.

Fragments Refactoring Actions
Contains built-in XML refactoring operations that pertain to XML fragments with some of the information preconfigured based upon the current context.

Insert XML fragment
Allows you to insert an XML fragment.

Replace element content with XML fragment
Allows you to replace the content of elements with an XML fragment.

Replace element with XML fragment
Allows you to replace elements with an XML fragment.

Review submenu
This submenu includes the following actions:
Track Changes

Enables or disables the Track Changes (on page 2971) support for the current document.

Accept Change(s) and Move to Next

Accepts the Tracked Change (on page 2971) located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a deletion or insertion change, only the selected content is accepted.

Accept All Changes

Accepts all Tracked Changes (on page 2971) in the current document.

Reject Change(s) and Move to Next

Rejects the Tracked Change (on page 2971) located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a deletion or insertion change, only the selected content is rejected.

Reject All Changes

Rejects all Tracked Changes (on page 2971) in the current document.

Comment Change

Opens a dialog box that allows you to add a comment to an existing Tracked Change (on page 2971). The comment will appear in a callout and a tooltip when hovering over the change. If the action is selected on an existing commented change, the dialog box will allow you to edit the comment.

Highlight

Enables the highlighting tool that allows you to mark text in your document.

Colors

Allows you to select the color for highlighting text.

Stop highlighting

Use this action to deactivate the highlighting tool.

Remove highlight(s)

Use this action to remove highlighting from the document.

Add Comment

Inserts a comment at the cursor position. The comment appears in a callout box and a tooltip (when hovering over the change).

Show/Edit Comment

Opens a dialog box that displays the discussion thread and allows the current user to edit comments that do not have replies. If you are not the author who
inserted the original comment, the dialog box just displays the comment without
the possibility of editing it.

Remove Comment

Removes a selected comment. If you remove a comment that contains replies, all
of the replies will also be removed.

Manage Reviews

Opens the Review view (on page 619).

Folding submenu

This submenu includes the following actions:

- **Toggle Fold**
  Toggles the state of the current fold.

- **Collapse Other Folds** (Ctrl + NumPad/ Command + NumPad/ on OS X)
  Folds all the elements except the current element.

- **Collapse Child Folds** (Ctrl + NumPad. Command + NumPad. on OS X)
  Folds the elements indented with one level inside the current element.

- **Expand Child Folds**
  Unfolds all child elements of the currently selected element.

- **Expand All** (Ctrl + NumPad* Command + NumPad* on OS X)
  Unfolds all elements in the current document.

About Element > Go to Definition

Moves the cursor to the definition of the current element.

Inspect Styles

Opens the CSS Inspector view (on page 597) that allows you to examine the CSS rules that
match the currently selected element.

Options

Opens the Author mode preferences page (on page 148) where you can configure various
options with regard to the Author editing mode.

TEI ODD Drag/Drop Actions

Dragging a file from the Project view (on page 368) and dropping it into a TEI ODD document that is edited
in Author mode, creates a link to the dragged file (the &lt;ptr&gt; element with the @target attribute) at the drop
location.
jTEI Document Type (Framework)

The jTEI (Journal of the Text Encoding Initiative) document type is a highly restrictive customization (only about 80 elements are included) of the TEI P5 framework.

File Definition

A file is considered to be a jTEI document when the root element is named TEI, it is in the namespace http://www.tei-c.org/ns/1.0, and the @rend attribute is set to "jTEI".

Default Document Templates

There is a default jTEI Article template available when creating new documents from templates (on page 335) and they can be found in: Framework Templates > TEI JTEI.

The default template is located in the \[OXYGEN_INSTALL_DIR\]/frameworks/tei/templates/TEI jTEI folder.

Default Schema for Validation and Content Completion

The default schema that is used if one is not detected is tei_jtei.rng and it is stored in \[OXYGEN_INSTALL_DIR\]/frameworks/tei/xml/tei/custom/schema/relaxng/.

Default CSS

The default CSS file (jtei.css) that is used for rendering jTEI in Author mode is stored in \[OXYGEN_INSTALL_DIR\]/frameworks/tei/xml/tei/css/.

By default, these default CSS files are merged with any that are specified in the document. For more information, see Configuring and Managing Multiple CSS Styles for a Framework (on page 1998).

Default XML Catalogs

The default XML Catalogs (on page 2972) for jTEI are as follows:

- \[OXYGEN_INSTALL_DIR\]/frameworks/tei/xml/tei/schema/dtd/catalog.xml
- \[OXYGEN_INSTALL_DIR\]/frameworks/tei/xml/tei/custom/schema/dtd/catalog.xml
- \[OXYGEN_INSTALL_DIR\]/frameworks/tei/xml/tei/stylesheet/catalog.xml
Transformation Scenarios

Oxygen XML Editor includes built-in transformation scenarios that allow you to transform jTEI documents to PDF and ODT. They can be found in the TEI JTEI section in the Configure Transformation Scenario(s) dialog box (on page 1443).

Related Information:
- Editing XML Documents in Author Mode (on page 547)
- Editing XML Documents in Text Mode (on page 476)
- Adding Tables in TEI Documents (on page 667)

JATS Document Type (Framework)

The JATS (NISO Journal Article Tag Suite) document type is a technical standard that defines an XML format for scientific literature.

File Definition

A file is considered to be a JATS document when the PUBLIC ID of the document contains the string -//NLM//DTD.

Default Document Templates

There are some default JATS templates available when creating new documents from templates (on page 335) and they can be found in: Framework Templates > JATSKit - NISO JATS and NLM BITS

The default templates for JATS documents are located in the [OXYGEN_INSTALL_DIR]/frameworks/jats/templates/ folder.

Default Schema for Validation and Content Completion

Default schemas that are used if one is not detected in the JATS document are stored in [OXYGEN_INSTALL_DIR]/frameworks/jats/lib/schemas/.

Default CSS

The default CSS files used for rendering JATS content in Author mode are stored in [OXYGEN_INSTALL_DIR]/frameworks/jats/lib/author-css/.

By default, these default CSS files are merged with any that are specified in the document. For more information, see Configuring and Managing Multiple CSS Styles for a Framework (on page 1998).
Default XML Catalog
The default XML Catalog (on page 2972), jatskit-catalog.xml, is stored in `{OXYGEN_INSTALL_DIR}/frameworks/jats/lib/schemas/`.

Transformation Scenarios
Oxygen XML Editor includes built-in transformation scenarios that allow you to transform JATS documents to a variety of outputs, such as PDF, HTML, and EPUB. They can be found in the JATSKit section in the Configure Transformation Scenario(s) dialog box (on page 1443).

Related Information:
- Editing XML Documents in Author Mode (on page 547)
- Editing XML Documents in Text Mode (on page 476)

JATS Author Mode Actions
A variety of actions are available for JATS documents that can be found in JATS menu, toolbar, contextual menu, and the Content Completion Assistant (on page 2965).

JATS Toolbar Actions
The following default actions are available on the JATS toolbar when editing in Author mode (by default, they are also available in the JATS menu and in various submenus of the contextual menu):

Paragraph Level Drop-Down Menu

- Insert Paragraph
  Insert a new paragraph element at current cursor position.

- Insert Unordered List
  Inserts an unordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an unordered list.

- Insert Ordered List
  Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

- Boxed Text
  Inserts or wraps content in a box with a shaded background.
**Code**

Inserts or wraps content in a `<code>` element.

**Display Quote**

Inserts or wraps content in a `<disp-quote>` element.

**Figure**

Inserts a `<fig>` element with a `<title>` (inside a `<caption>` element). This action opens a dialog box that allows you to enter the text for the title for the figure.

**Graphic Figure**

Inserts a `<fig>` element with a `<title>` (inside a `<caption>` element), and a `<graphic>` element. A dialog box is displayed that allows you to enter the title for the figure, followed by a dialog box that allows you to select the URL of the graphic to be inserted.

**Bold**

Surrounds the selected text with a `<bold>` tag. You can use this action on multiple non-contiguous selections.

**Italic**

Surrounds the selected text with an `<italic>` tag. You can use this action on multiple non-contiguous selections.

**Underline**

Surrounds the selected text with an `<underline>` tag. You can use this action on multiple non-contiguous selections.

**Monospace**

Inserts or wraps content with a `<monospace>` element.

**Insert Table**

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content, text plus markup, that is rendered inside a block element (on page 2964)) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

**Note:**

If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that **Only lists, paragraphs, or inline content can be converted to tables.**
Insert Row
Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

Delete Row(s)
Deletes the table row located at the cursor position or multiple rows in a selection.

Insert Column
Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

Delete Column(s)
Deletes the table column located at the cursor position or multiple columns in a selection.

Join Cells
Joins the content of the selected cells (both horizontally and vertically).

Split Cell
Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

Insert Image
Inserts an image reference (on page 672) at the cursor position. Depending on the current location, an image-type element is inserted.

Insert List Item
Inserts a list item in the current list type.

Insert MathML
Opens the XML Fragment Editor that allows you to insert and edit MathML notations (on page 703).

Subscript
Surrounds the selected text with a subscript tag, used for inserting a character (number, letter, or symbol) that will appear slightly below the baseline and slightly smaller than the rest of the text.

Superscript
Surrounds the selected text with a superscript tag, used for inserting a character (number, letter, or symbol) that will appear slightly above the baseline and slightly smaller than the rest of the text.

JATS Contextual Menu Actions
The following actions are available in the contextual menu when editing in Author mode (most of them are also available in the JATS menu at the top of the interface):
Add File to Review Task

This action can be used to add the current document to a task in the Content Fusion Tasks Manager view. Oxygen Content Fusion is a flexible, intuitive collaboration platform designed to adapt to any type of documentation review workflow. This functionality is available through a pre-installed connector add-on (on page 2353). To fully take advantage of all of the benefits and features of Content Fusion, your organization will need an Oxygen Content Fusion Enterprise Server. For more information, see the Oxygen Content Fusion website.

Edit Attributes

Displays an in-place attributes editor (on page 586) that allows you to manage the attributes of an element.

Edit Profiling Attributes

Allows you to change the profiling attributes (on page 623) defined on all selected elements.

Cut (Ctrl + X (Command + X on OS X))

Removes the currently selected content from the document and places it in the clipboard.

Copy (Ctrl + C (Command + C on OS X))

Places a copy of the currently selected content in the clipboard.

Paste (Ctrl + V (Command + V on OS X))

Inserts the current clipboard content into the document at the cursor position.

Image Map Editor

This action is available in the contextual menu when it is invoked on an image. This action applies an image map to the current image (if one does not already exist) and opens the Image Map Editor dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

Boxed Text

Inserts or wraps content in a box with a shaded background.

Insert submenu

This submenu includes the following insert actions:

Figure

Inserts a fig element with a title (inside a caption element). This action opens a dialog box that allows you to enter the text for the title for the figure.

Graphic Figure

Inserts a fig element with a title (inside a caption element), and a graphic element. A dialog box is displayed that allows you to enter the title for the figure, followed by a dialog box that allows you to select the URL of the graphic to be inserted.
Display Quote
Inserts or wraps content in a `<disp-quote>` element.

Insert Paragraph
Inserts a new `paragraph` element at current cursor position.

Insert Image
Inserts an image reference (on page 672) at the cursor position. Depending on the current location, an image-type element is inserted.

Insert Entity
Allows you to insert a predefined entity or character entity. Surrogate character entities (range #x10000 to #x10FFFF) are also accepted. Character entities can be entered in one of the following forms:

- `#<decimal value>` - e.g. #65
- `&#<decimal value>` - e.g. &#65
- `#x<hexadecimal value>` - e.g. #x41
- `&#x<hexadecimal value>` - e.g. &#x41

Style submenu
This submenu includes the following text styling actions:

Monospace
Inserts or wraps content with a `<monospace>` element.

Bold
Emphasizes the selected text by surrounding it with a `bold` tag. You can use this action on multiple non-contiguous selections.

Italic
Emphasizes the selected text by surrounding it with an `italic` tag. You can use this action on multiple non-contiguous selections.

Underline
Emphasizes the selected text by surrounding it with an `underline` tag. You can use this action on multiple non-contiguous selections.

List > Insert Unordered List
Inserts an unordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an unordered list.

List > Insert Ordered List
Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

Code

Inserts or wraps content in a `<code>` element.

Select submenu

This submenu allows you to select the following:

Element

Selects the entire element at the current cursor position.

Content

Selects the entire content of the element at the current cursor position, excluding the start and end tag. Performing this action repeatedly will result in the selection of the content of the ancestor of the currently selected element content.

Parent

Selects the entire parent element at the current cursor position.

Text submenu

This submenu contains the following actions:

To Lower Case

Converts the selected content to lower case characters.

To Upper Case

Converts the selected content to upper case characters.

Capitalize Sentences

Converts to upper case the first character of every selected sentence.

Capitalize Words

Converts to upper case the first character of every selected word.

Count Words

Counts the number of words and characters (no spaces) in the entire document or in the selection for regular content and read-only content.

Note:

The content marked as deleted with change tracking (on page 2971) is ignored when counting words.

Convert Hexadecimal Sequence to Character (Ctrl + Shift + X (Command + Shift + X on OS X))
Converts a sequence of hexadecimal characters to the corresponding Unicode character (on page 427). The action can be invoked if there is a selection containing a valid hexadecimal sequence or if the cursor is placed at the right side of a valid hexadecimal sequence. A valid hexadecimal sequence can be composed of 2 to 4 hexadecimal characters and may or may not be preceded by the 0x or 0X prefix. Examples of valid sequences and the characters they will be converted to:

- 0x0045 will be converted to E
- 0x0125 to ĥ
- 265 to ɥ
- 2190 to ←

**Note:**
For more information about finding the hexadecimal value of a character, see Finding the Decimal, Hexadecimal, or Character Entity Equivalent (on page 430).

**Refactoring submenu**

Contains a series of actions designed to alter the XML structure of the document:

- ** первой** Some action
  Encloses the currently selected text in an XML comment, or removes the comment if it is commented.

- **Move Up (Alt + UpArrow)**
  Moves the current node or selected nodes in front of the previous node.

- **Move Down (Alt + DownArrow)**
  Moves the current node or selected nodes after the subsequent node.

- ** вторая** Some action
  Splits the content of the closest element that contains the position of the cursor. Thus, if the cursor is positioned at the beginning or at the end of the element, the newly created sibling will be empty.

- **Join Elements**
  Joins two adjacent block elements (on page 2964) that have the same name. The action is available only when the cursor position is between the two adjacent block elements. Also, joining two block elements can be done by pressing the Delete or Backspace keys and the cursor is positioned between the boundaries of these two elements.

- **Surround with Tags (Ctrl + E (Command + E on OS X))**
Allows you to choose a tag to enclose a selected portion of content. If there is no selection, the start and end tags are inserted at the cursor position.

- If the Position cursor between tags option (on page 183) is selected in the Content Completion preferences page, the cursor is placed between the start and end tag.
- If the Position cursor between tags option (on page 183) is not selected in the Content Completion preferences page, the cursor is placed at the end of the start tag, in an insert-attribute position.

Surround with ‘[tag]’ (Ctrl + ForwardSlash (Command + ForwardSlash on OS X))

Surround the selected content with the last tag used.

Rename Element

The element from the cursor position, and any elements with the same name, can be renamed according with the options from the Rename dialog box.

Delete Element Tags

Deletes the tags of the closest element that contains the position of the cursor. This operation is also executed if the start or end tags of an element are deleted by pressing the Delete or Backspace keys.

Remove All Markup

Removes all the XML markup inside the selected block of content and keeps only the text content.

Remove Text

Removes the text content of the selected block of content and keeps the markup intact with empty elements.

Attributes Refactoring Actions

Contains built-in XML refactoring operations that pertain to attributes with some of the information preconfigured based upon the current context.

Add/Change attribute

Allows you to change the value of an attribute or insert a new one.

Convert attribute to element

Allows you to change an attribute into an element.

Delete attribute

Allows you to remove one or more attributes.

Rename attribute

Allows you to rename an attribute.
Replace in attribute value

Allows you to search for a text fragment inside an attribute value and change the fragment to a new value.

Comments Refactoring Actions

Contains built-in XML refactoring operations that pertain to comments with some of the information preconfigured based upon the current context.

Delete comments

Allows you to delete comments found inside one or more elements.

Elements Refactoring Actions

Contains built-in XML refactoring operations that pertain to elements with some of the information preconfigured based upon the current context.

Delete element

Allows you to delete elements.

Delete element content

Allows you to delete the content of elements.

Insert element

Allows you to insert new elements.

Rename element

Allows you to rename elements.

Unwrap element

Allows you to remove the surrounding tags of elements, while keeping the content unchanged.

Wrap element

Allows you to surround elements with element tags.

Wrap element content

Allows you to surround the content of elements with element tags.

Fragments Refactoring Actions

Contains built-in XML refactoring operations that pertain to XML fragments with some of the information preconfigured based upon the current context.

Insert XML fragment

Allows you to insert an XML fragment.

Replace element content with XML fragment

Allows you to replace the content of elements with an XML fragment.

Replace element with XML fragment
Allows you to replace elements with an XML fragment.

Review submenu

This submenu includes the following actions:

- **Track Changes**
  Enables or disables the Track Changes (on page 2971) support for the current document.

- **Accept Change(s) and Move to Next**
  Accepts the Tracked Change (on page 2971) located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a deletion or insertion change, only the selected content is accepted.

- **Accept All Changes**
  Accepts all Tracked Changes (on page 2971) in the current document.

- **Reject Change(s) and Move to Next**
  Rejects the Tracked Change (on page 2971) located at the cursor position or all of the changes in a selection and then moves to the next change. If you select a part of a deletion or insertion change, only the selected content is rejected.

- **Reject All Changes**
  Rejects all Tracked Changes (on page 2971) in the current document.

- **Comment Change**
  Opens a dialog box that allows you to add a comment to an existing Tracked Change (on page 2971). The comment will appear in a callout and a tooltip when hovering over the change. If the action is selected on an existing commented change, the dialog box will allow you to edit the comment.

- **Highlight**
  Enables the highlighting tool that allows you to mark text in your document.

  **Colors**
  Allows you to select the color for highlighting text.

  **Stop highlighting**
  Use this action to deactivate the highlighting tool.

  **Remove highlight(s)**
  Use this action to remove highlighting from the document.

- **Add Comment**
  Inserts a comment at the cursor position. The comment appears in a callout box and a tooltip (when hovering over the change).
Show/Edit Comment

Opens a dialog box that displays the discussion thread and allows the current user to edit comments that do not have replies. If you are not the author who inserted the original comment, the dialog box just displays the comment without the possibility of editing it.

Remove Comment

Removes a selected comment. If you remove a comment that contains replies, all of the replies will also be removed.

Manage Reviews

Opens the Review view (on page 619).

Folding submenu

This submenu includes the following actions:

- **Toggle Fold**
  Toggles the state of the current fold.

- **Collapse Other Folds (Ctrl + NumPad/ (Command + NumPad/ on OS X))**
  Folds all the elements except the current element.

- **Collapse Child Folds (Ctrl + NumPad. (Command + NumPad. on OS X))**
  Folds the elements indented with one level inside the current element.

- **Expand Child Folds**
  Unfolds all child elements of the currently selected element.

- **Expand All (Ctrl + NumPad* (Command + NumPad* on OS X))**
  Unfolds all elements in the current document.

About Element > Go to Definition

Moves the cursor to the definition of the current element.

Inspect Styles

Opens the CSS Inspector view (on page 597) that allows you to examine the CSS rules that match the currently selected element.

Options

Opens the Author mode preferences page (on page 148) where you can configure various options with regard to the Author editing mode.

JATS Drag/Drop Actions

Dragging a file from the Project view (on page 368) and dropping it into a JATS document that is edited in Author mode, creates a link to the dragged file (the `ext-link` element with the `@xlink:href` attribute) at the drop location. Dragging an image file from the default file system application (Windows Explorer on Windows
or Finder on macOS, for example) and dropping it into a JATS document inserts an image element (the `<inline-graphic>` element with the `@xlink:href` attribute) at the drop location, similar to the Insert Image toolbar action.

**Tip:**
For information about customizing Author mode actions for a particular framework (document type), see the Customizing the Author Editing Experience for a Framework section.

Related Information:
Customizing the Author Editing Experience for a Framework

### EPUB Document Type (Framework)

**EPUB** is an e-book file format that is a ZIP archive and can be downloaded and read on devices such as phones, tablets, computers, or e-readers. Oxygen XML Editor includes an Archive Browser view that allows you to view the contents and structure of this type of file.

Three distinct frameworks are supported for the EPUB document type:

- **NCX** - A declarative global navigation definition.
- **OCF** - The Open Container Format (OCF) defines a mechanism by which all components of an Open Publication Structure (OPS) can be combined into a single file system entity.
- **OPF** - The Open Packaging Format (OPF) defines the mechanism by which all components of a published work that conforms to the Open Publication Structure (OPS) standard (including metadata, reading order, and navigational information) are packaged in an OPS Publication.

**Note:**
Oxygen XML Editor supports OPF 2.0, OPF 3.0, and OPF 3.1.

### File Definition

A file is considered to be an EPUB document if it has a file extension of `.epub`.

### Default Document Templates

There are a variety of default EPUB templates available when creating new documents from templates and they can be found the following folders in Framework Templates: NCX, OCF, OPF 2.0, OPF 3.0, and OPF 3.1.

- The default templates for the NCX document types are located in the `[OXYGEN_INSTALL_DIR]/frameworks/ncx/templates` folder.
- The default templates for the OCF document types are located in the `[OXYGEN_INSTALL_DIR]/frameworks/ocf/templates` folder.
• The default template for the OPF 2.0 document type is located in the \[OXYGEN_INSTALL_DIR]/frameworks/opf/templates/2.0 folder.
• The default template for the OPF 3.0 document type is located in the \[OXYGEN_INSTALL_DIR]/frameworks/opf/templates/3.0 folder.
• The default template for the OPF 3.1 document type is located in the \[OXYGEN_INSTALL_DIR]/frameworks/opf/templates/3.1 folder.

Default Schema
The default schema files for the various types of EPUB document types are located in the following directories:

• The default schema files for the NCX document types are located in the \[OXYGEN_INSTALL_DIR]/frameworks/ncx/schemas folder.
• The default schema files for the OCF document types are located in the \[OXYGEN_INSTALL_DIR]/frameworks/ocf/schemas folder.
• The default schema files for the OPF 2.0 document type is located in the \[OXYGEN_INSTALL_DIR]/frameworks/opf/schemas/2.0 folder.
• The default schema files for the OPF 3.0 document type is located in the \[OXYGEN_INSTALL_DIR]/frameworks/opf/schemas/3.0 folder.
• The default schema files for the OPF 3.1 document type is located in the \[OXYGEN_INSTALL_DIR]/frameworks/opf/schemas/3.1 folder.

Related Information:
Working with Archive Files (on page 1864)

Other Supported Document Types
Along with the fully supported built-in frameworks (document types) (on page 1192), Oxygen XML Editor also provides limited support (including document templates) for editing a variety of other document types. All the specialized views, editors, actions, and options are dynamic according to the type of file that is opened or created. Other document types that are supported in Oxygen XML Editor include:

• EPUB (NCX, OCF, OPF 2.0, 3.0, & 3.1) (on page 1325) - A standard for e-book files.
• OOXML (on page 1864) - An XML-based file format for representing spreadsheets, charts, presentations, and word processing documents.
• ODF (on page 1864) - An free and open-source XML-based file format for electronic office documents, such as spreadsheets, charts, presentations, and word processing documents.
• DocBook Targetset (on page 1236) - For resolving cross-references when using olinks.
• Ant Build Scripts (on page 870) - A tool for automating software build processes, written in Java and primarily intended for use with Java.
• XSLT Stylesheets (on page 824) - A document type that provides a visual mode for editing XSLT stylesheets.
• **WSDL** *(on page 985)* - Web Services Description Language is an XML language for describing the functionality offered by a web service.

• **Schematron** *(on page 1099)* - For making assertions about the presence or absence of patterns in XML documents. This document type applies to the ISO Schematron version.

• **Schematron Quick Fixes (SQF) (on page 758)** - An extension of the ISO standard Schematron, allows developers to define *Quick Fixes (on page 2970)* for Schematron errors.

• **StratML (Part 1 & 2) (on page 1091)** - Part 1 and 2 of the Strategy Markup Language specification.

• **XProc (on page 1097)** - A document type for processing XProc script files.

• **XML Schema (on page 883)** - Documents that provide support for editing annotations.

• **SVG (on page 1154)** - Scalable Vector Graphics is a language for describing two-dimensional graphics in XML.

• **MathML (on page 703)** - Mathematical Markup Language (2.0 and 3.0) is an application of XML for describing mathematical notations.

• **XLIFF (1.2, 2.0, 2.1) (on page 1091)** - XML Localization Interchange File Format is a standard for passing data between tools during a localization process.

• **XQuery (on page 968)** - The common query language for XML.

• **CSS (on page 1010)** - Cascading Style Sheets is a language used for describing the look and formatting of a document.

• **LESS (on page 1014)** - A dynamic style sheet language that can be compiled into CSS.

• **Relax NG Schema (on page 1017)** - A schema language that specifies a pattern for the structure and content of an XML document.

• **NVDL Schema (on page 1036)** - Namespace Validation Dispatching Language allows you to specify sections of XML documents to be validated against various schemas.

• **JSON (on page 1044)** - JavaScript Object Notation is a lightweight data-interchange format.

• **Markdown (on page 1165)** - A lightweight markup language with plain text formatting syntax that can be converted to HTML or DITA.

• **JavaScript (on page 1092)** - Programming language of HTML and the Web.

• **XMLSpec** - A markup language for W3C specifications and other technical reports.

• **DIATAVAL** - DITA conditional processing profile to identify the values you want to conditionally process for a particular output, build, or other purpose.

• **Daisy XML** - A technical standard for digital audio books, periodicals, and computerized text. It is designed to be an audio substitute for print material.

• **EAD** - Encoded Archival Description is an XML standard for encoding archival finding aids.

• **KML** - Keyhole Markup Language is an XML notation for expressing geographic visualization in maps and browsers.

• **Maven Project & Settings** - Project or settings file for Maven build automation tool that is primarily used for Java projects.

• **Oasis XML Catalog** - An *XML Catalog (on page 2972)* document that describes a mapping between external entity references and locally-cached equivalents.

• **Other Non-XML Files (on page 363)** - Oxygen XML Editor also includes a simple text editor and a variety of helpful features for creating and editing non-XML files.
10. Additional XML Editing Frameworks (Document Types)

Oxygen XML Editor supports custom frameworks (document types) contributed by the XML community (for example, the S1000D framework). They provide support for additional functionality and XML vocabularies.

Similar to the built-in frameworks, the additional frameworks may define:

- A default grammar used for validation and content completion in both Author mode and Text mode.
- CSS stylesheets for rendering XML documents in Author mode.
- User actions invoked from toolbars or menus in Author mode.
- Built-in transformation scenarios used for publishing XML documents.
- XML Catalogs used for mapping resources.
- New document templates to make it easy to create XML documents.
- User-defined extensions for customizing the interaction with the content author in Author mode.

S1000D Document Type (Framework)

S1000D is an international specification for the procurement and production of technical publications (mainly used in aerospace and aviation industries). It is an XML-based specification for preparing, managing, and using equipment maintenance and operations information.

S1000D is articulated based on three main notions:

- **Data Module** - It is an XML file that defines a standalone information unit.
- **Data Module Structure** - It defines how a Data Module is divided:
  - The Identification and Status part that identifies the Data Module within the CSDB structure.
  - The Content part that is the detailed information of the Data Module.
- **Common Source DataBase (CSDB)** - It defines how the Data Modules are arranged inside a publication.

Oxygen XML Editor does not have default built-in support for S1000D, but a company called Amplexor has developed a framework that can be installed in Oxygen XML Editor to add support for S1000D documents.

To install the framework in Oxygen XML Editor, follow these steps:
1. Download or clone the framework on GitHub and install it as an additional framework (on page 113).
2. Download the S1000D specifications package that contains samples and schemas at S1000D Downloads.
3. Copy the XML Schema files from [ZIP]\XML Schema Package\xml_schema_flat into the corresponding version of the xml_schema_flat folder.

**Note:**
To display the CGM images, you have to install the CGM Image Support Add-on (on page 2352).

If you want more advanced S1000D editing features, you can ask some of our partners:

- Amplexor
- Dakota Systems
- 4D Concept (also sells a S1000D commercial solution)

**OpenAPI (Swagger) Document Type (Framework)**

The OpenAPI specification is a community-driven open specification that defines a standard, programming language-agnostic interface description for HTTP APIs, which allows both humans and computers to discover and understand the capabilities of a service without requiring access to source code, additional documentation, or inspection of network traffic. Use cases for machine-readable API definition documents include interactive documentation, code generation for documentation, automation of test cases, and more. OpenAPI documents describe an APIs services and are represented in either YAML or JSON formats.

In Oxygen XML Editor, you can, of course, edit OpenAPI documents in Text mode, but Oxygen XML Editor also includes a built-in framework that renders OpenAPI (Swagger) documents in the Author visual editing mode. The framework is an extension of the JSON framework. When opening a detected OpenAPI document in Author mode, you will have access to some form controls, collapsible sections, and other features to help you visualize and edit these documents.

**Tip:**
There is an OpenAPI sample document named petsore.json located in [OXYGEN-INSTALL-DIR]/samples/json/openapi that you can use to see how these documents are rendered in Oxygen XML Editor.

For more details about the OpenAPI Specification, along with example documents, go to https://github.com/OAI/OpenAPI-Specification.
11. Publishing

XML documents can be transformed into a variety of user-friendly output formats that can be viewed by end-users. This process is known as a transformation.

Oxygen XML Editor includes numerous built-in transformation possibilities to publish XML content in various output formats (such as WebHelp, PDF, CHM, EPUB, JavaHelp, Eclipse Help, XHTML, etc.)

For transformations that are not included in your installed version of Oxygen XML Editor, simply install the tool chain required to perform the specific transformation and process the files in accordance with the processor instructions. A multitude of target formats are possible. The basic condition for a transformation to any format is that your source document is well-formed.

Transformation Scenarios

A transformation scenario is a set of complex operations and settings that gives you the possibility to obtain outputs of multiple types (XML, HTML, PDF, EPUB, etc.) from the same source of XML files and stylesheets.

Note:

You need to use the appropriate stylesheet according to the source definition and the desired output. For example, if you want to transform into an HTML format using a DocBook stylesheet, your source XML document should conform with the DocBook DTD.

Executing a transformation scenario implies multiple actions, such as:

- Validating the input file.
- Obtaining intermediate output files (for example, formatting objects for the XML to PDF transformation).
- Using transformation engines to produce the output.

Before transforming an XML document in Oxygen XML Editor, you need to define a transformation scenario to apply to that document. A scenario is a set of values for various parameters that define a transformation. It is not related to a particular document, but rather to a document type. Oxygen XML Editor includes preconfigured built-in transformation scenarios (on page 1331), but you can also create new transformation scenarios (on page 1361).

When creating new transformation scenarios, the types that are available include:
• **Scenarios that Apply to XML Files** - This type of scenario contains the location of an XSLT stylesheet that is applied on the edited XML document, as well as other transformation parameters. For more information, see XML Transformation with XSLT (on page 1361) and XML Transformation with XQuery (on page 1377).

• **Scenarios that Apply to XSLT Files** - This type of scenario contains the location of an XML document that the edited XSLT stylesheet is applied to, as well as other transform parameters. For more information, see XSLT Transformation (on page 1406).

• **Scenarios that Apply to XQuery Files** - This type of scenario contains the location of an XML source, that the edited XQuery file is applied to, as well as other transform parameters. When the XML source is a native XML database, the XML source field of the scenario is empty because the XML data is read with XQuery-specific functions, such as `document()`. When the XML source is a local XML file, the URL of the file is specified in the XML input field of the scenario. For more information, see XQuery Transformation (on page 1431).

• **Scenarios that Apply to SQL Files** - This type of scenario specifies a database connection for the database server that runs the SQL file that is associated with the scenario. The data processed by the SQL script is located in the database.

• **Scenarios that Apply to XProc Files** - This type of scenario contains the location of an XProc script, as well as other transform parameters. For more information, see SQL Transformation (on page 1439).

• **DITA-OT Scenarios** - This type of scenario provides the parameters for an Ant transformation that executes a DITA-OT build script. Oxygen XML Editor includes a built-in version of Ant and a built-in version of DITA-OT, although you can also set other versions in the scenario. For more information, see DITA-OT Transformation (on page 1387).

• **ANT Scenarios** - This type of scenario contains the location of an Ant build script, as well as other transform parameters. For more information, see Ant Transformation (on page 1402).

---

**Note:**

Status messages generated during the transformation process are displayed in the **Information view (on page 471).**

---

**Built-in Transformation Scenarios**

Oxygen XML Editor includes preconfigured built-in transformation scenarios that are used for common transformations. They can be found in the various sections in the **Configure Transformation Scenario(s) dialog box (on page 1443)** or **Transformation Scenarios view (on page 1450).** All the built-in document types (frameworks) (on page 2967) that are included in Oxygen XML Editor have various transformation scenarios in their specific sections, including the most popular frameworks, such as DITA, DocBook, TEI, XHTML, JATS, OOXML, and more.

To obtain the desired output, use one of the following actions from the toolbar or **Transform** submenu in the contextual menu of the **Project view (on page 368):**
Apply Transformation Scenario(s) (Ctrl + Shift + T (Command + Shift + T on OS X)) - If you have associated transformation scenarios for the current document, this action will simply apply the association (on page 1442) and begin the transformation process. If an association is not detected, this action will open the Configure Transformation Scenario(s) dialog box (on page 1443) where you can choose the scenarios you want to apply.

Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X)) - This action will open the Configure Transformation Scenario(s) dialog box (on page 1443) where you can choose the scenarios you want to apply.

Note:

- You can apply a transformation even if the current document is not associated with a transformation scenario.
- If the document contains an xml-stylesheet processing instruction that references an XSLT stylesheet (commonly used to display the document in web browsers), Oxygen XML Editor prompts you to associate the document with a built-in transformation scenario.
- The default transformation scenario is suggested based on the processing instruction from the edited document.

Related Information:

DITA Map Transformation Scenarios
Built-in transformation scenarios allow you to transform DITA maps (on page 2966) to a variety of outputs, such as WebHelp, PDF, ODF, XHTML, EPUB, CHM, Kindle, and MS Word. Oxygen XML Editor also includes a special Run DITA-OT Integrator (on page 1352) that can be used to integrate a DITA-OT plugin and a DITA Map Metrics Report transformation that generates a statistics report for your DITA map. All of them are listed in the DITA Map section in the Configure Transformation Scenario(s) dialog box (on page 1443).

A variety of transformations scenarios are available for DITA maps (on page 2966):

- Built-in transformation scenarios allow you to transform a DITA map to a variety of outputs, such as WebHelp, PDF, ODF, XHTML, EPUB, CHM, Kindle, and MS Word.
- Run DITA-OT Integrator (on page 1352) - Use this transformation scenario if you want to integrate a DITA-OT plugin (on page 2923). This scenario runs an Ant task that integrates all the plugins from the DITA-OT/plugins directory.
DITA Map Metrics Report - Use this type of transformation scenario if you want to generate a DITA map statistics report. It contains information such as:

- The number of processed maps and topics.
- Content reuse percentage.
- Number of elements, attributes, words, and characters used in the entire DITA map structure.
- DITA conditional processing attributes used in the DITA maps.
- Processing instructions.
- External links.
- All `@outputclass` attribute values gathered from the DITA project.

**Important:**

If you have cross references that point to content outside the scope of the DITA map, that referenced content will not be counted. For example, if you have links to topics that are not included in the DITA map hierarchy, the content in those topics is ignored when generating the statistics.

DITA Map WebHelp Responsive Transformation

DITA content can be transformed into several types of WebHelp Responsive systems (with or without a feedback section). The WebHelp Responsive layout and features (on page 1455) are designed to adapt to any device and screen size to provide an optimal viewing and interaction experience. Oxygen XML Editor also provides numerous possibilities for customizing the WebHelp Responsive output (on page 1534).

WebHelp Responsive Transformation Scenario

To publish a DITA map (on page 2966) as WebHelp Responsive output, follow these steps:

1. Select the Configure Transformation Scenario(s) action from the DITA Maps Manager (on page 2662) toolbar.
2. Select the DITA Map WebHelp Responsive scenario from the DITA Map section.
3. If you want to configure the transformation, click the Edit button.

**Step Result:** This opens an Edit scenario configuration dialog box that allows you to configure various options in the following tabs:
Templates Tab (on page 2867) - This tab contains a set of built-in publishing templates (on page 1497) that you can use for the layout of your WebHelp system output. You can also create your own publishing templates or edit existing ones (on page 1535).

Parameters Tab (on page 2873) - This tab includes numerous parameters that can be set to customize your WebHelp system output. See the Parameters section (on page ) below for details about the most commonly used parameters for WebHelp Responsive transformations.

Feedback Tab (on page 2874) - This tab is for those who want to add the Oxygen Feedback comments component at the bottom of each WebHelp page so that you can interact with your readers.

Filters Tab (on page 2875) - This tab allows you to filter certain content elements from the generated output.

Advanced Tab (on page 2876) - This tab allows you to specify some advanced options for the transformation scenario.

Output Tab (on page 2878) - This tab allows you to configure options that are related to the location where the output is generated.

4. Click **Apply associated** to process the transformation.

**Result:** When the DITA Map WebHelp Responsive transformation is complete, the output is automatically opened in your default browser.

**General Parameters for Customizing WebHelp Responsive Output**

To customize a transformation scenario, you can edit various parameters, including the following most commonly used ones:

- **default.language**
  
  This parameter is used if the language is not detected in the DITA map. The default value is en-us.

- **clean.output**
  
  Deletes all files from the output folder before the transformation is performed (only no and yes values are valid and the default value is no).

- **editlink.remote.ditamap.url**
  
  Use this parameter in conjunction with editlink.web.author.url to add an Edit link next to the topic title in the WebHelp output. When a user clicks the link, the topic is opened in Oxygen XML Web Author where they can make changes that can be saved to a file server. The value should be set as the custom URL of the main DITA map. For example, a GitHub custom URL might look like this: https://getFileContent/oxyengxml/userguide/master/UserGuide.ditamap.

- **editlink.web.author.url**
  
  This parameter needs to be used in conjunction with editlink.remote.ditamap.url to add an Edit link next to the topic title in the WebHelp output. When a user clicks the link, the topic is opened in Oxygen XML Web Author where they can make changes that can be saved to a file server. The value should be set as the URL of the Web Author installation. For example: https://www.oxygenxml.com/oxygen-xml-web-author/.
editlink.present.only.path.to.topic

When this parameter is set to "true", the DITA topic path is displayed to the right of each topic title in the WebHelp Responsive output. Also, when this parameter is used, the editlink.ditamap.edit.url, editlink.remote.ditamap.url, and editlink.web.author.url parameters are ignored.

fix.external.refs.com.oxygenxml (Only supported when the DITA-OT transformation process is started from Oxygen XML Editor)

The DITA Open Toolkit usually has problems processing references that point to locations outside of the directory of the processed DITA map. This parameter is used to specify whether or not the application should try to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references. The fix has no impact on your edited DITA content. Allowed values: true or false (default).

force.unique

When set to true (default value), the transformation will be forced to create unique output files for each instance of a resource when a map contains multiple references to a single topic.

use.stemming

Controls whether or not you want to include stemming search algorithms into the published output (default setting is false).

webhelp.custom.resources

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

webhelp.favicon

The file path that points to an image to be used as a favicon in the WebHelp output.

webhelp.reload.stylesheet

Set this parameter to true if you have out of memory problems when generating WebHelp. It will increase processing time but decrease the memory footprint. The default value is false.

webhelp.search.custom.excludes.file

The path of the file that contains name patterns for HTML files that should not be indexed by the WebHelp search engine. Each exclude pattern must be on a new line. The patterns are considered to be relative to the output directory, and they accept wildcards such as * (matches zero or more characters) or ? (matches one character). For more information about the patterns, see https://ant.apache.org/manual/dirtasks.html#patterns.

webhelp.search.japanese.dictionary

The file path of the dictionary that will be used by the Kuromoji morphological engine for indexing Japanese content in the WebHelp pages. The encoding for the dictionary must be UTF8.

webhelp.search.enable.pagination
Specifies whether or not search results will be displayed on multiple pages. Allowed values are yes or no.

**webhelp.search.index.elements.to.exclude**

Specifies a list of HTML elements that will not be indexed by the search engine. The value of the @class attribute can be used to exclude specific HTML elements from indexing. For example, the `div.not-indexed` value will not index all `<div>` elements that have a `@class` attribute with the value of `not-indexed`. Use a comma separator to specify more than one element.

**webhelp.search.page.numberOfLines**

Specifies the number of search results items displayed on each page. This parameter is only used when the `webhelp.search.enable.pagination` parameter is enabled.

**webhelp.search.rating**

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the Search tab (default setting is `true`).

**webhelp.search.stop.words.include**

Specifies a list of words that will be ignored by the search engine. Use a comma separator to specify more than one word.

**webhelp.show.changes.and.comments**

When set to `yes`, user comments, replies to comments, and tracked changes are published in the WebHelp output. The default value is `no`.

**webhelp.sitemap.base.url**

Base URL for all the `<loc>` elements in the generated `sitemap.xml` file. The value of a `<loc>` element is computed as the relative file path from the @href attribute of a `<topicref>` element from the DITA map, appended to this base URL value. The `<loc>` element is mandatory in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `sitemap.xml` file is not generated.

**webhelp.sitemap.change.frequencies**

The value of the `<changefreq>` element in the generated `sitemap.xml` file. The `<changefreq>` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `<changefreq>` element is not added in `sitemap.xml`. Allowed values: `<empty string>` (default), `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, `never`.

**webhelp.sitemap.priority**

The value of the `<priority>` element in the generated `sitemap.xml` file. It can be set to any fractional number between 0.0 (least important priority) and 1.0 (most important priority). For example, 0.3, 0.5, or 0.8. The `<priority>` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `<priority>` element is not added in `sitemap.xml`. 
Parameters Specific to Oxygen WebHelp Responsive

**webhelp.fragment.feedback**

You can integrate Oxygen Feedback with your WebHelp Responsive output to provide a comments area at the bottom of each page where readers can offer feedback. When you create an Oxygen Feedback site configuration, an HTML fragment is generated during the final step of the creation process and that fragment should be set as the value for this parameter.

**webhelp.default.collection.type.sequence**

Specifies if the sequence value will be used by default when the @collection-type attribute is not specified. This option is helpful if you want to have Next and Previous navigational buttons generated for all HTML pages. Allowed values are no (default) and yes.

**webhelp.enable.search.autocomplete**

Specifies if the Autocomplete feature is enabled in the WebHelp search text field. The default value is yes.

**webhelp.enable.html.fragments.cleanup**

Enables or disables the automatic conversion of HTML fragments to well-formed XML. If set to true (default), the transformation automatically converts non-well-formed HTML content to a well-formed XML equivalent. If set to false, the transformation will fail if at least one HTML fragment is not well-formed.

**webhelp.fragment.after.body**

This parameter can be used to display a given XHTML fragment after the body in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.body.main.page**

This parameter can be used to display a given XHTML fragment after the body in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.body.topic.page**

This parameter can be used to display a given XHTML fragment after the body in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.body.search.page**

This parameter can be used to display a given XHTML fragment after the body in the search results page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.body.terms.page**
This parameter can be used to display a given XHTML fragment after the body in the index terms page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.logo_and_title

This parameter can be used to display a given XHTML fragment after the logo and title in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.search.input

This parameter can be used to display a given XHTML fragment after the search field in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.search.input.main.page (deprecated)

This parameter is deprecated. Use webhelp.fragment.after.search.input.main.page instead.

webhelp.fragment.after.search.input.main.page

This parameter can be used to display a given XHTML fragment after the search field in all the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.search.input.topic.page

This parameter can be used to display a given XHTML fragment after the search field in all the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.search.input.search.page

This parameter can be used to display a given XHTML fragment after the search field in all the search results page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.search.input.terms.page

This parameter can be used to display a given XHTML fragment after the search field in all the index terms page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.toc_or_tiles

This parameter can be used to display a given XHTML fragment after the table of contents or tiles in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.top_menu

This parameter can be used to display a given XHTML fragment after the top menu in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.
webhelp.fragment.before.body

This parameter can be used to display a given XHTML fragment before the page body in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.body.main.page

This parameter can be used to display a given XHTML fragment before the page body in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.body.topic.page

This parameter can be used to display a given XHTML fragment before the page body in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.body.search.page

This parameter can be used to display a given XHTML fragment before the page body in the search results page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.body.terms.page

This parameter can be used to display a given XHTML fragment before the page body in the index terms page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.logo_and_title

This parameter can be used to display a given XHTML fragment before the logo and title. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.search.input

This parameter can be used to display a given XHTML fragment before the search field in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.main.page.search (deprecated)

This parameter is deprecated. Use webhelp.fragment.before.search.input.main.page instead.

webhelp.fragment.before.search.input.main.page

This parameter can be used to display a given XHTML fragment before the search field in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.search.input.topic.page
This parameter can be used to display a given XHTML fragment before the search field in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.search.input.search.page**

This parameter can be used to display a given XHTML fragment before the search field in the search results page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.search.input.terms.page**

This parameter can be used to display a given XHTML fragment before the search field in the index terms page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.toc_or_tiles**

This parameter can be used to display a given XHTML fragment before the table of contents or tiles in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.top_menu**

This parameter can be used to display a given XHTML fragment before the top menu in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.footer**

This parameter can be used to display a given XHTML fragment as the page footer in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.head**

This parameter can be used to display a given XHTML fragment in the header section in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.head.main.page**

This parameter can be used to display a given XHTML fragment in the header section in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.head.topic.page**

---

**Important:**

This parameter should only be used if you are using a valid, purchased license of Oxygen XML Editor (do not use it with a trial license).
This parameter can be used to display a given XHTML fragment in the header section in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.head.search.page**

This parameter can be used to display a given XHTML fragment in the header section in the search results page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.head.terms.page**

This parameter can be used to display a given XHTML fragment in the header section in the index terms page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.welcome**

This parameter can be used to display a given XHTML fragment as a welcome message (or title). The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.header**

This parameter can be used to display a given XHTML fragment after the header section in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.header.main.page**

This parameter can be used to display a given XHTML fragment after the header section in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.header.topic.page**

This parameter can be used to display a given XHTML fragment after the header section in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.header.search.page**

This parameter can be used to display a given XHTML fragment after the header section in the search results page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.header.terms.page**

This parameter can be used to display a given XHTML fragment after the header section in the index terms page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.search.input**
This parameter can be used to display a given XHTML fragment before the search field in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.search.input**

This parameter can be used to display a given XHTML fragment after the search field in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.main.content.area**

This parameter can be used to display a given XHTML fragment before the main content section in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.main.content.area.main.page**

This parameter can be used to display a given XHTML fragment before the main content section in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.main.content.area.topic.page**

This parameter can be used to display a given XHTML fragment before the main content section in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.main.content.area.search.page**

This parameter can be used to display a given XHTML fragment before the main content section in the search results page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.main.content.area.terms.page**

This parameter can be used to display a given XHTML fragment before the main content section in the index terms page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.main.content.area**

This parameter can be used to display a given XHTML fragment after the main content section in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.main.content.area.main.page**

This parameter can be used to display a given XHTML fragment after the main content section in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.main.content.area.topic.page**
This parameter can be used to display a given XHTML fragment after the main content section in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.topic.toolbar**

This parameter can be used to display a given XHTML fragment before the toolbar buttons above the topic content in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.topic.toolbar**

This parameter can be used to display a given XHTML fragment after the toolbar buttons above the topic content in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.topic.breadcrumb**

This parameter can be used to display a given XHTML fragment before the breadcrumb component in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.topic.breadcrumb**

This parameter can be used to display a given XHTML fragment after the breadcrumb component in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.publication.toc**

This parameter can be used to display a given XHTML fragment before the publication's table of contents component in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.publication.toc**

This parameter can be used to display a given XHTML fragment before the publication's table of contents component in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.topic.content**

This parameter can be used to display a given XHTML fragment before the topic's content in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.topic.content**

This parameter can be used to display a given XHTML fragment after the topic's content in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.feedback**
This parameter can be used to display a given XHTML fragment before the Oxygen Feedback commenting component in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.feedback

This parameter can be used to display a given XHTML fragment after the Oxygen Feedback commenting component in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.topic.toc

This parameter can be used to display a given XHTML fragment before the topic's table of contents component in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.topic.toc

This parameter can be used to display a given XHTML fragment after the topic's table of contents component in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.custom.search.engine.results

This parameter can be used to replace the search results area with custom XHTML content. The value of the parameter is the path to an XHTML file that contains your custom content.

webhelp.fragment.custom.search.engine.script

This parameter can be used to replace WebHelp's built-in search engine with your own custom search engine. The value of the parameter is the path to an XHTML file that contains the scripts required for your custom search engine to run.

webhelp.merge.nested.topics.related.links

Specifies if the related links from nested topics will be merged with the links in the parent topic. Thus the links will be moved from the topic content to the related links component and all of the links from the same group (for example, Related Tasks, Related References, Related Information) are merged into a single group. The default value is yes.

webhelp.search.stop.words.exclude

Specifies a list of words that will be excluded from the default list of stop words that are filtered out before the search processing. Use comma separators to specify more than one word (for example: if, for, is).

webhelp.show.breadcrumb

Specifies if the breadcrumb component will be presented in the output. The default value is yes.

webhelp.show.child.links

Specifies if child links will be generated in the output for all topics that have subtopics. The default value is no.

webhelp.show.indexterms.link
Specifies if an icon that links to the index will be presented in the output. The default value is yes.

**webhelp.show.main.page.tiles**

Specifies if the tiles component will be presented in the main page of the output. For a tree style layout, this parameter should be set to no.

**webhelp.show.main.page.toc**

Specifies if the table of contents will be presented in the main page of the output. The default value is yes.

**webhelp.show.navigation.links**

Specifies if navigation links will be presented in the output. The default value is yes.

**webhelp.show.print.link**

Specifies if a print link or icon will be presented within each topic in the output. The default value is yes.

**webhelp.show.related.links**

Specifies if the related links component will be presented in the WebHelp Responsive output. The default value is yes. The `webhelp.merge.nested.topics.related.links` parameter can be used in conjunction with this one to merge the related links from nested topics into the links in the parent topic.

**webhelp.show.publication.toc**

Specifies if a table of contents will be presented on the left side of each topic in the output. The default value is yes.

**webhelp.show.topic.toc**

Specifies if a topic table of contents will be presented on the right side of each topic in the output. This table of contents contains links to each `<section>` within the current topic that contains an @id attribute and the section corresponding to the current scroll position is highlighted. The default value is yes.

**webhelp.show.top.menu**

Specifies if a menu will be presented at the topic of the main page in the output. The default value is yes.

**webhelp.publication.toc.hide.chunked.topics**

Specifies if the table of contents will contain links for chunked topics. The default value is yes.

**webhelp.publication.toc.links**

Specifies which links will be included in the table of contents. The possible values are:

- **chapter** (default) - The TOC will include links for the current topic, its children, its siblings, and its direct ancestor (including the direct ancestor's siblings), and the parent chapter.
- **topic** - The TOC will only include links for the current topic and its direct children.
- **all** - The TOC will include all links.
webhelp.publication.toc.tooltip.position

By default, if a topic contains a `<shortdesc>` element, its content is displayed in a tooltip when the user hovers over its link in the table of contents. This parameter controls whether or not this tooltip is displayed and its position relative to the link. The possible values are:

- `left` (default)
- `right`
- `top`
- `bottom`
- `hidden` - The tooltip will not be displayed.

webhelp.top.menu.depth

Specifies the maximum depth level of the topics that will be included in the top menu. The default value is 3. A value of 0 means that the menu has unlimited depth.

webhelp.topic.collapsible.elements.initial.state

Specifies the initial state of collapsible elements (tables with titles, nested topics with titles, sections with titles, index term groups). The possible values are `collapsed` or `expanded` (default value).

Parameters for Adding a Link to PDF Documentation in WebHelp Responsive Output

The following transformation parameters can be used to generate a PDF link component in the WebHelp Responsive output (for example, it could link to the PDF equivalent of the documentation):

- **webhelp.pdf.link.url**
  Specifies the target URL for the PDF link component.

- **webhelp.pdf.link.text**
  Specifies the text for the PDF link component.

- **webhelp.pdf.link.icon.path**
  Specifies the path or URL of the image icon to be used for the PDF link component. If not specified, a default icon is used.

- **webhelp.show.pdf.link**
  Specifies whether or not the PDF link component is shown in the WebHelp Responsive output. Allowed values are: `yes` (default) and `no`.

- **webhelp.pdf.link.anchor.enabled**
  Specifies whether or not the current topic ID should be appended as the name destination at the end of the PDF link. Allowed values are: `yes` (default) and `no`. 
DITA Map PDF - based on HTML5 & CSS Transformation

Oxygen XML Editor includes a built-in DITA Map PDF - based on HTML5 & CSS transformation scenario based on a DITA-OT CSS-based PDF Publishing plugin that converts DITA maps to PDF using a CSS-based processing engine and an HTML5 intermediate format. Oxygen XML Editor comes bundled with a built-in CSS-based PDF processing engine called Oxygen PDF Chemistry. Oxygen XML Editor also supports some third-party processors.

For those who are familiar with CSS, this makes it very easy to style and customize the PDF output of your DITA projects without having to work with xsl:fo customizations. This transformation also includes some built-in publishing templates that you can use for the layout of your PDF output and you can create your own templates or edit existing ones.

The following CSS-based PDF processors can be used:

- **Oxygen PDF Chemistry** - A built-in processor that is bundled with Oxygen XML Editor. For more information, see the Oxygen PDF Chemistry User Guide. This is the supported processor.
- **Prince Print with CSS** (not included in the Oxygen XML Editor installation kit) - A third-party component that needs to be purchased from http://www.princexml.com.
- **Antenna House Formatter** (not included in the Oxygen XML Editor installation kit) - A third-party component that needs to be purchased from http://www.antennahouse.com/antenna1/formatter/.

How to Create the Transformation Scenario

To create a DITA Map PDF - based on HTML5 & CSS transformation scenario, follow these steps:

1. Click the Configure Transformation Scenario(s) button from the DITA Maps Manager (on page 2662) toolbar.
2. Select the DITA Map PDF - based on HTML5 & CSS transformation scenario.
3. If you want to configure the transformation, click the Edit button.

**Step Result:** This opens an Edit scenario configuration dialog box that allows you to configure various options in the following tabs:
• **Templates Tab (on page 2867)** - This tab contains a set of built-in publishing templates that you can use for the layout of your WebHelp system output. You can also create your own publishing templates by saving one from the gallery and changing it.

**Figure 443. DITA Map to PDF Templates**

- **Parameters Tab (on page 2873)** - This tab includes numerous parameters that can be set to customize the transformation.
- **Filters Tab (on page 2875)** - This tab allows you to filter certain content elements from the generated output.
- **Advanced Tab (on page 2876)** - This tab allows you to specify some advanced options for the transformation scenario.
- **Output Tab (on page 2878)** - This tab allows you to configure options that are related to the location where the output is generated.

4. In the **Parameters** tab, configure any of the following parameters (if applicable):
   - **args.css** - Specifies a path to a custom CSS to be used in addition to those specified in the publishing template. The files must have URL syntax and be separated using semicolons. Also, the **dita.css.list** parameter must be left empty to use these files in addition to the selection in the **Styles** drop-down menu.
   - **css.processor.type** - This is where you choose the processor type. You can select between **Oxygen PDF Chemistry**, **Prince XML**, or **Antenna House**.
   - **css.processor.path.chemistry** (if you are using the **Oxygen PDF Chemistry** processor) - Specifies the path to the **Oxygen PDF Chemistry** executable file that will be run to generate the PDF. If this parameter is not set, the transformation will use the processor specified in the **CSS-based Processors** preferences page (on page 235).
• **css.processor.path.prince** (if you are using the **Prince Print with CSS** processor) - Specifies the path to the Prince executable file that will be run to produce the PDF. If you installed Prince using its default settings, you can leave this blank.

• **css.processor.path.antenna-house** (if you are using the **Antenna House Formatter** processor) - Specifies the path to the Antenna House executable file that will be run to produce the PDF. If you installed Antenna House using its default settings, you can leave this blank.

• **show.changes.and.comments** - When set to *yes*, user comments, replies to comments, and tracked changes are published in the PDF output. The default value is *no*.

• **figure.title.placement** - Controls the position of the figure title relative to the image. Allowed values are "top" and "bottom", "top" is the default

5. Click **OK** and run the transformation scenario.

**Customizing the Output**

For information about customizing the output, see CSS-based DITA to PDF Customization *(on page 1660)*.

**Related Information:**

- Editing a Transformation Scenario *(on page 1440)*
- Configure Transformation Scenario(s) Dialog Box *(on page 1443)*
- Oxygen PDF Chemistry User Guide
- CSS-based DITA to PDF Customization *(on page 1660)*

**DITA Map PDF - based on XSL-FO Transformation**

Oxygen XML Editor comes bundled with the DITA Open Toolkit that provides a mechanism for converting **DITA maps** *(on page 2966)* to PDF output.

**Creating a DITA Map PDF - based on XSL-FO Transformation Scenario**

To create a **DITA Map PDF - based on XSL-FO** transformation scenario, follow these steps:

1. Click the **Configure Transformation Scenario(s)** button from the **DITA Maps Manager** *(on page 2662)* toolbar.

2. Select **DITA Map PDF - based on XSL-FO** and click the **Edit** button (or use the **Duplicate** button if your **framework** *(on page 2967)* is read-only).

3. Use the various tabs to configure the transformation scenario. In the **Parameters** tab, you can use a variety of parameters to customize the output. For example, the following parameters are just a few of the most commonly used ones:

   - **show.changes.and.comments** - If set to *yes*, user comments, replies to comments, and tracked changes are published in the PDF output.
   - **customization.dir** - Specifies the path to a customization directory.
   - **editlink.present.only.path.to.topic** - When this parameter is set to "true", the DITA topic path is displayed to the right of each topic title in the PDF output.

4. Click **OK** and then the **Apply Associated** button to run the transformation scenario.
DITA Map MS Office Word Transformation

Oxygen XML Editor comes bundled with a transformation scenario that allows you to convert DITA maps (on page 2966) to Microsoft Office Word documents. It utilizes the DITA to Word plugin created by Jarno Elovirta. This plugin contains a Word document named Normal.docx (located in: \[\text{OXYGEN_INSTALL_DIR}\]/frameworks/dita/DITA-OT3.x/plugins/com.elovirta.ooxml/resources) that is used by the transformation scenario as a template to generate the final Word document.

**Tip:**
You can make general modifications to the Normal.docx template file to alter the published output.

**Configuring the Transformation Scenario**

To configure a DITA Map to MS Office Word transformation scenario, follow these steps:

1. Open the DITA map in the DITA Maps Manager (on page 2662).
2. Click the Configure Transformation Scenario(s) button from the DITA Maps Manager toolbar.
3. Select DITA Map MS Office Word.
4. For advanced customizations, in the Parameters tab you can use any of the following parameters that are unique to this transformation scenario to specify paths to files that affect the output in various ways:
   - `dotx.file` - Specifies the path to a Word template file (.docx) that will be used in the transformation to generate the final Word document. Set this parameter if you want to use a different template file other than the Normal.docx file that is used by default.
   - `document.flat.xsl` - Specifies the path to a pre-process clean-up stylesheet.
   - `core.xsl` - Specifies the path to a core metadata stylesheet.
   - `custom.xsl` - Specifies the path to a custom metadata stylesheet.
   - `document.xsl` - Specifies the path to a main document stylesheet.
   - `comments.xsl` - Specifies the path to a comments stylesheet.
   - `numbering.xsl` - Specifies the path to a list and title numbering stylesheet.
   - `footnotes.xsl` - Specifies the path to a footnote stylesheet.
   - `document.xml.xsl` - Specifies the path to a document relations metadata stylesheet.
   - `inkscape.exec` - Specifies the path to an Inkscape (open-source vector graphics editor) executable file.
5. Click OK and run the transformation scenario.

**Result:** The result of the transformation will automatically be opened in your system's default word processing application (such as Microsoft Word).
DITA Map CHM (Compiled HTML Help) Transformation

To perform a Compiled HTML Help (CHM) transformation, Oxygen XML Editor needs Microsoft HTML Help Workshop to be installed on your computer. Oxygen XML Editor automatically detects if HTML Help Workshop is installed and uses it.

**Note:**

HTML Help Workshop might fail if the files used for transformation contain accents in their names, due to different encodings used when writing the .hhp and .hhc files. If the transformation fails to produce the CHM output but the .hhp (HTML Help Project) file is already generated, you can manually try to build the CHM output using HTML Help Workshop.

Changing the Output Encoding

Oxygen XML Editor uses the htmlhelp.locale parameter to correctly display specific characters of different languages in the output of the Compiled HTML Help (CHM) transformation. By default, the DITA Map CHM transformation scenario that comes bundled with Oxygen XML Editor has the htmlhelp.locale parameter set to en-US.

To customize this parameter, follow this procedure:

1. Use the **Configure Transformation Scenario(s)** (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the **Document > Transformation** menu.
2. Select the DITA Map CHM transformation scenario and click the **Edit** button.
3. In the **Parameter** tab, search for the htmlhelp.locale parameter and change its value to the desired language tag.

**Note:**

The format of the htmlhelp.locale parameter is LL-CC, where LL represents the language code (en, for example) and CC represents the country code (us, for example). The language codes are contained in the ISO 639-1 standard and the country codes are contained in the ISO 3166-1 standard. For further details about language tags, go to [http://www.rfc-editor.org/rfc/rfc5646.txt](http://www.rfc-editor.org/rfc/rfc5646.txt).

Customizing the CHM Output

There are several possibilities available for customizing the CHM output:
• You can use a custom CSS stylesheet to customize how the HTML content is rendered in the output:
  1. Create the custom CSS.
  2. Select the DITA Map CHM transformation scenario and click the Edit button.
  3. In the Parameter tab, set the args.css parameter to point to the location of your custom CSS and make sure the args.copy.css parameter is set to yes to instruct the transformation to copy the custom CSS to the output folder.
  4. Run the transformation.
• If you are familiar with XSLT, there are two XSLT stylesheets that are used in the transformation to compile various settings and components in the CHM output. They are found in the following directory: OXYGEN_INSTALL_DIR/frameworks/dita/DITA-OT3.x/plugins/org.dita.htmlhelp/xsl/map2htmlhelp. The files are as follows:
  ◦ map2hhcImpl.xsl - This file is used to compile the table of contents.
  ◦ map2hhpImpl.xsl - This file contains information for compiling the CHM and various settings that are read by the HTML Help Workshop when creating the output.

DITA Map Kindle Transformation

Oxygen XML Editor requires KindleGen to generate Kindle output from DITA maps (on page 2966). To install KindleGen for use by Oxygen XML Editor, follow these steps:

1. Go to www.amazon.com/kindleformat/kindlegen and download the zip file that matches your operating system.
2. Unzip the file on your local disk.
3. Start Oxygen XML Editor and open a DITA map in the DITA Maps Manager view (on page 2662).
4. Click the Configure Transformation Scenario(s) button.
5. Select the DITA Map Kindle transformation and click the Edit button to edit it.
6. Go to Parameters tab and set the kindlegen.executable parameter as the path to the KindleGen directory.
7. Accept the changes.

Run DITA-OT Integrator Transformation

Oxygen XML Editor comes bundled with a transformation scenario designed to integrate DITA-OT plugins (on page 2969). These DITA-OT plugins are used for various customizations. It is called Run DITA-OT Integrator and is found in the DITA Map section of the Configure Transformation Scenario(s) dialog box (on page 1443).

⚠️ Attention:
The integration will be performed on the DITA-OT version specified in the DITA Open Toolkit section of the DITA preferences page (on page 239).
Running the Transformation Scenario
To integrate a DITA-OT plugin, follow these steps:

1. If Oxygen XML Editor was installed in the default location, you may need to restart and run it as an administrator.
2. Select the **Apply Transformation Scenario(s)** or **Configure Transformation Scenario(s)** (on page 1443) action from the DITA Maps Manager toolbar (you could also use the same action on the main toolbar or open the Transformation Scenarios view (on page 1450)).
3. Select the **Run DITA-OT Integrator** transformation scenario. If the integrator is not visible, select the **Show all scenarios** action that is available in the **Settings** drop-down menu.
4. Apply the scenario (on page 1442).
5. Check the **Results** panel at the bottom of the application to make sure the build was successful.
6. Restart Oxygen XML Editor with your normal permissions.

Related Information:

  - Configure Transformation Scenario(s) Dialog Box (on page 1443)
  - Installing a DITA-OT Plugin (on page 2923)
  - Integrating a DITA Specialization (on page 2931)

Solving DITA Transformation Errors
If a DITA transformation results in errors or warnings, the information is displayed in the message panel at the bottom of the editor. The information includes the severity, description of the problem, the name of the resource, and the path of the resource.

To help prevent and solve DITA transformation problems, follow these steps:

1. **Validate the DITA map (on page 2706)** by using the **Validate and Check for Completeness** action that is available on the DITA Maps Manager (on page 2662) toolbar and in the DITA Maps menu.
2. If this action results in validation errors, solve them prior to executing the transformation. Also, you should pay attention to the warning messages because they may identify problems in the transformation.
3. Run the DITA transformation scenario (on page 1387).
4. If the transformation results in errors or warnings, they are displayed in the **Results panel (on page 508)** at the bottom of the editor. The following information is presented to help you troubleshoot the problems:

   - **Severity** - The first column displays the following icons that indicate the severity of the problem:
     - **Informational** - The transformation encountered a condition of which you should be aware.
     - **Warning** - The transformation encountered a problem that should be corrected.
     - **Error** - The transformation encountered a more severe problem, and the output is affected or cannot be generated.
5. Use this information or other resources from the online DITA-OT community to solve the transformation problems before re-executing the transformation scenario.

6. If you need to contact the Oxygen technical support team, they will need you to send the entire transformation scenario execution log. To obtain it:
   a. Go to the Options > Preferences > DITA preferences page and set the Show console output option to Always.
   b. Execute the transformation scenario again. The console output messages are displayed in the DITA-OT view.
   c. Copy the entire log, save it in a text file, then send it to the Oxygen technical support team.
   d. After your issue has been solved, go back to the Options > Preferences > DITA preferences page and set the Show console output option to When build fails.

Related Information:
Troubleshooting DITA Transformation Problems (on page 2885)

DITA Topic Transformation Scenarios

Oxygen XML Editor includes built-in transformation scenarios for transforming individual DITA Topics to HTML5, XHTML, or PDF output. They can be found in the DITA section in the Configure Transformation Scenario(s) dialog box (on page 1443).

The available transformations scenarios for individual DITA topics include:

- **DITA HTML5** - This DITA-OT transformation scenario generates HTML5 output from a single DITA topic.
- **DITA XHTML** - This DITA-OT transformation scenario generates XHTML output from a single DITA topic. This was the first transformation scenario created for the DITA Open Toolkit and it originally served as the basis for all HTML-based transformations.
- **DITA PDF - based on HTML5 & CSS** - This transformation scenario converts individual DITA topics to PDF using a CSS-based processing engine and an HTML5 intermediate format. Oxygen XML Editor comes bundled with a built-in CSS-based PDF processing engine called Oxygen PDF Chemistry. Oxygen XML Editor also supports some third-party processors.

For those who are familiar with CSS, this makes it very easy to style and customize the PDF output of your DITA projects without having to work with xsl:fo customizations. Another advantage of this transformation scenario is that you can use the same customization CSS (on page 1693) or publishing template (on page 1672) that you use for converting entire DITA maps.

The transformation scenario automatically detects the currently selected context DITA map (root map) (on page 2667) so that keys and references are properly resolved (the detected context map is set as the value of the args.root.map parameter (this can be changed in the Parameters tab). It also
automatically detects the currently applied profiling condition set (on page 2901) to be used as the default filtering option in the transformation scenario (this can be changed in the Filters tab).

The transformation scenario also supports a parameter named `args.enable.root.map.key.processing` that can be used to specify whether or not the values for `@keyref` and `@conkeyref` attributes within the transformed topics are resolved. The possible values are:

- **no** - This means that the values for all `@keyref` and `@conkeyref` attributes are ignored in the transformation. This results in lower processing times.
- **yes** - This means that the values for any `@keyref` and `@conkeyref` attributes found in the transformed topic are processed and resolved using the value of the `args.root.map` parameter.
- **auto** - This means that the process will search for any `@keyref` and `@conkeyref` attributes within the transformed topic and if any are found, the values will be processed and resolved using the value of the `args.root.map` parameter. If none are found, the `@keyref` and `@conkeyref` attributes are ignored.

- **DITA PDF - based on XSL-FO** - This DITA-OT transformation scenario converts individual DITA topics to PDF using an `xsl:fo` processor.

Related Information:

- Configure Transformation Scenario(s) Dialog Box (on page 1443)
- Applying Associated Transformation Scenarios (on page 1442)
- DITA Map Transformation Scenarios (on page 2843)

**DocBook Transformation Scenarios**

Built-in transformation scenarios allow you to transform DocBook documents to a variety of outputs, such as WebHelp, PDF, HTML, HTML Chunk, XHTML, XHTML Chunk, and EPUB. Oxygen XML Editor also includes a DocBook 5.1 transformation scenario for Assembly documents. All of them are listed in the DocBook 4 and DocBook 5 sections in the Configure Transformation Scenario(s) dialog box (on page 1443).

Related Information:
- Editing a Transformation Scenario (on page 1440)
- Configure Transformation Scenario(s) Dialog Box (on page 1443)
- Applying Associated Transformation Scenarios (on page 1442)

**DocBook to WebHelp Classic Transformation**

DocBook documents can be transformed into several types of WebHelp systems (with or without a feedback section). The WebHelp Classic layout and features (on page 1620) are designed for desktop systems and include a familiar classical style. Oxygen XML Editor also provides numerous possibilities for customizing the WebHelp Classic output (on page 1634).
WebHelp Classic Transformation Scenario

To publish a DocBook document as a WebHelp Classic system, follow these steps:

1. Click the Configure Transformation Scenario(s) action from the toolbar (or the Document > Transformation menu).
2. Select the DocBook WebHelp Classic scenario from the DocBook 4 or DocBook 5 section.
3. Click Apply associated.

Result: When the DocBook WebHelp Classic transformation is complete, the output is automatically opened in your default browser.

WebHelp Classic with Feedback Transformation Scenario (Deprecated)

Note:
See Deploying the Oxygen Feedback Comments Component (on page 1627).

To publish a DocBook document as a WebHelp Classic with Feedback system, follow these steps:

1. Click Configure Transformation Scenarios.
2. Select the DocBook WebHelp Classic with Feedback scenario from the DocBook 4 or DocBook 5 section.
3. Click Apply associated.
4. Enter the documentation product ID and the documentation version.

Result: When the DocBook WebHelp Classic with Feedback transformation is complete, your default browser opens the installation.html file. This file contains information about the output location, system requirements, installation instructions, and deployment of the output. Follow the instructions to complete the system deployment. For more information, see Deploying a PHP-based Feedback-Enabled System (Deprecated) (on page ).

For more information about the feedback-enabled WebHelp system, watch our video demonstration:

https://www.youtube.com/embed/eoQ2uxHVppE

Customizing DocBook WebHelp Transformation Scenarios

To customize a DocBook WebHelp transformation scenario, you can edit various parameters, including the following most commonly used ones:

**default.language**

This parameter is used if the language is not detected in the DITA map. The default value is en-US.

**clean.output**

Deletes all files from the output folder before the transformation is performed (only no and yes values are valid and the default value is no).
l10n.gentext.default.language

This parameter is used to identify the correct stemmer that differs from language to language. For example, for English the value of this parameter is `en` or for French it is `fr`, and so on.

use.stemming

Controls whether or not you want to include stemming search algorithms into the published output (default setting is `false`).

webhelp.copyright

Adds a small copyright text that appears at the end of the Table of Contents pane.

webhelp.custom.resources

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

webhelp.favicon

The file path that points to an image to be used as a favicon in the WebHelp output.

webhelp.footer.file

Path to an XML file that includes the footer content for your WebHelp output pages. You can use this parameter to integrate social media features (such as widgets for Facebook™, Twitter™, Google Analytics, or Google+™). The file must be well-formed, each widget must be in separate `<div>` or `<span>` element, and the code for each `<script>` element is included in an XML comment (also, the start and end tags for the XML comment must be on a separate line). The following code excerpt is an example for adding a Facebook™ widget:

```xml
<div id="facebook">
  <div id="fb-root"/>
  <script>
    <!-- (function(d, s, id) { var js, fjs = d.getElementsByTagName(s)[0];
      if (d.getElementById(id)) return;
      js = d.createElement(s); js.id = id;
      js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
      fjs.parentNode.insertBefore(js, fjs); })
    (document, 'script', 'facebook-jssdk'); -->
  </script>
  <div data-share="true" data-show-faces="true" data-action="like"
    data-layout="standard" class="fb-like"/>
</div>
```

webhelp.footer.include

Specifies whether or not to include footer in each WebHelp page. Possible values: `yes`, `no`. If set to `no`, no footer is added to the WebHelp pages. If set to `yes` and the webhelp.footer.file parameter has a value, then the content of that file is used as footer. If the webhelp.footer.file has no value then a default Oxygen footer is inserted in each WebHelp page.
webhelp.logo.image.target.url

Specifies a target URL that is set on the logo image. When you click the logo image, you will be redirected to this address.

webhelp.logo.image

Specifies a path to an image displayed as a logo in the left side of the output header.

webhelp.product.id (available only for Feedback-enabled systems)

This parameter specifies a short name for the documentation target, or product (for example, mobile-phone-user-guide, hvac-installation-guide).

Note:
You can deploy documentation for multiple products on the same server.

Restriction:
The following characters are not allowed in the value of this parameter: < > / \ ' ( ).

webhelp.product.version (available only for Feedback-enabled systems)

Specifies the documentation version number (for example, 1.0, 2.5, etc.). New user comments are bound to this version.

Note:
Multiple documentation versions can be deployed on the same server.

Restriction:
The following characters are not allowed in the value of this parameter: < > / \ ' ( ).

webhelp.search.ranking

If this parameter is set to false then the 5-star rating mechanism is no longer included in the search results that are displayed on the Search tab (default setting is true).

webhelp.skin.css

Path to a CSS file that sets the style theme in the WebHelp Classic output. It can be one of the built-in skin CSS from the OXYGEN_INSTALL_DIR\frameworks\docbook\xsl\com.oxygenxml.webhelp.classic\predefined-skins directory, or it can be a custom skin CSS generated with the Oxygen Skin Builder web application.

DocBook to DITA Transformation

Oxygen XML Editor includes a built-in transformation scenario that is designed to convert DocBook content to DITA. This transformation scenario is based upon a DITA Open Toolkit plugin that is available at sourceforge.net.

To convert a DocBook document to DITA, follow these steps:

1. Use one of the following two methods to begin the transformation process:
   • To apply the transformation scenario to a newly opened file, use the **Apply Transformation Scenario(s)** (`Ctrl + Shift + T` (Command + Shift + T on OS X)) action from the toolbar or the Document > Transformation menu.
   • To customize the transformation or change the scenario that is associated with the document, use the **Configure Transformation Scenario(s)** (`Ctrl + Shift + C` (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu.
2. Select the **DocBook to DITA** transformation scenario in the **DocBook 4** or **DocBook 5** section.
3. Click the **Apply associated** button to run the transformation.

   **Step Result:** The transformation will convert as many of the DocBook elements into equivalent DITA elements as it can recognize in its mapping process. For elements that cannot be mapped, the transformation will insert XML comments so that you can see which elements could not be converted.
4. Adjust the resulting DITA composite to suit your needs. You may have to remove comments, fix validation errors, adjust certain attributes, or split the content into individual topics.

DocBook to PDF Transformation

Oxygen XML Editor includes a built-in transformation scenario that is designed to convert DocBook content to PDF.

To convert a DocBook document to PDF, follow these steps:
1. Use one of the following two methods to begin the transformation process:
   
   • To apply the transformation scenario to a newly opened file, use the **Apply Transformation Scenario(s)** (Ctrl + Shift + T (Command + Shift + T on OS X)) action from the toolbar or the Document > Transformation menu.
   
   • To customize the transformation or change the scenario that is associated with the document, use the **Configure Transformation Scenario(s)** (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu.

2. Select the DocBook PDF transformation scenario in the DocBook 4 or DocBook 5 section.

3. Click the **Apply associated** button to run the transformation.

For information about customizing the PDF output for DocBook content, see [DocBook to PDF Output Customization (on page 1851)](on_page_1851).

**Related Information:**
- Editing a Transformation Scenario (on page 1440)
- Configure Transformation Scenario(s) Dialog Box (on page 1443)
- DocBook to PDF Output Customization (on page 1851)

### DocBook to EPUB Transformation

Oxygen XML Editor includes a built-in transformation scenario that is designed to convert DocBook content to EPUB. The EPUB specification recommends the use of *OpenType* fonts (recognized by their `.otf` file extension) whenever possible. To use a specific font, follow these steps:

1. Declare it in your CSS file, as in the following example:

   ```
   @font-face { 
   font-family: "MyFont";
   font-weight: bold;
   font-style: normal;
   src: url(fonts/MyFont.otf);
   }
   ```

2. In the CSS, specify where this font is used. To set it as default for `<h1>` elements, use the `font-family` rule, as in the following example:

   ```
   h1 { 
   font-size:20pt;
   margin-bottom:20px;
   font-weight: bold;
   font-family: "MyFont";
   text-align: center;
   }
   ```

3. Open the **Configure Transformation Scenario(s)** dialog box (on page 1443), select the DocBook EPUB transformation scenario in the DocBook 4 or DocBook 5 section, and click **Edit**.
4. In the Parameters tab, set the `epub.embedded.fonts` parameter to `fonts/MyFont.otf`. If you need to provide more files, use commas to separate their file paths.

**Note:**
The `html.stylesheet` parameter allows you to include a custom CSS in the output EPUB.

5. Run the transformation scenario.

**DocBook PDF (Show Change Tracking and Comments)**

Oxygen XML Editor includes a built-in transformation scenario that is designed to show tracked changes and comment in DocBook to PDF output.

To include comments and tracked changes (stored within your DocBook 5 documents) in the PDF output, follow these steps:

1. Click the **Configure Transformation Scenario(s)** button.
2. Select **DocBook PDF (Show Change Tracking and Comments)** in the DocBook 5 section.
3. If you need to configure the transformation, click the **Edit** (on page 1440) or **Duplicate** (on page 1442) button, make your changes to the scenario, and click **OK**.
4. Click the **Apply Associated** button to run the transformation scenario.

**Result:** Comment threads and tracked changes will now appear in the PDF output. Details about each comment or change will be available in the footer section for each page.

**Creating New Transformation Scenarios**

Defining a transformation scenario is the first step in the process of transforming a document. This section includes information on the types of new scenarios that are available in Oxygen XML Editor and how to create each type of transformation.

**XML Transformation with XSLT**

This type of transformation specifies the transformation parameters and location of an XSLT stylesheet that is applied to the edited XML document. This scenario is useful when you develop an XML document and the XSLT document is in its final form.

To create an XML transformation with XSLT scenario, use one of the following methods:

- Use the ⚙ Configure Transformation Scenario(s) (**Ctrl + Shift + C (Command + Shift + C on OS X)**) action from the toolbar or the **Document > Transformation** menu. Then click the **New** button and select **XML transformation with XSLT**.
- Go to **Window > Show View** and select ⚙ Transformation Scenarios to display this view (on page 1450). Click the ⚙ New Scenario drop-down menu button and select **XML transformation with XSLT**.
Both methods open the **New Scenario** dialog box.

The upper part of the dialog box allows you to specify the **Name** of the transformation scenario and the following **Storage** options:

- **Project Options** *(on page 2970)* - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- **Global Options** *(on page 2967)* - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

### XSLT Tab

When you create a new transformation scenario *(on page 1361)* or edit an existing one *(on page 1440)*, a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The **XSLT** tab contains the following options:

#### XML URL

Specifies the source XML file. You can specify the path by using the text field, its history drop-down, the ✡ **Insert Editor Variables** *(on page 292)* button, or the browsing actions in the 🗄️ ➔ **Browse** drop-down list. You can also use the 🗄️ ➔ **Open in editor** button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, then the file is used directly from its remote location.

**Note:**

If the transformer engine is Saxon 9.x and a custom URI resolver is configured in the advanced Saxon preferences page *(on page 220)*, the XML input of the transformation is passed to that URI resolver. If the transformer engine is one of the built-in XSLT 2.0 / 3.0 engines and the name of an initial template *(on page 1363)* is specified in the scenario, the XML URL field can be empty. The XML URL field can also be empty if you use external XSLT processors *(on page 1376)*. Otherwise, a value is mandatory in this field.

#### XSL URL

Specifies the source XSL file that the transformation will use. You can specify the path by using the text field, its history drop-down, the ✡ **Insert Editor Variables** *(on page 292)* button, or the browsing actions in the 🗄️ ➔ **Browse** drop-down list. You can also use the 🗄️ ➔ **Open in editor** button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, the file is used directly from its remote location.
Use "xml-stylesheet" declaration

If selected, the scenario applies the stylesheet specified explicitly in the XML document with the xml-stylesheet processing instruction. By default, this option is deselected and the transformation applies the XSLT stylesheet that is specified in the XSL URL field.

Transformer

This drop-down menu presents all the transformation engines available to Oxygen XML Editor for performing a transformation. These include the built-in engines and the external engines defined in the Custom Engines preferences page (on page 230). The engine you choose is used as the default transformation engine. Also, if an XSLT or XQuery document does not have an associated validation scenario, this transformation engine is used in the validation process (if it provides validation support).

Advanced options

Allows you to configure the advanced options of the Saxon HE/PE/EE engine (on page 1365) for the current transformation scenario. To configure the same options globally, go to the Saxon-HE/PE/EE preferences page (on page 217). For the current transformation scenario, these Advanced options override the options configured in that preferences page.

Parameters

Opens a Configure parameters dialog box (on page 1363) that allows you to configure the XSLT parameters used in the current transformation. In this dialog box, you can also configure the parameters for additional XSLT stylesheets (on page 1363). If the XSLT transformation engine is custom-defined, you cannot use this dialog box to configure the parameters sent to the custom engine. Instead, you can copy all parameters from the dialog box using contextual menu actions and edit the custom XSLT engine to include the necessary parameters in the command line that starts the transformation process.

Extensions

Opens a dialog box for configuring the XSLT extension JARS or classes (on page 1365) that define extension Java functions or extension XSLT elements used in the transformation.

Additional XSLT stylesheets

Opens a dialog box for adding XSLT stylesheets (on page 1365) that are applied on the main stylesheet specified in the XSL URL field. This is useful when a chain of XSLT stylesheets must be applied to the input XML document.

XSLT Parameters

The global parameters of the XSLT stylesheet used in a transformation scenario can be configured by using the Parameters button in the XSLT tab of a new or edited transformation scenario dialog box.

The resulting dialog box includes a table that displays all the parameters of the current XSLT stylesheet, all imported and included stylesheets, and all additional stylesheets (on page 1365), along with their descriptions and current values. You can also add, edit, and remove parameters, and you can use the Filter
text box to search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

If the XPath column is selected, the parameter value is evaluated as an XPath expression before starting the XSLT transformation.

Example:
For example, you can use expressions such as:

```plaintext
doc('test.xml')//entry
//person[@atr='val']
```

Note:
1. The `doc` function solves the argument relative to the XSL stylesheet location. You can use full paths or editor variables (on page 292) (such as `$cfdu` [current file directory]) to specify other locations: `doc('${cfdu}/test.xml')//*`
2. You cannot use XSLT Functions. Only XPath functions are allowed.

Below the table, the following actions are available for managing the parameters:

**New**
Opens the Add Parameter dialog box that allows you to add a new parameter to the list. An editor variable (on page 292) can be inserted in the text box using the Insert Editor Variables button. If the Evaluate as XPath option is selected, the parameter will be evaluated as an XPath expression.

**Edit**
Opens the Edit Parameter dialog box that allows you to edit the selected parameter. An editor variable (on page 292) can be inserted in the text box using the Insert Editor Variables button. If the Evaluate as XPath option is selected, the parameter will be evaluated as an XPath expression.

**Unset**
Resets the selected parameter to its default value. Available only for edited parameters with set values.

**Delete**
Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

The bottom panel presents the following:

- The default value of the parameter selected in the table.
- A description of the parameter, if available.
- The system ID of the stylesheet that declares it.
XSLT Extensions

The **Extensions** button opens a dialog box that allows you to specify the **JARS** and classes that contain extension functions called from the XSLT file of the current transformation scenario. You can use the **Add**, **Edit**, and **Remove** buttons to configure the extensions.

**Tip:**
You can specify the path to the resources using wildcards (for example, `${oxygenHome}/lib/*.jar`).

An extension function called from the XSLT file of the current transformation scenario will be searched, in the specified extensions, in the order displayed in this dialog box. To change the order of the items, select the item to be moved and click the **Move up** or **Move down** buttons.

Additional XSLT Stylesheets

Use the **Additional XSLT Stylesheets** button in the **XSLT** tab to display a list of additional XSLT stylesheets to be used in the transformation and you can add files to the list or edit existing entries. The following actions are available:

- **Add**
  - Adds a stylesheet in the **Additional XSLT stylesheets** list using a file browser dialog box. You can type an editor variable (on page 292) in the file name field of the browser dialog box. The name of the stylesheet will be added in the list after the current selection.

- **Remove**
  - Deletes the selected stylesheet from the **Additional XSLT stylesheets** list.

- **Open**
  - Opens the selected stylesheet in a separate view.

- **Up**
  - Moves the selected stylesheet up in the list.

- **Down**
  - Moves the selected stylesheet down in the list.

Advanced Saxon HE/PE/EE XSLT Transformation Options

The XSLT transformation scenario allows you to configure advanced options that are specific for the Saxon HE (Home Edition), PE (Professional Edition), and EE (Enterprise Edition) engines. They are the same options as those in the **Saxon HE/PE/EE preferences page** (on page 217) but they are configured as a specific set of transformation options for each transformation scenario, while the values set in the preferences page apply as
global options. The advanced options configured in a transformation scenario override the global options (on page 2967) defined in the preferences page.

**Saxon-HE/PE/EE Options**
The advanced options for Saxon 9.9.1.5 Home Edition (HE), Professional Edition (PE), and Enterprise Edition (EE) are as follows:

**Mode ("-im")**
A Saxon-specific option that sets the initial mode for the transformation. If this value is also specified in a configuration file (on page 1366), the value in this option takes precedence.

**Template ("-it")**
A Saxon-specific option that sets the name of the initial XSLT template to be executed. If this value is also specified in a configuration file (on page 1366), the value in this option takes precedence.

**Tip:**
If your stylesheet includes `<xsl:template name="xsl:initial-template">`, Oxygen XML Editor will automatically detect and use it as the initial template, so this option is not needed in this case.

**Use a configuration file ("-config")**
Select this option if you want to use a Saxon 9.9.1.5 configuration file that will be executed for the XSLT transformation and validation processes. You can specify the path to the configuration file by entering it in the URL field, or by using the Insert Editor Variables button, or using the browsing actions in the Browse drop-down list.

**Debugger trace into XPath expressions (applies to debugging sessions)**
Instructs the XSLT Debugger (on page 1975) to step into XPath expressions.

**Enable Optimizations ("-opt")**
This option is selected by default, which means that optimization is enabled. If not selected, the optimization is suppressed, which is helpful when reducing the compiling time is important, optimization conflicts with debugging, or optimization causes extension functions with side-effects to behave unpredictably.

**Line numbering ("-l")**
Line numbers where errors occur are included in the output messages.

**Expand attributes defaults ("-expand")**
Specifies whether or not the attributes defined in the associated DTD or XML Schema are expanded in the output of the transformation you are executing.

**DTD validation of the source ("-dtd")**
Specifies whether or not the source document will be validated against their associated DTD.
You can choose from the following:

- **On** - Requests DTD validation of the source file and of any files read using the `document()` function.
- **Off** - (default setting) Suppresses DTD validation.
- **Recover** - Performs DTD validation but treats the errors as non-fatal.

**Note:**
Any external DTD is likely to be read even if not used for validation, since DTDs can contain definitions of entities.

**Recoverable errors ("-warnings")**

Specifies how dynamic errors are handled. The following options can be selected:

- **Recover silently ("silent")** - Continues processing without reporting the error.
- **Recover with warnings ("recover")** - Issues a warning but continues processing.
- **Signal the error and do not attempt recovery ("fatal")** - Issues an error and stops processing.

**Strip whitespaces ("-strip")**

Specifies how the `strip whitespaces` operation is handled. You can choose one of the following values:

- **All ("all")** - Strips all whitespace text nodes from source documents before any further processing, regardless of any `@xml:space` attributes in the source document.
- **Ignore ("ignorable")** - Strips all ignorable whitespace text nodes from source documents before any further processing, regardless of any `@xml:space` attributes in the source document. Whitespace text nodes are ignorable if they appear in elements defined in the DTD or schema as having element-only content.
- **None ("none")** - Strips no whitespace before further processing.

**Enable profiling ("-TP")**

If selected, profiling of the execution time in a stylesheet is enabled. The corresponding text field is used to specify the path to the output file where the profiling information will be saved. As long as the option is selected, and the output file specified, it will gather timed tracing information and create a profile report to the specified file.

**Saxon-PE/EE Options**
The following advanced options are specific for Saxon 9.9.1.5 Professional Edition (PE) and Enterprise Edition (EE) only:

**Register Saxon-JS extension functions and instructions**
Registers the Saxon-CE extension functions and instructions when compiling a stylesheet using the Saxon 9.9.1.5 processors.

Note:
Saxon-CE, being JavaScript-based, was designed to run inside a web browser. This means that you will use Oxygen XML Editor only for developing the Saxon-CE stylesheet, leaving the execution part to a web browser. See more details about executing such a stylesheet on Saxonica’s website.

Allow calls on extension functions ("-ext")
If selected, the stylesheet is allowed to call external Java functions. This does not affect calls on integrated extension functions, including Saxon and EXSLT extension functions. This option is useful when loading an untrusted stylesheet (such as from a remote site using http://[URL]). It ensures that the stylesheet cannot call arbitrary Java methods and thus gain privileged access to resources on your machine.

Enable assertions ("-ea")
In XSLT 3.0, you can use the `<xsl:assert>` element to make assertions in the form of XPath expressions, causing a dynamic error if the assertion turns out to be false. If this option is selected, XSLT 3.0 `<xsl:assert>` instructions are enabled. If it is not selected (default), the assertions are ignored.

Saxon-EE Options
The advanced options that are specific for Saxon 9.9.1.5 Enterprise Edition (EE) are as follows:

XML Schema version
Use this option to change the default XML Schema version for this transformation. To change the default XML Schema version globally, open the Preferences dialog box (Options > Preferences) (on page 98) and go to XML > XML Parser > XML Schema and use the Default XML Schema version option (on page 209).

Validation of the source file ("-val")
Requests schema-based validation of the source file and of any files read using `document()` or similar functions. It can have the following values:

- **Schema validation ("strict")** - This mode requires an XML Schema and allows for parsing the source documents with strict schema-validation enabled.
- **Lax schema validation ("lax")** - If an XML Schema is provided, this mode allows for parsing the source documents with schema-validation enabled but the validation will not fail if, for example, element declarations are not found.
- **Disable schema validation** - This specifies that the source documents should be parsed with schema-validation disabled.

Validation errors in the result tree treated as warnings ("-outval")
Normally, if validation of result documents is requested, a validation error is fatal. Selecting this option causes such validation failures to be treated as warnings.

**Write comments for non-fatal validation errors of the result document**

The validation messages for non-fatal errors are written (wherever possible) as a comment in the result document itself.

**Enable streaming mode**

Selecting this option will allow an XSLT to run in streaming mode. It is not selected by default.

**Other Options**

**Initializer class**

Equivalent to the `-init` Saxon command-line argument. The value is the name of a user-supplied class that implements the `net.sf.saxon.lib.Initializer` interface. This initializer is called during the initialization process, and may be used to set any options required on the configuration programmatically. It is particularly useful for tasks such as registering extension functions, collations, or external object models, especially in Saxon-HE where the option cannot be set via a configuration file. Saxon only calls the initializer when running from the command line, but the same code may be invoked to perform initialization when running user application code.

**Using Saxon Integrated Extension Functions**

Saxon, the transformation and validation engine used by Oxygen XML Editor, can be customized by adding custom functions (called **Integrated Extension Functions**) that can be called from XPath.

To define such a function, follow these steps:

1. Create a file with a Java class that extends `net.sf.saxon.lib.ExtensionFunctionDefinition`. Here is an example:

```java
private static class ShiftLeft extends ExtensionFunctionDefinition {
    @Override
    public StructuredQName getFunctionQName() {
        return new StructuredQName("eg", "http://example.com/saxon-extension", "shift-left");
    }
}

@Override
public SequenceType[] getArgumentTypes() {
    return new SequenceType[]{SequenceType.SINGLE_INTEGER, SequenceType.SINGLE_INTEGER};
}

@Override
public SequenceType getResultType(SequenceType[] suppliedArgumentTypes) {
```
```java
return SequenceType.SINGLE_INTEGER;
}

@Override
public ExtensionFunctionCall makeCallExpression() {
    return new ExtensionFunctionCall() {
        @Override
        public SequenceIterator call(SequenceIterator[] arguments, XPathContext context) throws XPathException {
            long v0 = ((IntegerValue)arguments[0].next()).longValue();
            long v1 = ((IntegerValue)arguments[1].next()).longValue();
            long result = v0<<v1;
            return Value.asIterator(Int64Value.makeIntegerValue(result));
        }
    }
};
}
```

2. Compile the class and add it to a JAR file.

3. Add a file called `net.sf.saxon.lib.ExtensionFunctionDefinition` that contains the fully qualified name of the Java class in the `META-INF/services/` folder of the JAR file.

**Note:**

To add more function definitions in the same JAR file, you need to add their fully qualified names on different lines.

To enable Oxygen XML Editor to pick up your custom function definition, the JAR file should be added to the classpath of the transformer. Here are some possibilities:

- If you develop a framework, you just need to link the JAR file in the Classpath tab (on page 118).
- In a validation scenario (on page 741), you can use the Extensions button to open a dialog box where you can add libraries.
- In a transformation scenario, you can use the Extensions button in the XSLT tab (on page 1363) to open a dialog box where you can add libraries.
- You can also create a plugin that contributes such a JAR file in the classpath (on page 2251).

**FO Processor Tab (XSLT Transformations)**

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The FO Processor tab contains the following options:

**Perform FO Processing**
Specifies whether or not an FO processor is applied (either the built-in Apache FOP engine or an external engine defined in Preferences) during the transformation.

Input

Choose between the following options to specify which input file to use:

- **XSLT result as input** - The FO processor is applied to the result of the XSLT transformation that is defined in the XSLT tab.
- **XML URL as input** - The FO processor is applied to the input XML file.

Method

The output format of the FO processing. The available options depend on the selected processor type.

Processor

Specifies the FO processor to be used for the transformation. It can be the built-in Apache FOP processor or an external processor (on page 231).

Output Tab (XSLT Transformations)

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The Output tab contains the following options:

**Prompt for file**

At the end of the transformation, a file browser dialog box is displayed for specifying the path and name of the file that stores the transformation result.

**Save As**

The path of the file where the result of the transformation is stored. You can specify the path by using the text field, the Insert Editor Variables (on page 292) button, or the Browse button.

**Open in Browser/System Application**

If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the file type of the result (for example, in Windows PDF files are often opened in Acrobat Reader).

Note:

To set the web browser that is used for displaying HTML/XHTML pages, go to Options > Preferences > Global, and set it in the Default Internet browser field.
• **Output file** - When **Open in Browser/System Application** is selected, you can use this button to automatically open the default output file at the end of the transformation.

• **Other location** - When **Open in Browser/System Application** is selected, you can use this option to open the file specified in this field at the end of the transformation. You can specify the path by using the text field, the 📋 Insert Editor Variables (on page 292) button, or the 📥 Browse button.

---

**Open in editor**

When this option is selected, at the end of the transformation, the default output file is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor, or if it is an XSL-FO file it is opened with the built-in FO editor).

**Show in results view as**

You can choose to view the results in one of the following:

• **XML** - If this is selected, Oxygen XML Editor displays the transformation result in an XML viewer panel at the bottom of the application window with syntax highlighting (on page 195).

• **SVG** - If this is selected, Oxygen XML Editor displays the transformation result in an integrated SVG viewer in the Results panel (on page 1157) at the bottom of the application window and renders the result as an SVG image.

• **XHTML** - This option is only available if **Open in Browser/System Application** is not selected. If selected, Oxygen XML Editor displays the transformation result in a built-in XHTML browser panel at the bottom of the application window.

---

**Important:**

When transforming very large documents, you should be aware that selecting this option may result in very long processing times. This drawback is due to the built-in Java XHTML browser implementation. To avoid delays for large documents, if you want to see the XHTML result of the transformation, you should use an external browser by selecting the **Open in Browser/System Application** option instead.

• **Image URLs are relative to** - If **Show in results view as XHTML** is selected, this option specifies the path used to resolve image paths contained in the transformation result. You can specify the path by using the text field, the 📋 Insert Editor Variables (on page 292) button, or the 📥 Browse button.
Attention:
If your input XSLT contains `<xsl:result-document>` elements, then the secondary results will be saved to the specified URIs while the principal result is specified in this Output tab. For more information, see: https://www.w3.org/TR/xslt-30/#element-result-document.

Configuring an XSLT Processor for Generating Output
This section explains how to configure an XSLT processor and extensions for such a processor in Oxygen XML Editor.

Supported XSLT Processors
Oxygen XML Editor includes the following XSLT processors:

- **Xalan 2.7.2** - Xalan-Java is an XSLT processor for transforming XML documents into HTML, text, or other XML document types. It implements XSL Transformations (XSLT) Version 1.0 and XML Path Language (XPath) Version 1.0.

- **Saxon 6.5.5** - Saxon 6.5.5 is an XSLT processor that implements the Version 1.0 XSLT and XPath with a number of powerful extensions. This version of Saxon also includes many of the new features that were first defined in the XSLT 1.1 working draft, but for conformance and portability reasons these are not available if the stylesheet header specifies `version="1.0"`.

- **Saxon 9.9.1.5 Home Edition (HE), Professional Edition (PE)** - Saxon-HE/PE implements the basic conformance level for XSLT 2.0 / 3.0 and XQuery 1.0. The term basic XSLT 2.0 / 3.0 processor is defined in the draft XSLT 2.0 / 3.0 specifications. It is a conformance level that requires support for all features of the language other than those that involve schema processing. The HE product remains open source, but removes some of the more advanced features that are present in Saxon-PE.

- **Saxon 9.9.1.5 Enterprise Edition (EE)** - Saxon EE is the schema-aware edition of Saxon and it is one of the built-in processors included in Oxygen XML Editor. Saxon EE includes an XML Schema processor, and schema-aware XSLT, XQuery, and XPath processors.

The validation in schema aware transformations is done according to the XML Schema 1.0 or 1.1. This can be configured in Preferences (on page 208).

Note:
Oxygen XML Editor implements a Saxon framework that allows you to create Saxon configuration files. Two templates are available: Saxon collection catalog and Saxon configuration. Both of these templates support content completion, element annotation, and attribute annotation.

Note:
Saxon can use the ICU-J localization library (saxon9-icu.jar) to add support for sorting and date/number formatting in a wide variety of languages. This library is not included in the Oxygen XML Editor installation kit. However, Saxon will use the default collation and
Localization support available in the currently used JRE. To enable this capability, follow these steps:

2. Unpack the downloaded archive.
3. Create a new XSLT transformation scenario (or edit an existing one). In the **XSLT** tab, click the **Extensions** button to open the list of additional libraries used by the transformation process.
4. Click **Add** and browse to the folder where you unpacked the downloaded archive and choose the **saxon9-icu.jar** file.

Note that the **saxon9-icu.jar** should **NOT** be added to the application library folder because it will conflict with another version of the ICU-J library that comes bundled with Oxygen XML Editor.

- **Saxon-CE (Client Edition)** is Saxonica's implementation of XSLT 2.0 for use on web browsers. Oxygen XML Editor provides support for editing stylesheets that contain Saxon-CE extension functions and instructions. This support improves the validation, content completion, and syntax highlighting.

  **Note:**

  Saxon-CE, being JavaScript-based, was designed to run inside a web browser. This means that you will use Oxygen XML Editor only for developing the Saxon-CE stylesheet, leaving the execution part to a web browser. See more details about [executing such a stylesheet on Saxonica's website](http://www.saxonica.com).

  **Note:**

  A specific template, named **Saxon-CE stylesheet**, is available in the **New document wizard (on page 335)**.

- **Xsltproc (libxslt)** - **Libxslt** is the XSLT C library developed for the Gnome project. **Libxslt** is based on **libxml2**, the XML C library developed for the Gnome project. It also implements most of the EXSLT set of processor-portable extensions, functions, and some of Saxon's evaluate and expression extensions.

  Oxygen XML Editor uses **Libxslt** through its command-line tool (**Xsltproc**). Depending on your operating system, you must download the Libxslt libraries on your machine from [http://xmlsoft.org/XSLT/downloads.html](http://xmlsoft.org/XSLT/downloads.html) and place them in a local folder. Then you need to update the **PATH** environmental variable to contain the parent folder where the **xsltproc** executable is located.

  **Tip:**

  As an example, a Windows installation of the Xsltproc engine would follow these steps:

  2. Unzip all of them into the same folder of your choice.
3. Edit the `PATH` environment variable and add the `bin` folder for all four archives:

```
Edit environment variable

D:\apache-maven-3.1.1\bin
D:\Python27
%PATH%
C:\Users\r\Desktop\abc\libxslt-1.1.26.win32\bin
C:\Users\r\Desktop\abc\libxml2-2.7.8.win32\bin
C:\Users\r\Desktop\abc\iconv-1.9.2.win32\bin
C:\Users\r\Desktop\abc\zlib-1.2.5\bin
```

4. Restart Oxygen XML Editor.

**Result:** You can now use the `xsltproc` processor as an XSLT engine in the XSLT transformation scenario.

**Note:**
The `xsltproc` processor can be configured from the [XSLTPROC options page](#).

**CAUTION:**
There is a known problem where file paths that contain spaces are not handled correctly in the LIBXML processor. For example, the built-in [XML Catalog](#) files of the built-in document types (DocBook, TEI, DITA, etc.) are not handled properly by LIBXML if Oxygen XML Editor is installed in the default location on Windows (C:\Program Files). This is because the built-in [XML catalog](#) files are stored in the `[OXYGEN_INSTALL_DIR]/frameworks` subdirectory of the installation directory, and in this case it contains a space character.

- **MSXML 4.0 (Legacy)** - MSXML 4.0 is available only on Windows platforms. It can be used for [transformation](#) and [validation of XSLT stylesheets](#).

Oxygen XML Editor uses the Microsoft XML parser through its command-line tool `msxsl.exe`.

Since `msxsl.exe` is only a wrapper, Microsoft Core XML Services (MSXML) must be installed on the computer. Otherwise, you will get a corresponding warning. You can get the latest Microsoft XML parser from the [Microsoft web-site](#).

- **MSXML .NET (Legacy)** - MSXML .NET is available only on Windows platforms. It can be used for [transformation](#) and [validation of XSLT stylesheets](#).

Oxygen XML Editor performs XSLT transformations and validations using the .NET Framework XSLT implementation (`System.Xml.Xsl.XsltTransform` class) through the `nxslt` command-line utility. The `nxslt` version included in Oxygen XML Editor is 1.6.

You should have the .NET Framework version 1.0 already installed on your system. Otherwise, you will get the following warning: `MSXML.NET requires .NET Framework version 1.0 to be installed. Exit code: 128`. 
You can get the .NET Framework version 1.0 from the Microsoft website.

- **.NET 1.0 (Legacy)** - A transformer based on the System.Xml 1.0 library available in the .NET 1.0 and .NET 1.1 frameworks from Microsoft (http://msdn.microsoft.com/xml/). It is available only on Windows.

You should have the .NET Framework version 1.0 or 1.1 already installed on your system. Otherwise, you will get the following warning:

```
MSXML.NET requires .NET Framework version 1.0 to be installed. Exit code: 128.
```

You can get the .NET Framework version 1.0 from the Microsoft website.

- **.NET 2.0 (Legacy)** - A transformer based on the System.Xml 2.0 library available in the .NET 2.0 Framework from Microsoft. It is available only on Windows.

You should have the .NET Framework version 2.0 already installed on your system. Otherwise, you will get the following warning:

```
MSXML.NET requires .NET Framework version 2.0 to be installed. Exit code: 128.
```

You can get the .NET Framework version 2.0 from the Microsoft website.

For information about configuring the XSLT preferences, see the XSLT options (on page 216) section.

### Configuring Custom XSLT Processors

Oxygen XML Editor allows you to configure custom processors to be used for running XSLT and XQuery transformations.

To add a new custom processor, follow these steps:

1. Open the **Preferences** dialog box (Options > Preferences) (on page 98) and go to XML > XSLT-FO-XQuery > Custom Engines.
2. Click the **New** button at the bottom of the dialog box.
3. Configure the parameters for the custom engine (on page 230).
4. Click **OK**.

**Note:**

You can not use these custom engines in the Debugger perspective (on page 1956).

The output messages of a custom processor are displayed in an output view at the bottom of the application window. If an output message follows the format of an Oxygen XML Editor linked message (on page 737), clicking it highlights the location of the message in an editor panel containing the file referenced in the message.

**Related Information:**

- Custom Engines Preferences (on page 230)
Configuring the XSLT Processor Extensions Paths

The Xalan and Saxon processors support the use of extension elements and extension functions. Unlike a literal result element, which the stylesheet simply transfers to the result tree, an extension element performs an action. The extension is usually used because the XSLT stylesheet fails in providing adequate functions for accomplishing a more complex task.

For more information about how to use extensions, see the following links:

- **Saxon 6.5.5** - http://saxon.sourceforge.net/saxon6.5.5/extensions.html
- **Saxon 9.9.1.5** - http://www.saxonica.com/documentation9.5/index.html#extensibility

To set an XSLT processor extension (a directory or a jar file), use the Extensions button (on page 1363) in the Edit scenario dialog box.

XML Transformation with XQuery

This type of transformation specifies the transform parameters and location of an XQuery file that is applied to the edited XML document.

Use the XML transformation with XQuery scenario to apply a transformation to have an XQuery file query an XML file for the output results.

To create an XML transformation with XQuery scenario, use one of the following methods:

- Use the Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu. Then click the New button and select XML transformation with XQuery.
- Go to Window > Show View and select Transformation Scenarios to display this view (on page 1450). Click the + New Scenario drop-down menu button and select XML transformation with XQuery.

Both methods open the New Scenario dialog box.

The upper part of the dialog box allows you to specify the Name of the transformation scenario and the following Storage options:

- **Project Options** (on page 2970) - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- **Global Options** (on page 2967) - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.
XQuery Tab

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The XQuery tab contains the following options:

**XML URL**

Specifies the source XML file. You can specify the path by using the text field, its history drop-down, the Insert Editor Variables (on page 292) button, or the browsing actions in the Browse drop-down list. You can also use the Open in editor button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, then the file is used directly from its remote location.

**Note:**

If the transformer engine is Saxon 9.x and a custom URI resolver is configured in the advanced Saxon preferences page (on page 220), the XML input of the transformation is passed to that URI resolver.

**XQuery URL**

Specifies the source XQuery file to be used for the transformation. You can specify the path by using the text field, its history drop-down, the Insert Editor Variables (on page 292) button, or the browsing actions in the Browse drop-down list. You can also use the Open in editor button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, the file is used directly from its remote location.

**Transformer**

This drop-down menu presents all the transformation engines available to Oxygen XML Editor for performing a transformation. These include the built-in engines and the external engines defined in the Custom Engines preferences page (on page 230). The engine you choose is used as the default transformation engine. Also, if an XSLT or XQuery document does not have an associated validation scenario, this transformation engine is used in the validation process (if it provides validation support).

**Advanced options**

Allows you to configure the advanced options of the Saxon HE/PE/EE engine (on page 1380) for the current transformation scenario. To configure the same options globally, go to the Saxon-HE/PE/EE preferences page (on page 217). For the current transformation scenario, these Advanced options override the options configured in that preferences page.

**Parameters**

Opens the Configure parameters dialog box (on page 1379) for configuring the XQuery parameters. You can use the buttons in this dialog box to add, edit, or remove parameters.
If the XQuery transformation engine is custom-defined, you can not use this dialog box to set parameters. Instead, you can copy all parameters from the dialog box using contextual menu actions and edit the custom XQuery engine to include the necessary parameters in the command line that starts the transformation process.

**Extensions**

Opens a dialog box for configuring the XQuery extension JARS or classes (on page 1380) that define extension Java functions or extension XSLT elements used in the transformation.

**XQuery Parameters**

The global parameters of the XQuery file used in a transformation scenario can be configured by using the Parameters button in the XQuery tab.

The resulting dialog box includes a table that displays all the parameters of the current XQuery file, along with their descriptions and current values. You can also add, edit, and remove parameters, and use the Filter text box to search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

If the XPath column is selected, the parameter value is evaluated as an XPath expression before starting the XQuery transformation.

**Example:**

For example, you can use expressions such as:

```
/doc('test.xml')//entry
//person[@atr='val']
```

**Note:**

1. The `doc` function solves the argument relative to the XQuery file location. You can use full paths or editor variables (on page 292) (such as `${cfdu}` [current file directory]) to specify other locations: `doc('${cfdu}/test.xml')//*`

2. Only XPath functions are allowed.

Below the table, the following actions are available for managing the parameters:

**New**

Opens the Add Parameter dialog box that allows you to add a new parameter to the list. An editor variable (on page 292) can be inserted in the text box using the Insert Editor Variables button. If the Evaluate as XPath option is selected, the parameter will be evaluated as an XPath expression.

**Edit**

Opens the Edit Parameter dialog box that allows you to edit the selected parameter. An editor variable (on page 292) can be inserted in the text box using the Insert Editor Variables
button. If the **Evaluate as XPath** option is selected, the parameter will be evaluated as an XPath expression.

**Unset**

Resets the selected parameter to its default value. Available only for edited parameters with set values.

**Delete**

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

The bottom panel presents the following:

- The default value of the parameter selected in the table.
- A description of the parameter, if available.
- The system ID of the stylesheet that declares it.

**Related Information:**

Editor Variables *(on page 292)*

**XQuery Extensions**

The **Extensions** button is used to specify the **JAR (on page 2967)** and classes that contain extension functions called from the XQuery file of the current transformation scenario. You can use the **Add**, **Edit**, and **Remove** buttons to configure the extensions.

An extension function called from the XQuery file of the current transformation scenario will be searched, in the specified extensions, in the order displayed in this dialog box. To change the order of the items, select the item to be moved and click the **Move up** or **Move down** buttons.

**Advanced Saxon HE/PE/EE XQuery Transformation Options**

The XQuery transformation scenario allows you to configure advanced options that are specific for the Saxon HE (Home Edition), PE (Professional Edition), and EE (Enterprise Edition) engines. They are the same options as those in the **Saxon HE/PE/EE preferences page (on page 225)** but they are configured as a specific set of transformation options for each transformation scenario, while the values set in the preferences page apply as global options. The advanced options configured in a transformation scenario override the global options *(on page 2967)* defined in the preferences page.

**Saxon-HE/PE/EE Options**

The advanced options for Saxon 9.9.1.5 Home Edition (HE), Professional Edition (PE), and Enterprise Edition (EE) are as follows:

- **Use a configuration file ("-config")**

  Sets a Saxon 9.9.1.5 configuration file that is used for XQuery transformation and validation scenarios.
Enable Optimizations ("-opt")

This option is selected by default, which means that optimization is enabled. If not selected, the optimization is suppressed, which is helpful when reducing the compiling time is important, optimization conflicts with debugging, or optimization causes extension functions with side-effects to behave unpredictably.

Use linked tree model ("-tree:linked")

This option activates the linked tree model.

Recoverable errors ("-warnings")

Specifies how dynamic errors are handled. The following options can be selected:

- **Recover silently ("silent")** - Continues processing without reporting the error.
- **Recover with warnings ("recover")** - Issues a warning but continues processing.
- **Signal the error and do not attempt recovery ("fatal")** - Issues an error and stops processing.

Strip whitespaces ("-strip")

Specifies how the strip whitespaces operation is handled. You can choose one of the following values:

- **All ("all")** - Strips all whitespace text nodes from source documents before any further processing, regardless of any @xml:space attributes in the source document.
- **Ignore ("ignorable")** - Strips all ignorable whitespace text nodes from source documents before any further processing, regardless of any @xml:space attributes in the source document. Whitespace text nodes are ignorable if they appear in elements defined in the DTD or schema as having element-only content.
- **None ("none")** - Strips no whitespace before further processing.

Enable profiling ("-TP")

If selected, profiling of the execution time in a query is enabled. The corresponding text field is used to specify the path to the output file where the profiling information will be saved. As long as the option is selected, and the output file specified, it will gather timed tracing information and create a profile report to the specified file.

**Note:**
The profiling support works only if the **Present as a sequence** transformation option (on page 1383) is not set.

Saxon-PE/EE Options

The following advanced options are specific for Saxon 9.9.1.5 Professional Edition (PE) and Enterprise Edition (EE) only:

- **Allow calls on extension functions ("-ext")**
If selected, calls on external functions are allowed. Selecting this option is recommended in an environment where untrusted stylesheets may be executed. It also disables user-defined extension elements and the writing of multiple output files, both of which carry similar security risks.

**Saxon-EE Options**

The advanced options that are specific for Saxon 9.9.1.5 Enterprise Edition (EE) are as follows:

**Validation of the source file ("-val")**

Requests schema-based validation of the source file and of any files read using `document()` or similar functions. It can have the following values:

- **Schema validation ("strict")** - This mode requires an XML Schema and allows for parsing the source documents with strict schema-validation enabled.
- **Lax schema validation ("lax")** - If an XML Schema is provided, this mode allows for parsing the source documents with schema-validation enabled but the validation will not fail if, for example, element declarations are not found.
- **Disable schema validation** - This specifies that the source documents should be parsed with schema-validation disabled.

**Validation errors in the result tree treated as warnings ("-outval")**

Normally, if validation of result documents is requested, a validation error is fatal. Selecting this option causes such validation failures to be treated as warnings.

**Write comments for non-fatal validation errors of the result document**

The validation messages for non-fatal errors are written (wherever possible) as a comment in the result document itself.

**Enable XQuery update ("-update:(on|off)")**

This option controls whether or not XQuery update syntax is accepted. The default value is off.

**Backup files updated by XQuery ("-backup:(on|off)")**

If selected, backup versions for any XML files updated with an XQuery Update are generated. This option is available when the Enable XQuery update option is selected.

**Other Options**

**Initializer class**

Equivalent to the `-init` Saxon command-line argument. The value is the name of a user-supplied class that implements the `net.sf.saxon.lib.Initializer` interface. This initializer is called during the initialization process, and may be used to set any options required on the configuration programmatically. It is particularly useful for tasks such as registering extension functions, collations, or external object models, especially in Saxon-HE where the option cannot be set via
a configuration file. Saxon only calls the initializer when running from the command line, but the same code may be invoked to perform initialization when running user application code.

**FO Processor Tab (XQuery Transformations)**

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The **FO Processor** tab contains the following options:

**Perform FO Processing**

Specifies whether or not an FO processor is applied (either the built-in Apache FOP engine or an external engine defined in Preferences) during the transformation.

**Input**

Choose between the following options to specify which input file to use:

- **XQuery result as input** - The FO processor is applied to the result of the XQuery transformation that is defined in the XQuery tab.
- **XML URL as input** - The FO processor is applied to the input XML file.

**Method**

The output format of the FO processing. The available options depend on the selected processor type.

**Processor**

Specifies the FO processor to be used for the transformation. It can be the built-in Apache FOP processor or an [external processor](on page 231).

**Output Tab (XQuery Transformations)**

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The **Output** tab contains the following options:

**Present as a sequence**

Selecting this option will reduce the time necessary to fetch the full results, as it will only fetch the first chunk of the results.

**Prompt for file**

At the end of the transformation, a file browser dialog box is displayed for specifying the path and name of the file that stores the transformation result.

**Save As**
The path of the file where the result of the transformation is stored. You can specify the path by using the text field, the `Insert Editor Variables (on page 292)` button, or the `Browse` button.

**Open in Browser/System Application**

If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the file type of the result (for example, in Windows PDF files are often opened in Acrobat Reader).

**Note:**
To set the web browser that is used for displaying HTML/XHTML pages, go to `Options > Preferences > Global`, and set it in the `Default Internet browser` field.

- **Output file** - When `Open in Browser/System Application` is selected, you can use this button to automatically open the default output file at the end of the transformation.
- **Other location** - When `Open in Browser/System Application` is selected, you can use this option to open the file specified in this field at the end of the transformation. You can specify the path by using the text field, the `Insert Editor Variables (on page 292)` button, or the `Browse` button.

**Open in editor**

When this is option is selected, at the end of the transformation, the default output file is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor, or if it is an XSL-FO file it is opened with the built-in FO editor).

**Show in results view as**

You can choose to view the results in one of the following:

- **XML** - If this is selected, Oxygen XML Editor displays the transformation result in an XML viewer panel at the bottom of the application window with syntax highlighting (on page 195).
- **SVG** - If this is selected, Oxygen XML Editor displays the transformation result in an integrated SVG viewer in the Results panel (on page 1157) at the bottom of the application window and renders the result as an SVG image.
- **XHTML** - This option is only available if `Open in Browser/System Application` is not selected. If selected, Oxygen XML Editor displays the transformation result in a built-in XHTML browser panel at the bottom of the application window.
Important:
When transforming very large documents, you should be aware that selecting this option may result in very long processing times. This drawback is due to the built-in Java XHTML browser implementation. To avoid delays for large documents, if you want to see the XHTML result of the transformation, you should use an external browser by selecting the Open in Browser/System Application option instead.

• Image URLs are relative to - If Show in results view as XHTML is selected, this option specifies the path used to resolve image paths contained in the transformation result. You can specify the path by using the text field, the Insert Editor Variables button, or the Browse button.

XML to PDF Transformation with CSS
This type of transformation uses the Oxygen PDF Chemistry processing engine to obtain PDF output by applying CSS styling to the edited XML document. This scenario is useful for those who are familiar with CSS and want to obtain PDF output as its final form.

To create an XML to PDF transformation with CSS scenario, use one of the following methods:

• Use the Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu. Then click the New button and select XML to PDF transformation with CSS.

• Go to Window > Show View and select Transformation Scenarios to display this view (on page 1450). Click the New Scenario drop-down menu button and select XML to PDF transformation with CSS.

Both methods open the New Scenario dialog box.

The upper part of the dialog box allows you to specify the Name of the transformation scenario and the following Storage options:

• Project Options (on page 2970) - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.

• Global Options (on page 2967) - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

For more information about the Oxygen PDF Chemistry processing engine and numerous tips for customizing the output, see the Oxygen Chemistry User Guide.
CSS Tab (XML to PDF Transformation with CSS)

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The CSS tab contains the following options:

**XML URL**

Specifies the source XML file. You can specify the path by using the text field, its history drop-down, the Insert Editor Variables (on page 292) button, or the browsing actions in the Browse drop-down list. You can also use the Open in editor button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, then the file is used directly from its remote location.

**CSS URL**

Optionally, you can use this option to specify the location of a custom CSS file to be applied to the transformation. If this option is left blank, only the CSS referenced directly from the document will be applied. You can specify the path by using the text field, its history drop-down, the Insert Editor Variables (on page 292) button, or the browsing actions in the Browse drop-down list. You can also use the Open in editor button to open the specified file in the editor panel.

**Apply CSS stylesheets set in the current framework**

If selected, CSS stylesheets that are specified in the framework (in the Document Type configuration CSS subtab (on page 119)) are applied to the transformation in addition to any CSS referenced directly in the document or specified in the CSS URL field (on page 1386).

**Note:**

If CSS files are specified in multiple ways, the transformation applies the CSS in the following order (from lowest priority to highest):

- CSS files that are specified in the framework (in the Document Type configuration CSS subtab (on page 119)).
- CSS files referenced directly in the document.
- CSS files specified in the CSS URL field (on page 1386).

**Processor options link**

Opens the CSS-based Processors preferences page (on page 235) where you can configure some options for generating PDF output.
Output Tab (XML to PDF Transformation with CSS)

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The Output tab contains the following options:

Output File section

**Save As**

The path of the file where the result of the transformation is stored. You can specify the path by using the text field, the Insert Editor Variables (on page 292) button, or the Browse button.

Open in Browser/System Application

If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the PDF file type (for example, in Windows PDF files are often opened in Acrobat Reader).

Debugging section

**Dump the intermediate annotated XML**

Select this option to include (dump) the intermediate, annotated XML file in the same location as the output file. This can be used for debugging purposes.

**Dump the FO file**

Select this option to include (dump) the FO file (before it is converted to PDF) in the same location as the output file. This can be used for debugging purposes.

Console options link

Opens the CSS-based Processors preferences page (on page 235) where you can configure some options for generating PDF output.

DITA-OT Transformation

This type of transformation specifies the parameters for an Ant transformation that executes a DITA-OT build script. Oxygen XML Editor includes a built-in version of Ant and a built-in version of DITA-OT, but other versions can be set in the scenario.

To create a DITA-OT Transformation scenario, use one of the following methods:

- Use the Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the DITA Maps Manager toolbar, main toolbar, or the Document > Transformation menu. Then click the New button and select DITA-OT Transformation.

- Go to Window > Show View and select Transformation Scenarios to display this view (on page 1450). Click the New Scenario drop-down menu button and select DITA-OT Transformation.
Both methods open the **DITA Transformation Type** dialog box that presents the list of possible outputs.

![DITA Transformation Type Dialog Box](image)

Select the desired type of output and click **OK**. This opens the **New Scenario** dialog box.

The upper part of the dialog box allows you to specify the **Name** of the transformation scenario and the following **Storage** options:

- **Project Options** (**on page 2970**) - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- **Global Options** (**on page 2967**) - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

**Skins Tab (DITA-OT Transformations)**

When you create a new transformation scenario (**on page 1361**) or edit an existing one (**on page 1440**), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The **Skins** tab is available for DITA-OT transformations with the **WebHelp Classic** output type and it provides a set of built-in skins that you can use as a base for your WebHelp system output.
A skin is a collection of CSS properties that can alter the look of the output by changing colors, font types, borders, margins, and paddings. This allows you to rapidly adapt the look and feel of your output.

**Figure 445. Skins Tab**

The Skins tab includes the following sections:

* **Built-in Skins**

  This section presents the built-in skins that are included in Oxygen XML Editor. The built-in skins cover a wide range of chromatic themes, ranging from a very light one to a high-contrast variant. To see how the skin looks when applied on a sample documentation project that is stored on the Oxygen XML Editor website, click the **Online preview** link.

* **Custom Skins**

  You can use this section to customize the look of the output.

  **CSS File**

  You can set this field to point to a custom CSS stylesheet or customized skin. A custom CSS file will overwrite a skin selection.

  **Note:**

  The output can also be styled by setting the `args.css` parameter in the **Parameters tab**. The properties taken from the stylesheet referenced in this parameter take precedence over the properties declared in the skin set in the **Skins tab**.
Create custom skin

Use this link to open the WebHelp Skin Builder (on page 1635) tool.

Templates Tab (DITA-OT Transformations)

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The Templates tab is available for DITA-OT transformations with WebHelp Responsive or PDF - based on HTML5 & CSS output types and it provides a set of built-in publishing templates (on page 1497). You can use one of them to publish your documentation or as a starting point for a new publishing template.

Filtering and Previewing Templates

You can click on the tags at the top of the pane to filter the templates and narrow your search. Each built-in template also includes an Online preview icon in the bottom-right corner that opens a webpage in your default browser providing a sample of how the main page will look when that particular template is used to generate the output.

Built-in Templates Locations

Oxygen XML Editor scans the following locations to find the built-in templates to display in the dialog box:
• **WebHelp Responsive Templates** - All built-in WebHelp Responsive publishing templates are stored in the following directory: `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/templates`.

• **PDF - based on HTML5 & CSS** - All built-in PDF publishing templates are stored in the following directories:
  - `DITA-OT-DIR/plugins/com.oxygenxml.pdf.css/templates`
  - `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/templates`

### Custom Templates Locations

Oxygen XML Editor scans the locations specified in the [DITA > Publishing preferences page (on page 245)](#) to find custom templates to display in the dialog box. You can access that preferences page directly from the Template tab by clicking on the **Configure Publishing Templates Gallery** link.

### Selecting Custom Templates

Once you are finished configuring your template, you can click the **Choose Custom Publishing Template** link to select your template.

You can also add your custom templates (on page 1537) to the list of templates displayed in the Templates tab. To do this, store them in a directory, then click the **Configure Publishing Templates Gallery** link to open the [DITA > Publishing preferences page (on page 245)](#) where you can add that directory to the list. All the templates contained in your template directory will be displayed in the preview pane along with all the built-in templates.

### Save Template As Button

You can use the **Save template as** button (at the bottom-left of the transformation dialog box) to export the currently selected template into a new template package that can be used as a starting point to [create your own custom template (on page 1679)](#). Clicking this button will open a template package configuration dialog box (on page 2870) that contains some options and displays the parameters that will be exported to your template package.

### Template Errors

When the Templates tab is opened, all templates (built-in and custom) are loaded and validated. Specifically, certain elements in the template descriptor file are checked for validity. If errors are encountered that prevents the template from loading, the following message will be displayed toward the bottom of the dialog box:

```
⚠️ Some templates could not be loaded. More details.
```

If you click the **More details** link, a window will open with more information about the encountered error. For example, it might offer a hint that the element is missing from the expected descriptor file structure.

Also, if a template could be loaded, but certain elements could not be found in the descriptor file, a warning icon (⚠️) will be displayed on the template's image (in the Templates tab of the transformation dialog box). For example, this happens if a valid preview-image element cannot be found.
Sharing Publishing Template

To share a publishing template with others, following these steps:

1. Copy your template in a new folder.
2. Go to Options > Preferences > DITA > Publishing (on page 245) and add that new folder to the list.
3. Switch the option as the bottom of that preferences page to Project Options.
4. Share your project file (.xpr).

For more information about customizing publishing templates, watch our video demonstration:

https://www.youtube.com/embed/zNmXfKWXwO8

Related Information:
- Publishing Templates (on page 1497)
- Publishing Template Package Contents for PDF Customizations (on page 1673)
- Publishing Template Package Contents for WebHelp Responsive Customizations (on page 1500)

Template Package Configuration Dialog Box

The Save template as button (at the bottom-left of the transformation dialog box for WebHelp Responsive or PDF - based on HTML5 & CSS transformations) can be used to export the currently selected template into a new template package that can be used as a starting point to create your own custom template (on page 1679). The result will be a ZIP archive that contains a template descriptor file and other resources (such as CSS files) that were attached to the selected template.

Clicking the Save template as button opens a template package configuration dialog box contains the following options and components:

**Name**
- Required field used to specify the name for the new template. This will become the text value of the `<name>` element in the template descriptor file. This information is displayed as the name of the template in the transformation scenario dialog box.

**Description**
- Optional field used to specify a template description. This will become the text value of the `<description>` element in the template descriptor file. This information is displayed when the user hovers over the template in the transformation scenario dialog box.

**Parameter Table**
- This table displays the parameters that will be exported. Only certain relevant parameters are exported. The parameters and their values will be inserted in the `<parameters>` section of the template descriptor file. If any of the parameter values point to a file path that references a template resource (such as CSS files, custom HTML fragments, images), those resources will automatically be copied to the new template package and their references will be changed accordingly.
Note:
Additional resources that are referenced in CSS files or other resources will not be copied to the new template package, so you will need to copy them manually and update their references in the template descriptor file.

Include WebHelp Customization

The same publishing template package can contain both a WebHelp Responsive and PDF customization and you can use the same template in both types of transformations (DITA Map WebHelp Responsive (on page 1333) or DITA Map to PDF - based on HTML5 & CSS (on page 1347)). This option specifies that the custom template will include a WebHelp Responsive customization.

Include HTML Page Layout Files

For WebHelp Responsive customizations, select this option if you want to copy the default HTML Page Layout Files (on page 1516) into your template package. They are helpful if you want to change the structure of the generated HTML pages.

Include PDF Customization

The same publishing template package can contain both a WebHelp Responsive and PDF customization and you can use the same template in both types of transformations (DITA Map WebHelp Responsive (on page 1333) or DITA Map to PDF - based on HTML5 & CSS (on page 1347)). This option specifies that the custom template will include a PDF customization.

Save as

Use this field to specify the name and path of the ZIP file where the template will be saved.
FO Processor Tab (DITA-OT Transformations)

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The FO Processor tab is available for DITA-OT transformations with a PDF output type.

This tab allows you to select an FO Processor to be used for the transformation.
You can choose one of the following processors:

**Apache FOP**

The default processor that comes bundled with Oxygen XML Editor.

**XEP**

The RenderX XEP processor. If XEP is already installed, Oxygen XML Editor displays the detected installation path under the drop-down menu. XEP is considered installed if it was detected in one of the following sources:

- XEP was configured as an external FO Processor in the FO Processors option page (on page 231).
- The system property `com.oxygenxml.xep.location` was set to point to the XEP executable file for the platform (for example: `xep.bat` on Windows).
- XEP was installed in the `DITA-OT-DIR/plugins/org.dita.pdf2/lib` directory of the Oxygen XML Editor installation directory.

**Antenna House**

The Antenna House (AH Formatter) processor. If Antenna House is already installed, Oxygen XML Editor displays the detected installation path under the drop-down menu. Antenna House is considered installed if it was detected in one of the following sources:

- Environment variable set by Antenna House installation (the newest installation version will be used).
- Antenna House was added as an external FO Processor in the Oxygen XML Editor preferences pages.
To further customize the PDF output obtained from the Antenna House processor, follow these steps:

1. **Edit** the transformation scenario.
2. Open the **Parameters tab** *(on page 2873)*.
3. Add the **env.AXF_OPT** parameter and point to the Antenna House configuration file.

**Parameters Tab (DITA-OT Transformations)**

When you create a new transformation scenario *(on page 1361)* or edit an existing one *(on page 1440)*, a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The **Parameters** tab allows you to configure the parameters sent to the DITA-OT build file.

The table in this tab displays all the parameters that the DITA-OT documentation specifies as available for each chosen type of transformation (for example, XHTML or PDF), along with their description and current values. You can find more information about each parameter in the DITA-OT Documentation. You can also add, edit, and remove parameters, and you can use the text box to filter or search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

Depending on the type of a parameter, its value can be one of the following:

- A simple text field for simple parameter values.
- A combo box with some predefined values.
- A file chooser and an editor variable *(on page 292)* selector to simplify setting a file path as the value of a parameter.

**Note:**

To input parameter values at runtime, use the **ask editor variable** *(on page 293)* in the **Value** column.

Below the table, the following actions are available for managing parameters:

**New**

Opens the **Add Parameter** dialog box that allows you to add a new parameter to the list. You can specify the **Value** of the parameter by using the **Insert Editor Variables** *(on page 292)* button or the **Browse** button. You can also use the **Open in editor** button to open the specified file in the editor panel.

**Unset**
Resets the selected parameter to its default value. Available only for edited parameters with set values.

Edit

Opens the Edit Parameter dialog box that allows you to change the value of the selected parameter or its description.

Delete

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

Parameters Contributed by an Oxygen Publishing Template

Transformation parameters that are defined in an Oxygen Publishing Template (on page 1672) descriptor file are displayed in italics. After creating a publishing template (on page 1679) and adding it to the templates gallery (on page 1537), when you select the template in the Templates tab (on page 2867), the Parameters tab will automatically be updated to include the parameters defined in the template descriptor file.

Related Information:
DITA Open Toolkit Documentation

Feedback Tab (DITA-OT Transformations)

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The Feedback tab is for those who want to provide a way for users to offer feedback and ask questions in the published output and it is available for the DITA Map WebHelp Responsive transformation type. To add a comments component in the output, you need to use Oxygen Feedback to create a site configuration for the website where your WebHelp output is published and use this Feedback tab to instruct the transformation to install the comments component at the bottom of each WebHelp page.

When you create a site configuration in the Oxygen Feedback administration interface, an HTML fragment is generated during the final step of the creation process. You need to click the Edit button at the bottom-right of this tab to open a dialog box where you will paste the generated HTML fragment. The HTML fragment can also be set in an Oxygen Publishing Template (on page 1672), either as an HTML fragment extension point (on page 1507) or as a transformation parameter (on page 1505) (the webhelp.fragment.feedback parameter). If the fragment is specified in multiple places, the order of precedence (from highest to lowest) is:

- The fragment specified directly in the Feedback tab.
- The fragment specified in a publishing template as an HTML fragment extension point.
- The fragment specified in a publishing template as a transformation parameter.
Filters Tab (DITA Transformations)

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The Filters tab allows you to add filters to remove certain content elements from the generated output.

You can choose one of the following options to define filters:

**Use DITAVAL file**

If you already have a DITAVAL file associated with the DITA map (on page 2966), you can specify the file to be used when filtering content. You can specify the path by using the text field, its history drop-down, the Insert Editor Variables (on page 292) button, or the browsing actions in the Browse drop-down list. You can find out more about constructing a DITAVAL file in the DITA Documentation.

**Note:**
If a filter file is specified in the args.filter parameter (in the Parameters tab (on page 2873)), the filters are combined (neither file takes precedence over the other).

**Use profiling condition set**
Sets the profiling condition set (on page 2901) that will be applied to your transformation.

**Exclude from output all elements with any of the following attributes**

By using the **New**, **Edit**, or **Delete** buttons at the bottom of the pane, you can configure a list of attributes (name and value) to exclude all elements that contain any of these attributes from the output.

**Note:**

The colors and styles of the profiled content (on page 2906) settings are used for rendering it in **Author** mode but are not applied in the output.

**Advanced Tab (DITA-OT Transformations)**

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The **Advanced** tab allows you to specify advanced options for the transformation scenario.

**Figure 450. Advanced Settings Tab**
You can specify the following parameters:

**Custom build file**

If you use a custom DITA-OT build file, you can specify the path to the customized build file. If empty, the `build.xml` file from the `dita.dir` parameter that is configured in the Parameters tab (on page 2873) is used. You can specify the path by using the text field, the Insert Editor Variables (on page 292) button, or the Browse button.

**Build target**

Optionally, you can specify a build target for the build file. If no target is specified, the default `init` target is used.

**Additional arguments**

You can specify additional command-line arguments to be passed to the transformation (such as `-verbose`).

**Ant Home**

You can choose between the default or custom Ant installation to run the transformation. The default path can be configured in the Ant preferences page (on page 236).

**Java Home**

You can choose between the default or custom Java installation to run the transformation. The default path is the Java installation that is used by Oxygen XML Editor.

> **Note:**
> It may be possible that the used Java version is incompatible with the DITA Open Toolkit engine. For example, DITA-OT 2.0 and newer requires Java 1.7 or newer. Thus, if you encounter related errors running the transformation, consider installing a Java VM that is supported by the DITA-OT publishing engine and using it in the Java Home text field.

**JVM Arguments**

This parameter allows you to set specific parameters for the Java Virtual Machine used by Ant. When performing a large transformation, you may want to increase the memory allocated to the Java Virtual Machine. This will help avoid Out of Memory error messages (OutOfMemoryError). For example, if it is set to `-Xmx2g`, the transformation process is allowed to use a maximum 2 gigabytes of memory. If you do not specify an `-Xmx` value in this field, by default the application will use a maximum of 512 megabytes when used with the 32-bit Java Virtual Machine and one gigabyte with the 64-bit Java Virtual Machine.

**Libraries**

By default, Oxygen XML Editor adds libraries (as high priority) that are not transformation-dependent and also patches for certain DITA Open Toolkit bugs. You can use this button to specify additional libraries (JAR (on page 2967) files or additional class paths) to be used by the transformer.
Tip:
You can specify the path to the additional libraries using wildcards (for example, `${oxygenHome}/lib/*.jar`).

Output Tab (DITA-OT Transformations)

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The Output tab allows you to configure options that are related to the location where the output is generated.

Figure 451. Output Settings Tab

You can specify the following parameters:

**Base directory**

All the relative paths that appear as values in parameters are considered relative to the base directory. The default value is the directory where the transformed map is located. You can specify the path by using the text field, the Insert Editor Variables (on page 292) button, or the Browse button.

**Temporary files directory**
This directory is used to store pre-processed temporary files until the final output is obtained. You can specify the path by using the text field, the Insert Editor Variables button, or the Browse button.

**Output directory**

The folder where the content of the final output is stored. You can specify the path by using the text field, the Insert Editor Variables button, or the Browse button.

**Note:**

If the DITA map or topic is opened from a remote location or a ZIP file, the parameters must specify absolute paths.

**Open in Browser/System Application**

If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the file type of the result (for example, in Windows PDF files are often opened in Acrobat Reader).

**Note:**

To set the web browser that is used for displaying HTML/XHTML pages, go to Options > Preferences > Global, and set it in the Default Internet browser field.

- **Output file** - When Open in Browser/System Application is selected, you can use this button to automatically open the default output file at the end of the transformation.
- **Other location** - When Open in Browser/System Application is selected, you can use this option to open the file specified in this field at the end of the transformation. You can specify the path by using the text field, the Insert Editor Variables button, or the Browse button.

**Open in editor**

When this option is selected, at the end of the transformation, the default output file is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor, or if it is an XSL-FO file it is opened with the built-in FO editor).

At the bottom of the pane there is a link to the Console options preferences page that contains options to control the display of the console output received from the publishing engine.

**Ant Transformation**

This type of transformation allows you to configure the options and parameters of an Ant build script.
An Ant transformation scenario is usually associated with an Ant build script. Oxygen XML Editor runs an Ant transformation scenario as an external process that executes the Ant build script with the built-in Ant distribution (Apache Ant (on page 2964) version 1.9.8) that is included with the application, or optionally with a custom Ant distribution configured in the scenario.

Tip:
Certain Ant tasks require additional JAR libraries (for example, Ant mail tasks). The additional libraries can be added by editing the Ant transformation scenario, and in the Output tab, click the Libraries button (on page 1403) in the bottom right corner. This opens a dialog box where you can add JAR libraries. For a list of library dependencies, see https://ant.apache.org/manual/install.html#librarydependencies.

To create an Ant transformation scenario, use one of the following methods:

- Use the Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu. Then click the New button and select ANT transformation.
- Go to Window > Show View and select Transformation Scenarios to display this view (on page 1450). Click the New Scenario drop-down menu button and select ANT transformation.

Both methods open the transformation configuration dialog box.

The upper part of the dialog box allows you to specify the Name of the transformation scenario and the following Storage options:

- Project Options (on page 2970) - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- Global Options (on page 2967) - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

Related Information:
Transforming Ant Build Files (on page 871)

Options Tab (Ant Transformations)

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The Options tab allows you to specify the following options:
Working directory

The path of the current directory of the Ant external process. You can specify the path by using the text field, the **Insert Editor Variables** link, or the **Browse** button.

Build file

The Ant script file that is the input of the Ant external process. You can specify the path by using the text field, the **Insert Editor Variables** link, or the **Browse** button.

Build target

Optionally, you can specify a build target for the Ant script file. If no target is specified, the Ant target that is specified as the default in the Ant script file is used.

Additional arguments

You can specify additional command-line arguments to be passed to the transformation (such as `-verbose`).

Ant Home

You can choose between the default or custom Ant installation to run the transformation. The default path can be configured in the Ant preferences page.

Java Home

You can choose between the default or custom Java installation to run the transformation. The default path is the Java installation that is used by Oxygen XML Editor.

JVM Arguments

This parameter allows you to set specific parameters for the Java Virtual Machine used by Ant. When performing a large transformation, you may want to increase the memory allocated to the Java Virtual Machine. This will help avoid Out of Memory error messages. For example, if it is set to `-Xmx2g`, the transformation process is allowed to use a maximum of 2 gigabytes of memory. If you do not specify an `-Xmx` value in this field, by default the application will use a maximum of 512 megabytes when used with the 32-bit Java Virtual Machine and one gigabyte with the 64-bit Java Virtual Machine.

Libraries

By default, Oxygen XML Editor adds libraries (as high priority) that are not transformation-dependent and also patches for certain DITA Open Toolkit bugs. You can use this button to specify additional libraries (JAR files or additional class paths) to be used by the transformer.

**Tip:**

You can specify the path to the additional libraries using wildcards (for example, `$(oxygenHome)/lib/*.jar`).
Parameters Tab (Ant Transformations)

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The **Parameters** tab allows you to configure the parameters that are accessible as Ant properties in the Ant build script.

The table displays all the parameters that are available in the Ant build script, along with their description and current values. You can also add, edit, and remove parameters, and use the **Filter** text box to search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

Depending on the type of a parameter, its value can be one of the following:

- A simple text field for simple parameter values.
- A combo box with some predefined values.
- A file chooser and an *editor variable (on page 292)* selector to simplify setting a file path as the value of a parameter.

**Note:**
To input parameter values at runtime, use the *ask editor variable (on page 293)* in the **Value** column.

Below the table, the following actions are available for managing parameters:

**New**

Opens the **Add Parameter** dialog box that allows you to add a new parameter to the list. You can specify the **Value** of the parameter by using the *Insert Editor Variables (on page 292)* button or the *Browse* button. You can also use the *Open in editor* button to open the specified file in the editor panel.

**Edit**

Opens the **Edit Parameter** dialog box that allows you to change the value of the selected parameter or its description.

**Delete**

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

These parameters are also available for the built-in validation processor and the *Content Completion Assistant (on page 2965)*.

**Related Information:**

- *Content Completion in Ant Build Files (on page 872)*
Output Tab (Ant Transformations)

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The Output tab contains the following options:

**Open**

Allows you to specify the file to open automatically when the transformation is finished. This is usually the output file of the Ant process. You can specify the path by using the text field, the 📂 Insert Editor Variables (on page 292) button, or the 🏷️ Browse button.

- **In System Application** - The file specified in the Open text box is opened in the system application that is set in the operating system as the default application for that type of file (for example, in Windows PDF files are often opened in Acrobat Reader).
- **In Editor** - The file specified in the Open text box is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor).

**Show console output**

Allows you to specify when to display the console output log in the message panel at the bottom of the editor. The following options are available:

- **When build fails** - Displays the console output log only if the build fails.
- **Always** - Displays the console output log, regardless of whether or not the build fails.

XSLT Transformation

This type of transformation specifies the parameters and location of an XML document that the edited XSLT stylesheet is applied on. This scenario is useful when you develop an XSLT document and the XML document is in its final form.

To create an XSLT transformation scenario, use one of the following methods:

- Use the 🔄 Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu. Then click the New button and select XSLT transformation.
- Go to Window > Show View and select 🏷️ Transformation Scenarios to display this view (on page 1450). Click the 🔄 New Scenario drop-down menu button and select XSLT transformation.

Both methods open the New Scenario dialog box.

The upper part of the dialog box allows you to specify the Name of the transformation scenario and the following Storage options:
• **Project Options (on page 2970)** - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.

• **Global Options (on page 2967)** - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

**XSLT Tab**

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The XSLT tab contains the following options:

**XML URL**

Specifies the source XML file. You can specify the path by using the text field, its history drop-down, the ✉️ **Insert Editor Variables (on page 292)** button, or the browsing actions in the 📦 ‒ **Browse** drop-down list. You can also use the 📝 **Open in editor** button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, then the file is used directly from its remote location.

**Note:**

If the transformer engine is Saxon 9.x and a custom URI resolver is configured in the [advanced Saxon preferences page (on page 220)](#), the XML input of the transformation is passed to that URI resolver. If the transformer engine is one of the built-in XSLT 2.0 / 3.0 engines and the name of an initial template (on page 1363) is specified in the scenario, the XML URL field can be empty. The XML URL field can also be empty if you use external XSLT processors (on page 1376). Otherwise, a value is mandatory in this field.

**XSL URL**

Specifies the source XSL file that the transformation will use. You can specify the path by using the text field, its history drop-down, the ✉️ **Insert Editor Variables (on page 292)** button, or the browsing actions in the 📦 ‒ **Browse** drop-down list. You can also use the 📝 **Open in editor** button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, the file is used directly from its remote location.

**Use "xml-stylesheet" declaration**

If selected, the scenario applies the stylesheet specified explicitly in the XML document with the **xml-stylesheet** processing instruction. By default, this option is deselected and the transformation applies the XSLT stylesheet that is specified in the XSL URL field.
Transformer

This drop-down menu presents all the transformation engines available to Oxygen XML Editor for performing a transformation. These include the built-in engines and the external engines defined in the Custom Engines preferences page (on page 230). The engine you choose is used as the default transformation engine. Also, if an XSLT or XQuery document does not have an associated validation scenario, this transformation engine is used in the validation process (if it provides validation support).

Advanced options

Allows you to configure the advanced options of the Saxon HE/PE/EE engine (on page 1365) for the current transformation scenario. To configure the same options globally, go to the Saxon-HE/PE/EE preferences page (on page 217). For the current transformation scenario, these Advanced options override the options configured in that preferences page.

Parameters

Opens a Configure parameters dialog box (on page 1363) that allows you to configure the XSLT parameters used in the current transformation. In this dialog box, you can also configure the parameters for additional XSLT stylesheets (on page 1363). If the XSLT transformation engine is custom-defined, you cannot use this dialog box to configure the parameters sent to the custom engine. Instead, you can copy all parameters from the dialog box using contextual menu actions and edit the custom XSLT engine to include the necessary parameters in the command line that starts the transformation process.

Extensions

Opens a dialog box for configuring the XSLT extension JARS or classes (on page 1365) that define extension Java functions or extension XSLT elements used in the transformation.

Additional XSLT stylesheets

Opens a dialog box for adding XSLT stylesheets (on page 1365) that are applied on the main stylesheets specified in the XSL URL field. This is useful when a chain of XSLT stylesheets must be applied to the input XML document.

XSLT Parameters

The global parameters of the XSLT stylesheet used in a transformation scenario can be configured by using the Parameters button in the XSLT tab of a new or edited transformation scenario dialog box.

The resulting dialog box includes a table that displays all the parameters of the current XSLT stylesheet, all imported and included stylesheets, and all additional stylesheets (on page 1365), along with their descriptions and current values. You can also add, edit, and remove parameters, and you can use the Filter text box to search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

If the XPath column is selected, the parameter value is evaluated as an XPath expression before starting the XSLT transformation.
Example:

For example, you can use expressions such as:

```xml
doc('test.xml')//entry
//person[@atr='val']
```

Note:

1. The `doc` function solves the argument relative to the XSL stylesheet location. You can use full paths or editor variables (on page 292) (such as `${cfdu}` [current file directory]) to specify other locations: `doc('${cfdu}/test.xml')//*`

2. You cannot use XSLT Functions. Only XPath functions are allowed.

Below the table, the following actions are available for managing the parameters:

New

Opens the Add Parameter dialog box that allows you to add a new parameter to the list. An editor variable (on page 292) can be inserted in the text box using the Insert Editor Variables button. If the Evaluate as XPath option is selected, the parameter will be evaluated as an XPath expression.

Edit

Opens the Edit Parameter dialog box that allows you to edit the selected parameter. An editor variable (on page 292) can be inserted in the text box using the Insert Editor Variables button. If the Evaluate as XPath option is selected, the parameter will be evaluated as an XPath expression.

Unset

Resets the selected parameter to its default value. Available only for edited parameters with set values.

Delete

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

The bottom panel presents the following:

- The default value of the parameter selected in the table.
- A description of the parameter, if available.
- The system ID of the stylesheet that declares it.

Related Information:

Editor Variables (on page 292)
XSLT Extensions

The Extensions button opens a dialog box that allows you to specify the JARS (on page 2967) and classes that contain extension functions called from the XSLT file of the current transformation scenario. You can use the Add, Edit, and Remove buttons to configure the extensions.

Tip:
You can specify the path to the resources using wildcards (for example, ${oxygenHome}/lib/*.jar).

An extension function called from the XSLT file of the current transformation scenario will be searched, in the specified extensions, in the order displayed in this dialog box. To change the order of the items, select the item to be moved and click the Move up or Move down buttons.

Additional XSLT Stylesheets

Use the Additional XSLT Stylesheets button in the XSLT tab to display a list of additional XSLT stylesheets to be used in the transformation and you can add files to the list or edit existing entries. The following actions are available:

Add

Adds a stylesheet in the Additional XSLT stylesheets list using a file browser dialog box. You can type an editor variable (on page 292) in the file name field of the browser dialog box. The name of the stylesheet will be added in the list after the current selection.

Remove

Deletes the selected stylesheet from the Additional XSLT stylesheets list.

Open

Opens the selected stylesheet in a separate view.

Up

Moves the selected stylesheet up in the list.

Down

Moves the selected stylesheet down in the list.

Advanced Saxon HE/PE/EE XSLT Transformation Options

The XSLT transformation scenario allows you to configure advanced options that are specific for the Saxon HE (Home Edition), PE (Professional Edition), and EE (Enterprise Edition) engines. They are the same options as those in the Saxon HE/PE/EE preferences page (on page 217) but they are configured as a specific set of transformation options for each transformation scenario, while the values set in the preferences page apply as global options. The advanced options configured in a transformation scenario override the global options (on page 2967) defined in the preferences page.
Saxon-HE/PE/EE Options
The advanced options for Saxon 9.9.1.5 Home Edition (HE), Professional Edition (PE), and Enterprise Edition (EE) are as follows:

Mode ("-im")
A Saxon-specific option that sets the initial mode for the transformation. If this value is also specified in a configuration file (on page 1366), the value in this option takes precedence.

Template ("-it")
A Saxon-specific option that sets the name of the initial XSLT template to be executed. If this value is also specified in a configuration file (on page 1366), the value in this option takes precedence.

Tip:
If your stylesheet includes <xsl:template name="xsl:initial-template">, Oxygen XML Editor will automatically detect and use it as the initial template, so this option is not needed in this case.

Use a configuration file ("-config")
Select this option if you want to use a Saxon 9.9.1.5 configuration file that will be executed for the XSLT transformation and validation processes. You can specify the path to the configuration file by entering it in the URL field, or by using the Insert Editor Variables button, or using the browsing actions in the Browse drop-down list.

Debugger trace into XPath expressions (applies to debugging sessions)
Instructs the XSLT Debugger (on page 1975) to step into XPath expressions.

Enable Optimizations ("-opt")
This option is selected by default, which means that optimization is enabled. If not selected, the optimization is suppressed, which is helpful when reducing the compiling time is important, optimization conflicts with debugging, or optimization causes extension functions with side-effects to behave unpredictably.

Line numbering ("-l")
Line numbers where errors occur are included in the output messages.

Expand attributes defaults ("-expand")
Specifies whether or not the attributes defined in the associated DTD or XML Schema are expanded in the output of the transformation you are executing.

DTD validation of the source ("-dtd")
Specifies whether or not the source document will be validated against their associated DTD.
You can choose from the following:
- On - Requests DTD validation of the source file and of any files read using the `document()` function.

- Off - (default setting) Suppresses DTD validation.

- Recover - Performs DTD validation but treats the errors as non-fatal.

**Note:**
Any external DTD is likely to be read even if not used for validation, since DTDs can contain definitions of entities.

### Recoverable errors ("-warnings")
Specifies how dynamic errors are handled. The following options can be selected:

- **Recover silently (“silent”)** - Continues processing without reporting the error.
- **Recover with warnings (“recover”)** - Issues a warning but continues processing.
- **Signal the error and do not attempt recovery (“fatal”)** - Issues an error and stops processing.

### Strip whitespaces (“-strip”)
Specifies how the `strip whitespaces` operation is handled. You can choose one of the following values:

- **All (“all”)** - Strips all whitespace text nodes from source documents before any further processing, regardless of any `@xml:space` attributes in the source document.
- **Ignore (“ignorable”)** - Strips all ignorable whitespace text nodes from source documents before any further processing, regardless of any `@xml:space` attributes in the source document. Whitespace text nodes are ignorable if they appear in elements defined in the DTD or schema as having element-only content.
- **None (“none”)** - Strips no whitespace before further processing.

### Enable profiling (“-TP”)
If selected, profiling of the execution time in a stylesheet is enabled. The corresponding text field is used to specify the path to the output file where the profiling information will be saved. As long as the option is selected, and the output file specified, it will gather timed tracing information and create a profile report to the specified file.

### Saxon-PE/EE Options
The following advanced options are specific for Saxon 9.9.1.5 Professional Edition (PE) and Enterprise Edition (EE) only:

**Register Saxon-JS extension functions and instructions**
Registers the Saxon-CE extension functions and instructions when compiling a stylesheet using the Saxon 9.9.1.5 processors.
Note:
Saxon-CE, being JavaScript-based, was designed to run inside a web browser. This means that you will use Oxygen XML Editor only for developing the Saxon-CE stylesheet, leaving the execution part to a web browser. See more details about executing such a stylesheet on Saxonica's website.

Allow calls on extension functions ("-ext")
If selected, the stylesheet is allowed to call external Java functions. This does not affect calls on integrated extension functions, including Saxon and EXSLT extension functions. This option is useful when loading an untrusted stylesheet (such as from a remote site using http://[URL]). It ensures that the stylesheet cannot call arbitrary Java methods and thus gain privileged access to resources on your machine.

Enable assertions ("-ea")
In XSLT 3.0, you can use the `<xsl:assert>` element to make assertions in the form of XPath expressions, causing a dynamic error if the assertion turns out to be false. If this option is selected, XSLT 3.0 `<xsl:assert>` instructions are enabled. If it is not selected (default), the assertions are ignored.

Saxon-EE Options
The advanced options that are specific for Saxon 9.9.1.5 Enterprise Edition (EE) are as follows:

XML Schema version
Use this option to change the default XML Schema version for this transformation. To change the default XML Schema version globally, open the Preferences dialog box (Options > Preferences) (on page 98) and go to XML > XML Parser > XML Schema and use the Default XML Schema version option (on page 209).

Validation of the source file ("-val")
Requests schema-based validation of the source file and of any files read using `document()` or similar functions. It can have the following values:

- **Schema validation ("strict")** - This mode requires an XML Schema and allows for parsing the source documents with strict schema-validation enabled.
- **Lax schema validation ("lax")** - If an XML Schema is provided, this mode allows for parsing the source documents with schema-validation enabled but the validation will not fail if, for example, element declarations are not found.
- **Disable schema validation** - This specifies that the source documents should be parsed with schema-validation disabled.

Validation errors in the result tree treated as warnings ("-outval")
Normally, if validation of result documents is requested, a validation error is fatal. Selecting this option causes such validation failures to be treated as warnings.
Write comments for non-fatal validation errors of the result document

The validation messages for non-fatal errors are written (wherever possible) as a comment in the result document itself.

Enable streaming mode

Selecting this option will allow an XSLT to run in streaming mode. It is not selected by default.

Other Options

Initializer class

Equivalent to the -init Saxon command-line argument. The value is the name of a user-supplied class that implements the net.sf.saxon.lib.Initializer interface. This initializer is called during the initialization process, and may be used to set any options required on the configuration programmatically. It is particularly useful for tasks such as registering extension functions, collations, or external object models, especially in Saxon-HE where the option cannot be set via a configuration file. Saxon only calls the initializer when running from the command line, but the same code may be invoked to perform initialization when running user application code.

Using Saxon Integrated Extension Functions

Saxon, the transformation and validation engine used by Oxygen XML Editor, can be customized by adding custom functions (called Integrated Extension Functions) that can be called from XPath.

To define such a function, follow these steps:

1. Create a file with a Java class that extends net.sf.saxon.lib.ExtensionFunctionDefinition. Here is an example:

```java
private static class ShiftLeft extends ExtensionFunctionDefinition {

    @Override
    public StructuredQName getFunctionQName() {
        return new StructuredQName("eg", "http://example.com/saxon-extension", "shift-left");
    }

    @Override
    public SequenceType[] getArgumentTypes() {
        return new SequenceType[] {SequenceType.SINGLE_INTEGER, SequenceType.SINGLE_INTEGER};
    }

    @Override
    public SequenceType getResultType(SequenceType[] suppliedArgumentTypes) {
        return SequenceType.SINGLE_INTEGER;
    }
}
```
```java
@Override
public ExtensionFunctionCall makeCallExpression() {

    return new ExtensionFunctionCall() {
        public SequenceIterator call(SequenceIterator[] arguments, XPathContext context)
            throws XPathException {

            long v0 = ((IntegerValue)arguments[0].next()).longValue();
            long v1 = ((IntegerValue)arguments[1].next()).longValue();
            long result = v0<<v1;

            return Value.asIterator(Int64Value.makeIntegerValue(result));
        }
    };
}
```

2. Compile the class and add it to a JAR file.
3. Add a file called `net.sf.saxon.lib.ExtensionFunctionDefinition` that contains the fully qualified name of the Java class in the `META-INF/services/` folder of the JAR file.

![Note:]

To add more function definitions in the same JAR file, you need to add their fully qualified names on different lines.

To enable Oxygen XML Editor to pick up your custom function definition, the JAR file should be added to the classpath of the transformer. Here are some possibilities:

- If you develop a framework, you just need to link the JAR file in the Classpath tab (on page 118).
- In a validation scenario (on page 741), you can use the Extensions button to open a dialog box where you can add libraries.
- In a transformation scenario, you can use the Extensions button in the XSLT tab (on page 1363) to open a dialog box where you can add libraries.
- You can also create a plugin that contributes such a JAR file in the classpath (on page 2251).

**FO Processor Tab (XSLT Transformations)**

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The **FO Processor** tab contains the following options:

**Perform FO Processing**

Specifies whether or not an FO processor is applied (either the built-in Apache FOP engine or an external engine defined in Preferences) during the transformation.
Input

Choose between the following options to specify which input file to use:

- **XSLT result as input** - The FO processor is applied to the result of the XSLT transformation that is defined in the XSLT tab.
- **XML URL as input** - The FO processor is applied to the input XML file.

Method

The output format of the FO processing. The available options depend on the selected processor type.

Processor

Specifies the FO processor to be used for the transformation. It can be the built-in Apache FOP processor or an external processor (on page 231).

Output Tab (XSLT Transformations)

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The **Output** tab contains the following options:

**Prompt for file**

At the end of the transformation, a file browser dialog box is displayed for specifying the path and name of the file that stores the transformation result.

**Save As**

The path of the file where the result of the transformation is stored. You can specify the path by using the text field, the Insert Editor Variables (on page 292) button, or the Browse button.

**Open in Browser/System Application**

If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the file type of the result (for example, in Windows PDF files are often opened in Acrobat Reader).

![Note:]

To set the web browser that is used for displaying HTML/XHTML pages, go to Options > Preferences > Global, and set it in the Default Internet browser field.
• **Output file** - When **Open in Browser/System Application** is selected, you can use this button to automatically open the default output file at the end of the transformation.

• **Other location** - When **Open in Browser/System Application** is selected, you can use this option to open the file specified in this field at the end of the transformation. You can specify the path by using the text field, the **Insert Editor Variables** (on page 292) button, or the **Browse** button.

**Open in editor**

When this is option is selected, at the end of the transformation, the default output file is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor, or if it is an XSL-FO file it is opened with the built-in FO editor).

**Show in results view as**

You can choose to view the results in one of the following:

- **XML** - If this is selected, Oxygen XML Editor displays the transformation result in an XML viewer panel at the bottom of the application window with syntax highlighting (on page 195).

- **SVG** - If this is selected, Oxygen XML Editor displays the transformation result in an integrated SVG viewer in the Results panel (on page 1157) at the bottom of the application window and renders the result as an SVG image.

- **XHTML** - This option is only available if **Open in Browser/System Application** is not selected. If selected, Oxygen XML Editor displays the transformation result in a built-in XHTML browser panel at the bottom of the application window.

**Important:**

When transforming very large documents, you should be aware that selecting this option may result in very long processing times. This drawback is due to the built-in Java XHTML browser implementation. To avoid delays for large documents, if you want to see the XHTML result of the transformation, you should use an external browser by selecting the **Open in Browser/System Application** option instead.

- **Image URLs are relative to** - If **Show in results view as XHTML** is selected, this option specifies the path used to resolve image paths contained in the transformation result. You can specify the path by using the text field, the **Insert Editor Variables** (on page 292) button, or the **Browse** button.
Attention:
If your input XSLT contains `<xsl:result-document>` elements, then the secondary results will be saved to the specified URIs while the principal result is specified in this Output tab. For more information, see: https://www.w3.org/TR/xslt-30/#element-result-document.

Configuring an XSLT Processor for Generating Output

This section explains how to configure an XSLT processor and extensions for such a processor in Oxygen XML Editor.

Supported XSLT Processors

Oxygen XML Editor includes the following XSLT processors:

- **Xalan 2.7.2 - Xalan-Java** is an XSLT processor for transforming XML documents into HTML, text, or other XML document types. It implements XSL Transformations (XSLT) Version 1.0 and XML Path Language (XPath) Version 1.0.

- **Saxon 6.5.5 - Saxon 6.5.5** is an XSLT processor that implements the Version 1.0 XSLT and XPath with a number of powerful extensions. This version of Saxon also includes many of the new features that were first defined in the XSLT 1.1 working draft, but for conformance and portability reasons these are not available if the stylesheet header specifies `version="1.0"`.

- **Saxon 9.9.1.5 Home Edition (HE), Professional Edition (PE) - Saxon-HE/PE** implements the basic conformance level for XSLT 2.0 / 3.0 and XQuery 1.0. The term basic XSLT 2.0 / 3.0 processor is defined in the draft XSLT 2.0 / 3.0 specifications. It is a conformance level that requires support for all features of the language other than those that involve schema processing. The HE product remains open source, but removes some of the more advanced features that are present in Saxon-PE.

- **Saxon 9.9.1.5 Enterprise Edition (EE) - Saxon EE** is the schema-aware edition of Saxon and it is one of the built-in processors included in Oxygen XML Editor. Saxon EE includes an XML Schema processor, and schema-aware XSLT, XQuery, and XPath processors.

The validation in schema aware transformations is done according to the XML Schema 1.0 or 1.1. This can be configured in Preferences (on page 208).

Note:
---
Oxygen XML Editor implements a Saxon framework that allows you to create Saxon configuration files. Two templates are available: Saxon collection catalog and Saxon configuration. Both of these templates support content completion, element annotation, and attribute annotation.

Note:
---
Saxon can use the ICU-J localization library (`saxon9-icu.jar`) to add support for sorting and date/number formatting in a wide variety of languages. This library is not included in the Oxygen XML Editor installation kit. However, Saxon will use the default collation and
localization support available in the currently used JRE. To enable this capability, follow these steps:

2. Unpack the downloaded archive.
3. Create a new XSLT transformation scenario (or edit an existing one). In the XSLT tab, click the Extensions button to open the list of additional libraries used by the transformation process.
4. Click Add and browse to the folder where you unpacked the downloaded archive and choose the saxon9-icu.jar file.

Note that the saxon9-icu.jar should NOT be added to the application library folder because it will conflict with another version of the ICU-J library that comes bundled with Oxygen XML Editor.

- **Saxon-CE (Client Edition)** is Saxonica's implementation of XSLT 2.0 for use on web browsers. Oxygen XML Editor provides support for editing stylesheets that contain Saxon-CE extension functions and instructions. This support improves the validation, content completion, and syntax highlighting.

  **Note:**

  Saxon-CE, being JavaScript-based, was designed to run inside a web browser. This means that you will use Oxygen XML Editor only for developing the Saxon-CE stylesheet, leaving the execution part to a web browser. See more details about executing such a stylesheet on Saxonica's website.

- **Xsltproc (libxslt)** - Libxslt is the XSLT C library developed for the Gnome project. Libxslt is based on libxml2, the XML C library developed for the Gnome project. It also implements most of the EXSLT set of processor-portable extensions, functions, and some of Saxon's evaluate and expression extensions.

  Oxygen XML Editor uses Libxslt through its command-line tool (Xsltproc). Depending on your operating system, you must download the Libxslt libraries on your machine from http://xmlsoft.org/XSLT/downloads.html and place them in a local folder. Then you need to update the PATH environmental variable to contain the parent folder where the xsltproc executable is located.

  **Tip:**

  As an example, a Windows installation of the Xsltproc engine would follow these steps:

  2. Unzip all of them into the same folder of your choice.
3. Edit the **PATH** environment variable and add the **bin** folder for all four archives:

**Edit environment variable**

```
D:\apache-maven-3.1.1\bin
D:\Python27
%PATH%
C:\Users\r\Desktop\abc\libxslt-1.1.26.win32\bin
C:\Users\r\Desktop\abc\libxml2-2.7.8.win32\bin
C:\Users\r\Desktop\abc\iconv-1.9.2.win32\bin
C:\Users\r\Desktop\abc\zlib-1.2.5\bin
```

4. Restart Oxygen XML Editor.

**Result:** You can now use the **xsltproc** processor as an XSLT engine in the XSLT transformation scenario.

**Note:**

The Xsltproc processor can be configured from the **XSLTPROC** options page (on page 220).

**CAUTION:**

There is a known problem where file paths that contain spaces are not handled correctly in the LIBXML processor. For example, the built-in **XML Catalog** (on page 2972) files of the built-in document types (DocBook, TEI, DITA, etc.) are not handled properly by LIBXML if Oxygen XML Editor is installed in the default location on Windows (C:\Program Files). This is because the built-in **XML catalog** files are stored in the \{OXYGEN_INSTALL_DIR\}/frameworks subdirectory of the installation directory, and in this case it contains a space character.

• **MSXML 4.0 (Legacy)** - MSXML 4.0 is available only on Windows platforms. It can be used for transformation (on page 1361) and validation of XSLT stylesheets (on page 827).

Oxygen XML Editor uses the Microsoft XML parser through its command-line tool **msxsl.exe**.

Since **msxsl.exe** is only a wrapper, Microsoft Core XML Services (MSXML) must be installed on the computer. Otherwise, you will get a corresponding warning. You can get the latest Microsoft XML parser from Microsoft web-site.

• **MSXML .NET (Legacy)** - MSXML .NET is available only on Windows platforms. It can be used for transformation (on page 1361) and validation of XSLT stylesheets (on page 827).

Oxygen XML Editor performs XSLT transformations and validations using the .NET Framework XSLT implementation (**System.Xml.Xsl.XslTransform** class) through the **nxslt** command-line utility. The **nxslt** version included in Oxygen XML Editor is 1.6.

You should have the .NET Framework version 1.0 already installed on your system. Otherwise, you will get the following warning: **MSXML.NET requires .NET Framework version 1.0 to be installed. Exit code: 128.**
You can get the .NET Framework version 1.0 from the Microsoft website.  

- .NET 1.0 (Legacy) - A transformer based on the System.Xml 1.0 library available in the .NET 1.0 and .NET 1.1 frameworks from Microsoft (http://msdn.microsoft.com/xml/). It is available only on Windows.

You should have the .NET Framework version 1.0 or 1.1 already installed on your system. Otherwise, you will get the following warning: MXML.NET requires .NET Framework version 1.0 to be installed. Exit code: 128.

You can get the .NET Framework version 1.0 from the Microsoft website.

- .NET 2.0 (Legacy) - A transformer based on the System.Xml 2.0 library available in the .NET 2.0 Framework from Microsoft. It is available only on Windows.

You should have the .NET Framework version 2.0 already installed on your system. Otherwise, you will get the following warning: MXML.NET requires .NET Framework version 2.0 to be installed. Exit code: 128.

You can get the .NET Framework version 2.0 from the Microsoft website.

For information about configuring the XSLT preferences, see the XSLT options (on page 216) section.

**Configuring Custom XSLT Processors**

Oxygen XML Editor allows you to configure custom processors to be used for running XSLT and XQuery transformations.

To add a new custom processor, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to XML > XSLT-FO-XQuery > Custom Engines.
2. Click the New button at the bottom of the dialog box.
3. Configure the parameters for the custom engine (on page 230).
4. Click OK.

Note:

You can not use these custom engines in the Debugger perspective (on page 1956).

The output messages of a custom processor are displayed in an output view at the bottom of the application window. If an output message follows the format of an Oxygen XML Editor linked message (on page 737), clicking it highlights the location of the message in an editor panel containing the file referenced in the message.

Related Information:

Custom Engines Preferences (on page 230)
Configuring the XSLT Processor Extensions Paths

The Xalan and Saxon processors support the use of extension elements and extension functions. Unlike a literal result element, which the stylesheet simply transfers to the result tree, an extension element performs an action. The extension is usually used because the XSLT stylesheet fails in providing adequate functions for accomplishing a more complex task.

For more information about how to use extensions, see the following links:

- Saxon 6.5.5 - http://saxon.sourceforge.net/saxon6.5.5/extensions.html

To set an XSLT processor extension (a directory or a jar file), use the Extensions button (on page 1363) in the Edit scenario dialog box.

XSL-FO (Apache FOP) Processor for Generating PDF Output

The Oxygen XML Editor installation package is distributed with the Apache FOP that is a Formatting Objects processor for transforming your XML documents to PDF. FOP is a print and output independent formatter driven by XSL Formatting Objects. FOP is implemented as a Java application that reads a formatting object tree and renders the resulting pages to a specified output.

To see the version of the built-in XSL-FO processor for your installation, go to Help > About > Libraries and search for Apache FOP.

Other FO processors can be configured in the FO Processors preferences page (on page 231).

Add a Font to the Built-in FO Processor - Simple Version

If the font that must be set to Apache FOP is one of the fonts that are installed in the operating system you should follow the next steps for creating and setting a FOP configuration file that looks for the font that it needs in the system fonts. It is a simplified version of the procedure for setting a custom font in Apache FOP (on page 1423).

1. Register the font in FOP configuration. (This is not necessary for DITA PDF transformations, skip to the next step)

   a. Create a FOP configuration file that specifies that FOP should look for fonts in the installed fonts of the operating system.

   ```xml
   <fop version="1.0">
     <renderers>
       <renderer mime="application/pdf">
         <fonts>
           <auto-detect/>
         </fonts>
       </renderer>
     </renderers>
   </fop>
   ```
b. Open the Preferences dialog box (Options > Preferences) (on page 98), go to XML > XSLT/FO/XQuery > FO Processors, and enter the path of the FOP configuration file in the Configuration file text field.

2. Set the font on the document content.
   This is done usually with XSLT stylesheet parameters and depends on the document type processed by the stylesheet.
   • For DocBook documents you can start with the built-in scenario called DocBook PDF, edit the XSLT parameters (on page 1361) and set the font name (for example, Arial Unicode MS) to the body.font.family and title.font.family parameters.
   • For TEI documents you can start with the built-in scenario called TEI PDF, edit the XSLT parameters (on page 1361) and set the font name (for example, Arial Unicode MS) to the bodyFont and sansFont parameters.
   • For DITA transformations to PDF using DITA-OT you should modify the following two files:
     - DITA-OT-DIR/plugins/org.dita.pdf2/cfg/fo/font-mappings.xml
       The <font-face> element included in each <physical-font> element that has the charset="default" attribute must contain the name of the font (for example, Arial Unicode MS)
     - DITA-OT-DIR/plugins/org.dita.pdf2.fop/fop/conf/fop.xconf - An <auto-detect> element must be inserted in the <fonts> element, which is inside the <renderer> element that has the mime="application/pdf" attribute:

```xml
<renderer mime="application/pdf">
  ...<font>
    <auto-detect/>
  </font>
  ...</renderer>
```

### Add a Font to the Built-in FO Processor - Advanced Version

If an XML document is transformed to PDF using the built-in Apache FOP processor but it contains some Unicode characters that cannot be rendered by the default PDF fonts, then a special font that is capable to render these characters must be configured and embedded in the PDF result.

⚠️ **Important:**

On Windows, fonts are located into the `C:\Windows\Fonts` directory. On Mac, they are placed in `/Library/Fonts`. To install a new font on your system, it is enough to copy it in the Fonts directory. If a special font is installed in the operating system, there is a simple way of telling FOP to look for it. See the simplified procedure for adding a font to FOP (on page 1422).
1. Locate the font.

First, find out the name of a font that has the glyphs for the special characters you used. One font that covers most characters, including Japanese, Cyrillic, and Greek, is Arial Unicode MS.

2. Register the font in the FOP configuration.

**Note:**

DITA PDF transformations have their own `fop.xconf` (`DITA-OT-DIR/plugins/org.dita.pdf2.fop/fop/conf/fop.xconf`). If the font is not installed in the system, it needs to be referenced in the `fop.xconf`.

a. For information about registering the font in the FOP Configuration, see: https://xmlgraphics.apache.org/fop/2.3/fonts.html.

b. Open the Preferences dialog box (Options > Preferences) (on page 98), go to XML > XSLT/FO/ XQuery > FO Processors, and enter the path of the FOP configuration file in the Configuration file text field.

3. Set the font on the document content.

This is usually done with XSLT stylesheet parameters and depends on the document type processed by the stylesheet.

**DocBook Example:** For DocBook documents, you can start with the built-in scenario called DocBook PDF, edit the XSLT parameters (on page 1361), and set the font name (for example, Arialuni) to the `body.font.family` and `title.font.family` parameters.

**TEI Example:** For TEI documents, you can start with the built-in scenario called TEI PDF, edit the XSLT parameters (on page 1361), and set the font name (for example, Arialuni) to the `bodyFont` and `sansFont` parameters.

**DITA Example:** For DITA to PDF transformations using DITA-OT modify the following two files:

- `DITA-OT-DIR/plugins/org.dita.pdf2/cfg/fo/font-mappings.xml` - The `<font-face>` element included in each `<physical-font>` element that has the `char-set="default"` attribute must contain the name of the font.
- `DITA-OT-DIR/plugins/org.dita.pdf2/fop/conf/fop.xconf` - A `<font>` element must be inserted in the `<fonts>` element, which is inside the `<renderer>` element that has the `mime="application/pdf"` attribute.

For more information, see: https://xmlgraphics.apache.org/fop/2.1/fonts.html.

---

**Adding Libraries to the Built-in FO Processor (XML with XSLT and FO)**

Starting with Oxygen XML Editor version 20.0, both hyphenation and PDF image support are enabled by default in the built-in Apache FO processor. For older version of Oxygen XML Editor, use the following procedures to enable such support.
Adding Hyphenation Support for XML with XSLT Transformation Scenarios

If you want to add newer hyphenation libraries or you are using an older version of Oxygen XML Editor, follow this procedure:

1. Create a folder called `fop` in the `[OXYGEN_INSTALL_DIR]/lib` folder.
2. Download the compiled JAR (on page 2967) from OFFO.
3. Copy the `fop-hyph.jar` file into the `[OXYGEN_INSTALL_DIR]/lib/fop` folder.
4. Restart Oxygen XML Editor.

Adding Support for PDF Images

To add support for PDF images in an older version of Oxygen XML Editor, follow these steps:

1. Create a folder called `fop` in the `[OXYGEN_INSTALL_DIR]/lib` folder.
2. Download the `fop-pdf-images` JAR libraries.
3. Copy the libraries into the `[OXYGEN_INSTALL_DIR]/lib/fop` folder.
4. Restart Oxygen XML Editor.

How to Enable Debugging for FO Processor Transformations

If you encounter errors when running PDF transformations that use an FO processor, it is possible to enable debugging/logging to help you identify the problem. To enable debugging/logging for FO processing, follow this procedure:

1. Locate and edit the following configuration file: `[OXYGEN_INSTALL_DIR]/tools/config/log4j2.xml`.

   - **Note:**
     - You need write access to this folder, so if you do not have administrator permissions, you may first need to copy the file to another location where you have write access.

2. Edit the `<Root>` element (inside the `<Loggers>` element), change its level to `debug`, and save the file.
3. Restart Oxygen XML Editor and re-run the transformation.

   - **Tip:**
     - To make it easier to analyze the data in the logs, it is recommended that you use a small input file when trying to reproduce the problem.

4. Once you are finished with the debugging session, remember to edit the `log4j2.xml` file and change the `<priority>` element back to its original value. Otherwise, performance could be affected.

XProc Transformation

This type of transformation specifies the parameters and location of an XProc script.

A sequence of transformations described by an XProc script can be executed with an XProc transformation scenario. To create an XProc transformation scenario, use one of the following methods:
• Use the Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu. Then click the New button and select XProc transformation.

• Go to Window > Show View and select Transformation Scenarios to display this view (on page 1450). Click the New Scenario drop-down menu button and select XProc transformation.

Both methods open the New Scenario dialog box.

The upper part of the dialog box allows you to specify the Name of the transformation scenario and the following Storage options:

• Project Options (on page 2970) - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.

• Global Options (on page 2967) - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

Related Information:
Integrating an External XProc Engine (on page 1430)
Editing XProc Scripts (on page 1097)

XProc Tab

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The XProc tab contains the following options:

XProc URL

Specify the source XProc file to be used by the transformation. You can specify the path by using the text field, its history drop-down, the Insert Editor Variables (on page 292) button, or the browsing actions in the Browse drop-down list. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, the file is used directly from its remote location.

Processor

Allows you to select the XProc engine to be used for the transformation. You can select the Add-on for Calabash XProc engine or a custom engine that is configured in the XProc Preferences page (on page 214).
Inputs Tab (XProc Transformations)

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The Inputs tab contains a list with the ports that the XProc script uses to read input data. Use the Filter text box to search for a specific term in the entire ports collection.

Each input port has an assigned name in the XProc script. The XProc engine reads data from the URL specified in the URL column.

The following actions are available for managing the input ports:

- **New**
  
  Opens an Edit dialog box that allows you to add a new port and its URL. The built-in editor variables (on page 292) and custom editor variables (on page 301) can be used to specify the URL.

- **Edit**
  
  Opens an Edit dialog box that allows you to modify the selected port and its URL. The built-in editor variables (on page 292) and custom editor variables (on page 301) can be used to specify the URL.

- **Delete**
  
  Removes the selected port from the list. It is available only for new ports that have been added to the list.

Parameters Tab (XProc Transformations)

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The Parameters tab presents a list of ports and parameters collected from the XProc script. The tab is divided into three sections:

- **List of Ports**
  
  In this section, you can use the New and Delete buttons to add or remove ports.

- **List of Parameters**
  
  This section presents a list of parameters for each port and includes columns for the parameter name, namespace URI, and its value. Use the Filter text box to search for a specific term in the entire parameters collection. You can use the New and Delete buttons to add or remove parameters. You can edit the value of each cell in this table by double-clicking the cell. You can also sort the parameters by clicking the column headers.

- **Editor Variable Information**
The built-in editor variables (on page 292) and custom editor variables (on page 301) can be used for specifying the URI. The message pane at the bottom of the dialog box provides more information about the editor variables that can be used.

Outputs Tab (XProc Transformations)

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The Outputs tab displays a list of output ports (along with the URL) collected from the XProc script. Use the Filter text box to search for a specific term in the entire ports collection. You can also sort the columns by clicking the column headers.

The following actions are available for managing the output ports:

New

Opens an Edit dialog box that allows you to add a new output port and its URL. An editor variable (on page 292) can be inserted for the URL by using the Insert Editor Variables button. There is also a Show in transformation results view option that allows you to select whether or not the results will be displayed in the output Results view (on page 508).

Edit

Opens an Edit dialog box that allows you to edit an existing output port and its URL. An editor variable (on page 292) can be inserted for the URL by using the Insert Editor Variables button. There is also a Show in transformation results view option that allows you to select whether or not the results will be displayed in the output Results view (on page 508).

Delete

Removes the selected output port from the list. It is available only for new ports that have been added to the list.

Additional options that are available at the bottom of this tab include:

Open in Editor

If this option is selected, the XProc transformation result is automatically opened in an editor panel.

Open in Browser/System Application

If this option is selected, you can specify a file to be opened at the end of the XProc transformation in the browser or system application that is associated with the file type. You can specify the path by using the text field, its history drop-down, the Insert Editor Variables button, or the browsing actions in the Browse drop-down list.

Results

The result of the XProc transformation can be displayed as a sequence in an output view with two sections:
• A list with the output ports on the left side.
• The content that correspond to the selected output port on the right side.

Figure 452. XProc Transformation Results View

Options Tab (XProc Transformations)

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The Options tab displays a list of the options collected from the XProc script. The tab is divided into two sections:

List of Options

This section presents a list of options and includes columns for the option name, namespace URI, and its value. Use the Filter text box to search for a specific term in the entire options collection. You can use the New and Delete buttons to add or remove options. You can edit the value of each cell in this table by double-clicking the cell. You can also sort the parameters by clicking the column headers. The names of edited options are displayed in bold.

Editor Variable Information

The built-in editor variables (on page 292) and custom editor variables (on page 301) can be used for specifying the URI. This section provides more information about the editor variables that can be used.

Calabash XProc Processor for Generating PDF Output

To generate PDF output from your XProc pipeline (when using the Calabash XProc processor), follow these steps:

2. Uncomment the `<system-property name="com.xmlcalabash.fo-processor" value="com.xmlcalabash.util.FoXEP"/>` system property.
3. Uncomment the `<system-property name="com.renderx.xep.CONFIG" file="../../../tools/xep/xep.xml"/>` system property. Edit the `@file` attribute to point to the configuration file that is usually located in the XEP installation folder.

4. Uncomment the references to the XEP libraries. Edit them to point to the matching library names from the XEP installation directory.

5. Restart Oxygen XML Editor.

### Integrating an External XProc Engine

Oxygen XML Editor includes a bundled version of the *Calabash* XProc engine that can be used for XProc transformations and validation, but you can also integrate other external XProc engines. When you edit an XProc transformation scenario, there is a **Processor** drop-down menu where you can select the XProc engine to be used for the transformation.

If you do not need the external XProc engine to be used for automatic validation or pass parameters/ports and it is not Java-based, you can simply add the external engine by using the **XProc preferences page (on page 214)**. Otherwise, if the external engine is Java-based, or it has validation support, or it can receive parameters or ports passed from the transformation, you need to integrate it using the plugin extension procedure below.

For example, there is a public project on GitHub that is an implementation for integrating Morgana XProc with Oxygen XML Editor: [https://github.com/xml-project/support-for-xmleditor](https://github.com/xml-project/support-for-xmleditor). Also, the Javadoc documentation of the XProc API is available for download from the application website as a zip file: *xprocAPI.zip*.

To create an XProc integration project, follow these steps:

1. Move the `oxygen.jar` file from `{OXYGEN_INSTALL_DIR}/lib` to the `lib` folder of your project.
2. Implement the `ro.sync.xml.transformer.xproc.api.XProcTransformerInterface` interface.
3. Create a **Java archive (JAR) (on page 2967)** from the classes you created.
4. Create an `engine.xml` file according to the `engine.dtd` file. The attributes of the `<engine>` element are as follows:
   a. **name** - The name of the XProc engine.
   c. **class** - The complete name of the class that implements `ro.sync.xml.transformer.xproc.api.XProcTransformerInterface`.
   d. **version** - The version of the integration.
   e. **engineVersion** - The version of the integrated engine.
   f. **vendor** - The name of the vendor / implementer.
   g. **supportsValidation** - `true` if the engine supports validation (otherwise, `false`).

   The `<engine>` element has only one child, `<runtime>`. The `<runtime>` element contains several `<library>` elements with the `@name` attribute containing the relative or absolute location of the libraries necessary to run this integration.

5. Create a new folder (for example, named `MyXProcEngine`) and place the `engine.xml` and all the libraries necessary to run the new integration in that folder.
6. Place that new folder (e.g. MyXprocEngine) inside a new plugin folder. This new plugin folder should also contain a plugin.xml file that points to the new engine folder (e.g. MyXprocEngine). The plugin.xml file would look like this (it is based on the AdditionalXProcEngine extension (on page 2262)):

```xml
<plugin
  id="morgana.xproc.addon"
  name="Contribute Morgana XProc"
  description="Contribute Morgana XProc"
  version="1.0"
  vendor="Syncro Soft"
  class="ro.sync.exml.plugin.Plugin"
  classLoaderType="preferReferencedResources">
  <extension type="AdditionalXProcEngine" path="MyXprocEngine/"/>
</extension>
</plugin>
```

**Related Information:**
- Editing XProc Scripts (on page 1097)
- Creating an XProc Transformation Scenario (on page 1425)
- Additional XProc Engine Plugin Extension (on page 2262)

**XQuery Transformation**

This type of transformation specifies the parameters and location of an XML source that the edited XQuery file is applied on.

**Note:**

When the XML source is a native XML database, the source field of the scenario is empty because the XML data is read with XQuery-specific functions, such as `document()`. When the XML source is a local XML file, the URL of the file is specified in the input field of the scenario.

To create an **XQuery transformation** scenario, use one of the following methods:

- Use the Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu. Then click the New button and select XQuery transformation.
- Go to Window > Show View and select Transformation Scenarios to display this view (on page 1450). Click the New Scenario drop-down menu button and select XQuery transformation.

Both methods open the New Scenario dialog box.

The upper part of the dialog box allows you to specify the Name of the transformation scenario and the following Storage options:
Project Options (on page 2970) - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.

Global Options (on page 2967) - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

XQuery Tab

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The XQuery tab contains the following options:

XML URL

Specifies the source XML file. You can specify the path by using the text field, its history drop-down, the Insert Editor Variables (on page 292) button, or the browsing actions in the Browse drop-down list. You can also use the Open in editor button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, then the file is used directly from its remote location.

Note:
If the transformer engine is Saxon 9.x and a custom URI resolver is configured in the advanced Saxon preferences page (on page 220), the XML input of the transformation is passed to that URI resolver.

XQuery URL

Specifies the source XQuery file to be used for the transformation. You can specify the path by using the text field, its history drop-down, the Insert Editor Variables (on page 292) button, or the browsing actions in the Browse drop-down list. You can also use the Open in editor button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, the file is used directly from its remote location.

Transformer

This drop-down menu presents all the transformation engines available to Oxygen XML Editor for performing a transformation. These include the built-in engines and the external engines defined in the Custom Engines preferences page (on page 230). The engine you choose is used as the default transformation engine. Also, if an XSLT or XQuery document does not have an associated validation scenario, this transformation engine is used in the validation process (if it provides validation support).
Advanced options

Allows you to configure the advanced options of the Saxon HE/PE/EE engine (on page 1380) for the current transformation scenario. To configure the same options globally, go to the Saxon-HE/PE/EE preferences page (on page 217). For the current transformation scenario, these Advanced options override the options configured in that preferences page.

Parameters

Opens the Configure parameters dialog box (on page 1379) for configuring the XQuery parameters. You can use the buttons in this dialog box to add, edit, or remove parameters. If the XQuery transformation engine is custom-defined, you can not use this dialog box to set parameters. Instead, you can copy all parameters from the dialog box using contextual menu actions and edit the custom XQuery engine to include the necessary parameters in the command line that starts the transformation process.

Extensions

Opens a dialog box for configuring the XQuery extension JARS or classes (on page 1380) that define extension Java functions or extension XSLT elements used in the transformation.

XQuery Parameters

The global parameters of the XQuery file used in a transformation scenario can be configured by using the Parameters button in the XQuery tab.

The resulting dialog box includes a table that displays all the parameters of the current XQuery file, along with their descriptions and current values. You can also add, edit, and remove parameters, and use the Filter text box to search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

If the XPath column is selected, the parameter value is evaluated as an XPath expression before starting the XQuery transformation.

Example:

For example, you can use expressions such as:

```xquery
doc('test.xml')//entry
//person[@atr='val']
```

Note:

1. The doc function solves the argument relative to the XQuery file location. You can use full paths or editor variables (on page 292) (such as $cfdu [current file directory]) to specify other locations: doc('$cfdu/test.xml')//*
2. Only XPath functions are allowed.

Below the table, the following actions are available for managing the parameters:
New

Opens the Add Parameter dialog box that allows you to add a new parameter to the list. An editor variable (on page 292) can be inserted in the text box using the Insert Editor Variables button. If the Evaluate as XPath option is selected, the parameter will be evaluated as an XPath expression.

Edit

Opens the Edit Parameter dialog box that allows you to edit the selected parameter. An editor variable (on page 292) can be inserted in the text box using the Insert Editor Variables button. If the Evaluate as XPath option is selected, the parameter will be evaluated as an XPath expression.

Unset

Resets the selected parameter to its default value. Available only for edited parameters with set values.

Delete

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

The bottom panel presents the following:

- The default value of the parameter selected in the table.
- A description of the parameter, if available.
- The system ID of the stylesheet that declares it.

Related Information:
Editor Variables (on page 292)

XQuery Extensions

The Extensions button is used to specify the JAR (on page 2967) and classes that contain extension functions called from the XQuery file of the current transformation scenario. You can use the Add, Edit, and Remove buttons to configure the extensions.

An extension function called from the XQuery file of the current transformation scenario will be searched, in the specified extensions, in the order displayed in this dialog box. To change the order of the items, select the item to be moved and click the Move up or Move down buttons.

Advanced Saxon HE/PE/EE XQuery Transformation Options

The XQuery transformation scenario allows you to configure advanced options that are specific for the Saxon HE (Home Edition), PE (Professional Edition), and EE (Enterprise Edition) engines. They are the same options as those in the Saxon HE/PE/EE preferences page (on page 225) but they are configured as a specific set of transformation options for each transformation scenario, while the values set in the preferences page apply as
global options. The advanced options configured in a transformation scenario override the global options (on page 2967) defined in the preferences page.

**Saxon-HE/PE/EE Options**
The advanced options for Saxon 9.9.1.5 Home Edition (HE), Professional Edition (PE), and Enterprise Edition (EE) are as follows:

**Use a configuration file ("-config")**
Sets a Saxon 9.9.1.5 configuration file that is used for XQuery transformation and validation scenarios.

**Enable Optimizations ("-opt")**
This option is selected by default, which means that optimization is enabled. If not selected, the optimization is suppressed, which is helpful when reducing the compiling time is important, optimization conflicts with debugging, or optimization causes extension functions with side-effects to behave unpredictably.

**Use linked tree model ("-tree:linked")**
This option activates the linked tree model.

**Recoverable errors ("-warnings")**
Specifies how dynamic errors are handled. The following options can be selected:

- **Recover silently ("silent")** - Continues processing without reporting the error.
- **Recover with warnings ("recover")** - Issues a warning but continues processing.
- **Signal the error and do not attempt recovery ("fatal")** - Issues an error and stops processing.

**Strip whitespaces ("-strip")**
Specifies how the strip whitespaces operation is handled. You can choose one of the following values:

- **All ("all")** - Strips all whitespace text nodes from source documents before any further processing, regardless of any @xml:space attributes in the source document.
- **Ignore ("ignoreable")** - Strips all ignorable whitespace text nodes from source documents before any further processing, regardless of any @xml:space attributes in the source document. Whitespace text nodes are ignorable if they appear in elements defined in the DTD or schema as having element-only content.
- **None ("none")** - Strips no whitespace before further processing.

**Enable profiling ("-TP")**
If selected, profiling of the execution time in a query is enabled. The corresponding text field is used to specify the path to the output file where the profiling information will be saved. As long as the option is selected, and the output file specified, it will gather timed tracing information and create a profile report to the specified file.
Note:
The profiling support works only if the Present as a sequence transformation option (on page 1383) is not set.

Saxon-PE/EE Options
The following advanced options are specific for Saxon 9.9.1.5 Professional Edition (PE) and Enterprise Edition (EE) only:

Allow calls on extension functions ("-ext")
If selected, calls on external functions are allowed. Selecting this option is recommended in an environment where untrusted stylesheets may be executed. It also disables user-defined extension elements and the writing of multiple output files, both of which carry similar security risks.

Saxon-EE Options
The advanced options that are specific for Saxon 9.9.1.5 Enterprise Edition (EE) are as follows:

Validation of the source file ("-val")
Requests schema-based validation of the source file and of any files read using document() or similar functions. It can have the following values:

- Schema validation ("strict") - This mode requires an XML Schema and allows for parsing the source documents with strict schema-validation enabled.
- Lax schema validation ("lax") - If an XML Schema is provided, this mode allows for parsing the source documents with schema-validation enabled but the validation will not fail if, for example, element declarations are not found.
- Disable schema validation - This specifies that the source documents should be parsed with schema-validation disabled.

Validation errors in the result tree treated as warnings ("-outval")
Normally, if validation of result documents is requested, a validation error is fatal. Selecting this option causes such validation failures to be treated as warnings.

Write comments for non-fatal validation errors of the result document
The validation messages for non-fatal errors are written (wherever possible) as a comment in the result document itself.

Enable XQuery update ("--update:(on|off)")
This option controls whether or not XQuery update syntax is accepted. The default value is off.

Backup files updated by XQuery ("--backup:(on|off)")
If selected, backup versions for any XML files updated with an XQuery Update are generated. This option is available when the Enable XQuery update option is selected.
Other Options

Initializer class

Equivalent to the \texttt{-init} Saxon command-line argument. The value is the name of a user-supplied class that implements the \texttt{net.sf.saxon.lib.Initializer} interface. This initializer is called during the initialization process, and may be used to set any options required on the configuration programmatically. It is particularly useful for tasks such as registering extension functions, collations, or external object models, especially in Saxon-HE where the option cannot be set via a configuration file. Saxon only calls the initializer when running from the command line, but the same code may be invoked to perform initialization when running user application code.

FO Processor Tab (XQuery Transformations)

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The FO Processor tab contains the following options:

Perform FO Processing

Specifies whether or not an FO processor is applied (either the built-in Apache FOP engine or an external engine defined in Preferences) during the transformation.

Input

Choose between the following options to specify which input file to use:

- **XQuery result as input** - The FO processor is applied to the result of the XQuery transformation that is defined in the XQuery tab.
- **XML URL as input** - The FO processor is applied to the input XML file.

Method

The output format of the FO processing. The available options depend on the selected processor type.

Processor

Specifies the FO processor to be used for the transformation. It can be the built-in Apache FOP processor or an external processor (on page 231).

Output Tab (XQuery Transformations)

When you create a new transformation scenario (on page 1361) or edit an existing one (on page 1440), a configuration dialog box is displayed that allows you to customize the transformation with various options in several tabs.

The Output tab contains the following options:

Present as a sequence
Selecting this option will reduce the time necessary to fetch the full results, as it will only fetch the first chunk of the results.

**Prompt for file**

At the end of the transformation, a file browser dialog box is displayed for specifying the path and name of the file that stores the transformation result.

**Save As**

The path of the file where the result of the transformation is stored. You can specify the path by using the text field, the `Insert Editor Variables (on page 292)` button, or the `Browse` button.

**Open in Browser/System Application**

If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the file type of the result (for example, in Windows PDF files are often opened in Acrobat Reader).

---

**Note:**

To set the web browser that is used for displaying HTML/XHTML pages, go to *Options > Preferences > Global*, and set it in the *Default Internet browser* field.

- **Output file** - When *Open in Browser/System Application* is selected, you can use this button to automatically open the default output file at the end of the transformation.
- **Other location** - When *Open in Browser/System Application* is selected, you can use this option to open the file specified in this field at the end of the transformation. You can specify the path by using the text field, the `Insert Editor Variables (on page 292)` button, or the `Browse` button.

---

**Open in editor**

When this is option is selected, at the end of the transformation, the default output file is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor, or if it is an XSL-FO file it is opened with the built-in FO editor).

**Show in results view as**

You can choose to view the results in one of the following:
• **XML** - If this is selected, Oxygen XML Editor displays the transformation result in an XML viewer panel at the bottom of the application window with syntax highlighting (on page 195).

• **SVG** - If this is selected, Oxygen XML Editor displays the transformation result in an integrated SVG viewer in the Results panel (on page 1157) at the bottom of the application window and renders the result as an SVG image.

• **XHTML** - This option is only available if **Open in Browser/System Application** is not selected. If selected, Oxygen XML Editor displays the transformation result in a built-in XHTML browser panel at the bottom of the application window.

**Important:**
When transforming very large documents, you should be aware that selecting this option may result in very long processing times. This drawback is due to the built-in Java XHTML browser implementation. To avoid delays for large documents, if you want to see the XHTML result of the transformation, you should use an external browser by selecting the **Open in Browser/System Application** option instead.

• **Image URLs are relative to** - If **Show in results view as XHTML** is selected, this option specifies the path used to resolve image paths contained in the transformation result. You can specify the path by using the text field, the **Insert Editor Variables** (on page 292) button, or the **Browse** button.

**SQL Transformation**

This type of transformation specifies a database connection for the database server that runs the SQL file associated with the scenario. The data processed by the SQL script is located in the database.

To create an SQL transformation scenario, use one of the following methods:

- Use the **Configure Transformation Scenario(s)** (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu. Then click the **New** button and select SQL transformation.

- Go to **Window > Show View** and select **Transformation Scenarios** to display this view (on page 1450). Click the **New Scenario** drop-down menu button and select SQL transformation.

Both methods open the **New Scenario** dialog box. This dialog box allows you to configure the following options that control the transformation:

**Name**

The unique name of the SQL transformation scenario.

**Storage**

Allows you to select one of the following storage options:
• **Project Options** *(on page 2970)* - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.

• **Global Options** *(on page 2967)* - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

**SQL URL**

Allows you to specify the URL of the SQL script. You can specify the path by using the text field, its history drop-down, the ✂️ *Insert Editor Variables* *(on page 292)* button, or the browsing actions in the 📦 · Browse drop-down list. You can also use the ✗️ *Open in editor* button to open the specified file in the editor panel.

**Connection**

Allows you to select a connection from a drop-down list. To configure a connection, use the 🛠️ *Advanced options* button to open the **Data Source preferences page** *(on page 246)*.

**Parameters**

Allows you to add or configure parameters for the transformation.

### Editing a Transformation Scenario

Editing a transformation scenario is useful if you need to configure some of its parameters.

**Note:**

Since transformation scenarios that are associated with built-in frameworks *(on page 2967)* are read-only, to edit one of these scenarios you will need to duplicate it and edit the duplicated scenario *(on page 1442)*.

To configure an existing transformation scenario, follow these steps:

1. Select the 🔲 *Configure Transformation Scenario(s)* *(Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu.

   **Step Result:** The *Configure Transformation Scenario(s)* dialog box *(on page 1443)* is opened.

2. Select the particular transformation scenario and click the Edit button at the bottom of the dialog box or from the contextual menu.

   **Tip:**

   You could also select the scenario and the 🔲 **Edit** button in the **Transformation Scenarios view** *(on page 1450)* to achieve the same result.
Result: This will open an **Edit scenario** configuration dialog box that allows you to configure various options in several tabs, depending on the type of transformation scenario that was selected.

![Edit Scenarios Configuration Dialog Box](image)

**Figure 453. Edit Scenarios Configuration Dialog Box**

**Transformation Types**

The **Configure Transformation Scenario(s)** dialog box *(on page 1443)* contains a **Type** column that shows you the transformation type for each of the listed scenarios. Each type of transformation contains some tabs with various configuration options.

The following is a list of the transformation types and their particular tabs (click the name of each tab below to see details about all the options that are available):

- **DITA-OT** - This type of transformation includes configurable options in the following tabs:
  - Templates Tab *(on page 2867)*
  - FO Processor Tab *(on page 2871)* (Available for PDF output)
  - Parameters Tab *(on page 2873)*
  - Filters Tab *(on page 2875)*
  - Advanced Tab *(on page 2876)*
  - Output Tab *(on page 2878)*
- **ANT** - This type of transformation includes configurable options in the following tabs:
  - Options Tab *(on page 1403)*
  - Parameters Tab *(on page 1404)*
  - Output Tab *(on page 1405)*
- **XSLT** - This type of transformation includes configurable options in the following tabs:
  - XSLT Tab *(on page 1362)*
  - FO Processor Tab *(on page 1370)*
  - Output Tab *(on page 1371)*
- **XProc** - This type of transformation includes configurable options in the following tabs:
  - XProc Tab *(on page 1426)*
  - Inputs Tab *(on page 1426)*
Duplicating a Transformation Scenario

Duplicating a transformation scenario is useful for creating a scenario that is similar to an existing one or to edit a built-in transformation scenario.

To configure an existing transformation scenario, follow these steps:

1. Select the Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu.

   **Step Result:** The Configure Transformation Scenario(s) dialog box (on page 1443) is opened.

2. Select the particular transformation scenario and click the Duplicate button at the bottom of the dialog box or from the contextual menu.

   **Tip:**
   You could also select the scenario and the Duplicate button in the Transformation Scenarios view (on page 1450) to achieve the same result.

**Result:** This will open an Edit scenario configuration dialog box that allows you to configure various options in several tabs, depending on the type of transformation scenario that was selected. For information about all the specific options in the various tabs, see the Transformation Types section (on page 1441).

Related Information:
- Creating New Transformation Scenarios (on page 1361)
- Editing a Transformation Scenario (on page 1440)
Applying Associated Transformation Scenarios

If you have associated transformation scenarios for the current document (in the Configure Transformation Scenario(s) dialog box (on page 1443) or Transformation Scenarios view (on page 1450)), Oxygen XML Editor included an Apply Transformation Scenario(s) action that allows you to quickly apply the associated transformation scenarios on the current document. Note that if an association is not detected, this action will open the Configure Transformation Scenario(s) dialog box (on page 1443) where you can choose the scenarios you want to apply.

The Apply Transformation Scenario(s) action can be initiated from any of the following methods:

- Use the Ctrl + Shift + T (Command + Shift + T on OS X) keyboard shortcut.
- Click the Apply Transformation Scenario(s) button on the main toolbar.
- Click the Apply Transformation Scenario(s) button on the toolbar in the Transformation Scenarios view (on page 1450).
- Right-click a file in the Project view (on page 368) and select Transform > Apply Transformation Scenario(s).
- Use the Apply Associated button in the Configure Transformation Scenario(s) dialog box (on page 1443).

Related Information:
Creating New Transformation Scenarios (on page 1361)
Editing a Transformation Scenario (on page 1440)
Configure Transformation Scenario(s) Dialog Box (on page 1443)
Transformation Scenarios View (on page 1450)

Configure Transformation Scenario(s) Dialog Box

You can use the Configure Transformation Scenarios(s) dialog box for editing existing transformation scenarios (on page 1440) or creating new ones (on page 1361).

To open this dialog box, use the Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X)) action from the toolbar or the Document > Transformation menu.
The dialog box includes the following options and features:

**Search Filter Field**

You can begin typing text in the search field at the top of the dialog box to filter the scenarios shown in the table below this field.

**Settings**

Use this drop-down to access the following options:

**Show all scenarios**

Select this option to display all the available scenarios, regardless of the document they are associated with.

**Show only the scenarios available for the editor**

Select this option to only display the scenarios that Oxygen XML Editor can apply for the current document type.

**Show associated scenarios**

Select this option to only display the scenarios associated with the document you are editing.

**Import scenarios**

This option opens the **Import scenarios** dialog box that allows you to select the scenarios file that contains the scenarios you want to import. If one of the
scenarios you import is identical to an existing scenario, Oxygen XML Editor ignores it. If a conflict appears (an imported scenario has the same name as an existing one), you can choose between two options:

- Keep or replace the existing scenario.
- Keep both scenarios.

**Note:** When you keep both scenarios, Oxygen XML Editor adds *imported* to the name of the imported scenario.

**Export selected scenarios**

Use this option to export selected scenarios individually. Oxygen XML Editor creates a *scenarios* file that contains the exported scenarios. This is useful if you want to share scenarios with others or export them to another computer.

**Scenarios Table Section**

The middle section of the dialog box is a table that displays the scenarios that you can apply to the current document. You can view both the scenarios associated with the current document type and the scenarios defined at project level (on page 2970). The table includes following sortable columns:

- **Association** - The checkboxes in this column mark whether or not a transformation scenario is associated with the current document.
- **Scenario** - This column presents the names of the transformation scenarios.
- **Type** - If the *Show Type* contextual menu option is selected, this column displays the type of the transformation scenario. For further details about the types of transformation scenarios that are available in Oxygen XML Editor, see the Transformation Types section (on page 1441).

If you right-click in the header area, the following options are accessible:

**Show Type**

Use this option to display the transformation type of each scenario.

**Show Storage**

Use this option to display the storage location of the scenarios.

**Group by Association**

Select this option to group the scenarios depending on whether or not they are associated with the current document.

**Group by Type**

Select this option to group the scenarios by their type.
Group by Storage
Select this option to group the scenarios by their storage location.

Ungroup all
Select this option to ungroup all the scenarios.

Reset Layout
Select this option to restore the default settings of the layout.

If you right-click any particular transformation scenario, the following actions are accessible:

Edit
This button opens the Edit Scenario configuration dialog box (on page 1440) that allows you to configure the options of the transformations scenario.

Duplicate
Use this button to create a duplicate transformation scenario (on page 1442).

Remove
Use this button to remove custom transformation scenarios.

Change storage
Allows you to change the storage location of a transformation scenario to Project Options (on page 2970) or Global Options (on page 2967). You are also able to keep the original storage location and make a copy of the selected scenario in the new storage location.

Import scenarios
This option opens the Import scenarios dialog box that allows you to select the scenarios file that contains the scenarios you want to import. If one of the scenarios you import is identical to an existing scenario, Oxygen XML Editor ignores it. If a conflict appears (an imported scenario has the same name as an existing one), you can choose between two options:

- Keep or replace the existing scenario.
- Keep both scenarios.

Note:
When you keep both scenarios, Oxygen XML Editor adds imported to the name of the imported scenario.

Export selected scenarios
Use this option to export selected scenarios individually. Oxygen XML Editor creates a scenarios file that contains the exported scenarios. This is useful if you want to share scenarios with others or export them to another computer.
Bottom Section

The bottom section of the dialog box contains the following actions and options:

New

This button allows you to create a new transformation scenario (on page 1361).

Edit

This button opens the Edit Scenario dialog box that allows you to configure the options of the transformations scenario. For information about all the specific options in the various tabs, see the Transformation Types section (on page 1441).

Note:
If you try to edit a transformation scenario associated with a defined document type, Oxygen XML Editor displays a warning message to inform you that this is not possible and gives you the option to create a duplicate transformation scenario (on page 1442) to edit instead.

Duplicate

Use this button to create a duplicate transformation scenario (on page 1442).

Remove

Use this button to remove transformation scenarios.

Note:
Removing scenarios associated with a defined document type is not allowed.

Association follows selection

Select this checkbox to automatically associate selected transformation scenarios with the current document. This option can also be used for multiple selections.

Note:
When this option is selected, the Association column is hidden.

Run in parallel (DITA-OT or Ant scenarios)

This option is available if you select multiple DITA-OT or Ant type scenarios. Selecting this option results in the transformations being done in parallel, instead of sequentially. It should help to reduce the amount of time it takes for the publishing to finish when transforming large projects.
Attention:
If multiple selected DITA-OT scenarios have the same output or temporary files folder, this option is not available since the process would need to read and write content to the same folder in this case.

Associated scenarios section
Displays the scenarios that are associated with the current document. Selecting a checkbox in the Association column in the list of scenarios will add that scenario to this section. To remove a scenario from being associated with the current document, simply click the remove icon (X) to the right of the scenario name.

Save and close
Saves the current configuration and closes the dialog box.

Apply associated
Use this button to apply the associated scenarios and run the transformation on the current document.

Cancel
Cancels any changes made in the dialog box and reverts to the previously saved association.

Tip:
Your selections in the Configure Transformation Scenarios(s) dialog box are persistent so the configured associations for the current document will be remembered after the dialog box is closed.

Related Information:
Editing a Transformation Scenario (on page 1440)

Applying Associated Transformation Scenarios (on page 1442)
Creating New Transformation Scenarios (on page 1361)
Sharing Transformation Scenarios (on page 1449)

Batch Transformations
A transformation action can be applied on a batch of selected files from the contextual menu of the Project view (on page 373) without having to open the files involved in the transformation. You can apply the same scenario to a batch of files or multiple scenarios to a single file or batch of files.
1. (Optional, but recommended) Organize the files you want to transform in logical folders.

   a. Create a logical folder in the **Project view (on page 368)** by using the **New > Logical Folder** action from the contextual menu of the root file.

   b. Add the files you want to transform to the logical folder by using the **Add Files** or **Add Edited File** actions from the contextual menu of the logical folder.

   **Note:** You can skip this step if the files are already in a dedicated folder that does not include any additional files or folders. You can also manually select the individual files in the **Project view (on page 368)** each time you want to transform them, but this can be tedious.

2. Select the files you want to transform (or the newly created logical folder) and from the contextual menu, select **Transform > Configure Transformation Scenario(s)** to choose one or more transformation scenarios to be applied on all the files in the logical folder.

3. Use Oxygen XML Editor **editor variables (on page 292)** to specify the input and output files. This ensures that each file from the selected set of resources is processed and that the output is not overwritten by the subsequent processing.

   a. Edit the transformation scenario to make sure the appropriate **editor variable (on page 292)** is assigned for the input file. For example, for a **DocBook PDF transformation**, make sure the **XML URL** input box is set to the **${currentFileURL}** editor variable (**on page 298**). For a DITA PDF transformation, make sure the **args.input** parameter is set to the **${cf}** editor variable (**on page 298**).

   b. Edit the transformation scenario to make sure the appropriate editor variable is assigned for the output file. For example, for an **XML transformation with XSLT**, switch to the **Output** tab and set the path of the output file using a construct of **editor variables (on page 292)**, such as **${cfd}/${cfn}.html**.

4. Now that the logical folder has been associated with one or more transformation scenarios, whenever you want to apply the same batch transformation, you can select **Transform > Transform with** from the contextual menu and the same previously associated scenario(s) will be applied.

5. If you want a different type of transformation to be applied to each file inside the logical folder, associate individual scenarios for each file and select **Transform > Apply Transformation Scenario(s)** from the contextual menu of the logical folder.

**Related Information:**
Editor Variables (**on page 292**)  

---

**Sharing Transformation Scenarios**

The transformation scenarios and their settings can be shared with other users by saving them at **project level (on page 2970)** or by exporting them to a **specialized scenarios file (on page 292)** that can then be imported.
When you create a new transformation scenario or edit an existing one, there is a Storage option to control whether the scenarios are stored in Project Options (on page 2970) or Global Options (on page 2967).

Selecting Project Options (on page 2970) stores the scenario in the project file and can be shared with other users that have access to the project. If your project is saved on a source versioning system (CVS, SVN, Source Safe, etc.) then your team will have access to the scenarios that you define. When you create a scenario at the project level, the URLs from the scenario become relative to the project URL.

Selecting Global Options (on page 2967) stores the scenario in the global options that are stored in the user home directory.

You can also change the storage options on existing transformation scenarios by using the Change storage action (on page 1443) from the contextual menu of the list of scenarios.

Related Information:
Sharing Application Settings (on page 282)

Transformation Scenarios View

You can manage the transformation scenarios by using the Transformation Scenarios view. To open this view, select Window > Show View > Transformation Scenarios.
Oxygen XML Editor supports multiple scenarios association. To associate multiple scenarios with a document, select the checkboxes in front of each scenario. You can also associate multiple scenarios with a document from the Configure Transformation Scenario(s) dialog box (on page 1443).

The Transformation Scenarios view presents both global and project-level (on page 2970) scenarios. By default, Oxygen XML Editor presents the items in the following order:

1. Scenarios that match the current framework (on page 2967).
2. Scenarios that match the current project.
3. Scenarios that match other frameworks.

**Toolbar/Contextual Menu Actions and Options**

The following actions and options are available on the toolbar or in the contextual menu:

- **Apply selected scenarios**
  
  Select this option to run the current transformation scenario.

- **Debug selected scenario**
Select this option to switch to the **Debugger perspective** *(on page 2969)* and initialize it with the parameters from the scenario (the XML, XSLT, or XQuery input, the transformation engine, the XSLT parameters).

**New**

This drop-down menu contains a list of the **scenarios that you can create** *(on page 1361)*. Oxygen XML Editor determines the most appropriate scenarios for the current type of file and displays them at the beginning of the list, followed by the rest of the scenarios.

**Duplicate**

Adds a new scenario to the list that is a duplicate of the current scenario. It is useful for creating a scenario that is similar to an existing one.

**Edit**

Opens the dialog box that allows you to configure various options in several tabs, depending on the type of transformation scenario that was selected. For information about all the specific options in the various tabs, see the **Transformation Types section** *(on page 1441)*.

**Remove**

Removes the current scenario from the list. This action is also available by using the **Delete** key.

**Change storage**

Use this option to change the storage location of the selected scenario. You are also able to keep the original storage location and make a copy of the selected scenario in the target storage location.

**Import scenarios**

This option opens the **Import scenarios** dialog box that allows you to select the **scenarios** file that contains the scenarios you want to import. If one of the scenarios you import is identical to an existing scenario, Oxygen XML Editor ignores it. If a conflict appears (an imported scenario has the same name as an existing one), you can choose between two options:

- Keep or replace the existing scenario.
- Keep both scenarios.

**Note:**

When you keep both scenarios, Oxygen XML Editor adds **imported** to the name of the imported scenario.

**Export selected scenarios**

Use this option to export transformation and validation scenarios individually. Oxygen XML Editor creates a **scenarios** file that contains the scenarios that you export.

**Settings**
This drop-down menu allows you to configure the following options (many of these options are also available if you right-click the name of a column):

**Show all scenarios**
Select this option to display all the available scenarios, regardless of the document they are associated with.

**Show only the scenarios available for the editor**
Select this option to only display the scenarios that Oxygen XML Editor can apply for the current document type.

**Show associated scenarios**
Select this option to only display the scenarios associated with the document you are editing.

**Change storage**
Use this option to change the storage location of the selected scenario to Project Options (on page 2970) or Global Options (on page 2967). You are also able to keep the original storage location and make a copy of the selected scenario in the new storage location.

**Import scenarios**
This option opens the Import scenarios dialog box that allows you to select the scenarios file that contains the scenarios you want to import. If one of the scenarios you import is identical to an existing scenario, Oxygen XML Editor ignores it. If a conflict appears (an imported scenario has the same name as an existing one), you can choose between two options:

- Keep or replace the existing scenario.
- Keep both scenarios.

**Note:**
When you keep both scenarios, Oxygen XML Editor adds imported to the name of the imported scenario.

**Export selected scenarios**
Use this option to export selected scenarios individually. Oxygen XML Editor creates a scenarios file that contains the exported scenarios. This is useful if you want to share scenarios with others or export them to another computer.

**Show Type**
Use this option to display the transformation type of each scenario.

**Show Storage**
Use this option to display the storage location of the scenarios.
**Group by Association**
Select this option to group the scenarios depending on whether or not they are associated with the current document.

**Group by Type**
Select this option to group the scenarios by their type.

**Group by Storage**
Select this option to group the scenarios by their storage location.

**Ungroup all**
Select this option to ungroup all the scenarios.

**Reset Layout**
Select this option to restore the default settings of the layout.

Your selections in the Transformation Scenarios view are persistent so the configured associations for the current document will be remembered whenever the document is opened.

### WebHelp Output Customization

**Oxygen XML WebHelp** provides the ability to generate two different types of output, **WebHelp Responsive** and **WebHelp Classic**. Each type has its own set of options and features. The **WebHelp Responsive** variant is available for DITA documents while the **WebHelp Classic** variants are available for DocBook.

**WebHelp Responsive Output for DITA**

**WebHelp Responsive** features a very flexible layout, is designed to adapt to any screen size to provide an optimal viewing and interaction experience. It is based upon the *Bootstrap* responsive front-end framework and is available for DITA document types.

WebHelp Responsive output can be generated by using the [DITA Map WebHelp Responsive](on page 1333) transformation scenario.

For an in-depth look at WebHelp Responsive features and the publishing process, watch our Webinar: [DITA Publishing and Feedback with Oxygen Tools](#).

**Layout and Features**

This section contains information about the layout and features of the WebHelp Responsive output.

**Layout of the Responsive Page Types**

You can select from several different styles of layouts (for example, by default, you can select either a *tiles* or *tree* style of layout). Furthermore, each layout includes a collection of skins that you can choose from, or you can customize your own.
Figure 456. WebHelp Responsive Output on a Normal Screen
Main Page

The Main Page is the home page generated in the WebHelp Responsive output. The main function of the home page is to display top-level information and provide links that help you easily navigate to any of the top-level topics of the publication. These links can be rendered in either a Tiles or Tree style of layout. The main page also consists of various other components, such as a logo, title, menu, search field, or index link.

Main Page - Tiles Layout

In the tiles presentation mode, a tile component is created for each chapter (first-level topic) in the publication. The tile presents a link to the topic and its short description.
Figure 458. Main Page - Tiles Layout

1. Logo Component (on page 1459)
2. Title Component (on page 1459)
3. Search Input Component (on page 1460)
4. Menu Component (on page 1460)
5. Index Terms Link Component (on page 1460)
6. Topic Tiles Component (on page 1460)
7. Footer Component (on page 1460)

Main Page - Tree Layout

In the tree presentation mode, links to the first and second level topics in the publication are displayed using a tree-like component.
Main Page Components

The layout components displayed in the main page are:

**Publication Title**

The title of the publication. It is usually taken from the DITA map title.

**Logo**

Displays a logo associated with the publication. Additionally, you can set a target URL that will be opened when you click on the logo image.

The logo image can be specified using the `webhelp.logo.image` transformation parameter (on page 1605). For the target URL, use the `webhelp.logo.image.target.url` parameter (on page 1605).
Menu

Helps you to navigate to your documentation. This component presents a set of links to all topics from your publication. For information about customizing the menu, see How to Customize the Menu (on page 1555) topic.

Index Terms Link

Presents a link to the index terms page. You can control if this component is displayed by using the webhelp.show.indexterms.link parameter (on page 1614).

Search Input

An input text field where you can enter search queries.

Topic Tiles

A tile associated with a main topic. Each topic tile has three sections that correspond to the topic title, short description, and image.

- **Topic Tile Title**
  Presents the navigation title of the associated topic.

- **Topic Tile Short Description**
  Presents the short description of the topic. It may be collected either from the topic or from the DITA map topic meta.

- **Topic Tile Image**
  Presents an image associated with the topic. The image association (on page 1555) is done in the DITA map.

Tree Table of Contents

An area that contains first and second-level topic titles from your publication.

Page Footer

WebHelp Responsive output footer.

Topic Page

The **Topic Page** is the page generated for each DITA topic in the WebHelp Responsive output. The HTML pages produced for each topic consist of the topic content along with various other additional components, such as a title, menu, navigation breadcrumb, print icon, or side table of contents.
Figure 460. Topic Page

1. Logo Component (on page 1461)
2. Title Component (on page 1461)
3. Search Input Component (on page 1462)
4. Menu Component (on page 1462)
5. Index Terms Link Component (on page 1462)
6. Expand/Collapse All Sections Component (on page 1462)
7. Navigation Links Component (on page 1462)
8. Print Link Component (on page 1462)
9. Breadcrumb Component (on page 1462)
10. Publication Table of Contents Component (on page 1462)
11. Topic Content Component (on page 1462)
12. Topic Table of Contents Component (on page 1463)

**Topic Page Components**

The layout components displayed in this page are:

**Publication Title**

The title of the publication. It is usually taken from the DITA map title.

**Logo**
Displays a logo associated with the publication. Additionally, you can set a target URL that will be opened when you click on the logo image.

The logo image can be specified using the webhelp.logo.image transformation parameter (on page 1605). For the target URL, use the webhelp.logo.image.target.url parameter (on page 1605).

Menu

Helps you to navigate to your documentation. This component presents a set of links to all topics from your publication. For information about customizing the menu, see How to Customize the Menu (on page 1555) topic.

Index Terms Link

Presents a link to the index terms page. You can control if this component is displayed by using the webhelp.show.indextermss.link parameter (on page 1614).

Search Input

An input text field where you can enter search queries.

Navigation Links

The navigation links (👉 Previous / ➤ Next arrows) can be used to navigate to the previous or next topic. These navigation links are controlled by the collection-type attribute. For example, if you set collection-type="sequence" on a parent topic reference, navigation links will be generated in the output for that topic and all of its child topics. You can also use the webhelp.default.collection.type.sequence parameter and set its value to yes to generate navigation links for all topics, regardless of whether or not the collection-type attribute is present.

Tip:

To hide the navigation links, you can edit the transformation scenario and set the value of the webhelp.show.navigation.links parameter to no.

Expand/Collapse Sections Button

Icon that expands or collapses sections listed in the side table of contents within a topic.

Print Link

A print icon that opens the print dialog box for your particular browser.

Breadcrumb

Presents the path of the current displayed DITA topic.

Topic Content

Presents the content of the associated DITA topic.

Publication Table of Contents

A Table of Content for the publication displayed in the left side.
Topic Table of Contents (On this page links)

A table of contents for the topic displayed on the right side with a heading named On this page and it contains links to each section within the current topic and the section corresponding to the current scroll position is highlighted. This component is generated for any topic that contains at least two `<section>` elements and each `<section>` must have an `@id` attribute.

Page Footer

WebHelp Responsive output footer.

Search Page

The Search Page presents search results in the WebHelp Responsive output. The HTML page consists of a search results component along with various other additional components, such as a title, menu, or index link.

When you enter search terms in the Search field, the results are displayed in a results page. When you click on a result, the topic is opened in the main pane and the search results are highlighted. If you want to remove the colored highlights, click the Toggle Highlights button at the top-right side of the page. The Search field also includes an autocomplete feature.

Figure 461. Search Results Page

1. Logo Component (on page 1464)
2. Title Component (on page 1464)
Search Page Components

The layout components displayed in the search page are:

**Publication Title**

The title of the publication. It is usually taken from the DITA map title.

**Logo**

Displays a logo associated with the publication. Additionally, you can set a target URL that will be opened when you click on the logo image.

The logo image can be specified using the `webhelp.logo.image` transformation parameter (on page 1605). For the target URL, use the `webhelp.logo.image.target.url` parameter (on page 1605).

**Menu**

Helps you to navigate to your documentation. This component presents a set of links to all topics from your publication. For information about customizing the menu, see How to Customize the Menu (on page 1555) topic.

**Index Terms Link**

Presents a link to the index terms page. You can control if this component is displayed by using the `webhelp.show.indexterms.link` parameter (on page 1614).

**Search Input**

An input text field where you can enter search queries.

**Search Results**

Each result includes the topic title that can be clicked to open that page. Under the title, a breadcrumb is displayed that shows the path of the topic and you can click any of the topics in the breadcrumb to open that particular page.

**Page Footer**

WebHelp Responsive output footer.

Autocomplete Suggestions in the Search Text Field

When you are typing in the search text field, proposals are presented to help you to compute the search query. The information proposed when you are typing is collected from:

- The search queries from the history of the previous searches.
- The titles collected from your documentation.
• Documentation index terms and keywords. For example, in a DITA topic, the keywords and index terms are specified in the topic prolog section like this:

```xml
<prolog>
  <metadata>
    <keywords>
      <indexterm>databases</indexterm>
    </keywords>
    <keyword>installing</keyword>
    <keyword>uninstalling</keyword>
    <keyword>prerequisites</keyword>
  </metadata>
</prolog>
```

Missing Terms

If you enter multiple search terms (other than stop words), for any result that the search engine found at least one term but not one or more of the other terms, the Missing terms will be listed below each result.

Related Information:
WebHelp Responsive Search Engine (on page 1467)

Index Terms Page

The Index Terms Page page consists of an index terms section along with various other additional components, such as a title, menu, or search field.

An alphabet that contains the first letter of the documentation index terms is generated at the top of the index page. Each letter represents a link to a specific indices section. The indexes are presented in multiple columns to make it easier to read this page.
Figure 462. Index Terms Page

1. Logo Component (on page 1466)  
2. Title Component (on page 1466)  
3. Menu Component (on page 1466)  
4. Index Terms Link Component (on page 1467)  
5. Index Terms Component (on page 1467)  
6. Alphabet Links Component (on page 1467)  
7. Footer Component (on page 1467)

Index Terms Page Components

The layout components displayed in this page are:

Publication Title

The title of the publication. It is usually taken from the DITA map title.

Logo

Displays a logo associated with the publication. Additionally, you can set a target URL that will be opened when you click on the logo image.

The logo image can be specified using the webhelp.logo.image transformation parameter (on page 1605). For the target URL, use the webhelp.logo.image.target.url parameter (on page 1605).

Menu
Helps you to navigate to your documentation. This component presents a set of links to all topics from your publication. For information about customizing the menu, see How to Customize the Menu (on page 1555) topic.

Index Terms Link

Presents a link to the index terms page. You can control if this component is displayed by using the webhelp.show.indexterm.link parameter (on page 1614).

Index Terms Alphabet

An alphabet that contains the first letter of index terms. Each letter represents a link to a specific indices section.

Index Terms

The first letter of the index along with the list of index terms.

Page Footer

WebHelp Responsive output footer.

Search Engine

Search engine has two main components:

Search indexer

It is also known as a spider. This component is active when you publish your documentation to WebHelp and it is responsible for creating the search index. This component traverses all HTML pages (for DITA topics) to gather information.

Search interface

This component is an interface between the user and the search index. It helps the user to search through the search index and displays results in the search page.

Search Field and Results Page

When you enter search terms in the Search field, the results are displayed in a results page. When you click on a result, the topic is opened in the main pane and the search results are highlighted. If you want to remove the colored highlights, click the Toggle Highlights button at the top-right side of the page. The Search field also includes an autocomplete feature.

Each result includes the topic title that can be clicked to open that page. Under the title, a breadcrumb is displayed that shows the path of the topic and you can click any of the topics in the breadcrumb to open that particular page.

If you enter multiple search terms (other than stop words), for any result that the search engine found at least one term but not one or more of the other terms, the Missing terms will be listed below each result.
5-Star Rating Mechanism and Sorting

The **Search** feature is also enhanced with a rating mechanism that computes scores for every result that matches the search criteria. These scores are then translated into a 5-star rating scheme and the stars are displayed to the right of each result. The search results are sorted depending on the following:

- Search entries that satisfy the phrase search criterion are presented first.
- The number of keywords found in a single page (the higher the number, the better).
- The context (for example, a word found in a title, scores better than a word found in unformatted text).

The search ranking order, sorted by relevance is as follows:

- The search term is included in a meta keyword.
- The search term is in the title of the page.
- The search term is in bold text in a paragraph.
- The search term is in normal text in a paragraph.

Tag Element Scoring Values

HTML tag elements are also assigned a scoring value and these values are evaluated for the search results. For information about editing these values, see [*How to Change Element Scoring in Search Results*](on page 1566).

Search Rules

Rules that are applied during a search include:

- You can use quotes to perform an exact search for multiple word phrases (for example, "grow flowers" will only return results if both words are found consecutively and exactly as they are typed in the search field). This type of search is known as a **phrase search**.
- **Boolean Search** is supported using the following operators: *and*, *or*, *not*. When there are two adjacent search terms without an operator, *or* is used as the default search operator (for example, *grow flowers* is the same as *grow or flowers*).
- The space character separates keywords (an expression such as *grow flowers* counts as two separate keywords.
- Words composed by merging two or more words with colon (":"), minus ("-"), underline ("_"), or dot ("." ) characters count as a single word.
- Your search terms should contain two or more characters (note that stop words will be ignored). This rule does not apply to CJK (Chinese, Japanese, Korean) languages.
- When searching for multi-word phrases in CJK (Chinese, Japanese, Korean) languages that often have multiple words appear in strings without a space separator, you need to add a space to separate the words. Otherwise, WebHelp will not find results. For example, Chinese uses a specialized character for space separators, but the current WebHelp implementation cannot detect such specialized characters, so to search for 开始之前 (it translates as "before you begin" or "before start"), you have to enter 开始 之前 (notice the space between the second and third symbols) in the search field.
Tip:
The `<indexterm>` and `<keywords>` DITA elements are an effective way to increase the ranking of a page (for example, content inside a `<keywords>` element weighs more than an `<H1>` HTML element).

Excluded Terms

To improve performance, the **Search** feature excludes certain *stop words*. For example, the English version of the *stop words* includes: a, an, and, are, as, at, be, but, by, for, if, in, into, is, it, no, not, of, on, or, such, that, the, their, then, there, these, they, this, to, was, will, with.

Context-Sensitive Help System

Context-sensitive help systems assist users by providing specific informational topics for certain components of a user interface, such as a button or window. This mechanism works based on mappings between a unique ID defined in the topic and a corresponding HTML page.

Generating Context-Sensitive Help

When WebHelp Responsive output is generated, the transformation process produces an XML mapping file called *context-help-map.xml* and copies it in the output folder of the transformation. This XML file maps an ID to a corresponding HTML page through an `<appContext>` element, as in the following example:

```xml
<map productID="oxy-webhelp" productVersion="1.1">
  <appContext helpID="myapp-functionid1" path="tasks/app-help1.html"/>
  <appContext helpID="myapp-functionid2" path="tasks/app-help1.html"/>
  ...
</map>
```

The possible attributes are as follows:

**helpID**

A Unique ID provided by a topic from two possible sources (`<resourceid>` element or `@id` attribute):

**resourceid**

The `<resourceid>` element is mapped into the `<appContext>` element and can be specified in either the `<topicrefs>` within a DITA map or in a `<prolog>` within a DITA topic. The `<resourceid>` element accepts the following attributes:
• **appname** - A name for the external application that references the topic. If this attribute is not specified, its value is considered to be empty ("").
• **appid** - An ID used by an application to identify the topic.
• **id** - Specifies a value that is used by a specific application to identify the topic, but this attribute is ignored if an @appid attribute is used.

**Note:**
Multiple @appid values can be associated with a single appname value (and multiple @appname values can be associated with a single @appid value), but the values for both attributes work in combination to specify a specific ID for a specific application, and therefore each combination of values for the @appid and @appname attributes should be unique within the context of a single root map (on page 2971). For example, suppose that you need two different functions of an application to both open the same WebHelp page.

**Example: <resourceid> Specified in a DITA Map**

The `<resourceid>` element can be specified in a `<topicmeta>` element within a `<topicref>`.

```xml
<map title="App Help">
  <topicref href="app-help1.dita" type="task">
    <topicmeta>
      <resourceid appname="myapp" appid="functionid1"/>
      <resourceid appname="myapp" appid="functionid2"/>
    </topicmeta>
  </topicref>
</map>
```

**Example: <resourceid> Specified in a DITA Topic**

The `<resourceid>` element can be specified in a `<prolog>` element within a DITA topic.

```xml
<task id="app-help1">
  <title>My App Help</title>
  <prolog>
    <resourceid appname="myapp" appid="functionid1"/>
    <resourceid appname="myapp" appid="functionid2"/>
  </prolog>
  ...
</task>
```

For more information about the `<resourceid>` element, see DITA Specifications: `<resourceid>`.
If a `<resourceid>` element is not declared in the DITA map or DITA topic (as described above), the `@id` attribute that is set on the topic root element is mapped into the `<appContext>` element.

**Important:**
You should ensure that these defined IDs are unique in the context of the entire DITA project. If the IDs are not unique, the transformation scenario will display warning messages in the transformation console output and the help system will not work properly.

**path**

The path to a corresponding WebHelp page. This path is relative to the location of the `context-help-map.xml` mapping file.

There are two ways of implementing context-sensitive help in your system:

- The XML mapping file can be loaded by a PHP script on the server side. The script receives the `contextId` value and will look it up in the XML file.
- Invoke the `index.html` WebHelp system file and pass the `contextId` parameter with a specific value. The WebHelp system will automatically open the help page associated with the value of the `contextId` parameter.

```
index.html?contextId=myDITATopic
```

**Note:**
The `contextId` parameter is not case-sensitive.

**Context-Sensitive Queries**

You can use the URL field in your browser to search for topics in a context-sensitive WebHelp system with the assistance of the following parameters:

**contextId**

The WebHelp JavaScript engine will look for this value in the `context-help-map.xml` mapping file and load the corresponding help page.

**Note:**
You can use an anchor (on page 2964) in the `contextId` parameter to jump to a specific section in a document. For example, `contextId=topicID#anchor`.

**appname**

You can use this parameter in conjunction with `contextId` to search for this value in the corresponding `appname` attribute value in the mapping file.
Another parameter indicates the search query:

`searchQuery`

You can use this parameter to perform a search operation when WebHelp is loaded. For example, if you want to open WebHelp showing all search results for *growing flowers*, the URL should look like this: `http://localhost/webhelp/index.html?searchQuery=growing flowers`.

### Accessibility

**Oxygen XML WebHelp Responsive** output is compliant with the Section 508 accessibility standard, making the output accessible for people with visual impairment and other disabilities. Documentation and interface components are considered accessible when they have support in place that allows those with disabilities to use assistive technologies to understand the content.

Generally speaking, the WebHelp Responsive output has two major parts: topic content and WebHelp Responsive-related components (publication TOC, breadcrumb, menu). While the WebHelp Responsive components are designed to comply with the accessibility rules, it is important to adhere to some rules when you write DITA topics so that the content is also accessible.

**Related Information:**

- DITA-OT Day 2017 Presentation: Accessibility in DITA-OT
- Writing Guidelines for Accessible Documentation
- Accessible Images

Images must have text alternatives that describe the information or function represented by them.

**Short Text Equivalents for Images**

When using the `<image>` element, specify a short alternative text with the `<alt>` element.

```
<image href="puffin.jpg">
  <alt>Puffin figure</alt>
</image>
```

**Long Descriptions of Images**

For complex images, when a short text equivalent does not suffice to adequately convey the function or role of an image, provide additional information in a file designated by the `<longdesc>` element.

```
<image href="puffin.jpg">
  <alt>Puffin figure</alt>
</image>
```
Accessible Image Maps

For image maps, text alternatives are needed on both the `<image>` element itself (to describe the informative context) and on each of the `<area>` elements (to convey the link destination or the action that will be initiated if the link is followed). The `<xref>` content within the `<area>` element contains the intended alternative text or hover text for that image map area.

```xml
<imagemap id="gear_pump_map">
  <image href="../images/Gear_pump_exploded.png" id="gear_pump_exploded">
    <alt>Gear Pump</alt>
  </image>
  <area>
    <shape>circle</shape>
    <coords>172, 265, 14</coords>
    <xref href="parts/bushings.dita#bushings_topic/bushings" format="dita">Bushings</xref>
  </area>
  <area>
    <shape>circle</shape>
    <coords>324, 210, 14</coords>
    <xref href="parts/ports.dita#ports_topic/suction_port" format="dita">Suction Port</xref>
  </area>
</imagemap>
```

Accessible Tables

Accessible HTML tables need markup that indicates header cells and data cells and defines their relationship. Header cells must be marked with `<th>`, and data cells with `<td>`, to make tables accessible. For more complex tables, explicit associations may be needed using `@scope`, `@id`, and `@headers` attributes.

Related Information:
- Darwin Information Typing Architecture (DITA) Specification `<image>` element
- Web Accessibility Tutorials: Alt Decision Tree
When you implement the table, it is best to use the `<table>` element (CALS table or OASIS Table Exchange Model). The `<table>` element includes all that you need to make a fully accessible table.

**Related Information:**
Darwin Information Typing Architecture (DITA) Specification `<table>` element

### Table with Header Cells in the Top Row Only
For this type of table, you have to embed the table rows in the `<thead>` element.

#### Table 38. Example: Oxygen Events

<table>
<thead>
<tr>
<th>Event</th>
<th>Date</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Evolution of TC 2018</td>
<td>May 31 - June 1, 2018</td>
<td>Sofia, Bulgaria</td>
</tr>
<tr>
<td>Markup UK</td>
<td>June 9 - 10, 2018</td>
<td>London, United Kingdom</td>
</tr>
<tr>
<td>Balisage 2018 - The Markup</td>
<td>July 31 - August 3, 2018</td>
<td>Rockville, Maryland, USA</td>
</tr>
</tbody>
</table>

```xml
<table colsep="1" rowsep="1" frame="all">
  <title>
    <b>Oxygen Events</b>
  </title>
  <tgroup cols="3">
    <colspec colname="COLSPEC0" colwidth="1*"/>
    <colspec colname="COLSPEC1" colwidth="1.1*"/>
    <colspec colname="newCol3" colwidth="1*"/>
    <thead>
      <row>
        <entry colname="COLSPEC0" valign="top">Event</entry>
        <entry colname="COLSPEC1" valign="top">Date</entry>
        <entry>Location</entry>
      </row>
    </thead>
    <tbody>
      <row>
        <entry>Evolution of TC 2018</entry>
        <entry>May 31 - June 1, 2018</entry>
        <entry>Sofia, Bulgaria</entry>
      </row>
      <row>
        <entry>Markup UK</entry>
        <entry>June 9 - 10, 2018</entry>
        <entry>London, United Kingdom</entry>
      </row>
    </tbody>
  </tgroup>
</table>
```
Table with Header Cells in the First Column Only

For this type of table, you have to set the `rowheader="firstcol"` attribute on the `<table>` element to identify the header column.

Table 39. Example: Oxygen Events

<table>
<thead>
<tr>
<th>Event</th>
<th>Evolution of TC 2018</th>
<th>Markup UK</th>
<th>Balisage 2018 - The Markup Conference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date</td>
<td>May 31 - June 1, 2018</td>
<td>June 9 - 10, 2018</td>
<td>July 31 - August 3, 2018</td>
</tr>
<tr>
<td>Location</td>
<td>Sofia, Bulgaria</td>
<td>London, United Kingdom</td>
<td>Rockville, Maryland, USA</td>
</tr>
</tbody>
</table>

```xml
<row>
    <entry>Event</entry>
    <entry>Evolution of TC 2018</entry>
    <entry>Markup UK</entry>
    <entry>Balisage 2018 - The Markup Conference</entry>
</row>

<row>
    <entry>Date</entry>
    <entry>May 31 - June 1, 2018</entry>
    <entry>June 9 - 10, 2018</entry>
</row>
```
<entry>July 31 - August 3, 2018</entry>
</row>

<row>
  <entry>Location</entry>
  <entry>Sofia, Bulgaria</entry>
  <entry>London, United Kingdom</entry>
  <entry>Rockville, Maryland, USA</entry>
</row>
</tbody>
</table>

### Table with Header Cells in the Top Row and First Column

For this type of table, you can use `<thead>` to identify header rows and `<rowheader>` to identify a header column.

#### Table 40. Example: Bus Timetable

<table>
<thead>
<tr>
<th></th>
<th>Monday</th>
<th>Tuesday</th>
<th>Wednesday</th>
<th>Thursday</th>
<th>Friday</th>
</tr>
</thead>
<tbody>
<tr>
<td>09:00 - 11:00</td>
<td>Closed</td>
<td>Open</td>
<td>Open</td>
<td>Closed</td>
<td>Closed</td>

Product Name/Version

Oxygen XML WebHelp Responsive

Product Description

Oxygen XML WebHelp Responsive enables you to publish DITA content on the web and present it in a user-friendly interface that is easy to navigate. You can design your WebHelp Responsive output to be available on desktop systems or various mobile devices. With Oxygen XML WebHelp Responsive, your published content is accessible, interactive, and convenient.

Date

May 2019

Contact Information

support@oxygenxml.com

Notes

Oxygen XML WebHelp Responsive has been designed and enhanced to adhere to the U.S. Government Section 508 accessibility standards and the Web Content Accessibility Guidelines (WCAG). For details, see WebHelp Responsive Accessibility (on page 1472).

Evaluation Methods Used:

The following applications were used for testing Oxygen XML WebHelp Responsive:

- Desktop browsers: Chrome, Firefox, Safari, Edge, and Internet Explorer
- Assistive technologies: NVDA, VoiceOver, JAWS, Microsoft Narrator

Applicable Standards/Guidelines

This report covers the degree of conformance for the following accessibility standards/guidelines:

<table>
<thead>
<tr>
<th>Standard/Guideline</th>
<th>Included In Report</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web Content Accessibility Guidelines 2.0</td>
<td>Level A - Yes</td>
</tr>

<td>No</td>
</tr>
</tbody>
</table>
Terms

The terms used in the Conformance Level information are defined as follows:

- **Supports**: The functionality of the product has at least one method that meets the criterion without known defects or meets with equivalent facilitation.
- **Partially Supports**: Some functionality of the product does not meet the criterion.
- **Does Not Support**: The majority of product functionality does not meet the criterion.
- **Not Applicable**: The criterion is not relevant to the product.
- **Not Evaluated**: The product has not been evaluated against the criterion. This can be used only in WCAG 2.0 Level AAA.

WCAG 2.x Report

Tables 1 and 2 also document conformance with:

Revised Section 508: Chapter 5 – 501.1 Scope, 504.2 Content Creation or Editing, and Chapter 6 – 602.3 Electronic Support Documentation.

**Note:**

When reporting on conformance with the WCAG 2.x Success Criteria, they are scoped for full pages, complete processes, and accessibility-supported ways of using technology as documented in the [WCAG 2.0 Conformance Requirements](#).

</table>
| • Using semantic elements to mark up structure.  
• Using semantic markup to mark emphasized or special text.  
• Using caption elements to associate data table captions with data tables. |

**1.3.2 Meaningful Sequence** (Level A)  
Also applies to:  
Revised Section 508  
• 501 (Web)(Software)  
• 504.2 (Authoring Tool)  
• 602.3 (Support Docs)  
Supports  
The product presents content in a meaningful sequence.  
Authors should use Unicode right-to-left mark (RLM) or left-to-right mark (LRM) to mix text direction inline.

**1.3.3 Sensory Characteristics** (Level A)  
Also applies to:  
Revised Section 508  
• 501 (Web)(Software)  
• 504.2 (Authoring Tool)  
• 602.3 (Support Docs)  
Supports  
Authors should ensure that items are referenced in the content in ways that do not depend on sensory perception.

**1.4.1 Use of Color** (Level A)  
Also applies to:  
Revised Section 508  
• 501 (Web)(Software)  
• 504.2 (Authoring Tool)  
• 602.3 (Support Docs)  
Supports  
(Cobalt template) Color is not used as the only visual means of conveying information, indicating an action, prompting a response, or distinguishing a visual element.

**1.4.2 Audio Control** (Level A)  
Also applies to:  
Revised Section 508  
• 501 (Web)(Software)  
• 504.2 (Authoring Tool)  
• 602.3 (Support Docs)  
Supports  
There is no sound that plays automatically.

</table>

2.4.1 **Bypass Blocks** (Level A)
Also applies to:
Revised Section 508
• 501 (Web)(Software) – Does not apply to non-web software
• 504.2 (Authoring Tool)
• 602.3 (Support Docs) – Does not apply to non-web docs

Supports
Each page contains a link at the top that goes directly to the main content area. Each page contains *ARIA* landmarks that identify the available regions.

2.4.2 **Page Titled** (Level A)
Also applies to:
Revised Section 508
• 501 (Web)(Software)
• 504.2 (Authoring Tool)
• 602.3 (Support Docs)

Supports
Each page contains a non-empty `<title>` element in the `<head>` section.

2.4.3 **Focus Order** (Level A)
Also applies to:
Revised Section 508
• 501 (Web)(Software)
• 504.2 (Authoring Tool)
• 602.3 (Support Docs)

Supports
Focusable components receive focus in an order that preserves meaning and operability.

2.4.4 **Link Purpose (In Context)** (Level A)
Also applies to:
Revised Section 508
• 501 (Web)(Software)
• 504.2 (Authoring Tool)
• 602.3 (Support Docs)

Supports
The purpose of each link can be determined from the link text alone or from the link text together with its programmatically-determined link context.
The authors can create hypertext links using text that describes the purpose of the hypertext.

Publishing Templates

An Oxygen Publishing Template defines all aspects of the layout and styles for output obtained from the following transformation scenarios:

- **WebHelp Responsive**
- **DITA Map PDF - based on HTML5 & CSS**

It is a self-contained customization package stored as a ZIP archive or folder that can easily be shared with others. It provides the primary method for customizing the output.

Some possible customization methods include:

- Add additional template resources to customize the output (such as logos, Favicon, or CSS files).
- Extend the default processing by specifying one or more XSLT extension points.
- Specify one or more transformation parameters to customize the output.
- Customize various aspects of the output through simple CSS styling.
- For WebHelp Responsive output, change the layout of the main page or topic pages by customizing which components will be displayed and where they will be positioned in the page.

The following graphics are possible sample structures for Oxygen Publishing Template packages:
For information about creating and customizing publishing templates, and how to adjust the WebHelp and PDF output through CSS styling and other customization methods, watch our Webinar: Creating Custom Publishing Templates for WebHelp and PDF Output. The Webinar slides and sample project are also available from that webpage.

- How to Create a Publishing Template (on page 1535)
- How to Edit a Packed Publishing Template (on page 1537)
- How to Add a Publishing Template to the Publishing Templates Gallery (on page 1537)
- How to Share a Publishing Template (on page 1683)

Publishing Templates Gallery

Oxygen XML Editor comes bundled with a variety of built-in templates. You can use one of them to publish your documentation or as a starting point for a new publishing template.
Built-in Templates

There are two categories of templates, Tiles and Tree. You can see the built-in templates in the Templates tab when editing a WebHelp Responsive transformation scenario in Oxygen XML Editor/Author. Each one also includes an Online preview icon in the bottom-right corner that opens a webpage in your default browser that provides a sample of how the main page will look when that particular template is used to generate the output.

Tiles Templates

The main page in the WebHelp output presents a tile for each main topic (chapter) of the documentation.

![Tile Templates](image)

Tree Templates

The main page in the WebHelp output presents a tree-like table of contents.

![Tree Templates](image)

Built-in Templates Location

All built-in templates are stored in the following directory: DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/templates.
Custom Templates

You can use a built-in template as a starting point for creating your own custom template (on page 1679). You can store all of your custom templates in a particular directory. Then, go to Options > Preferences > DITA > Publishing and add your directory to the list, and all the templates stored in that directory will be displayed in the preview pane in the transformation scenario's Template tab along with all the built-in templates.

Sharing Publishing Template

To share a publishing template with others, following these steps:

1. Copy your template in a new folder.
2. Go to Options > Preferences > DITA > Publishing and add that new folder to the list.
3. Switch the option as the bottom of that preferences page to Project Options.
4. Share your project file (.xpr).

Publishing Template Package Contents for WebHelp Responsive Customizations

An Oxygen Publishing Template package for WebHelp output must contain a template descriptor file and at least one CSS file, and may contain other resources (such as graphics, XHTML files, XSLT files, etc.). All the template resources can be stored in either a ZIP archive or in a folder. It is recommended to use a ZIP archive because it is easier to share with others.

Template Descriptor File

Each publishing template includes a descriptor file that defines the meta-data associated with the template. It is an XML file that defines all the resources included in a template (such as CSS files, images, JS files, and transformation parameters).

The template descriptor file must have the .opt file extension and must be located in the template's root folder.

A template descriptor might look like this:

```xml
<publishing-template>
  <name>Flowers</name>

  <webhelp>
    <tags>
      <tag>tree</tag>
      <tag>light</tag>
    </tags>
    <preview-image file="flowers-tree.png"/>
  </webhelp>

  <!-- Resources (CSS, favicon, logo and others) -->
  <resources>
```
Tip:
It is recommended to edit the template descriptor in Oxygen XML Editor/Author because it provides content completion and validation support.

Template Name and Description

Each template descriptor file requires a <name> element. This information is displayed as the name of the template in the transformation scenario dialog box.

Optionally, you can include a <description> and it displayed when the user hovers over the template in the transformation scenario dialog box.

Template Author

Optionally, you can include author information in the descriptor file and it displayed when the user hovers over the template in the transformation scenario dialog box. This information might be useful if users run into an issue or have questions about a certain template.

If you include the <author> element, a <name> is required and optionally you can include <email>, <organization>, and <organizationUrl> information.
Webhelp Element

The `<webhelp>` element contains various details that define the WebHelp Responsive output. It is a required element if you intend on using a WebHelp Responsive transformation scenario. The elements that are allowed in this `<webhelp>` section specify the template tags (on page 1502), template preview image (on page 1503), resources (on page 1503) (such as CSS, JS, fonts, logos), transformation parameters (on page 1505), HTML fragment extensions (on page 1507) (used to add fragments to placeholders), XSLT extensions (on page 1506), or HTML page layout files (on page 1516).

```
<webhelp>
  <tags>
    ...
  </tags>
  <preview-image file="MyPreview.png"/>
  <resources>
    ...
  </resources>
  <html-page-layouts>
    ...
  </html-page-layouts>
  <parameters>
    ...
  </parameters>
</webhelp>
```

Template Tags

The `<tags>` section provides meta information about the template (such as layout type or color theme). Each tag is displayed at the top of the **Templates** tab window in the transformation scenario dialog box and they help the user filter and find particular templates.
<publishing-template>

...<webhelp>
<tags>
<tag>tree</tag>
<tag>dark</tag>
</tags>
</publishing-template>

Template Preview Image

The <preview-image> element is used to specify an image that will be displayed in the transformation scenario dialog box. It provides a visual representation of the template to help the user select the right template. The image dimensions should be 200 x 115 pixels and the supported image formats are: JPEG, PNG, or GIF.

You can also include an <online-preview-url> element to specify the URL of a published sample of your template. This will display an Online preview icon in the bottom-right corner the image in the transformation scenario dialog box and if the user clicks that icon, it will open the specified URL in their default browser.

<publishing-template>

...<webhelp>
...<preview-image file="ashes/ashes-tree.png"/>
<online-preview-url>https://www.example.com/samples/tiles/ashes</online-preview-url>
</publishing-template>

Template Resources

The <resources> section of the descriptor file specifies a set of resources (CSS, JS, fonts, logos, graphics, etc.) that are used to customize various components in the generated output. These resources will be copied to the output folder during the transformation process. At least one CSS file must be included, while the other types of resources are optional.

This section is defined using the resources element and the types of resources that can be specified include:

- **CSS files** - One or more CSS files that will define the styles of all generated HTML pages. They are referenced using the <css> element.
- **Favicon** - You can specify the path to an image for the favicon associated with your website. It is referenced using the <favicon> element.
- **Logo** - You can specify the path to a logo image that will be displayed in the left side of the output header. It is referenced using the <logo> element. Optionally, you can also specify:
  - <target-url> - will redirect the user to the specified URL if they click the logo in the output.
  - <alt> - provides an alternate text for the logo image.
- **JavaScript AMD module** - The path to a JavaScript module that uses the AMD (Asynchronous Module Definition) format. This module will be loaded in the output HTML pages using the RequireJS library.
It can be referenced using the `<js-amd-module>` element. For more information, see How to Insert JavaScript AMD Modules (on page 1549).

- **Additional Resources (graphics, JS, fonts, folders)** - For other resources (such as images referenced in CSS, JavaScript, fonts, entire folders, etc.) that need to be included in the output, you need to instruct the transformation to include them in the output folder. You can specify one or more sets of additional resources to be copied to the output folder by using the `<fileset>` element and you can use one or more `<include>` and `<exclude>` elements. This semantic is similar to the ANT FileSet.

```xml
<publishing-template>
  ...
  <webhelp>
    ...
    <resources>
      <css file="css/custom_styles.css"/>
      <css file="css/custom_fonts.css"/>
      <favicon file="images/favicon.png"/>
      <logo file="images/logo.png"
            target-url="http://www.example.com"
            alt="Alternate text for the logo image"/>
      <js-amd-module file="js/template-main.js"/>
      <fileset>
        <include name="common/**/*"/>
        <include name="JS/**/*"/>
        <exclude name="**/*.svn"/>
        <exclude name="**/*.git"/>
      </fileset>
    </resources>
  </webhelp>
</publishing-template>
```

**Note:**
All relative paths specified in the descriptor file are relative to the template root folder.

The resources specified in the template descriptor are copied to the following output folder:
`[WebHelp_OUTPUT_DIR]/oxygen-webhelp/template`. The following graphic illustrates the mapping between the template resources and the location where they will be copied to the output folder:
Figure 465. Template Resources Mapping

Related Information:
How to Add a Favicon in WebHelp Systems (on page 1562)

Transformation Parameters
You can also set one or more WebHelp transformation parameters in the descriptor file.

```xml
<publishing-template>
  ...
  <webhelp>
    ...
    <parameters>
      ...
      <parameter
        name="webhelp.show.main.page.toc"
        value="yes"/>
      <parameter
        name="webhelp.top.menu.depth"
        value="3"/>
      <parameter
        name="webhelp.fragment.welcome"
        value="html-fragment/webhelp.fragment.welcome.html"
        type="filePath"/>
    </parameters>
  </webhelp>
</publishing-template>
```

The following information can be specified in the `<parameter>` element:

**Parameter name**

The name of the parameter. It may be one of the WebHelp Responsive transformation parameters (on page 1605) or a DITA-OT HTML-based output parameter.
Note: It is not recommended to specify an input/output parameter in the descriptor file (such as the input Map, DITAVAL file, or temporary directory).

Attention: JVM arguments like -Xmx cannot be specified as a transformation parameter.

Parameter Value

The value of the parameter. It should be a relative path to the template root folder for file paths parameters.

Parameter Type

The type of the parameter: string or filepath. The string value is default.

After creating a publishing template (on page 1679) and adding it to the templates gallery (on page 1537), when you select the template in the transformation scenario dialog box, the Parameters tab will automatically be updated to include the parameters defined in the descriptor file. These parameters are displayed in italics.

XSLT Extension Points

The publishing templates can include one or more supported XSLT extension points (on page 1617). They are helpful when you want to change the structure of the HTML pages that are primarily generated from XSLT processing. They can be specified using the <xslt> element in the descriptor file using the following structure:

```xml
<publishing-template>
  ...
  <webhelp>
    ...
    <xslt>
      <extension
        id="com.oxygenxml.webhelp.xsl.dita2webhelp"
        file="xsl/customDita2webhelp.xsl"/>
      <extension
        id="com.oxygenxml.webhelp.xsl.createMainPage"
        file="xsl/customMainPage.xsl"/>
    </xslt>
  </webhelp>
  ...
</publishing-template>
```

For a full list of the supported extension points, see: XSLT-Import and XSLT-Parameter Extension Points (on page 1617).
Note:
You can read the value of a WebHelp transformation parameter from your XSLT extension stylesheets by using the `getParameter(param.name)` function from the `http://www.oxygenxml.com/functions` namespace.

**HTML Fragment Placeholders**

The HTML pages contain component placeholders that can be used to insert custom HTML fragments either by specifying a well-formed XHTML fragment or referencing a path to a file that contains a well-formed XHTML fragment (for details on how the file or fragment needs to be constructed, see How to Insert Custom HTML Content (on page 1544)).

These fragments and their placeholder location are defined in the descriptor file using a `<fragment>` element inside the `<html-fragments>` section. You can specify one or more HTML fragment extension points in the descriptor file using the following structure:

```xml
<publishing-template>

  ...

  <webhelp>

    ...

    <html-fragments>

      <fragment>
        file="html-fragments/webhelp_fragment_welcome.html"
        placeholder="webhelp.fragment.welcome"/>

      <fragment>
        file="html-fragments/webhelp_fragment_footer.html"
        placeholder="webhelp.fragment.footer"/>

    </html-fragments>

  </webhelp>

</publishing-template>
```

Some of these placeholders are left empty in the default output configurations, but you can use them to insert custom content.

Each placeholder has an associated parameter value in the transformation. Some of the placeholder parameters are global and can be used in all type of pages (`main page`, `topic page`, `search results page`, `index terms page`), while others are applicable for certain type of pages. The following diagram illustrates the predefined placeholders that are global (can be used in any of the types of pages).
Figure 466. Global Predefined Placeholders Diagram

1. Header (on page 1508)
2. After Header (on page 1508)
3. Before Body (on page 1508)
4. Before Logo and Title (on page 1508)
5. After Logo and Title (on page 1509)
6. Before Top Menu (on page 1509)
7. After Top Menu (on page 1509)
8. Before Search Input (on page 1509)
9. After Search Input (on page 1509)
10. Before Main Content (on page 1509)
11. After Main Content (on page 1509)
12. Footer (on page 1509)
13. After Body (on page 1509)

Global Placeholder Parameters

The following placeholder parameters can be used in any of the type of pages (main page, topic page, search results page, index terms page). The parameter values can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment:

- 1 = webhelp.fragment.head - Displays the specified XHTML fragment in the header section.
- 2 = webhelp.fragment.after.header - Displays the specified XHTML fragment after the header section.
- 3 = webhelp.fragment.before.body - Displays the specified XHTML fragment before the body.
- 4 = webhelp.fragment.before.logo_and_title - Displays the specified XHTML fragment before the logo and title.
• 5 = webhelp.fragment.after.logo_and_title - Displays the specified XHTML fragment after the logo and title.
• 6 = webhelp.fragment.before.top_menu - Displays the specified XHTML fragment before the top menu.
• 7 = webhelp.fragment.after.top_menu - Displays the specified XHTML fragment after the top menu.
• 8 = webhelp.fragment.before.search.input - Displays the specified XHTML fragment before the search input component.
• 9 = webhelp.fragment.after.search.input - Displays the specified XHTML fragment after the search input component.
• 10 = webhelp.fragment.before.main.content.area - Displays the specified XHTML fragment before the main content area.
• 11 = webhelp.fragment.after.main.content.area - Displays the specified XHTML fragment after the main content area.
• 12 = webhelp.fragment.footer - Displays the specified XHTML fragment in the footer section.
• 13 = webhelp.fragment.after.body - Displays the specified XHTML fragment after the body.

Main Page Placeholder Parameters
The following placeholder parameters can be used in the main page. The parameter values can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment:

• webhelp.fragment.head.main.page - Displays the specified XHTML fragment in the header section.
• webhelp.fragment.after.header.main.page - Displays the specified XHTML fragment after the header section.
• webhelp.fragment.before.body.main.page - Displays the specified XHTML fragment before the body.
• webhelp.fragment.before.search.input.main.page - Displays the specified XHTML fragment before the search input component.
• webhelp.fragment.after.search.input.main.page - Displays the specified XHTML fragment after the search input component.
• webhelp.fragment.before.main.content.area.main.page - Displays the specified XHTML fragment before the main content area.
• webhelp.fragment.after.main.content.area.main.page - Displays the specified XHTML fragment after the main content area.
• webhelp.fragment.after.body.main.page - Displays the specified XHTML fragment after the body.
• webhelp.fragment.before.toc_or_tiles - Displays the specified XHTML fragment before the main table of contents or tiles component on the main page.
• webhelp.fragment.after.toc_or_tiles - Displays the specified XHTML fragment after the main table of contents or tiles component on the main page.

Topic Page Placeholder Parameters
The following placeholder parameters can be used in the topic page. The parameter values can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment:
• webhelp.fragment.head.topic.page - Displays the specified XHTML fragment in the header section.
• webhelp.fragment.after.header.topic.page - Displays the specified XHTML fragment after the header section.
• webhelp.fragment.before.body.topic.page - Displays the specified XHTML fragment before the body.
• webhelp.fragment.before.search.input.topic.page - Displays the specified XHTML fragment before the search input component.
• webhelp.fragment.after.search.input.topic.page - Displays the specified XHTML fragment after the search input component.
• webhelp.fragment.before.main.content.area.topic.page - Displays the specified XHTML fragment before the main content area.
• webhelp.fragment.after.main.content.area.topic.page - Displays the specified XHTML fragment after the main content area.
• webhelp.fragment.after.body.topic.page - Displays the specified XHTML fragment after the body.
• webhelp.fragment.before.topic.toolbar - Displays the specified XHTML fragment before the toolbar buttons above the topic content in the topic page.
• webhelp.fragment.after.topic.toolbar - Displays the specified XHTML fragment after the toolbar buttons above the topic content in the topic page.
• webhelp.fragment.before.topic.breadcrumb - Displays the specified XHTML fragment before the breadcrumb component in the topic page.
• webhelp.fragment.after.topic.breadcrumb - Displays the specified XHTML fragment after the breadcrumb component in the topic page.
• webhelp.fragment.before.publication.toc - Displays the specified XHTML fragment before the publication's table of contents component in the topic page.
• webhelp.fragment.after.publication.toc - Displays the specified XHTML fragment after the publication's table of contents component in the topic page.
• webhelp.fragment.before.topic.content - Displays the specified XHTML fragment before the topic's main content in the topic page.
• webhelp.fragment.after.topic.content - Displays the specified XHTML fragment after the topic's main content in the topic page.
• webhelp.fragment.before.feedback - Displays the specified XHTML fragment before the Oxygen Feedback commenting component in the topic page.
• webhelp.fragment.after.feedback - Displays the specified XHTML fragment after the Oxygen Feedback commenting component in the topic page.
• webhelp.fragment.before.topic.toc - Displays the specified XHTML fragment before the topic's table of contents component in the topic page.
• webhelp.fragment.after.topic.toc - Displays the specified XHTML fragment after the topic's table of contents component in the topic page.

Search Results Page Placeholder Parameters
The following placeholder parameters can be used in the search results page. The parameter values can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment:
• `webhelp.fragment.head.search.page` - Displays the specified XHTML fragment in the header section.
• `webhelp.fragment.after.header.search.page` - Displays the specified XHTML fragment after the header section.
• `webhelp.fragment.before.body.search.page` - Displays the specified XHTML fragment before the body.
• `webhelp.fragment.before.search.input.search.page` - Displays the specified XHTML fragment before the search input component.
• `webhelp.fragment.after.search.input.search.page` - Displays the specified XHTML fragment after the search input component.
• `webhelp.fragment.before.main.content.area.search.page` - Displays the specified XHTML fragment before the main content area.
• `webhelp.fragment.after.main.content.area.search.page` - Displays the specified XHTML fragment after the main content area.
• `webhelp.fragment.after.body.search.page` - Displays the specified XHTML fragment after the body.
• `webhelp.google.search.script` - Replaces the search input component with a Google search component.

Index Terms Page Placeholder Parameters
The following placeholder parameters can be used in the search results page. The parameter values can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment:

- `webhelp.fragment.head.terms.page` - Displays the specified XHTML fragment in the header section.
- `webhelp.fragment.after.header.terms.page` - Displays the specified XHTML fragment after the header section.
- `webhelp.fragment.before.body.terms.page` - Displays the specified XHTML fragment before the body.
- `webhelp.fragment.before.search.input.terms.page` - Displays the specified XHTML fragment before the search input component.
- `webhelp.fragment.after.search.input.terms.page` - Displays the specified XHTML fragment after the search input component.
- `webhelp.fragment.before.main.content.area.terms.page` - Displays the specified XHTML fragment before the main content area.
- `webhelp.fragment.after.main.content.area.terms.page` - Displays the specified XHTML fragment after the main content area.
- `webhelp.fragment.after.body.terms.page` - Displays the specified XHTML fragment after the body.

Using String Values in Placeholder Parameter Values
If you use strings for values of HTML fragment placeholder parameter values, the string values are written to files in the transformation's temporary directory. The values of the associated parameters reference the paths of the temporary files. This means that the HTML fragments will have a uniform processing in the WebHelp's XSLT Module.

Example:

Suppose the placeholder parameter has the following string value:
# String value

```xml
webhelp.fragment.welcome = <p>This is an HTML paragraph.</p>
```

A new file that contains the parameter's value is created:

```xml
[temp-dir]/whr-html-fragments/webhelp_fragment_welcome.xml
```  

```xml
<p>This is an HTML paragraph.</p>
```

The parameter's value then becomes:

```xml
webhelp.fragment.welcome= [temp-dir]/whr-html-fragments/webhelp_fragment_welcome.xml
```

Related Information:

How to Insert Custom HTML Content (on page 1544)

## WebHelp Responsive Macros

You can use the `whc:macro` layout component to specify a macro value (a variable that will be expanded when the output files are generated).

A macro has the following syntax:

```xml
${macro-name}
```

or

```xml
${macro-name(macro-parameter)}
```

A macro name can accept any alphanumeric characters, as well as the following characters: `−` (minus), `_` (underscore), `.` (dot), `:` (colon). The value of a parameter may contain any character except the `}` (close curly bracket) character.

### Implementations

The following `macros` are supported:

- **i18n**
  
  For localizing a string.
  
  ```xml
  ${i18n(string.id)}
  ```

- **param**
  
  Returns the value of a transformation parameter.
  
  ```xml
  ${param(webhelp.show.main.page.tiles)}
  ```

- **env**
  
  Returns the value of an environment variable.
  
  ```xml
  ${env(JAVA_HOME)}
  ```

- **system-property**
Returns the value of a system property.

\$\{\text{system-property(os.name)}\}

**timestamp**

Can be used to format the current date and time. Accepts a string (as a parameter) that determines how the date and time will be formatted (format string or *picture string* as it is known in the XSLT specification). The format string must comply with the rules of the XSLT *dateTime* function specification.

\$\{\text{timestamp}([h1]:[m01] [P] [M01]/[D01]/[Y0001])\}

**path**

Returns the path associated with the specified path ID. The following paths IDs are supported:

- **oxygen-webhelp-output-dir** - The path to the output directory. The path is relative to the current HTML file.
- **oxygen-webhelp-assets-dir** - The path to the oxygen-webhelp subdirectory from the output directory. The path is relative to the current HTML file.
- **oxygen-webhelp-template-dir** - The path to the template directory. The path is relative to the current HTML file.

\$\{\text{path(oxygen-webhelp-template-dir)}\}

**Note:**

New paths IDs can be added by overriding the `wh-macro-custom-path` template from `com.oxygenxml.webhelp.responsive\xsl\template\macroExpander.xsl`:

```xml
<!-- Extension template for expanding a custom path macro. -->
<xsl:template name="wh-macro-custom-path">
  <xsl:param name="pathId"/>
  <xsl:value-of select="$pathId"/>
</xsl:template>
```

**map-xpath**

Can be used to execute an XPath expression over the DITA map file from the temporary directory.

**Tip:**

Available in all template layout HTML pages.

\$\{map-xpath(/map/title)\}

**topic-xpath**

Can be used to execute an XPath expression over the current topic.
Tip: Available only in the topic HTML page template (`wt_topic.html`).

```xml
${topic-xpath(string-join(//shortdesc//text(), ' '))}
```

**oxygen-webhelp-build-number**

Returns the current WebHelp distribution ID (build number).

```xml
${oxygen-webhelp-build-number}
```

## Extensibility

To add new macros, you can add an XSLT extension to overwrite the `wh-macro-extension` template from the `com.oxygenxml.webhelp.responsive\xsl\template\macroExpander.xsl` file.

```xml
<!-- Extension template for expanding custom macro constructs -->
<xsl:template name="wh-macro-extension">
  <xsl:param name="name"/>
  <xsl:param name="params"/>
  <xsl:param name="contextNode"/>
  <xsl:param name="matchedString"/>

  <xsl:choose>
    <xsl:when test="$contextNode instance of attribute()">
      <xsl:value-of select="$matchedString"/>
    </xsl:when>
    <xsl:otherwise>
      <xsl:message>Cannot expand macro:
      <xsl:copy-of select="$contextNode"/>
    </xsl:otherwise>
  </xsl:choose>
</xsl:template>
```

The `wh-macro-extension` template has the following parameters:

- **name** - The name of the current macro.
- **params** - List of parameters of the current macro as a string sequence. The current macros parsing mechanism only allows macros with a maximum of one parameter. Consequently, this list will contain at most one element.
- **contextNode** - The current element or attribute where the macro was declared.
- **matchedString** - The entire value of the matched macro as specified in the HTML template page.
Combining WebHelp Responsive and PDF Customizations in a Template Package

An Oxygen Publishing Template package can contain both a WebHelp Responsive and PDF customization in the same template package and you can use that same template in both types of transformations. The template descriptor file can define the customization for both types by including both a `<webhelp>` and `<pdf>` element and some of the resources can be reused. Resources referenced in elements in the `<webhelp>` element will only be used for WebHelp transformations, and resources referenced in the elements in the `<pdf>` element will only be used in PDF transformations.

```xml
<publishing-template>
  <name>Flowers</name>
  <description>Flowers themed light-colored template</description>

  <webhelp>
    <tags>
      <tag>purple</tag>
      <tag>light</tag>
    </tags>
    <preview-image file="flowers-preview.png"/>
    <resources>
      <css file="flowers-wh.css"/>
      <css file="flowers-page-styling.css"/>
    </resources>
    <parameters>
      <parameter name="webhelp.show.main.page.tiles" value="no"/>
      <parameter name="webhelp.show.main.page.toc" value="yes"/>
    </parameters>
  </webhelp>

  <pdf>
    <tags>
      <tag>purple</tag>
      <tag>light</tag>
    </tags>
    <preview-image file="flowers-preview.png"/>
    <resources>
      <css file="flowers-pdf.css"/>
      <css file="flowers-page-styling.css"/>
    </resources>
    <parameters>
      <parameter name="show.changes.and.comments" value="yes"/>
    </parameters>
  </pdf>
</publishing-template>
```

Publishing Template Package Contents for PDF Customizations (on page 1673)

**HTML Page Layout Files**

The HTML page layout files define the default layout of the generated pages in the output for the built-in template. There are four types of pages (*main*, *search*, *topic*, *index*) and each type of page is a simple HTML file. Each page type has various components that appear by default and each component has a corresponding element and when that element is included in the HTML file, the corresponding components will appear in the output.

**Warning:**

It is no longer recommended for you to customize these files because if you upgrade to a newer version of Oxygen, those files may no longer produce the desired results and if new components have been added, you won't have access to them. Instead, use any of the other methods described in Publishing Template Package Contents for WebHelp Responsive Customizations (on page 1500).

If you do choose to customize these HTML files, each type of page is defined inside an `<html-page-layout-files>` element in the descriptor file.

```xml
<publishing-template>
    ...
    <webhelp>
        ...
        <!-- HTML page layout files -->
        <html-page-layout-files>
            <page-layout-file page="main" file="page-templates/wt_index.html"/>
            <page-layout-file page="search" file="page-templates/wt_search.html"/>
            <page-layout-file page="topic" file="page-templates/wt_topic.html"/>
            <page-layout-file page="index-terms" file="page-templates/wt_terms.html"/>
        </html-page-layout-files>
    </webhelp>
    ...
</publishing-template>
```

If you do use the `html-page-layout-files` element, you must specify all four types of pages (*main*, *search*, *topic*, *index*). When not specified, the files from the `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/oxygen-webhelp/page-templates` folder will be used to define the layout of each type of page.

**HTML Page Components**

Each type of page contains various components that control the layout of that page. The rendering of each component depends on the context where it is placed and its content depends on the transformed DITA map (on page 2966).
Some of the components can be used in all four types of pages, while some are only available for certain pages. For instance, the *Publication Title* component can be used in all pages, but the *Navigation Breadcrumb* component can only be used in the *Topic Page*.

To include a component in the output of a particular type of page, you have to reference a specific element in that particular HTML file. All the elements associated with a component should belong to the `http://www.oxygenxml.com/webhelp/components` namespace.

Every component can contain custom content or reference another component. To specify where the component content will be located in the output, you can use the `<whc:component_content>` element as a descendant of the component element. It can specify the location as before, after, or it can wrap the component content. The following snippet contains an example of each:

```xml
<whc:webhelp_search_input class="navbar-form wh_main_page_search"
   role="form">
   <div class="custom-content-before">Enter search terms here:</div>
   <div class="custom-wrapper">
       <whc:component_content/>
   </div>
   <div class="custom-content-after">Results will be displayed in a new window.</div>
</whc:webhelp_search_input>
```

**Main Page**

The *Main Page* is the home page generated in the WebHelp Responsive output. The name of the HTML file that defines this page is `wt_index.html` and it is located in the following directory: `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/oxygen-webhelp/page-templates`.

The main function of the home page is to display top-level information and provide links that help you easily navigate to any of the top-level topics of the publication. These links can be rendered in either a *Tiles* or *Tree* style of layout. The HTML page produced for the home page also consists of various other components, such as a logo, title, menu, search field, or index link.
Figure 467. Examples of Main Page Components for a Tiles Style of Layout

1. Publication Logo (on page 1519)
2. Publication Title (on page 1519)
3. Search Input (on page 1520)
4. Main Menu (on page 1520)
5. Index Terms Link (on page 1521)
6. Topic Tiles (on page 1520)
7. Print Link (on page 1520)
The following components can be referenced in the Main Page (wt_index.html) file:

**Publication Title (webhelp_publication_title)**

This component generates the publication title in the output. To generate this component, the `<whc:webhelp_publication_title>` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_publication_title
```

In the output, you will find an element with the class: `wh_publication_title`.

**Publication Logo (webhelp_logo)**

This component generates a logo image in the output. To generate this component, the `<whc:webhelp_logo>` element must be specified in the HTML file as in the following example:
In addition, you must also specify the path of the logo image in the `webhelp.logo.image` transformation parameter (in the Parameters tab in the transformation scenario). You can set the `webhelp.logo.image.target.url` parameter to generate a link to a URL when you click the logo image.

In the output, you will find an element with the class: `wh_logo`.

**Search Input** (*webhelp_search_input*)

This component is used to generate the input widget associated with search function in the output. To generate this component, the `<whc:webhelp_search_input>` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_search_input
```

In the output, you will find an element with the class: `wh_search_input`.

**Print Link** (*webhelp_print_link*)

This component is used to generate a print icon that opens the print dialog box for your particular browser. To generate this component, the `<whc:webhelp_print_link>` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_print_link
```

In the output, you will find an element with the class: `wh_print_link`.

**Main Menu** (*webhelp_top_menu*)

This component generates a menu with all the documentation topics. To generate this component, the `<whc:webhelp_top_menu>` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_top_menu
```

In the output, you will find an element with the class: `wh_top_menu`.

You can control the maximum level of topics that will be included in the menu using the `webhelp.top.menu.depth` transformation parameter (in the Parameters tab of the transformation scenario).

For information about customizing the menu, see How to Customize the Menu (on page 1555).

**Main Page Topic Tiles** (*webhelp_tiles*)

This component generates the tiles section in the main page. This section will contain a tile for each root topic of the published documentation. Each topic tile has three sections that correspond to the topic title, short description, and image. To generate this component, the `<whc:webhelp_tiles>` element must be specified in the HTML file as in the following example:
In the output, you will find an element with the class: `wh_tiles`.

If you want to control the HTML structure that is generated for a WebHelp tile you can also specify the template for a tile by using the `<whc:webhelp_tile>` component, as in the following example:

```xml
<whc:webhelp_tile class="col-md-4">
  <!-- Place holder for tile's image -->
  <whc:webhelp_tile_image/>

  <div class="wh_tile_text">
    <!-- Place holder for tile's title -->
    <whc:webhelp_tile_title/>

    <!-- Place holder for tile's shordesc -->
    <whc:webhelp_tile_shortdesc/>
  </div>
</whc:webhelp_tile>
```

For information about customizing the tiles, see How to Configure the Tiles on the WebHelp Responsive Main Page (on page 1559).

**Main Page Table of Contents** (webhelp_main_page_toc)

This component generates a simplified Table of Contents. It is simplified because it contains only two levels from the documentation hierarchy. To generate this component, the `<whc:webhelp_main_page_toc>` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_main_page_toc
```

In the output, you will find an element with the class: `wh_main_page_toc`.

**Index Terms Link** (webhelp_indexterms_link)

This component can be used to generate a link to the index terms page (indexterms.html). If the published documentation does not contain any index terms, then the link will not be generated. To generate this component, the `<whc:webhelp_indexterms_link>` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_indexterms_link
```

In the output, you will find an element with the class: `wh_indexterms_link`. This element will contain a link to the `indexterms.html` page.

**Link to Skins Resources** (webhelp_skin_resources)
This component can be used to add a link to resources for the current WebHelp skin (such as the CSS file). To generate this component, the `<whc:webhelp_skin_resources>` element must be specified in the HTML file as in the following example:

```
<whc:webhelp_skin_resources/>
```

In the output, you will find a link to the skin resources.

**Topic Page**

The *Topic Page* is the page generated for each DITA topic in the WebHelp Responsive output. The name of the HTML file that defines this page is `wt_topic.html` and it is located in the following directory: `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/oxygen-webhelp/page-templates`.

The HTML pages produced for each topic consist of the topic content along with various other additional components, such as a title, menu, navigation breadcrumb, print icon, or side table of contents.

**Figure 469. Examples of Topic Page Components**

1. Publication Logo (on page 1523)
2. Publication Title (on page 1523)
3. Search Input (on page 1523)
4. Main Menu (on page 1525)
5. Index Terms Link (on page 1526)
6. Expand/Collapse All Sections (on page 1525)
7. Navigation Links (on page 1524)
8. Print Link (on page 1524)
9. Breadcrumb (on page 1523)
10. Publication Table of Contents (on page 1524)
11. Topic Content (on page 1524)
12. Topic Table of Contents (on page 1525)

The following components can be referenced in the Topic Page (wt_topic.html) file:

**Publication Title** (**webhelp_publication_title**)  
This component generates the publication title in the output. To generate this component, the `<whc:webhelp_publication_title>` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_publication_title
```

In the output, you will find an element with the class: `wh_publication_title`.

**Publication Logo** (**webhelp_logo**)  
This component generates a logo image in the output. To generate this component, the `<whc:webhelp_logo>` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_logo
```

In addition, you must also specify the path of the logo image in the `webhelp.logo.image` transformation parameter (in the Parameters tab in the transformation scenario). You can set the `webhelp.logo.image.target.url` parameter to generate a link to a URL when you click the logo image.

In the output, you will find an element with the class: `wh_logo`.

**Search Input** (**webhelp_search_input**)  
This component is used to generate the input widget associated with search function in the output. To generate this component, the `<whc:webhelp_search_input>` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_search_input
```

In the output, you will find an element with the class: `wh_search_input`.

**Topic Breadcrumb** (**webhelp_breadcrumb**)  
This component generates a breadcrumb that displays the path of the current topic. To generate this component, the `<whc:webhelp_breadcrumb>` element must be specified in the HTML file as in the following example:
<whc:webhelp_breadcrumb

In the output, you will find an element with the class: wh_breadcrumb. This element will contain a
list with items that correspond to the topics in the path. The first item in the list has a link to the
main page with the home class. The last item in the list corresponds to the current topic and has
the active class set.

**Navigation Links (webhelp_navigation_links)**

This component generates navigation links to the next and previous topics. To generate this
component, the `<whc:webhelp_navigation_links>` element must be specified in the HTML file as in
the following example:

```xml
<whc:webhelp_navigation_links
```

In the output, you will find an element with the class: wh_navigation_links. This element will
contain the links to the next and previous topics.

**Print Link (webhelp_print_link)**

This component is used to generate a print icon that opens the print dialog box for your
particular browser. To generate this component, the `<whc:webhelp_print_link>` element must be
specified in the HTML file as in the following example:

```xml
<whc:webhelp_print_link
```

In the output, you will find an element with the class: wh_print_link.

**Topic Content (webhelp_topic_content)**

This component generates the content of a topic and it represent the content of the HTML
files as they are produced by the DITA-OT processor. To generate this component, the
`<whc:webhelp_topic_content>` element must be specified in the HTML file as in the following
example:

```xml
<whc:webhelp_topic_content
```

In the output, you will find an element with the class: wh_topic_content.

**Publication TOC (webhelp_publication_toc)**

This component generates a mini table of contents for the current topic (on the left side). It will
contain links to the children of the current topic, its siblings, and all of its ancestors. To generate
this component, the `<whc:webhelp_publication_toc>` element must be specified in the HTML file as
in the following example:

```xml
<whc:webhelp_publication_toc
```
In the output, you will find an element with the class: `wh_publication_toc`. This element will contain links to the topics that are close to the current topic.

**Topic TOC (webhelp_topic_toc)**

This component generates a topic table of contents for the current topic (on the right side) with a heading named *On this page*. It contains links to each section within the current topic and the section corresponding to the current scroll position is highlighted. The topic must contain at least two `<section>` elements and each `<section>` must have an `@id` attribute. To generate this component, the `<whc:webhelp_topic_toc>` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_topic_toc
```

In the output, you will find an element with the class: `wh_topic_toc`. This element will contain links to the topics that are close to the current topic.

**Expand/Collapse Sections (webhelp_expandCollapse_sections)**

This component is used to generate an icon that expands or collapses sections listed in the side table of contents within a topic. To generate this component, the `<whc:webhelp_expandCollapse_sections>` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_expandCollapse_sections
```

In the output, you will find an element with the class: `webhelp_expandCollapse_sections`.

**Topic Feedback (webhelp_feedback)**

This component generates a placeholder for where the comments section will be presented. To generate this component, the `<whc:webhelp_feedback>` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_feedback
```

**Main Menu (webhelp_top_menu)**

This component generates a menu with all the documentation topics. To generate this component, the `<whc:webhelp_top_menu>` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_top_menu
```

In the output, you will find an element with the class: `wh_top_menu`.

You can control the maximum level of topics that will be included in the menu using the `webhelp.top.menu.depth` transformation parameter (in the Parameters tab of the transformation scenario).
For information about customizing the menu, see How to Customize the Menu (on page 1555).

**Index Terms Link** (webhelp_indexterms_link)

This component can be used to generate a link to the index terms page (indexterms.html). If the published documentation does not contain any index terms, then the link will not be generated. To generate this component, the `<whc:webhelp_indexterms_link>` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_indexterms_link
```

In the output, you will find an element with the class: wh_indexterms_link. This element will contain a link to the indexterms.html page.

**Child Links** (webhelp_child_links)

For all topics with subtopics (child topics), this component generates a list of links to each child topic. To generate this component, the `<whc:webhelp_child_links>` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_child_links
```

**Related Links** (webhelp_related_links)

For all topics that contain related links, this component generates a list of related links that will appear in the output. To generate this component, the `<whc:webhelp_related_links>` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_related_links
```

**Link to Skins Resources** (webhelp_skin_resources)

This component can be used to add a link to resources for the current WebHelp skin (such as the CSS file). To generate this component, the `<whc:webhelp_skin_resources>` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_skin_resources/>
```

In the output, you will find a link to the skin resources.

**Search Results Page**

The Search Results Page is the page generated that presents search results in the WebHelp Responsive output. The name of the HTML file that defines this page is `wt_search.html` and it is located in the following directory: `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/oxygen-webhelp/page-templates`.

The HTML page that is produced consists of a search results component along with various other additional components, such as a title, menu, or index link.
Figure 470. Examples of Search Results Page Components

1. Publication Logo (on page 1527)
2. Publication Title (on page 1527)
3. Search Input (on page 1528)
4. Main Menu (on page 1528)
5. Index Terms Link (on page 1529)
6. Search Results (on page 1528)
7. Print Link (on page 1528)

The following components can be referenced in the Search Results Page (wt_search.html) file:

**Publication Title** \(\text{webhelp_publication_title}\)

This component generates the publication title in the output. To generate this component, the \(<\text{whc:webhelp_publication_title}>\) element must be specified in the HTML file as in the following example:

\[
<\text{whc:webhelp_publication_title xmlns:whc="http://www.oxygenxml.com/webhelp/components"}>
\]

In the output, you will find an element with the class: \(\text{wh_publication_title}\).

**Publication Logo** \(\text{webhelp_logo}\)
This component generates a logo image in the output. To generate this component, the `<whc:webhelp_logo>` element must be specified in the HTML file as in the following example:

```
<whc:webhelp_logo
```

In addition, you must also specify the path of the logo image in the `webhelp.logo.image` transformation parameter (in the Parameters tab in the transformation scenario). You can set the `webhelp.logo.image.target.url` parameter to generate a link to a URL when you click the logo image.

In the output, you will find an element with the class `wh_logo`.

**Search Input (webhelp_search_input)**

This component is used to generate the input widget associated with search function in the output. To generate this component, the `<whc:webhelp_search_input>` element must be specified in the HTML file as in the following example:

```
<whc:webhelp_search_input
```

In the output, you will find an element with the class `wh_search_input`.

**Search Results (webhelp_search_results)**

This component is used to generate a placeholder to signal where the search results will be presented in the output. To generate this component, the `<whc:webhelp_search_results>` element must be specified in the HTML file as in the following example:

```
<whc:webhelp_search_results
```

In the output, you will find an element with the class `wh_search_results`.

**Print Link (webhelp_print_link)**

This component is used to generate a print icon that opens the print dialog box for your particular browser. To generate this component, the `<whc:webhelp_print_link>` element must be specified in the HTML file as in the following example:

```
<whc:webhelp_print_link
```

In the output, you will find an element with the class `wh_print_link`.

**Main Menu (webhelp_top_menu)**

This component generates a menu with all the documentation topics. To generate this component, the `<whc:webhelp_top_menu>` element must be specified in the HTML file as in the following example:

```
<whc:webhelp_top_menu
```
In the output, you will find an element with the class: `wh_top_menu`.

You can control the maximum level of topics that will be included in the menu using the `webhelp.top.menu.depth` transformation parameter (in the Parameters tab of the transformation scenario).

For information about customizing the menu, see How to Customize the Menu (on page 1555).

**Index Terms Link (webhelp_indexterms_link)**

This component can be used to generate a link to the index terms page (`indexterms.html`). If the published documentation does not contain any index terms, then the link will not be generated. To generate this component, the `<whc:webhelp_indexterms_link>` element must be specified in the HTML file as in the following example:

```xml
```

In the output, you will find an element with the class: `wh_indexterms_link`. This element will contain a link to the `indexterms.html` page.

**Link to Skins Resources (webhelp_skin_resources)**

This component can be used to add a link to resources for the current WebHelp skin (such as the CSS file). To generate this component, the `<whc:webhelp_skin_resources>` element must be specified in the HTML file as in the following example:

```xml
<whc:webhelp_skin_resources/>
```

In the output, you will find a link to the skin resources.

**Index Terms Page**

The *Index Terms Page* is the page generated that presents index terms in the WebHelp Responsive output. The name of the HTML file that defines this page is `wt_terms.html` and it is located in the following directory: `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/oxygen-webhelp/page-templates`.

The HTML page that is produced consists of an index terms section along with various other additional components, such as a title, menu, or search field.

An alphabet that contains the first letter of the documentation index terms is generated at the top of the index page. Each letter represents a link to a specific indices section.
The following components can be referenced in the *Index Terms Page* (wt_terms.html) file:

**Publication Title** ([webhelp_publication_title](http://www.oxygenxml.com/webhelp/components))

This component generates the publication title in the output. To generate this component, the `<whc:webhelp_publication_title>` element must be specified in the HTML file as in the following example:

```html
<whc:webhelp_publication_title
```

In the output, you will find an element with the class: `wh_publication_title`.

**Publication Logo** ([webhelp_logo](http://www.oxygenxml.com/webhelp/components))

This component generates a logo image in the output. To generate this component, the `<whc:webhelp_logo>` element must be specified in the HTML file as in the following example:

```html
<whc:webhelp_logo
```
In addition, you must also specify the path of the logo image in the `webhelp.logo.image` transformation parameter (in the Parameters tab in the transformation scenario). You can set the `webhelp.logo.image.target.url` parameter to generate a link to a URL when you click the logo image.

In the output, you will find an element with the class: `wh_logo`.

**Search Input (webhelp_search_input)**

This component is used to generate the input widget associated with search function in the output. To generate this component, the `<whc:webhelp_search_input>` element must be specified in the HTML file as in the following example:

```xml
```

In the output, you will find an element with the class: `wh_search_input`.

**Print Link (webhelp_print_link)**

This component is used to generate a print icon that opens the print dialog box for your particular browser. To generate this component, the `<whc:webhelp_print_link>` element must be specified in the HTML file as in the following example:

```xml
```

In the output, you will find an element with the class: `wh_print_link`.

**Main Menu (webhelp_top_menu)**

This component generates a menu with all the documentation topics. To generate this component, the `<whc:webhelp_top_menu>` element must be specified in the HTML file as in the following example:

```xml
```

In the output, you will find an element with the class: `wh_top_menu`.

You can control the maximum level of topics that will be included in the menu using the `webhelp.top.menu.depth` transformation parameter (in the Parameters tab of the transformation scenario).

For information about customizing the menu, see How to Customize the Menu (on page 1555).

**Index Terms Link (webhelp_indexterms_link)**

This component can be used to generate a link to the index terms page (`indexterms.html`). If the published documentation does not contain any index terms, then the link will not be generated.

To generate this component, the `<whc:webhelp_indexterms_link>` element must be specified in the HTML file as in the following example:

```xml
```
In the output, you will find an element with the class: `wh_indexterms_link`. This element will contain a link to the `indexterms.html` page.

**Link to Skins Resources (webhelp_skin_resources)**

This component can be used to add a link to resources for the current WebHelp skin (such as the CSS file). To generate this component, the `<whc:webhelp_skin_resources>` element must be specified in the HTML file as in the following example:

```html
<whc:webhelp_skin_resources/>
```

In the output, you will find a link to the skin resources.

**Generating WebHelp Responsive Output**

The publishing process can be initiated from a transformation scenario within Oxygen XML Editor/Author, from a command line outside Oxygen XML Editor/Author, or from an integration server.

**Running from Oxygen XML Editor/Author**

To publish a [DITA map (on page 2966)](#) as WebHelp Responsive output, follow these steps:

1. Select the Configure Transformation Scenario(s) action from the DITA Maps Manager toolbar.
2. Select the DITA Map WebHelp Responsive scenario from the DITA Map section.
3. If you want to configure the transformation, click the Edit button.

**Step Result:** This opens an Edit scenario configuration dialog box that allows you to configure various options in the following tabs:

- **Templates Tab** - This tab contains a set of built-in skins that you can use for the layout of your WebHelp system output.
- **Parameters Tab** - This tab includes numerous transformation parameters that can be set to customize your WebHelp system output.
- **Feedback Tab** - This tab is for those who want to add the Oxygen Feedback comments component at the bottom of each WebHelp page so that you can interact with your readers.
- **Filters Tab** - This tab allows you to filter certain content elements from the generated output.
- **Advanced Tab** - This tab allows you to specify some advanced options for the transformation scenario.
- **Output Tab** - This tab allows you to configure options that are related to the location where the output is generated.

4. Click Apply associated to process the transformation.

**Result:** When the DITA Map WebHelp Responsive transformation is complete, the output is automatically opened in your default browser.
Automating the WebHelp Responsive Output for DITA

DITA-based WebHelp output can be generated from an automated publishing process using a command line outside of Oxygen XML Editor/Author or an automatic publishing system, such as Jenkins or Travis. However, to do this, you must purchase an additional Oxygen XML WebHelp license.

- Generating WebHelp Responsive Output for DITA

Deploying an Oxygen Feedback Comments Component

You can add a comments component in your WebHelp Responsive output to provide a simple and efficient way for your community to interact and offer feedback. The comments component is contributed by Oxygen Feedback, a modern comment management system that can be integrated with your WebHelp Responsive output to provide a comments area at the bottom of each WebHelp page where readers can add new comments or reply to existing ones.

Oxygen Feedback includes a modern, user-friendly administration interface where you can moderate comments, manage users, view statistics, and configure settings. It is very easy to integrate and there are no requirements for installing additional software. You simply need to create an Oxygen Feedback site configuration in the administration interface, copy the HTML installation fragment that is generated at the end of the creation process, and paste the generated fragment in the Feedback tab in the WebHelp Responsive transformation scenario dialog box (on page 2874).

An add-on is also available that contributes a Feedback Comments Manager view in Oxygen XML Editor/Author where the documentation team can see all the comments added in your WebHelp output. This means they can react to user feedback by making corrections and updating the source content without leaving the application.

Adding the Feedback System to WebHelp Responsive Documentation

Prerequisite

To install and manage Oxygen Feedback, you will need to obtain a license for the product. This requires that you choose a subscription plan during the installation procedure. To see the subscription plans prior to installing the product, go to: https://www.oxygenxml.com/oxygen_feedback/buy_feedback.html.

Installation Procedure

1. Log in to your Feedback account from the administration login page (https://feedback.oxygenxml.com/login). You can click on Log in with Google or Log in with Facebook to create an account using your Google or Facebook credentials, or click the Sign Up tab to create an account using your name and email address.
2. Click the Add site button to create a site configuration. If you have not already selected a subscription plan, you will be directed to a page where you can choose from several options.
3. In the Settings page, enter a Name and Description for the site configuration. There are some optional settings that can be adjusted according to your needs. For more details, see the Site Settings topic. Click Continue.
4. In the Initial version page, enter the Base URL for your website (you can add additional URLs by clicking the Add button). You can also specify an Initial version if you want it to be something other than 1.0. If you do not plan to have multiple versions, leave the version as 1.0. For more details, see the Initial Version topic. Click Continue.

5. In the Installation page, choose a site generation option:
   a. If you will generate the documentation using a transformation scenario in Oxygen XML Editor/Author, select the Oxygen XML Editor option and continue with these steps:
      i. Copy the generated HTML fragment and click Finish.
      ii. In Oxygen XML Editor/Author, open the Configure Transformation Scenario(s) dialog box.
      iii. Select and duplicate the DITA Map WebHelp Responsive scenario.
      iv. Go to the Feedback tab.
      v. Click the Edit button and paste the generated installation fragment.
   b. If you will generate the documentation using a command-line script, select the Oxygen XML WebHelp option and continue with these steps:
      i. Copy the generated HTML fragment and click Finish.
      ii. Create an XML file (for example, feedback-install.xml) with the generated installation fragment.
      iii. Use the webhelp.fragment.feedback parameter in your command-line script to specify the path to the file you just created. For example:

```
dita.bat -Dwebhelp.fragment.feedback=c:\path\to\feedback-install.xml
```

6. [Optional] If you want the Oxygen Feedback comments component to fill the entire page width, contribute a custom CSS file (use the args.css parameter to reference it) that contains the following style rule:

```css
div.footer {
  float: none;
}
```

For more details about Oxygen Feedback, how to configure settings, moderate comments, view statistics, and much more, see the Oxygen Feedback user guide.

**Customizing WebHelp Responsive Output**

Oxygen XML Editor provides support for customizing the WebHelp Responsive output to suit your specific needs. The WebHelp Responsive output is based upon the Bootstrap responsive front-end framework and is available for DITA document types.

To change the overall appearance of your WebHelp Responsive output, you can use several different customization methods or a combination of methods. If you are familiar with CSS and coding, you can style your WebHelp output through your own custom stylesheets. You can also customize your output by modifying existing templates, create your own layout pages, or by configuring certain options and parameters in the transformation scenario.
This section includes topics that explain various ways to customize your WebHelp Responsive system output, such as how to configure the tiles on the main page, add logos in the title area, integrate with social media, localizing the interface, and much more.

For an in-depth look at WebHelp Responsive features and some customization tips, watch our Webinar: **DITA Publishing and Feedback with Oxygen Tools.**

## Working with Publishing Templates

An *Oxygen Publishing Template* (on page 2969) defines all aspects of the layout and styles of the **WebHelp Responsive** output. It is a self-contained customization package stored as a ZIP archive or folder that can easily be shared with others. It provides the primary method for customizing the output. The recommended method for customizing the **WebHelp Responsive** output is to use a custom publishing template.

This section contains topics about how to create, edit, publish, and share publishing templates.

### Related Information:

[Publishing Template Package Contents for WebHelp Responsive Customizations](on page 1500)

### How to Create a Publishing Template

To create a customization, you can start from scratch or from an existing template, and then adapt it according to your needs.

### Creating a Template Starting from Scratch

To create a new *Oxygen Publishing Template*, follow these steps:

1. Create a folder that will contain all the template files.
2. In *Oxygen XML Editor/Author*, open the new document wizard (use File > New or the ✉️ New toolbar button), then choose the *Publishing Template Descriptor* template.
Figure 472. Choosing the Publishing Template Descriptor Document Template

3. Save the .opt file into your customization directory.
4. Open the .opt file in the editor and customize it to suit your needs.

Creating a Template Starting from an Existing Template

If you are using a WebHelp Responsive or DITA Map PDF - based on HTML5 & CSS transformation, the easiest way to create a new Oxygen Publishing Template (on page 2969) is to select an existing template in the transformation scenario dialog box and use the Save template as button to save that template into a new template package that can be used as a starting point.

To create a new Oxygen Publishing Template, follow these steps:

1. Open the transformation scenario dialog box and select the publishing template you want to export and use as a starting point.
2. Optional: You can set one or more transformation parameters from the Parameters tab and the edited parameters will be exported along with the selected template. You will see which parameters will be exported in the dialog box that is displayed after the next step.
3. Click the Save template as button.
   Step Result: This opens a template package configuration dialog box that contains some options and displays the parameters that will be exported to your template package.
4. Specify a name for the new template.
5. Optional: Specify a template description.
6. **Optional:** The same publishing template package can contain both a WebHelp Responsive and PDF customization and you can use the same template in both types of transformations ([DITA Map WebHelp Responsive](#) or [DITA Map to PDF - based on HTML5 & CSS](#)). You can use the **Include WebHelp customization** and **Include PDF customization** options to specify whether your custom template will include both types of customizations.

7. **Optional:** For **WebHelp Responsive** customizations, you can select the **Include HTML Page Layout Files** option if you want to copy the default **HTML Page Layout Files** (on page 1516) in your template package. They are helpful if you want to change the structure of the generated HTML pages.

8. In the **Save as** field, specify the name and path of the ZIP file where the template will be saved.

   **Step Result:** A new ZIP archive will be created on disk in the specified location with the specified name.

9. Open the .opt file in the editor and customize it to suit your needs.

For more information about creating and customizing publishing templates, watch our video demonstration:

https://www.youtube.com/embed/zNmXfKWXwO8

**Related Information:**
- [Publishing Template Package Contents for PDF Customizations](#) (on page 1673)
- [Publishing Template Package Contents for WebHelp Responsive Customizations](#) (on page 1500)

**How to Edit a Packed Publishing Template**

To edit an existing **Oxygen Publishing Template** (on page 2969) package, follow these steps:

1. Unzip the ZIP archive associated with the **Oxygen Publishing Template** in a separate folder.
2. Link the folder associated with the template in the **Project** view.
3. Using the **Project** view, you can modify the resources (CSS, JS, fonts) within the **Oxygen Publishing Template** folder to fit your needs.
4. Open the publishing template descriptor file (.opt extension) in the editor and modify it to suit your needs.
5. **Optional:** Once you finish your customization, you can archive the folder as a ZIP file.

**Related Information:**
- [Publishing Template Package Contents for PDF Customizations](#) (on page 1673)
- [Publishing Template Package Contents for WebHelp Responsive Customizations](#) (on page 1500)

**How to Add a Publishing Template to the Publishing Templates Gallery**

To add the publishing template to your templates gallery, follow these steps:

1. Open the transformation scenario dialog box by editing a WebHelp Responsive transformation.
2. In the **Templates** tab, click the **Configure Publishing Templates Gallery** link to.
   
   This will open the preferences page.
3. Click the **Add** button and specify the location of your template directory. Your template directory is now added to the **Additional Publishing Templates Galleries** list.
4. Click **OK** to return to the transformation scenario dialog box. All the templates contained in your template directory will be displayed in the preview pane along with all the built-in templates.

### How to Use a Publishing Template from a Command Line

Before you run the transformation, you need to know if the publishing template has a single template descriptor file or multiple descriptor files *(on page 1500)*. If you don't know, open the ZIP archive or folder and check for files with the `.opt` extension.

#### Using a Publishing Template with a Single Descriptor

A template with a single descriptor is used for a single customization.

To run from a command line, you need to use the `webhelp.publishing.template` parameter *(on page 1605)*. This parameter specifies the path to the ZIP archive (or root folder) that contains your custom WebHelp Responsive template.

**Command-Line Example:**

- **Windows:**

  ```
  dita.bat
  --format=webhelp-responsive
  --input=\path\to\mySample.ditamap
  --output=\path\to\output
  -Dwebhelp.publishing.template=custom-template
  ```

- **Linux/macOS:**

  ```
  dita
  --format=webhelp-responsive
  --input=/path/to/mySample.ditamap
  --output=/path/to/output
  -Dwebhelp.publishing.template=custom-template
  ```

**Tip:**

You can also start the `dita` process by passing it a [DITA OT Project File](https://github.com/dita-ot/dita-ot). Inside the project file you can specify as parameters for the `webhelp-responsive` transformation type the WebHelp-related parameters.

#### Using a Publishing Template with Multiple Descriptors

A template with multiple descriptors contains multiple customizations.
Because the publishing template is self-contained, it is used to reuse resources that are common to multiple publications.

To run from a command line, you need to use the `webhelp.publishing.template` (on page 1605) and `webhelp.publishing.template.descriptor` (on page 1605) parameters.

The `webhelp.publishing.template` (on page 1605) parameter specifies the path to the ZIP archive (or root folder) while the `webhelp.publishing.template.descriptor` (on page 1605) parameter specifies the name of the descriptor you want to use.

**Command-Line Example:**

- **Windows:**
  ```
  dita.bat
  --format=webhelp-responsive
  --input=c:\path\to\mySample.ditamap
  --output=c:\path\to\output
  -Dwebhelp.publishing.template=custom-template
  -Dwebhelp.publishing.template.descriptor=flowers.opt
  ```

- **Linux/macOS:**
  ```
  dita
  --format=webhelp-responsive
  --input=/path/to/mySample.ditamap
  --output=/path/to/output
  -Dwebhelp.publishing.template=custom-template
  -Dwebhelp.publishing.template.descriptor=flowers.opt
  ```

**Tip:**
You can also start the `dita` process by passing it a [DITA OT Project File](#). Inside the project file you can specify as parameters for the `webhelp-responsive` transformation type the WebHelp-related parameters.

**How to Share a Publishing Template**

To share a publishing template with others, following these steps:

1. Copy your template in a new folder in your project.
2. Go to Options > Preferences > DITA > Publishing and add that new folder to the list.
3. Switch the option as the bottom of that preferences page to Project Options.
4. Share your project file (.xpr).
Troubleshooting: Errors Encountered when Loading Templates

When the Templates tab of a WebHelp Responsive transformation scenario dialog box is opened, all templates (built-in and custom) are loaded and validated. Specifically, certain elements in the template descriptor file (on page 1500) are checked for validity. If errors are encountered that prevents the template from loading, the following message will be displayed toward the bottom of the dialog box:

⚠️ Some templates could not be loaded. More details

If you click the More details link, a window will open with more information about the encountered error. For example, it might offer a hint that the element is missing from the expected descriptor file structure (on page 1500).

Also, if a template could be loaded, but certain elements could not be found in the descriptor file (on page 1500), a warning icon (⚠️) will be displayed on the template's image (in the Templates tab of the transformation dialog box). For example, this happens if a valid preview-image element (on page 1503) cannot be found.

Converting Old Templates to Newer Versions

WebHelp templates that were created in older versions of Oxygen XML Editor can be converted to the Publishing Template format that was introduced in Oxygen XML Editor version 20.0. This section contains several procedures for converting old templates depending on the version they were created in.

Convert Version 21 Publishing Templates to Version 22

If you have a custom Publishing Template that was created in Oxygen XML Editor version 21.0 or 21.1, the following conversion procedure is required for the template to be compatible with Oxygen XML Editor version 22:

1. In the Project view, add the root directory for your custom Publishing Template (you can use a linked folder (on page 368) and the easiest way to do this is to drag and drop the folder).

   Note:
   If your template is stored as a ZIP archive, you first need to unzip it.

2. Expand your template directory, right-click the page-templates subfolder, and select Refactoring > XML Refactoring.

3. In the XML Refactoring dialog box, scroll to the Publishing Template section and select Migrate HTML Page Layout Files to v22, then click Next.

4. The Scope should be left as Selected project resources.

5. You can use the Preview button to open a comparison panel where you can review all the changes that will be made by the refactoring operation before applying the changes.

6. Click Finish to perform the conversion.

Result: The converted Publishing Template can now be used in version 22.
Convert Version 20 Publishing Templates to Version 21

If you have a custom Publishing Template that was created in Oxygen XML Editor version 20.0 or 20.1, the following conversion procedure is required for the template to be compatible with Oxygen XML Editor version 21.0 or 21.1:

1. In the Project view, add the root directory for your custom Publishing Template (you can use a linked folder) and the easiest way to do this is to drag and drop the folder.

   **Note:** If your template is stored as a ZIP archive, you first need to unzip it.

2. Expand your template directory, right-click the page-templates subfolder, and select Refactoring > XML Refactoring.

3. In the XML Refactoring dialog box, scroll to the Publishing Template section and select Migrate HTML Page Layout Files to v21, then click Next.

4. The Scope should be left as Selected project resources.

5. You can use the Preview button to open a comparison panel where you can review all the changes that will be made by the refactoring operation before applying the changes.

6. Click Finish to perform the conversion.

**Result:** The converted Publishing Template can now be used in version 21.0 or 21.1.

Convert Version 19 (and Older) Publishing Templates to Version 20

With the introduction of the Publishing Template concept in Oxygen XML Editor version 20.0, the old WebHelp output template formats (version 19.1 and older) are no longer supported. However, they can be easily converted to the new format (version 20.0 or 20.1) by following this procedure:

1. Set Oxygen XML Editor to point to the DITA-OT distribution that contains your old template:
   a. Go to Options > Preferences > DITA.
   b. Select Custom in the DITA Open Toolkit section and specify the DITA-OT directory that contains your old template.

2. Edit a WebHelp Responsive transformation scenario.

3. Select your old custom template in the Templates tab.
4. Click on the **Save Template as** button, complete the required fields, and save the template.
5. Reset the option set in step 1 to its previous value.
6. Edit the **WebHelp Responsive** transformation scenario again.
7. This time, use the **Choose custom template** button to select your converted template.
8. Save the scenario and use it to generate the WebHelp Responsive output.

**Result:** The converted template is now in a Publishing Template format for version 20.

**Related Information:**

Convert Version 20 Publishing Templates to Version 21 *(on page 1541)*

### Convert Version 19 (and Older) Publishing Templates to Version 21

If you have a custom template that was created in Oxygen XML Editor version 19.1 or older and you want to convert it to be compatible with Oxygen XML Editor version 21.0 or 21.1, you need to apply two conversion procedures:

1. Convert the old template to a version 20 Publishing Template by using this procedure: **Convert Version 19 (and Older) Publishing Templates to Version 20 *(on page 1541)*.
2. Convert that version 20 Publishing Template to version 21 by using this procedure: **Convert Version 20 Publishing Templates to Version 21 *(on page 1541)*.

**Result:** The converted Publishing Template can now be used in version 21.0 or 21.1.

### Changing the Layout and Styles

This section contains topics that explain how to customize the output using CSS, inserting HTML fragments, changing the layout of the main page, and more.

### How to Use CSS Styling to Customize the Output

The most common way to customize WebHelp Responsive output is to use custom CSS styling. This method can be used to make small, simple styling changes or more advanced, precise changes. To implement the styling in your WebHelp output, you simply need to create the custom CSS file and reference it in your transformation scenario (using an **Oxygen Publishing Template *(on page 2969)* or a transformation parameter). This custom file will be the final CSS to be applied so its content will override the styles in the other pre-existing CSS files.

### Using CSS Inspector to Identify Content for Custom CSS File

You can use your browser's CSS inspector to identify the pertinent code in the current CSS files and you can even make changes directly in the CSS inspector to test the results so that you know exactly what content to use in your custom CSS file.

In most popular browsers (such as Chrome, Firefox, and Edge), you can access the CSS inspector by using **F12** or by selecting **Inspect Element** (or simply **Inspect**) from the contextual menu.
**Tip:**
When using Safari on macOS, you must first enable the Develop menu by going to the Advanced settings and selecting *Show Develop menu in menu bar*. Then you can select *Show Web Inspector* from the Develop menu or click *Command + Option + I*.

---

**Create the Custom CSS**

As a practical example, the following procedure would change the background color of the footer bar in the WebHelp output:

1. Use the browser’s CSS inspector to identify the current CSS code that styles the footer bar. In this particular case, the pertinent code that would be identified is:

   ```css
   .wh_footer {
     font-size: 15px;
     line-height: 1.7em;
     background-color: #000;
   }
   ```

2. If you want to test the color you want to apply as the background of this particular element, use the browser’s CSS inspector to change the value of the `background-color` attribute. After you find a suitable color, copy that new code.

3. Create a custom CSS file and paste or enter the copied code. For example:

   ```css
   .wh_footer {
     background-color: #255890;
   }
   ```

4. Save the custom CSS file at a location of your convenience.

5. Reference the CSS file in a WebHelp Responsive transformation using an [Oxygen Publishing Template](on page 1543) or the `args.css` parameter ([on page 1544](#)).

---

**Referencing the CSS Using a Publishing Template**

1. If you have not already created a Publishing Template, see *How to Create a Publishing Template* ([on page 1679](#)).

2. Using the Project view, copy your custom CSS in a folder inside the publishing template root folder (for example, in the `custom_footer_template/resources` folder).

3. Open the template descriptor file ([on page 1500](#)) associated with your publishing template and add your custom CSS in the `resources` section.

   ```xml
   <publishing-template>
     ...
     <webhelp>
       ...
     <resources>
   ```
4. Open the DITA Map WebHelp Responsive transformation scenario.
5. Click the Choose Custom Publishing Template link and select your template.
6. Click OK to save the changes to the transformation scenario.
7. Run the transformation scenario.

**Result:** Your custom CSS will be applied as a final layer on top of any existing CSS rules and the output will reflect the changes you made.

### Referencing the CSS Using the args.css Parameter

1. Edit the DITA Map WebHelp Responsive transformation scenario and open the Parameters tab.
2. Set the args.css parameter to the path of your custom CSS file.
3. Set the args.copycss parameter to yes to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
4. Click OK to save the changes to the transformation scenario.
5. Run the transformation scenario.

**Result:** Your custom CSS will be applied as a final layer on top of any existing CSS rules and the output will reflect the changes you made.

### How to Insert Custom HTML Content

You can add custom HTML content in the WebHelp Responsive output by inserting it in a well-formed XML file (or specifying it in a well-formed XHTML fragment) that will be referenced in the transformation (either from an Oxygen Publishing Template (on page 2969) or using one of the HTML fragment placeholder parameters (on page 1606)). This content may include references to additional JavaScript, CSS, and other types of resources, or such resources can be inserted inline within the HTML content that is inserted in the XML file.

**The XML File**

There are several things to consider regarding this XML file:

- **Well-Formedness** - If the content of the file is not XML Well-formed (on page 726), the transformation will automatically convert non-well-formed HTML content to a well-formed XML equivalent (assuming the webhelp.enable.html.fragments.cleanup transformation parameter is set to true).

For example, if the HTML content includes several `script` or `link` elements, the XML fragment would have multiple root elements and to make it well-formed, it would be wrapped it in an `<html>` element. This element tag will be filtered out and only its children will be copied to the output documents. Similarly, you can wrap your content in `<head>`, `<body>`, `<html/head>`, or `<html/body>` elements.
Note:
The converted fragments are stored in a file located in the `whr-html-fragments` subfolder of the transformation's temporary directory.

Tip:
If you do not want the transformation to automatically convert non-well-formed content into well-formed XML content, you can set the `webhelp.enable.html.fragments.cleanup` transformation parameter to `false`. This will instead cause the transformation to fail if at least one HTML fragment is not well-formed.

• Referencing Resources in the XML File - You can include references to local resources (such as JavaScript or CSS files) by using the built-in `${oxygen-webhelp-output-dir}` macro to specify their paths relative to the output directory:

```html
<html>
  <script type="text/javascript" src="${oxygen-webhelp-output-dir}/js/test.js"/>
  <link rel="stylesheet" type="text/css" href="${oxygen-webhelp-output-dir}/css/test.css"/>
</html>
```

If you want that the path of your resource to be relative to the templates directory (on page 1497), you can use the `${oxygen-webhelp-template-dir}` macro.

To copy the referenced resources to the output directory, follow the procedure in: How to Copy Additional Resources to Output Directory (on page 1591).

• Inline JavaScript or CSS Content:

JavaScript:

```html
<script type="text/javascript">
  /* Include JavaScript code here. */

  function myFunction() {
    return true;
  }
</script>
```

CSS:

```html
<style>
  /* Include CSS style rules here. */

  *{
    color:red
  }
</style>
```
Note:
If you have special characters (e.g. & or <) that break the well-formedness of the XML fragment, it is important to place the content inside an XML comment.

Otherwise, the WebHelp transformation automatically wraps inline JavaScript or CSS content in an XML comment. Also, if the commented content contains constructs that are not allowed in an XML comment, those constructs are escaped.

[Important] XML comment tags (both the start and end tags) must be on lines by themselves. If they are on the same line as any of the script's content, it will likely result in a JavaScript error.

```html
<script type="text/javascript">
<!--
/* Include JavaScript code here. */

function myFunction() {
    return true;
}
-->
</script>
```

Using WebHelp Macros

The XML file can use WebHelp macros, which are variables that will be expanded when the content of the HTML fragment file will be copied in the final output.

There are two possibilities for using macros:

- **Directly in attribute values** - For example, if you want to reference a JavaScript file from the Publishing Template directory, you can use the following construct:

  ```html
  <script type="text/javascript" src="${path(oxygen-webhelp-template-dir)}/"></script>
  ```

- **In text content** - Using the `<whc:macro>` template component:

  ```html
  <script type="text/javascript">
  var outDirPath = '<whc:macro value="${path(oxygen-webhelp-output-dir)}" xmlns:whc="http://www.oxygenxml.com/webhelp/components">'</;
  console.log("The output directory path is ", outDirPath);
  </script>
  ```

Note:
When using the `<whc:macro>` element, you should also include the xmlns:whc="http://www.oxygenxml.com/webhelp/components" namespace declaration for the whc prefix. This is necessary for the XML fragment to be well-formed.
The following *macros* are supported:

### i18n

For localizing a string.

\[
\text{$\{i18n\text{\{string.id\}\}}$}
\]

### param

Returns the value of a transformation parameter.

\[
\text{$\{param\{webhelp.show.main.page.tiles\}\}$}
\]

### env

Returns the value of an environment variable.

\[
\text{$\{env\{JAVA\_HOME\}\}$}
\]

### system-property

Returns the value of a system property.

\[
\text{$\{system-property\{os.name\}\}$}
\]

### timestamp

Can be used to format the current date and time. Accepts a string (as a parameter) that determines how the date and time will be formatted (format string or *picture string* as it is known in the XSLT specification). The format string must comply with the rules of the XSLT `format-dateTime` function specification.

\[
\text{$\{timestamp\{[h1]:[m01] \ [P] \ [M01]/[D01]/[Y0001]\}\}$}
\]

### path

Returns the path associated with the specified path ID. The following paths IDs are supported:

- **oxygen-webhelp-output-dir** - The path to the output directory. The path is relative to the current HTML file.
- **oxygen-webhelp-assets-dir** - The path to the `oxygen-webhelp` subdirectory from the output directory. The path is relative to the current HTML file.
- **oxygen-webhelp-template-dir** - The path to the template directory. The path is relative to the current HTML file.

\[
\text{$\{path\{oxygen-webhelp-template-dir\}\}$}
\]

---

**Note:**

New paths IDs can be added by overriding the `wh-macro-custom-path` template from `com.oxygenxml.webhelp.responsive\xsl\template\macroExpander.xsl`:

```
<!-- Extension template for expanding a custom path macro. -->
<xsl:template name="wh-macro-custom-path">
  <xsl:param name="pathId"/>
```
map-xpath

Can be used to execute an XPath expression over the DITA map file from the temporary directory.

Tip:
Available in all template layout HTML pages.

\${map-xpath(/map/title)}

topic-xpath

Can be used to execute an XPath expression over the current topic.

Tip:
Available only in the topic HTML page template (wt_topic.html).

\${topic-xpath(string-join(//shortdesc//text(), ' '))}

oxygen-webhelp-build-number

Returns the current WebHelp distribution ID (build number).

\${oxygen-webhelp-build-number}

Referencing the HTML fragment using a Publishing Template

1. If you have not already created a Publishing Template, see Working with Publishing Templates (on page 1535).
2. Insert the HTML content in a file that is XML well-formed (for example, custom-html.xml).
3. Using the Project view, copy your custom XML file in a folder inside publishing the template root folder (for example, in the custom_footer_template/html-fragments folder).
4. Open the template descriptor file (on page 1500) associated with your publishing template and add a reference to the custom HTML fragment in the html-fragments section.

\n
<publishing-template>
  ...
  <webhelp>
    ...
    <html-fragments>
      <fragment
        file="html-fragments/custom-html.xml"
        placeholder="webhelp.fragment.head"/>
    </html-fragments>
  </webhelp>
  ...
</publishing-template>
Note: If you want to insert the content in another location within the output document, you can reference the XML file from any other HTML Fragment extension points (on page 1507).

5. Open the DITA Map WebHelp Responsive transformation scenario.
6. Click the Choose Custom Publishing Template link and select your template.
7. Click OK to save the changes to the transformation scenario.
8. Run the transformation scenario.

Results: Your additional content will be included at the end of the <head> element of your output document.

Referencing the HTML Fragment using a Transformation Parameter

1. Insert the HTML content in a well-formed XML file.
2. Edit the DITA Map WebHelp Responsive transformation scenario and open the Parameters tab.
3. Edit the value of the webhelp.fragment.head parameter and set it to the absolute path of your XML file.

Note: If you want to insert the content in another location within the output document, you can reference the XML file from any other HTML Fragment extension points (on page 1507).

4. Click OK to save the changes to the transformation scenario.
5. Run the transformation scenario.

Results: Your additional content will be included at the end of the <head> element of your output document.

PUBLISHING TEMPLATE PACKAGE CONTENTS FOR WEBHELP RESPONSIVE CUSTOMIZATIONS (ON PAGE 1500)

How to Insert JavaScript AMD Modules

In the WebHelp Responsive output, you may want to include a JavaScript module that uses the Asynchronous Module Definition (AMD) format. Unlike the traditional JavaScript resources that are loaded using <script> tags, these modules are loaded using the RequireJS library. For the traditional JavaScript libraries, the standard procedure to contribute your script to the output would be to use an HTML fragment file as described here (on page 1544).

Although following the procedure that uses HTML fragments (on page 1544) would result in having your JS file included in the output, loading the JS code in the browser will result in an error. Since your JS module uses the AMD API, it cannot be loaded using a <script> element. For example, because many jQuery plugins use the AMD format, it will be difficult for you to use those libraries in your custom WebHelp output.

Normally, a JavaScript AMD module can be loaded in one of the following ways:
As a top-level script, using the `@data-main` attribute of the `<script>` element used to load the `RequireJS` library.

```html
<script data-main="js/template-main.js" src="js/require.js"></script>
```

However, since WebHelp already loads its internal JS modules using `RequireJS`, a top-level script is already specified and you cannot specify another top-level script in the same page. Therefore, this approach cannot be used to load your custom JS module in Oxygen XML WebHelp, leaving you with only the following option.

As a dependency module, using a `require()` call from the top-level (main) script or from one of its dependency modules. This means that you would have to alter one of the WebHelp core JS libraries and inject a `require()` call to load your custom module:

```javascript
require(['js/template-main.js']);
```

**Note:**

Altering the WebHelp core libraries is not recommended because when you will upgrade the WebHelp plugin to a newer version, those modifications will be lost.

### Contributing JavaScript AMD Modules Using a Publishing Template

Oxygen XML WebHelp provides the ability to contribute a custom JavaScript Asynchronous Module Definition (AMD) resource in the output by referencing it in the Publishing Template descriptor file (on page 1500). This module is automatically copied to the output directory and it is automatically loaded in the output HTML pages using a `require()` call. Thus, you can include your scripts in the output without altering WebHelp's core JavaScript libraries.

This module may contain all of your custom functionality or can be used to load other AMD JavaScript modules. The additional sub-modules can be stored either locally in your custom Publishing Template or on a remote web server.

**Important:**

To enable loading of a JS module you should set the `webhelp.enable.template.js.module.loading` parameter to `yes` (the default value is `no`) in the Publishing Template descriptor file or in the transformation scenario.

### The JavaScript Modules

The JS Modules sample template contains a main JavaScript module (`template-main.js`) that loads other modules stored in the template package or in a remote location on the Internet.

```javascript
define(['require'], function (require) {
  require(['./red', './italic', './tables']);
});
```

Besides the main JavaScript example, the template contains 3 other sub-modules:
• **red.js** - Changes the font color of the publication title.

```javascript
define(['jquery'], function ($) {

    $(document).ready(function () {
        // Make the title red
        $('.wh_publication_title a').attr('style', 'color:red');
    });
});
```

• **italic.js** - Changes the font style of your publication title.

```javascript
define(['jquery'], function ($) {

    $(document).ready(function () {
        // Make the title italic
        $('.wh_publication_title a').wrapInner('<i></i>');
    });
});
```

• **tables.js** - Loads the DataTables jQuery plugin from a CDN.

```javascript
define(['jquery',
    'https://cdn.datatables.net/1.10.16/js/jquery.dataTables.min.js'], function ($) {

    $(document).ready(function () {
        $('.table').DataTable();
    });
});
```

The JavaScript modules are stored in the Publishing Template package as follows:

```
[template-dir]
[js]
    template-main.js
    italic.js
    red.js
    tables.js
```

**Notes:**

- The main module should be referenced in the Publishing Template descriptor file (on page 1500) by specifying its path relative to the base directory of the template.

```xml
<js-amd-module file="js/template-main.js"/>
```

- The main JS module is copied automatically to the output directory, but the sub-modules are not. To instruct the Publishing Template engine to copy those modules to the output directory you should include a `<fileset>` section in the Publishing Template descriptor file (on page 1500).
```xml
<fileset>
  <include name="js/*.js"/>
</fileset>
```

- The main module can reference other modules bundled in the publishing template package as follows:
  - **Relative to template directory** - Prefix their paths with the ID of the template directory: `template-base-dir` (for example: `template-base-dir/js/italic`).
  - **Relative to the name of the current JS module** - Use `./` to prefix the paths of the referenced modules.
  - The `.js` extension should be omitted for local modules, because the RequireJS library will add it automatically.

**Related Information:**

How to Insert Custom HTML Content *(on page 1544)*

### How to Change Numbering Styles for Ordered Lists

Ordered lists (`<ol>`) are usually numbered in XHTML output using numerals. If you want to change the numbering to alphabetical, follow these steps:

1. Define a custom `[outputclass]` value and set it as an attribute of the ordered list, as in the following example:

   ```xml
   <ol outputclass="number-alpha">
     <li>A</li>
     <li>B</li>
     <li>C</li>
   </ol>
   ```

2. Add the following code snippet in a custom CSS file:

   ```css
   ol.number-alpha{
     list-style-type:lower-alpha;
   }
   ```

3. Reference the CSS file in a WebHelp Responsive transformation using an Oxygen Publishing Template *(on page 1552)* or the `args.css` parameter *(on page 1553)*.

### Referencing the Custom CSS from a Publishing Template

1. If you have not already created a Publishing Template, see How to Create a Publishing Template *(on page 1679)*.

2. Using the Project view, copy your custom CSS in a folder inside the publishing template root folder (for example, in the `custom_footer_template/resources` folder).
3. Open the template descriptor file (on page 1500) associated with your publishing template and add your custom CSS in the resources section.

   <publishing-template>
   ...
   <webhelp>
   ...
   <resources>
   ...
   <css file="resources/MyCustom.css"/>

4. Open the DITA Map WebHelp Responsive transformation scenario.
5. Click the Choose Custom Publishing Template link and select your template.
6. Click OK to save the changes to the transformation scenario.
7. Run the transformation scenario.

**Result:** Your custom CSS will be applied as a final layer on top of any existing CSS rules and the output will reflect the changes you made.

**Referencing the CSS Using the args.css Parameter**

1. Edit the DITA Map WebHelp Responsive transformation scenario and open the Parameters tab.
2. Set the args.css parameter to the path of your custom CSS file.
3. Set the args.copycss parameter to yes to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
4. Click OK to save the changes to the transformation scenario.
5. Run the transformation scenario.

**Result:** Your custom CSS will be applied as a final layer on top of any existing CSS rules and the output will reflect the changes you made.

**Adding Syntax Highlights for Codeblocks in the Output**

Syntax Highlighting makes it easier to read the semantics of the structured content by displaying each type of code (language) in different colors and fonts. The application provides the ability to add syntax highlights in codeblocks for DITA to PDF or HTML-based output through the use of the @outputclass attribute and a variety of predefined values are available.

To provide syntax highlighting in the codeblocks that appear in the output, add the @outputclass attribute on the <codeblock> element and set its value to one of the predefined language values. The Content Completion Assistant offers a list of the possible values when adding the @outputclass attribute in Text mode but there are also two very simple ways to set the value in Author mode:
Select the `<codeblock>` element in the editor and in the Attributes view, click on the Value cell for the `@outputclass` attribute and select one of the predefined values (for example, `language-xml`).

Select the `<codeblock>` element in the editor and use the Alt + Enter keyboard shortcut to open the in-place attributes editor window. Then select one of the predefined values from the Value drop-down menu.

The predefined values that can be selected are:

- language-bourne
- language-c
- language-cpp
- language-csharp
- language-css
- language-ini
- language-java
- language-javascript
- language-json
- language-lua
- language-perl
- language-php
- language-python
- language-ruby
- language-sql
- language-xml
- language-xquery

⚠️ **Attention:**

It is recommended that you do not add inline elements in the codeblocks when using this `@outputclass` attribute, as it may lead to improper highlighting.

**Example:**

This codeblock:

```xml
<codeblock outputclass="language-xml">
  <p>This code is an example of how to use a coderef.</p>
  <codeblock><coderef href="MyExternalCode.xsl"/></codeblock>
</codeblock>
```

would look like this in the output:

```xml
<p>This code is an example of how to use a coderef.</p>
<codeblock><coderef href="MyExternalCode.xsl"/></codeblock>
```
How to Show or Hide Navigation Links in Topic Pages

The topic pages (on page 1460) in WebHelp Responsive output can contain navigation links (Previous / Next arrows) that can be used to navigate to the previous or next topic.

How to Control Which Topic Pages Include Navigation Links

The navigation links are controlled by the @collection-type attribute. For example, if you set collection-type="sequence" on a parent topic reference in your DITA map, navigation links will be generated in the output for all of its child topics (from children to parent, and from child to previous sibling and next sibling).

```xml
<map id="example_map" title="Example Map">
  <topicref href="../topics/ParentTopic.dita" collection-type="sequence">
    <topicref href="../topics/Childtopic.dita"/>
  </topicref>
</map>
```

How to Generate Navigation Links for All Topics (Ignoring the Collection Type Attribute)

You can use the webhelp.default.collection.type.sequence parameter in the transformation and set its value to yes to generate navigation links for all topics, regardless of whether or not the collection-type attribute is present.

How to Hide All Navigation Links

To hide all navigation links, use the webhelp.show.navigation.links parameter in the transformation and set its value to no.

How to Change the Main Page Layout

This section contains topics that explain how to customize the layout of the main page in the WebHelp Responsive output.

How to Customize the Menu

By default, the menu component is displayed in all WebHelp Responsive pages. However, you might want to hide it completely, or only display some of its menu entries.

How to Hide Some of the Menu Entries

There are two methods for doing this. One of them involves editing the DITA map (on page 2966) and marking the topics that do not need to be included in the menu, and another one that uses a small CSS customization.

Editing the DITA Map

To edit the metadata in the DITA map to control which topics will not be displayed in the menu, follow these steps:
1. Open the DITA map in the Text editing mode of Oxygen XML Editor.
2. Add the following metadata information in the `topicref` element (or any of its specializations) for each topic you do not want to be displayed in the menu:

   ```xml
   <topicmeta>
     <data name="wh-menu">
       <data name="hide" value="yes"/>
     </data>
   </topicmeta>
   ```

Customizing the CSS
To customize the CSS to control which topics will not be displayed in the menu, follow these steps:

1. Make sure you set an ID on the topic that you do not want to include in the menu.
2. Create a new CSS file that contains a rule that hides the menu entry generated for the topic (identified by the topic ID `growing-flowers` in the following example). The CSS file should have content that is similar to this:

   ```css
   .wh_top_menu *[data-id='growing-flowers'] { display:none; }
   ```
3. Reference the CSS file in a WebHelp Responsive transformation using an Oxygen Publishing Template (on page 1543) or the `args.css` parameter (on page 1544).

How to Hide the Entire Menu
If you do not want to include a main menu in the pages of the WebHelp Responsive output, you can instruct the transformation scenario to skip the menu generation completely.

Using a Publishing Template
To hide the menu using an Oxygen Publishing Template (on page 1497), follow this procedure:

1. If you have not already created a Publishing Template, see How to Create a Publishing Template (on page 1679).
2. Open the template descriptor file (on page 1500) associated with your publishing template and add the `webhelp.show.top.menu` parameter in the `parameters` section with its value set to `no`.

   ```xml
   <publishing-template>
     ...
     <webhelp>
       ...
       <parameters>
         <parameter name="webhelp.show.top.menu" value="no"/>
       </parameters>
     </webhelp>
   </publishing-template>
   ```
3. Open the DITA Map WebHelp Responsive transformation scenario.
4. Click the Choose Custom Publishing Template link and select your template.
5. Click OK to save the changes to the transformation scenario.
6. Run the transformation scenario.

**Using a Transformation Scenario in Oxygen XML Editor/Author**

To hide the menu using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Edit the DITA Map WebHelp Responsive transformation scenario and choose a template.
2. Open the Parameters tab and set the webhelp.show.top.menu parameter to no.
3. Click OK to save the changes to the transformation scenario.
4. Run the transformation scenario.

**How to Add a Welcome Message in the WebHelp Responsive Main Page**

The main page of the WebHelp Responsive output contains a set of empty placeholders (on page 1507) that can be used to display customized text fragments. These placeholders are available to you through WebHelp Responsive transformation scenario parameters. For example, the placeholder identified through the webhelp.fragment.welcome parameter displays text content above the search box in the main page.

**Using a Publishing Template**

To add a customized welcome message in the main page of the WebHelp Responsive output using an Oxygen Publishing Template (on page 1497), follow this procedure:

1. If you have not already created a Publishing Template, see How to Create a Publishing Template (on page 1679).
2. Open the template descriptor file (on page 1500) associated with your publishing template and add the webhelp.fragment.welcome parameter in the parameters section with its value set to one of the following:
   - A small well-formed XHTML fragment (such as: `<i>Welcome to the User Guide</i>`).
   - A path to a file that contains well-formed XHTML content.

```xml
<publishing-template>
  ...
  <webhelp>
    ...
    <parameters>
      <parameter name="webhelp.fragment.welcome" value="c:\myMessage.xhtml"/>
    </parameters>
  </webhelp>
</publishing-template>
```

3. Open the DITA Map WebHelp Responsive transformation scenario.
4. Click the Choose Custom Publishing Template link and select your template.
5. Click OK to save the changes to the transformation scenario.
6. Run the transformation scenario.
**Result:** In the WebHelp output, your custom message will be displayed above the search box in the main page.

### Using a Transformation Scenario in Oxygen XML Editor/Author

**Important:** Running WebHelp transformations from a script outside of **Oxygen XML Editor/Author** requires an additional license and some additional setup:

- You must have a valid license for the **Oxygen XML WebHelp Plugin** (https://www.oxygenxml.com/buy_webhelp.html).
- The **Oxygen XML WebHelp Plugin** must be installed and integrated.

To add a customized welcome message in the main page of the WebHelp Responsive output using a transformation scenario from within **Oxygen XML Editor/Author**, follow this procedure:

1. Edit the **DITA Map WebHelp Responsive** transformation scenario and choose a *template*.
2. Open the **Parameters** tab and set the `webhelp.fragment.welcome` parameter with its value set to one of the following:
   - A small well-formed XHTML fragment (such as: `<i>Welcome to the User Guide</i>`).
   - A path to a file that contains well-formed XHTML content.
3. Click **OK** to save the changes to the transformation scenario.
4. Run the transformation scenario.

**Result:** In the WebHelp output, your custom message will be displayed above the search box in the main page.

### How to Create a Custom Footer

The main page of the WebHelp Responsive output contains a set of empty placeholders (on page 1507) that can be used to display customized text fragments. These placeholders are available to you through WebHelp Responsive transformation scenario parameters. For example, the placeholder identified through the `webhelp.fragment.footer` parameter displays the custom content at the bottom of the page.

### Using a Publishing Template

To create a custom footer in the WebHelp Responsive output using an **Oxygen Publishing Template** (on page 1497), follow this procedure:

1. If you have not already created a Publishing Template, see **How to Create a Publishing Template** (on page 1679).
2. Open the *template descriptor file* (on page 1500) associated with your publishing template and add the `webhelp.fragment.footer` parameter in the **parameters** section with its value set to one of the following:
   - A small well-formed XHTML fragment.
   - A path to a file that contains well-formed XHTML content.
Result: In the WebHelp output, your custom footer will be displayed at the bottom of the page.

Using a Transformation Scenario in Oxygen XML Editor/Author

Important:
Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated.

To create a custom footer in the WebHelp Responsive output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Edit the DITA Map WebHelp Responsive transformation scenario and choose a template.
2. Open the Parameters tab and set the webhelp.fragment.footer parameter with its value set to one of the following:
   - A small well-formed XHTML fragment.
   - A path to a file that contains well-formed XHTML content.
3. Click OK to save the changes to the transformation scenario.
4. Run the transformation scenario.

Result: In the WebHelp output, your custom footer will be displayed at the bottom of the page.
How to Configure the Tiles on the WebHelp Responsive Main Page

The tiles version of the main page of the WebHelp Responsive output displays a tile for each topic found on the first level of the DITA map (on page 2966). However, you might want to customize the way they look or even to hide some of them.

Depending on your particular setup, you can choose to customize the tiles either by setting metadata information in the DITA map or by customizing the CSS that is associated with the DITA map.

How to Hide Some of the Tiles

If your documentation is very large or there is a large number of topics on the first level, you might want to hide some of the tiles. Also, this might be useful if you only want to display the topics in the first page that are most relevant to your intended audience.

There are two methods for doing this. One of them involves editing the DITA map and marking the topics that do not need to be displayed as tiles, and another one that uses a small CSS customization level to hide some tiles identified by the ID of the topic.

Editing the DITA Map

To edit the metadata in the DITA map to control which topics on the first level of the DITA map will not be displayed as a tile, follow these steps:

1. Open the DITA map in the Text editing mode of Oxygen XML Editor.
2. Add the following metadata information in the <topicref> element (or any of its specializations) for each first-level topic that you do not want to be displayed as a tile:

   ```xml
   <topicmeta>
   <data name="wh-tile">
     <data name="hide" value="yes"/>
   </data>
   </topicmeta>
   ```

Customizing the CSS

To customize the CSS to control which topics on the first level of the DITA map will not be displayed as a tile, follow these steps:

1. Make sure you set an ID on the topic you want to hide.
2. Create a new CSS file that contains a rule that hides the tile generated for the topic (identified in the following example by the topic ID growing-flowers). The CSS file should have content that is similar to this:

   ```css
   .wh_tile [data-id='growing-flowers'] {
   display: none;
   }
   ```
3. Reference the CSS file in a WebHelp Responsive transformation using an Oxygen Publishing Template (on page 1543) or the args.css parameter (on page 1544).
How to Add an Image to the Tiles

There are two methods that you can use to add an image to a tile. One of them involves editing the DITA map, and the other uses a CSS customization.

Editing the DITA Map

To edit the metadata in the DITA map to set an image to be displayed in a tile, follow these steps:

1. Open the DITA map in the Text editing mode of Oxygen XML Editor.
2. Add the following metadata information in the `<topicref>` element (or any of its specializations) for each first-level topic that will have an image displayed in the corresponding tile:

   ```xml
   <topicmeta>
   <data name="wh-tile">
     <data name="image" href="img/tile-image.png" format="png"/>
     <data name="attr-width" value="64"/>
     <data name="attr-height" value="64"/>
   </data>
   </topicmeta>
   ```

   **Note:**
   The `@attr-width` and `@attr-height` attributes can be used to control the size of the image, but they are optional.

Customizing the CSS

To customize the CSS to set an image to be displayed in a tile, follow these steps:

1. Make sure you set an ID on the topic that you want the tile to include an image.
2. Create a new CSS file that contains a rule that associates an image with a specific tile. The CSS file should have content that is similar to this:

   ```css
   .wh_tile[data-id='growing-flowers']> div { 
     background-image: url('resources/flower.png');
   }
   ```

3. Reference the CSS file in a WebHelp Responsive transformation using an Oxygen Publishing Template (on page 1543) or the `args.css` parameter (on page 1544).

Adding Graphics and Media Resources

This section contains topics that explain how to add media resources to the published output or the output directory.
**How to Add a Logo Image in the Title Area**

You can customize WebHelp Responsive output to include a logo in the title area. It will be displayed before the publication title. You can also specify a URL that can be used to send users to a specific website when they click the logo image.

This customization can be done using an Oxygen Publishing Template or using a transformation scenario from within Oxygen XML Editor/Author.

**Using a Publishing Template**

To add a logo in the title area of your WebHelp output using an Oxygen Publishing Template, follow this procedure:

1. If you have not already created a Publishing Template, see How to Create a Publishing Template.
2. Open the template descriptor file associated with your publishing template and add the `webhelp.logo.image` parameter in the `parameters` section with its value set to the path of your logo.
3. If you also want to add a link to your website when you click the logo image, set its URL in the `webhelp.logo.image.target.url` parameter.

```
<publishing-template>
  ...
  <webhelp>
    ...
    <parameters>
      <parameter name="webhelp.logo.image" value="c:\myLogo.jpg"/>
      <parameter name="webhelp.logo.image.target.url" value="http://sample.com"/>
    </parameters>
  </webhelp>
</publishing-template>
```
4. Open the DITA Map WebHelp Responsive transformation scenario.
5. Click the Choose Custom Publishing Template link and select your template.
6. Click OK to save the changes to the transformation scenario.
7. Run the transformation scenario.

**Using a Transformation Scenario in Oxygen XML Editor/Author**

To add a logo in the title area of your WebHelp output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Edit the DITA Map WebHelp Responsive transformation scenario and choose a template.
2. Open the Parameters tab and set the `webhelp.logo.image` parameter to the path of your logo.
3. If you also want to add a link to your website when you click the logo image, set its URL in the `webhelp.logo.image.target.url` parameter.
4. Click OK to save the changes to the transformation scenario.
5. Run the transformation scenario.
How to Add a Favicon in WebHelp Systems

You can add a custom favicon to your WebHelp output by simply using a parameter in the transformation scenario to point to your favicon image.

This customization can be done using an Oxygen Publishing Template or using a transformation scenario from within Oxygen XML Editor/Author.

Using a Publishing Template
To add a favicon to your WebHelp output using an Oxygen Publishing Template (on page 1497), follow this procedure:

1. If you have not already created a Publishing Template, see Working with Publishing Templates (on page 1535).
2. Open the template descriptor file (on page 1500) associated with your publishing template and add the <favicon> element in the resources section. The path to the image is relative to the template root folder.

   ```xml
   <publishing-template>
       ...
       <webhelp>
           ...
           <resources>
               ...
               <favicon file="images/favicon.png"/>
       </webhelp>
   </publishing-template>
   ```
3. Open the DITA Map WebHelp Responsive transformation scenario.
4. Click the Choose Custom Publishing Template link and select your template.
5. Click OK to save the changes to the transformation scenario.
6. Run the transformation scenario.

Result: Browsers that provide favicon support display the favicon (typically in the browser’s address bar, in the list of bookmarks, and in the history).

Using a Transformation Scenario in Oxygen XML Editor/Author
To add a favicon to your WebHelp output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Edit the DITA Map WebHelp Responsive transformation scenario and choose a template.
2. Open the Parameters tab and set the webhelp.favicon parameter to the path of your image.
3. Click OK to save the changes to the transformation scenario.
4. Run the transformation scenario.

How to Add Video and Audio Objects in DITA WebHelp Output

You can insert references to video and audio media resources (such as videos, audio clips, or embedded HTML frames) in your DITA topics and then publish them to WebHelp output. The media objects can be played directly in all HTML5-based outputs, including WebHelp systems.
To add media objects in the WebHelp output generated from DITA documents, follow the procedures below.

**Adding Videos to DITA WebHelp Output**

1. Edit the DITA topic and insert a reference to the video through one of the following methods:
   - Use the [Insert Media Object toolbar action (on page 2740)](##).
   - Drag (or copy) the video file from your system explorer or the [Project view (on page 368)](##) and drop (or paste) it into your document.
   - Manually add an `<object>` element, as in one of the following examples:
     ```xml
     <object outputclass="video" type="video/mp4" data="MyVideo.mp4"/>
     ```
     or, instead of the `@data` attribute, you can specify the video using a parameter like this:
     ```xml
     <object outputclass="video">
       <param name="src" value="videos/MyVideo.mp4"/>
     </object>
     ```

2. Apply a [DITA to WebHelp transformation](##) to obtain the output.

**Result:** The transformation converts the `<object>` element to an HTML5 `<video>` element.

```xml
<video controls="controls"> <source type="video/mp4" src="MyVideo.mp4"></source> </video>
```

**Adding Audio Clips to DITA WebHelp Output**

1. Edit the DITA topic and insert a reference to the audio clip through one of the following methods:
   - Use the [Insert Media Object toolbar action (on page 2740)](##).
   - Drag (or copy) the audio file from your system explorer or the [Project view (on page 368)](##) and drop (or paste) it into your document.
   - Manually add an `<object>` element, as in one of the following examples:
     ```xml
     <object outputclass="audio" type="audio/mpeg" data="MyClip.mp3"/>
     ```
     or, instead of the `@data` attribute, you can specify the video using a parameter like this:
     ```xml
     <object outputclass="audio">
       <param name="src" value="audio/MyClip.mp3"/>
     </object>
     ```

2. Apply a [DITA to WebHelp transformation](##) to obtain the output.

**Result:** The transformation converts the `<object>` element to an HTML5 `<audio>` element.

```xml
<audio controls="controls"> <source type="audio/mpeg" src="MyClip.mp3"></source> </audio>
```
Adding Embedded HTML Frames (such as YouTube videos) to DITA WebHelp Output

1. Edit the DITA topic and insert a reference to the embedded object by using the Insert Media Object toolbar action (on page 2740) or by manually adding an `<object>` element, as in one of the following examples:
   ```html
   <object outputclass="iframe" data="https://www.youtube.com/embed/m_vv2s5Trn4"/>
   ```
   or, instead of the `data` attribute, you can specify the object using a parameter like this:
   ```html
   <object outputclass="iframe">
     <param name="src" value="http://www.youtube.com/embed/m_vv2s5Trn4"/>
   </object>
   ```

2. If you want the video to be allowed to play in full screen mode once the document is converted to XHTML output, also add an `allowfullscreen` parameter and set its value to `true`:
   ```html
   <object outputclass="iframe" data="https://www.youtube.com/embed/m_vv2s5Trn4"/>
   <param name="allowfullscreen" value="true"/>
   </object>
   ```

Tip:
If you copy the embed code from the source and paste it into the Insert Media dialog box (see the specific instructions: here (on page 2743)), the `allowfullscreen` parameter will automatically be added and all you have to do is set the value to `true`.

3. Apply a DITA to WebHelp transformation to obtain the output.

Result: The transformation converts the `<object>` element to an HTML5 `<iframe>` element.
   ```html
   <iframe controls="controls" src="https://www.youtube.com/embed/m_vv2s5Trn4"/>
   </iframe>
   ```

For more information, see the following video demonstration:

https://www.youtube.com/embed/lIX11gS4WaU

Adding Video, Audio, and Embedded HTML Resources in DITA Topics (on page 2740)

How to Add MathML Equations in WebHelp Output

Currently, only Firefox can render MathML equations embedded in the HTML code. MathJax is a solution to properly view MathML equations embedded in HTML content in a variety of browsers.

If you have DocBook content that has embedded MathML equations and you want to properly view the equations in published HTML output types (such as WebHelp), you need to add a reference to the MathJax script in the head element of all HTML files that have the equation embedded.

For example:
Searching the Output

This section contains topics that explain how to use some of the search features in WebHelp Responsive output.

How to Change Element Scoring in Search Results

The WebHelp Search feature is enhanced with a rating mechanism that computes scores for every page that matches the search criteria. HTML tag elements are assigned a scoring value and these values are evaluated for the search results. The WebHelp directory includes a properties file that defines the scoring values for tag elements and this file can be edited to customize the values according to your needs.

To edit the scoring values of HTML tag element for enhancing WebHelp search results, follow these steps:

1. Edit the scoring properties file for DITA. The properties file includes instructions and examples to help you with your customization. The file is located in: \DITA-OT-DIR\plugins\com.oxygenxml.webhelp.responsive\indexer\scoring.properties.

The values that can be edited in the scoring.properties file:

```plaintext
h1 = 10
h2 = 9
h3 = 8
h4 = 7
h5 = 6
h6 = 5
b = 5
strong = 5
em = 3
i = 3
u = 3
div.toc = -10
title = 20
div.ignore = ignored
meta_keywords = 20
meta_indexterms = 20
meta_description = 25
shortdesc = 25
```
2. Save your changes to the file.
3. Re-run your WebHelp transformation.

How to Exclude Certain DITA Topics from Search Results

There are several ways to exclude certain DITA resources from your WebHelp system's search results. This is useful if you have topics in your DITA map structure that you do not want to be included in search results for your WebHelp system. The first method involves setting a parameter in the WebHelp transformation scenario and the second involves setting an attribute for each DITA topic reference that you want to exclude.

Transformation Parameter Method

To exclude DITA topics from WebHelp search results using a transformation parameter, follow these steps:

1. Create a simple text file that will contain your excluded file patterns. Each pattern must be on a new line. The patterns are considered to be relative to the output directory and they accept wildcards such as '*' (matches zero or more characters) or '?' (matches one character). For more information about the patterns, see https://ant.apache.org/manual/dirtasks.html#patterns.

   Example: Suppose that in your project, you want to exclude all files located in the resources directory and all files located in the topics directory that have a .bak file extension. You could create a simple text file (for example, named exclude.properties), and add the following lines:

   
   resources/*
   topics/*.bak

2. Set the webhelp.search.custom.excludes.file parameter to specify the path to the file that contains the excluded file patterns (for example, exclude.properties in step 1). The parameter can be specified in the parameters section of the template descriptor file associated with your publishing template or in the Parameters tab of the transformation scenario dialog box in Oxygen XML Editor/Author.

3. Run the transformation.

Search Attribute Method

The WebHelp Search engine does not index DITA topics that have the @search attribute set to no.

To exclude DITA topics from WebHelp search results using this attribute, follow these steps:

1. Edit the DITA map and for any <topicref> that you want to exclude from search results, set the @search attribute to no. For example:

   <topicref href="../topics/internal-topic1.dita" search="no"/>

2. Save your changes to the DITA map.

3. Run your WebHelp system transformation.
How to Optimize Search Results

A DITA Map WebHelp transformation scenario can be configured to produce a sitemap.xml file that is used by search engines to aid crawling and indexing mechanisms. A sitemap lists all pages of a WebHelp system and allows web admins to provide additional information about each page, such as the date it was last updated, change frequency, and importance of each page in relation to other pages in your WebHelp deployment.

The structure of the sitemap.xml file looks like this:

```xml
<urlset xmlns="http://www.sitemaps.org/schemas/sitemap/0.9">
  <url>
    <loc>http://www.example.com/topics/introduction.html</loc>
    <lastmod>2014-10-24</lastmod>
    <changefreq>weekly</changefreq>
    <priority>0.5</priority>
  </url>
  <url>
    <loc>http://www.example.com/topics/care.html#care</loc>
    <lastmod>2014-10-24</lastmod>
    <changefreq>weekly</changefreq>
    <priority>0.5</priority>
  </url>
  ...
</urlset>
```

Each page has a <url> element structure containing additional information, such as:

- **loc** - The URL of the page. This URL must begin with the protocol (such as http), if required by your web server. It is constructed from the value of the webhelp.sitemap.base.url parameter from the transformation scenario and the relative path to the page (collected from the href attribute of a topicref element in the DITA map).

  **Note:**
  The value must have fewer than 2,048 characters.

- **lastmod** (optional) - The date when the page was last modified. The date format is YYYY-MM-DD.

- **changefreq** (optional) - Indicates how frequently the page is likely to change. This value provides general information to assist search engines, but may not correlate exactly to how often they crawl the page. Valid values are: always, hourly, daily, weekly, monthly, yearly, and never. The first time the sitemap.xml file is generated, the value is set based upon the value of the webhelp.sitemap.change.frequency parameter in the DITA WebHelp transformation scenario. You can change the value in each url element by editing the sitemap.xml file.
Note:
The value always should be used to describe documents that change each time they are accessed. The value never should be used to describe archived URLs.

• priority (optional) - The priority of this page relative to other pages on your site. Valid values range from 0.0 to 1.0. This value does not affect how your pages are compared to pages on other sites. It only lets the search engines know which pages you deem most important for the crawlers. The first time the sitemap.xml file is generated, the value is set based upon the value of the webhelp.sitemap.priority parameter in the DITA WebHelp transformation scenario. You can change the value in each url element by editing the sitemap.xml file.

Creating and Editing the sitemap.xml File
Follow these steps to produce a sitemap.xml file for your WebHelp system, which can then be edited to fine-tune search engine optimization:

1. Edit the transformation scenario you currently use for obtaining your WebHelp output. This opens the Edit DITA Scenario dialog box.
2. Open the Parameters tab and set a value for the following parameters:
   • webhelp.sitemap.base.url - The URL of the location where your WebHelp system is deployed.
     Note: This parameter is required for Oxygen XML Editor to generate the sitemap.xml file.
   • webhelp.sitemap.change.frequency - How frequently the WebHelp pages are likely to change (accepted values are: always, hourly, daily, weekly, monthly, yearly, and never).
   • webhelp.sitemap.priority - The priority of each page (value ranging from 0.0 to 1.0).
3. Run the transformation scenario.
4. Look for the sitemap.xml file in the transformation's output folder. Edit the file to fine-tune the parameters of each page, according to your needs.

How to Index Japanese Content
To optimize the indexing of Japanese content in WebHelp pages, the Lucene Kuromoji Japanese analyzer can be used. This analyzer is included in the Oxygen XML Editor/Author installation kit.

Restriction:
The Kuromoji analyzer does not work if your WebHelp output is accessed locally. In this scenario, a warning message will be displayed informing you that the Kuromoji analyzer is disabled. It is possible to hide this warning message by using a transformation parameter named webhelp.enable.search.kuromoji. By default, its value is yes, which means the Kuromoji analyzer is enabled by default. To hide the warning message, set the value of the webhelp.enable.search.kuromoji parameter to no using either of the methods listed below. When that
parameter is set to no, the Kuromoji analyzer is disabled even if you deploy your WebHelp output on a web server.

**Using a Publishing Template**

To add a logo in the title area of your WebHelp output using an *Oxygen Publishing Template (on page 1497)*, follow this procedure:

1. If you have not already created a Publishing Template, see *How to Create a Publishing Template (on page 1679)*.
2. Open the template descriptor file (on page 1500) associated with your publishing template and add the `default.language` parameter in the `parameters` section with its value set to `ja-jp`.

   ```xml
   <publishing-template>
     ...
     <webhelp>
       ...
       <parameters>
         <parameter name="default.language" value="ja-jp"/>
       </parameters>
     </webhelp>
   </publishing-template>
   ```

3. Open the *DITA Map WebHelp Responsive* transformation scenario.
4. Click the *Choose Custom Publishing Template* link and select your template.
5. Click OK to save the changes to the transformation scenario.
6. Run the transformation scenario.

**Using a Transformation Scenario in Oxygen XML Editor/Author**

To activate the Japanese indexing in your WebHelp output using a transformation scenario from within *Oxygen XML Editor/Author*, follow this procedure:

1. Edit a *DITA to WebHelp* transformation scenario and in the *Parameters* tab, set the value of the `default.language` parameter to `ja-jp`.

   **Note:**

   Alternatively, you could set the `@xml:lang` attribute on the root of the *DITA map (on page 2966)* and the referenced topics to `ja-jp`. Another alternative for DITA output is to use the `webhelp.search.japanese.dictionary` parameter to specify a path to a Japanese dictionary that will be used by the Kuromoji morphological engine (note that the encoding for the dictionary must be UTF8).

2. Run the WebHelp transformation scenario to generate the output.

**Localization**

This section contains topics that explain how to use the localization support in WebHelp Responsive output.
How to Localize the Interface of WebHelp Responsive Output

Oxygen XML Editor comes with support for the following built-in languages: English, French, German, Japanese, and Chinese. It is possible to edit existing localization strings or add a new language.

Static labels used in the WebHelp output are stored in translation files that have the `strings-lang1-lang2.xml` name format, where `lang1` and `lang2` are ISO language codes. For example, the US English labels are kept in the `strings-en-us.xml` file.

These translation files are collected from two locations:

- `DITA-OT-DIR/plugins/org.dita.base/xsl/common` folder - DITA-OT's default translations (generated text for `<note>`, `<fig>`, and `<table>` elements).
- `DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/oxygen-webhelp/resources/localization` folder - These translations are contributed by the WebHelp plugin and extend the default ones provided by DITA-OT. The labels defined in this folder take precedence over the DITA-OT defaults.

There are two major reasons you may want to use modify the translation files: to modify the existing strings or to translate to a new language.

Related Information:
- How to Index Japanese Content (on page 1569)
- Customizing Generated Text

Modifying the Existing Strings

To modify the generated text for WebHelp transformations, you need to create a DITA-OT extension plugin that uses the `dita.xsl.strings` extension point. The following procedure is for changing English labels, but you can adapt it for any language:

1. Create a `com.oxygenxml.webhelp.localization` plugin directory inside the `DITA-OT-DIR/plugins/` location.
2. Create a `plugin.xml` file inside that `com.oxygenxml.webhelp.localization` directory with the following content:

```
<plugin id="com.oxygenxml.webhelp.localization">
  <require plugin="com.oxygenxml.webhelp.responsive"/>
  <feature extension="dita.xsl.strings" file="webhelp-extension-strings.xml"/>
</plugin>
```
3. Create a `webhelp-extension-strings.xml` file with the following content:

```
<langlist>
  <lang xml:lang="en" filename="strings-en-us.xml"/>
```

4. Copy the strings you want to change from the translation files (on page 1570) to the strings-en-us.xml file. Make sure you leave the name attribute unchanged because this is the key used to look up the string. A sample content might be:

```
<lang xml:lang="en-US">
    <str name="Figure">Fig</str>
    <str name="Draft comment">ADDRESS THIS DRAFT COMMENT</str>
</lang>
```

5. Use the Run DITA-OT Integrator transformation scenario (on page 1352) found in the DITA Map section in the Configure Transformation Scenario(s) dialog box (on page 1443).

Adding a New Language

To add a new language for WebHelp transformations, you need to create a DITA-OT extension plugin that uses the dita.xsl.strings extension point. The following sample procedure is for adding translation files for the Polish language, but you can adapt it for any language:

1. Create a com.oxygenxml.webhelp.localization plugin directory inside the DITA-OT-DIR/plugins/ location.
2. Create a plugin.xml file inside that com.oxygenxml.webhelp.localization directory with the following content:

```
<plugin id="com.oxygenxml.webhelp.localization">
    <require plugin="com.oxygenxml.webhelp.responsive"/>
    <feature extension="dita.xsl.strings" file="webhelp-extension-strings.xml"/>
</plugin>
```

3. Create a webhelp-extension-strings.xml file with the following content:

```
<langlist>
    <lang xml:lang="pl" filename="strings-pl-pl.xml"/>
    <lang xml:lang="pl-PL" filename="strings-pl-pl.xml"/>
</langlist>
```

5. In the strings-pl-pl.xml file, change the @xml:lang attribute on the root element that conforms with the new language.

```
<strings xml:lang="pl-PL">
    ...
</strings>
```

6. Translate the content of each <str> element (make sure to leave the name attribute unchanged).
7. Copy the common DITA-OT strings defined in the DITA-OT-DIR/xsl/common/strings-en-us.xml file. It defines a set generated text available for HTML-based transformations (such as <note>, <fig>, and <table> elements). Translate the content of each <str> element.

8. Use the Run DITA-OT Integrator transformation scenario (on page 1352) found in the DITA Map section in the Configure Transformation Scenario(s) dialog box (on page 1443).

How to Activate Support for Right-to-Left (RTL) Languages

To activate support for RTL (right-to-left) languages in WebHelp output, edit the DITA map (on page 2966) and set the @xml:lang attribute on its root element (<map>). The corresponding attribute value can be set for following RTL languages:

- ar-eg - Arabic
- he-il - Hebrew
- ur-pk - Urdu

Integrating Social Media and Google Tools in the WebHelp Output

This section contains topics that explain how to integrate some of the most popular social media sites in WebHelp output.

How to Add a Facebook Like Button in WebHelp Responsive Output

It is possible to integrate Facebook™ into your WebHelp Responsive output and you can specify where you want the widget to appear in your WebHelp page.
Using a Publishing Template

To add a Facebook™ Like widget to your WebHelp output using an Oxygen Publishing Template (on page 1497), follow this procedure:

1. Go to the Facebook Developers website.
2. Fill in the displayed form, then click the Get Code button.
3. Copy the two code snippets and paste them into a `<div>` element inside an XML file called `facebook-widget.xml`. Make sure you follow these rules:
   - The file must be well-formed.
   - The code for each `<script>` element must be included in an XML comment.
   - The start and end tags for the XML comment must be on a separate line. The content of the XML file should look like this:

   ```xml
   <div id="facebook">
     <div id="fb-root"/>
     <script>
       <!--
         (function(d, s, id) {
           var js, fjs = d.getElementsByTagName(s)[0];
           if (d.getElementById(id)) return;
           js = d.createElement(s); js.id = id;
           js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
           fjs.parentNode.insertBefore(js, fjs);
         }(document, 'script', 'facebook-jssdk'));
       -->
     </script>
     <div class="fb-like" data-layout="standard" data-action="like"
         data-show-faces="true" data-share="true"/>
   </div>
   
   <div id="facebook">
     <div id="fb-root"/>
     <script>
       <!--
         (function(d, s, id) {
           var js, fjs = d.getElementsByTagName(s)[0];
           if (d.getElementById(id)) return;
           js = d.createElement(s); js.id = id;
           js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
           fjs.parentNode.insertBefore(js, fjs);
         }(document, 'script', 'facebook-jssdk'));
       -->
     </script>
     <div class="fb-like" data-layout="standard" data-action="like"
         data-show-faces="true" data-share="true"/>
   </div>
   
   4. Open the template descriptor file (on page 1500) associated with your publishing template.
5. Use one of the parameters that begin with `webhelp.fragment` (on page 1507) in the `html-fragments` section of the descriptor file. Set the value of that parameter to reference the `facebook-widget.xml` file that you created earlier.

   ```xml
   <publishing-template>
     
     <webhelp>
       
       <html-fragments>
         <fragment
           file="HTML-fragments/facebook-widget.xml"
           placeholder="webhelp.fragment.after.toc_or_tiles"/>
         </html-fragments>
       </webhelp>
   </publishing-template>
   ```
6. Open the DITA Map WebHelp Responsive transformation scenario.
7. Click the Choose Custom Publishing Template link and select your template.
8. Click OK to save the changes to the transformation scenario.
9. Run the transformation scenario.

Using a Transformation Scenario in Oxygen XML Editor/Author
To add a Facebook™ Like widget to your WebHelp output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Go to the Facebook Developers website.
2. Fill in the displayed form, then click the Get Code button.
3. Copy the two code snippets and paste them into a <div> element inside an XML file called facebook-widget.xml. Make sure you follow these rules:
   • The file must be well-formed.
   • The code for each <script> element must be included in an XML comment.
   • The start and end tags for the XML comment must be on a separate line. The content of the XML file should look like this:

   ```xml
   <div id="facebook">
     <div id="fb-root"/>
     <script>
       <!--(function(d, s, id) {
         var js, fjs = d.getElementsByTagName(s)[0];
         if (d.getElementById(id)) return;
         js = d.createElement(s); js.id = id;
         js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
         fjs.parentNode.insertBefore(js, fjs);
       }(document, 'script', 'facebook-jssdk'));
     <!--
     <div class="fb-like" data-layout="standard" data-action="like"
       data-show-faces="true" data-share="true"/>
   </div>
   ```

4. Edit the DITA Map WebHelp Responsive transformation scenario and choose a template.
5. Switch to the Parameters tab. Depending on where you want to display the button, edit one of the parameters that begin with webhelp.fragment (on page 1507). Set that parameter to reference the facebook-widget.xml file that you created earlier.
6. Click Ok and run the transformation scenario.
How to Add Tweet Button in WebHelp Responsive Output

It is possible to integrate Twitter into your WebHelp Responsive output and you can specify where you want the widget to appear in your WebHelp page.

Using a Publishing Template

To add a Twitter™ Tweet widget to your WebHelp Responsive output using an Oxygen Publishing Template (on page 1497), follow this procedure:

1. Go to the Tweet button generator page.
2. Fill in the displayed form. The Preview and code area displays the code that you will need.
3. Copy the code snippet displayed in the Preview and code area and paste it into a `<div>` element inside an XML file called `tweet-button.xml`. Make sure you follow these rules:
   - The file must be well-formed.
   - The code for each `<script>` element must be included in an XML comment.
   - The start and end tags for the XML comment must be on a separate line.

The content of the XML file should look like this:

```xml
<div id="twitter">
  <a href="https://twitter.com/share" class="twitter-share-button">Tweet</a>
  <script>
    !function(d, s, id) {
      var js, fjs = d.getElementsByTagName(s)[0], p = /^http:/i.test(d.location) ? 'http': 'https';
      if (!d.getElementById(id)) {
        js = d.createElement(s); js.id = id;
        js.src = p + '//platform.twitter.com/widgets.js';
        fjs.parentNode.insertBefore(js, fjs);
      };
    }(document, 'script', 'twitter-wjs');
  </script>
</div>
```

4. Open the template descriptor file (on page 1500) associated with your publishing template.
5. Use one of the parameters that begin with webhelp.fragment (on page 1507) in the html-fragments section of the descriptor file. Set the value of that parameter to reference the `tweet-button.xml` file that you created earlier.

```xml
<publishing-template>
  ...
</publishing-template>
```
<webhelp>
  ...
  <html-fragments>
    <fragment
      file="HTML-fragments/tweet-button.xml"
      placeholder="webhelp.fragment.after.toc_or_tiles"/>
  </html-fragments>
</webhelp>

6. Open the DITA Map WebHelp Responsive transformation scenario.
7. Click the Choose Custom Publishing Template link and select your template.
8. Click OK to save the changes to the transformation scenario.
9. Run the transformation scenario.

Using a Transformation Scenario in Oxygen XML Editor/Author

To add a Twitter™ Tweet widget to your WebHelp Responsive output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Go to the Tweet button generator page.
2. Fill in the displayed form. The Preview and code area displays the code that you will need.
3. Copy the code snippet displayed in the Preview and code area and paste it into a <div> element inside an XML file called tweet-button.xml. Make sure you follow these rules:
   • The file must be well-formed.
   • The code for each <script> element must be included in an XML comment.
   • The start and end tags for the XML comment must be on a separate line.

The content of the XML file should look like this:

```xml
div id="twitter">
  <a href="https://twitter.com/share" class="twitter-share-button">Tweet</a>
  <script>
<!--
!function (d, s, id) {
    var js, fjs = d.getElementsByTagName(s)[0], p = /^http:/.test(d.location)
    ? 'http': 'https';
    if (!d.getElementById(id)) {
      js = d.createElement(s);
      js.id = id;
      js.src = p + '://platform.twitter.com/widgets.js';
      fjs.parentNode.insertBefore(js, fjs);
    }
  }
}(document,
  'script', 'twitter-wjs');
```
4. Edit the DITA Map WebHelp Responsive transformation scenario and choose a template.

5. Switch to the Parameters tab. Depending on where you want to display the button, edit one of the parameters that begin with webhelp.fragment (on page 1507). Set that parameter to reference the tweet-button.xml file that you created earlier.

6. Click Ok and run the transformation scenario.

How to Integrate Google Analytics in WebHelp Responsive Output

You can use Google Analytics to track and report site data for your WebHelp Responsive output.

Using a Publishing Template

To integrate Google Analytics into your WebHelp Responsive output using an Oxygen Publishing Template (on page 1497), follow this procedure:

1. Create a new Google Analytics account (if you do not already have one) and log on.

2. Choose the Analytics solution that best fits the needs of your website.

3. Follow the on-screen instructions to obtain a Tracking Code that contains your Tracking ID. A Tracking Code looks like this:

```html
<script>
(function(i,s,o,g,r,a,m){i['GoogleAnalyticsObject']=r;i[r]=i[r]||function(){
(i[r].q=i[r].q||[]).push(arguments)},i[r].l=1*new Date();a=s.createElement(o),
m=s.getElementsByTagName(o)[0];a.async=1;a.src=g;m.parentNode.insertBefore(a,m)
}(window,document,'script','//www.google-analytics.com/analytics.js','ga'));

ga('create', 'UA-XXXXXXXX-X', 'auto');
ga('send', 'pageview');
</script>
```

4. Save the Tracking Code (obtained in the previous step) in a new XML file called googleAnalytics.xml. Note that the file should only contain the tracking code.

5. Open the template descriptor file (on page 1500) associated with your publishing template.

6. Use the webhelp.fragment.after.body parameter (on page 1606) in the html-fragments section of the descriptor file. Set the value of that parameter to reference the googleAnalytics.xml file that you created earlier. The content of this file will be copied at the end of all generated output pages, right before the ending <body> element. This ensures that the page is loaded before the Google Analytics servers are contacted, thus reducing page loading time.

```xml
<publishing-template>
...
<webhelp>
...
</webhelp>
</publishing-template>
```
Using a Transformation Scenario in Oxygen XML Editor/Author

To integrate Google Analytics into your WebHelp Responsive output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Create a new Google Analytics account (if you do not already have one) and log on.
2. Choose the Analytics solution that best fits the needs of your website.
3. Follow the on-screen instructions to obtain a Tracking Code that contains your Tracking ID. A Tracking Code looks like this:

   ```html
   <script>
   (function(i,s,o,g,r,a,m){i['GoogleAnalyticsObject']=r;i[r]=i[r]||function(){
   (i[r].q=i[r].q||[]).push(arguments)},i[r].l=1*new Date();a=s.createElement(o),
m=s.getElementsByTagName(o)[0];a.async=1;a.src=g;m.parentNode.insertBefore(a,m)
   })(window,document,'script','//www.google-analytics.com/analytics.js','ga');

   ga('create', 'UA-XXXXXXXX-X', 'auto');
   ga('send', 'pageview');
   </script>
   ```

4. Save the Tracking Code (obtained in the previous step) in a new XML file called googleAnalytics.xml. Note that the file should only contain the tracking code.
5. Edit the DITA Map WebHelp Responsive transformation scenario and choose a template.
6. Switch to the Parameters tab. Edit the webhelp.fragment.after.body parameter (on page 1606) and set it to reference the googleAnalytics.xml file that you created earlier. The content of this file will be copied at the end of all generated output pages, right before the ending </body> element. This ensures that the page is loaded before the Google Analytics servers are contacted, thus reducing page loading time.
7. Click Ok and run the transformation scenario.

How to Integrate Google Search in WebHelp Responsive Output

It is possible to integrate the Google Search Engine into your WebHelp Responsive output and you can specify where you want the results to appear in your WebHelp page.
Using a Publishing Template
To integrate the Google Search Engine into your WebHelp Responsive output using an Oxygen Publishing Template (on page 1497), follow this procedure:

1. Go to the Google Custom Search Engine page using your Google account.
2. Select the Create a custom search engine button.
3. Follow the on-screen instructions to create a search engine component for your site.

Important:
For the Layout, you must select Results only for the Google Search Engine to work with Oxygen XML WebHelp Responsive.

4. At the end of this process you should obtain a code snippet that looks like this:

```html
<script>
(function() {
  var cx = '000888210889775889983:8mn4x_mf-yg';
  var gcse = document.createElement('script');
gcse.type = 'text/javascript';
gcse.async = true;
  var s = document.getElementsByTagName('script')[0];
s.parentNode.insertBefore(gcse, s);
})();
</script>
```

5. Save the script into a well-formed HTML file called googlecse.html.
6. Open the template descriptor file (on page 1500) associated with your publishing template and add the webhelp.google.search.script parameter in the parameters section with its value set to reference the googlecse.html file that you created earlier.
7. You can also use the `webhelp.google.search.results` parameter to choose where to display the search results.
   a. Create an HTML file with the following content: `<div class="gcse-searchresults-only" data-autoSearchOnLoad="true" data-queryParameterName="searchQuery"></div>` (you must use the HTML5 version for the GCSE). For more information about other supported attributes, see Google Custom Search: Supported Attributes.
   b. Set the value of the `webhelp.google.search.results` parameter to the file path of the file you just created. If this parameter is not specified, the following code is used: `<div class="gcse-searchresults-only" data-autoSearchOnLoad="true" data-queryParameterName="searchQuery"></div>`.

8. Open the DITA Map WebHelp Responsive transformation scenario.

9. Click the Choose Custom Publishing Template link and select your template.

10. Click OK to save the changes to the transformation scenario.

11. Run the transformation scenario.

**Using a Transformation Scenario in Oxygen XML Editor/Author**

To integrate the Google Search Engine into your WebHelp Responsive output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Go to the Google Custom Search Engine page using your Google account.

2. Select the Create a custom search engine button.

3. Follow the on-screen instructions to create a search engine for your site.

   **Important:**
   For the **Layout**, you must select **Results only** for the Google Search Engine to work with Oxygen XML WebHelp Responsive.

4. At the end of this process you should obtain a code snippet that looks like this:

   ```html
   <script>
   (function() {
       var cx = 
         '000888210889775888983:8mn4k_mf-yg';
       var gcse = document.createElement('script');
       gcse.type = 'text/javascript';
       gcse.async = true;
       var s = document.getElementsByTagName('script')[0];
       s.parentNode.insertBefore(gcse, s);
   })();
   </script>
   ```

5. Save the script into a well-formed HTML file called `googlecse.html`.
6. Edit the **DITA Map WebHelp Responsive** transformation scenario and choose a template.
7. Switch to the **Parameters** tab and edit the `webhelp.google.search.script` parameter to reference the `googlecse.html` file that you created earlier.
8. You can also use the `webhelp.google.search.results` parameter to choose where to display the search results.
   a. Create an HTML file with the following content:
      ```html
      <div class="gcse-searchresults-only" data-autoSearchOnLoad="true" data-queryParameterName="searchQuery"></div>
      ```
      (you must use the HTML5 version for the GCSE). For more information about other supported attributes, see **Google Custom Search: Supported Attributes**.
   b. Set the value of the `webhelp.google.search.results` parameter to the file path of the file you just created. If this parameter is not specified, the following code is used:
      ```html
      <div class="gcse-searchresults-only" data-autoSearchOnLoad="true" data-queryParameterName="searchQuery"></div>
      ```

9. Click **Ok** and run the transformation scenario.

**XSLT Extensions for WebHelp Responsive**

Since WebHelp Responsive output is primarily obtained by running XSLT transformations over the DITA input files, one customization method would be to override the default XSLT templates that are used by the WebHelp Responsive transformations.

There are two methods available to override the XSLT stylesheets implied by the WebHelp Responsive transformation.

- **Use XSLT-import extension points from an Oxygen Publishing Template (on page 2969).**
  
  **Note:**
  Use this method if you want to affect only the transformations that use this publishing template.

- **Use XSLT-import extension points from a DITA-OT extension plugin.**
  
  **Note:**
  This method will affect all the outputs generated with the WebHelp system.

**Related Information:**

WebHelp Responsive XSLT-Import and XSLT-Parameter Extension Points (on page 1617)

**How to Use XSLT Extension Points from a Publishing Template**

This example demonstrates how to use WebHelp XSLT-import Extension Points from an Oxygen Publishing Template (on page 1672).
Use Case 1: Add Copyright Information Extracted from a DITA Bookmap

Suppose you want to customize the WebHelp Responsive main page by adding information about the legal rights associated with the book in the footer (for example, copyright dates and owner). This information is specified in the bookmap:

```xml
<bookrights>
  <copyrfirst>
    <year>2002</year>
  </copyrfirst>
  <copyrlast>
    <year>2017</year>
  </copyrlast>
  <bookowner>
    <organization>SyncRO Soft SRL</organization>
  </bookowner>
</bookrights>
```

The XSLT stylesheet that generates the main page is located in: DITA-OT-DIR\plugins\com.oxygenxml.webhelp.responsive\xsl\mainFiles\createMainPage.xsl. This XSLT stylesheet declares the `copy_template` mode that processes the main page template (on page 1517) to expand its components. The main page template declares a component for the footer section that looks like this:

```xml
<div class="footer-container text-center">
  <whc:include_html href="${webhelp.fragment.footer}"
</div>
```

In the following example, the extension stylesheet will add a template that matches this component. It applies the default processing and adds the copyright information at the end.

```xsl
<xsl:template match="*:div[contains(@class, 'footer-container')]" mode="copy_template">
  <!-- Apply the default processing -->
  <xsl:next-match/>

  <!-- Add a div containing the copyright information -->
  <div class="copyright_info">
    Generated by <oxygen/> XML WebHelp © 2002 - 2017 SyncRO Soft SRL All rights reserved.
  </div>
</xsl:template>
```
To add this functionality using a Oxygen Publishing Template, follow these steps:

1. If you have not already created a Publishing Template, see How to Create a Publishing Template (on page 1679).
2. Link the folder associated with the publishing template to your current project in the Project view.
   You should have the custom_footer_template folder linked in your project.
3. Using the Project view, create an xslt folder inside the project root folder.
   You should have the custom_footer_template/xsl folder in your project.
4. Create your customization stylesheet (for example, custom_mainpage.xsl) in the custom_footer_template/xsl folder. Edit it to override the template that produces the footer section:

```xml
<xsl:template match="*:div[contains(@class, 'footer-container')]
    mode="copy_template">
  <!-- Apply the default processing -->
  <xsl:next-match/>
</xsl:template>
```
5. Open the template descriptor file *(on page 1500)* associated with your publishing template and set the XSLT stylesheet created in the previous step with the `com.oxygenxml.webhelp.xsl.createMainPage` XSLT extension point.
6. Open the DITA Map WebHelp Responsive transformation scenario.
7. Click the Choose Custom Publishing Template link and select your template.
8. Click OK to save the changes to the transformation scenario.
9. Run the transformation scenario.

Use Case 2: Add Generation Time in the Output Footer

Another possible customization for the main page is to add the generation time in its footer. A transformation parameter is used to control whether or not this customization is active.

Figure 474. Generation Time Added in the WebHelp Footer

To add this functionality, follow these steps:

1. In the customization stylesheet that you just created (for example, custom_mainpage.xsl), modify the template by adding the following XSLT code at the end.

   `<xsl:if test="oxyf:getParameter('webhelp.footer.add.generation.time') = 'yes'">
     <div class="generation_time">
       Generation date: <xsl:value-of select="format-dateTime(
         current-dateTime(),
         '[h1]:[m01] [P] on [M01]/[D01]/[Y0001].')"/>
     </div>
   </xsl:if>`

   Note: You can read the value of a WebHelp transformation parameter from your XSLT extension stylesheets by using the `getParameter(param.name)` function from the `http://www.oxygenxml.com/functions` namespace.

2. Open the template descriptor file (on page 1500) associated with your publishing template and set the `webhelp.footer.add.generation.time` parameter to the default value.

   `<publishing-template>`
   ...
   `<webhelp>`
   ...
   `<parameters>`
3. Open the DITA Map WebHelp Responsive transformation scenario.
4. In the Parameters tab, you can change the value of the webhelp.footer.add.generation.time parameter.
5. Click OK to save the changes to the transformation scenario.
6. Run the transformation scenario.

How to Use XSLT Extension Points from a DITA-OT Plugin

In this example, the main page footer is modified by adding copyright information extracted from the DITA bookmap or by adding the output generation time. The first use-case uses an XSLT-Import extension point while the second uses an XSLT-Parameter extension point.

Note:
This customization is available as a GitHub project at: https://github.com/oxygenxml/com.oxygenxml.webhelp.responsive.custom.footer.

Use Case 1: WebHelp XSLT-Import extension point to add copyright information extracted from a DITA Bookmap

Suppose you want to customize the WebHelp Responsive main page by adding information about the legal rights associated with the book in the footer (for example, copyright dates and owner). This information is specified in the bookmap:

```
<bookrights>
  <copyrfirst>
    <year>2002</year>
  </copyrfirst>
  <copyrlast>
    <year>2017</year>
  </copyrlast>
  <bookowner>
    <organization>SyncRO Soft SRL</organization>
  </bookowner>
</bookrights>
```

Figure 475. Example: Copyright Information Added in the WebHelp Footer
The XSLT stylesheet that generates the main page is located in: DITA-OT-DIR\plugins\com.oxygenxml.webhelp.responsive\xsl\mainFiles\createMainPage.xsl. This XSLT stylesheet declares the `copy_template` mode that processes the main page template to expand its components. The main page template (on page 1517) declares a component for the footer section that looks like this:

```xml
<div class="footer-container text-center">
    <whc:include_html href="${webhelp.fragment.footer}"
</div>
```

In the following example, the extension stylesheet will add a template that matches this component. It applies the default processing and adds the copyright information at the end.

```xml
<xsl:template match="*:div[contains(@class, 'footer-container')]" mode="copy_template">
    <!-- Apply the default processing -->
    <xsl:next-match/>

    <!-- Add a div containing the copyright information -->
    <div class="copyright_info">
        <xsl:choose>
            <!-- Adds the start-end years if they are defined -->
            <xsl:when test="exists($toc/*:topicmeta/*:bookrights/*:copyrfirst) and
                         exists($toc/*:topicmeta/*:bookrights/*:copyrlast)">
                <span class="copyright_years">
                    ©<xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:copyrfirst"/>
                    -<xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:copyrlast"/>
                </span>
            </xsl:when>

            <!-- Adds only the first year if last is not defined. -->
            <xsl:when test="exists($toc/*:topicmeta/*:bookrights/*:copyrfirst)">
                <span class="copyright_years">
                    ©<xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:copyrfirst"/>
                </span>
            </xsl:when>
        </xsl:choose>

        <!-- Adds the organization if defined -->
        <xsl:if test="exists($toc/*:topicmeta/*:bookrights/*:bookowner/*:organization)">
            <span class="organization">
                <xsl:text> </xsl:text><xsl:text>. All rights reserved.</xsl:text>
            </span>
        </xsl:if>
    </div>
</xsl:template>
```
You can implement this functionality with a WebHelp extension plugin that uses the `com.oxygenxml.webhelp.xsl.createMainPage` extension point (on page 1619). This extension point allows you to specify a customization stylesheet that will override the template described above.

To add this functionality as a DITA-OT plugin, follow these steps:

1. In the `DITA-OT-DIR\plugins\` folder, create a folder for this plugin (for example, `com.oxygenxml.webhelp.responsive.custom.footer`).
2. Create a `plugin.xml` file (in the folder you created in step 1) that specifies the extension point and your customization stylesheet. For example:

   ```xml
   <plugin id="com.oxygenxml.webhelp.responsive.custom.footer">
     <feature extension="com.oxygenxml.webhelp.xsl.createMainPage">
       <file>custom_mainpage.xsl</file>
     </feature>
   </plugin>
   ```
3. Create your customization stylesheet (for example, `custom_mainpage.xsl`), and edit it to override the template that produces the footer section:

   ```xml
   <xsl:template match="*:div[contains(@class, 'footer-container')]">  
     <!-- Apply the default processing -->  
     <xsl:next-match/>
   </xsl:template>

   <!-- Add a div containing the copyright information -->  
   <div class="copyright_info">
     <xsl:choose>
       <!-- Adds the start-end years if they are defined -->  
       <xsl:when test="exists($toc/*/topicmeta/*/bookrights/*:copyrfirst) and exists($toc/*/topicmeta/*/bookrights/*:copyrlast)">
         <span class="copyright_years">©<xsl:value-of select="$toc/*/topicmeta/*/bookrights/*:copyrfirst"/>
          -<xsl:value-of select="$toc/*/topicmeta/*/bookrights/*:copyrlast"/>
       </span>
       </xsl:when>

       <!-- Adds only the first year if last is not defined. -->  
       <xsl:when test="exists($toc/*/topicmeta/*/bookrights/*:copyrfirst)">
         <span class="copyright_years">©<xsl:value-of select="$toc/*/topicmeta/*/bookrights/*:copyrfirst"/>
       </span>
       </xsl:when>
     </xsl:choose>
   </div>
   ```
Use the Run DITA-OT Integrator transformation scenario *(on page 1352)* found in the DITA Map section in the Configure Transformation Scenario(s) dialog box *(on page 1443)*.

5. Run a DITA Map WebHelp Responsive transformation scenario to obtain the customized side TOC.

**Use-Case 2: WebHelp XSLT-Parameter Extension Point to Control if Generation Time is Displayed in the Output**

Another possible customization for the main page is to add the generation time in its footer. You can use an XSLT-Parameter extension point to control whether or not this customization is active. In this case, you can use the `com.oxygenxml.webhelp.xsl.createMainPage.param` extension point *(on page 1619)*.

![Figure 476. Generation Time Added in the WebHelp Footer](image)

To add this functionality, follow these steps:

1. Create a DITA-OT plugin structure by following the first 3 steps in the procedure above *(on page 1587)*.

2. In the customization stylesheet that you just created (for example, `custom_mainpage.xsl`), declare `webhelp.footer.add.generation.time` as a global parameter and modify the template by adding the following XSLT code at the end.

   ```xml
   <xsl:if test="$webhelp.footer.add.generation.time = 'yes'">
     <div class="generation_time">
       Generation date: <xsl:value-of select="format-dateTime(
         current-dateTime(), '[h1]:[m01] [P] on [M01]/[D01]/[Y0001].')"/>
     </div>
   </xsl:if>
   </xsl:template>
   ```

3. Edit the plugin.xml file to specify the `com.oxygenxml.webhelp.xsl.createMainPage.param` extension point and a custom parameter file by adding the following line:

   ```xml
   <feature extension="com.oxygenxml.webhelp.xsl.createMainPage.param" file="params.xml"/>
   ```
4. Create a custom parameter file (for example, `params.xml`). It should look like this:

```xml
<dummy>
  <param name="webhelp.footer.add.generation.time" expression="${webhelp.footer.add.generation.time}" if="webhelp.footer.add.generation.time"/>
</dummy>
```

5. Use the Run DITA-OT Integrator transformation scenario (on page 1352) found in the DITA Map section in the Configure Transformation Scenario(s) dialog box (on page 1443).

6. Edit a DITA Map WebHelp Responsive transformation scenario and in the Parameters tab (on page 2873), specify the desired value (yes or no) for your custom parameter (`webhelp.footer.add.generation.time`).

7. Run the transformation scenario.

Miscellaneous Customization Topics

This section contains miscellaneous topics about how to customize the WebHelp Responsive output.

How to Copy Additional Resources to Output Directory

You can copy additional resources (such as graphics, JavaScript, CSS, entire folders, or other resources) to the output directory either by using an Oxygen Publishing Template (on page 2969) or the `webhelp.custom.resources` parameter.

Copying Additional Resources to the Output Directory using a Publishing Template

1. If you have not already created a Publishing Template, see How to Create a Publishing Template (on page 1679).

2. Add a new `<fileset>` element in the resources section of the template descriptor file (on page 1503).

```xml
<publishing-template>
  ...
  <webhelp>
    ...
    <resources>
      <fileset>
        <include name="custom-resources/**/**/>
        <exclude name="**/*.git"/>
      </fileset>
    </resources>
  </webhelp>
  ...
</publishing-template>
```
3. Open the **DITA Map WebHelp Responsive** transformation scenario.
4. Click the **Choose Custom Publishing Template** link and select your template.
5. Click **OK** to save the changes to the transformation scenario.
6. Run the transformation scenario.

**Results:** All files from the custom resources directory will be copied to the [WebHelp Output Directory](#)/oxygen-webhelp/template folder.

### Copying Additional Resources to the Output Directory using a Transformation Parameter

1. Place all your resources in the same directory.
2. Edit the **DITA Map WebHelp Responsive** transformation scenario and open the **Parameters** tab.
3. Edit the value of the `webhelp.custom.resources` parameter and set it to the absolute path of the directory in step 1.
4. Click **OK** to save the changes to the transformation scenario.
5. Run the transformation scenario.

**Results:** All files from the new directory will be copied to the root of the WebHelp output directory.

### How to Add an Edit Link to Launch Oxygen XML Web Author

You can embed *Edit* links in the DITA WebHelp Responsive output that will automatically launch a particular document in **Oxygen XML Web Author**. A reviewer can then click the link to open the particular file in Oxygen XML Web Author where they can make or propose changes.

### Using a Publishing Template

To embed an *Edit* link in the DITA Map WebHelp Responsive output using an **Oxygen Publishing Template** (on page 1497), follow this procedure:

1. If you have not already created a Publishing Template, see **Working with Publishing Templates** (on page 1535).
2. Open the **template descriptor file** (on page 1500) associated with your publishing template and add the following parameters with their values set to the URLs:

   - `editlink.ditamap.edit.url` - The URL of the DITA map used to publish your content. The easiest way to obtain the URL is to open the map in Web Author and copy the URL from the browser’s address bar.
   - `editlink.additional.query.parameters` - Optional query parameters to be appended to each generated edit link. Each parameter must start with & (e.g. `&tags-mode=no-tags`).

```xml
<publishing-template>
   ...
</publishing-template>
```
3. Open the DITA Map WebHelp Responsive transformation scenario.
4. Click the Choose Custom Publishing Template link and select your template.
5. Click OK to save the changes to the transformation scenario.
6. Run the transformation scenario.

Result: In the WebHelp output, all topics will have an Edit link to the right side of the title and clicking the link will launch that particular document in Oxygen XML Web Author.

For example:

- Windows:

- macOS/Linux:

Using a Transformation Scenario in Oxygen XML Editor/Author
To embed an Edit link in the DITA Map WebHelp Responsive output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Edit a DITA Map WebHelp Responsive transformation scenario and open the Parameters tab.
2. Set values for the following parameters:
   - `editlink.ditamap.edit.url` - The URL of the Oxygen XML Web Author that have opened the DITA map for editing.
   - `editlink.additional.query.parameters` - Optional query parameters to be appended to each generated edit link. Must start with & (e.g. &tags-mode=no-tags).
3. Run the transformation scenario.

Result: In the WebHelp output, all topics will have an Edit link to the right side of the title and clicking the link will launch that particular document in Oxygen XML Web Author.

Web Author Customization Guide: Embedding an Edit Link that will Launch Web Author
How to Flag DITA Content in WebHelp Output

Flagging content in WebHelp output involves defining a set of images that will be used for marking content across your information set.

To flag DITA content, you need to create a filter file that defines properties that will be applied on elements to be flagged. Generally, flagging is supported for block elements (on page 2964) (such as paragraphs), but not for phrase-level elements within a paragraph. This ensures that the images that will flag the content are easily scanned by the reader, instead of being buried in the text.

Using a Publishing Template

To flag content in DITA Map to WebHelp output using an Oxygen Publishing Template (on page 1497), follow this procedure:

1. Create a DITA filter file (DITAVAL) and add it in a directory of your choice (for example, named myFile.ditaval).
2. Define the property for the elements you want to be flagged. For example, if you want to flag any element that has the @audience attribute set to programmer, the content of the DITAVAL file should look like this:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<val>
  <prop att="audience" val="programmer" action="flag" img="D:\resource\delta.gif" alt="sample alt text"/>
</val>
```

**Note:**

For an element to be flagged, at least one attribute-value pair needs to have a property declared in the DITAVAL file.

3. Open the template descriptor file (on page 1500) associated with your publishing template and add the args.filter parameter in the parameters section with its value set to the path of the DITAVAL file you created.

```xml
<publishing-template>
  ...
  <webhelp>
    ...
    <parameters>
      <parameter name="args.filter" value="resources/myFile.ditaval"/>
    </parameters>
  </webhelp>
</publishing-template>
```

4. Open the DITA Map WebHelp Responsive transformation scenario.
5. Click the Choose Custom Publishing Template link and select your template.
6. Click OK to save the changes to the transformation scenario.
7. Run the transformation scenario.
Using a Transformation Scenario in Oxygen XML Editor/Author

To flag content in the DITA Map to WebHelp output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Create a DITA filter file (DITAVAL) and add it in a directory of your choice (for example, named myFile.ditaval).
2. Define the property for the elements you want to be flagged. For example, if you want to flag any element that has the @audience attribute set to programmer, the content of the DITAVAL file should look like this:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<val>
  <prop att="audience" val="programmer" action="flag" img="D:\resource\delta.gif" alt="sample alt text"/>
</val>
```

Note:
For an element to be flagged, at least one attribute-value pair needs to have a property declared in the DITAVAL file.

3. Edit a DITA Map to WebHelp transformation scenario.
4. Specify the DITAVAL file in the Filters tab (with the Use DITAVAL File option).
5. Run the transformation scenario.

Related Information:
Filtering Profiling Values with a DITAVAL File (on page 2914)

How to Deploy the Output on a SharePoint Site

Since WebHelp output must be published locally, on the same machine where the WebHelp process is running, to publish your files directly to a SharePoint library you need to map a network drive to connect to SharePoint and change your file extensions to .aspx, as described in the steps below.

Using a Script Outside of Oxygen XML Editor/Author

To publish WebHelp Responsive output on a SharePoint site using an Oxygen Publishing Template (on page 1497), follow this procedure:

1. Map a network drive to connect to your SharePoint library. For more information, see: https://support.microsoft.com/en-us/kb/2616712.
2. To allow browsers to open your published files (rather than downloading them), you need to change the file extensions from .html to .aspx.
3. Open the template descriptor file (on page 1500) associated with your publishing template and add the args.outext parameter in the parameters section with its value set to .aspx.
<publishing-template>
   ...
   <webhelp>
      ...
      <parameters>
         <parameter name="args.outext" value=".aspx"/>
      </parameters>
   </webhelp>
</publishing-template>

4. Open the DITA Map WebHelp Responsive transformation scenario.
5. Click the Choose Custom Publishing Template link and select your template.
6. Click OK to save the changes to the transformation scenario.
7. Run the transformation scenario.

Using a Transformation Scenario in Oxygen XML Editor/Author
To publish WebHelp Responsive output on a SharePoint site using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Map a network drive to connect to your SharePoint library. For more information, see: https://support.microsoft.com/en-us/kb/2616712.
2. To allow browsers to open your published files (rather than downloading them), you need to change the file extensions from .html to .aspx. Fortunately, this can be done in the transformation.
   a. Edit the WebHelp transformation scenario and open the Parameters tab.
   b. Set the args.outext parameter to .aspx.
   c. Run the transformation scenario.

How to View MathML Equations in HTML Output
By default, only Firefox can render MathML equations embedded in the HTML code. MathJax is a solution to properly view MathML equations embedded in HTML content in a variety of browsers.

If you have DocBook or DITA content that has embedded MathML equations and you want to properly view the equations in published HTML output types (WebHelp, CHM, EPUB, etc.), you need to add a reference to the MathJax script in the head element of all HTML files that have the equation embedded.

For example:

```html
<script type="text/javascript"
   src="https://cdnjs.cloudflare.com/ajax/libs/mathjax/2.7.1/MathJax.js?config=TeX-AMS-MML_HTMLorMML"
>
</script>
```

Alternate Method for DITA
For DITA documents, you can also use the following procedure:
1. Create an XML file that contains a script similar to the one shown in the example above.
2. Edit the DITA Map transformation scenario and open the **Parameters** tab.
3. Set the following parameter to point to the XML file created in step 1:
   - **WebHelp Responsive Systems** - Set the `webhelp.fragment.head` parameter to point to your XML file.
   - **WebHelp Classic Systems** - Set the `webhelp.head.script` parameter to point to your XML file.
   - **Any other type of HTML-based publishing** - Set the `args.hdf` parameter to point to your XML file.
4. Run the transformation scenario.

**Result:** The equation should now be properly rendered in other browsers, such as Edge, IE, or Chrome.

### How to Disable Caching in WebHelp Responsive Output

In cases where a set of WebHelp Responsive pages need to be updated on a regular basis to deliver the latest version of the documentation, the WebHelp pages should always be requested from the server upon reloading it in a web browser on the client side, (rather than re-using an outdated cached version in the browser).

To disable caching in WebHelp Responsive output, follow this procedure:

1. Create a new well-formed XML file and add the following code snippet:

   ```html
   <meta http-equiv="Pragma" content="no-cache" />
   <meta http-equiv="Expires" content="-1" />
   ```

   **Note:**
   The code should look like this:
   ```html
   <!DOCTYPE html>
   <html xmlns="http://www.w3.org/1999/xhtml">
     <head>
       <meta http-equiv="Pragma" content="no-cache" />
       <meta http-equiv="Expires" content="-1" />
     </head>
   </html>
   ```

2. Edit the **DITA Map WebHelp Responsive** transformation scenario and open the **Parameters** tab.
3. Edit the value of the `webhelp.fragment.head` parameter and set it to the absolute path of your XML file.
4. Click **OK** to save the changes to the transformation scenario.
5. Run the transformation scenario.

**Result:** Your additional content is included at the end of the `<head>` element of your output document.

### How to Configure a Custom Search Engine

It is possible to integrate a custom search engine into your WebHelp Responsive output. This is done by using the following transformation parameters:
webhelp.fragment.custom.search.engine.results

This parameter can be used to replace the search results area with custom XHTML content. The value of the parameter is the path to an XHTML file that contains your custom content.

webhelp.fragment.custom.search.engine.script

This parameter can be used to replace WebHelp's built-in search engine with your own custom search engine. The value of the parameter is the path to an XHTML file that contains the scripts required for your custom search engine to run.

To integrate a custom search engine into your WebHelp Responsive output, follow these steps:

1. If you have not already created a Publishing Template, see How to Create a Publishing Template (on page 1679).
2. Create the following items in the folder that contains your publishing descriptor file (the .opt file):
   - A file named custom-search-results-fragment.xml.
   - A file named custom-search-script-fragment.xml.
   - A folder named js.
3. In the custom-search-results-fragment.xml file, define the HTML structure that will be used as the search results area. For example:

   ```html
   <div id="custom-search-results">...</div>
   ```

   **Note:**
   The custom search engine script will need to find an HTML element from the HTML structure that will be used as the search results area and write the search results inside it. In this example, it is the `<div>` element with the id `custom-search-results`.

4. In the js folder, create a file named custom-search.js.
5. As a starting point, you can copy the following content to the custom-search.js file:

   ```javascript
   $(document).ready(function () {
       const params = new URLSearchParams(window.location.search);
       const searchQuery = params.get('searchQuery');
       // Implement your custom search engine
       // Display the search results
   });
   ```

   **Important:**
   The value entered by the user in the search page will be available in the URL's query parameters in a parameter named `searchQuery`. 
6. Implement your custom search engine.

**Note:**
The search results should be pushed into the `<div>` element created earlier with the id `custom-search-results`.

7. In the `custom-search-script-fragment.xml` file, define the scripts that are required for your custom search engine to run. For example:

```xml
<div>
  <script src="${oxygen-webhelp-template-dir}/js/custom-search.js"></script>
</div>
```

8. Copy the `js` folder to the output folder during the transformation process. For this, open the `.opt` file and add the following content in the `<resources>` section (see Template Resources (on page 1503) for more details):

```xml
<fileset>
  <include name="js/**"/>
</fileset>
```

9. Set the transformation parameters needed to enable the custom search engine. For this, open the `.opt` file and add the following content inside the `<webhelp>` element:

```xml
<html-fragments>
  <fragment file="custom-search-script-fragment.xml"
    placeholder="webhelp.fragment.custom.search.engine.script"/>
  <fragment file="custom-search-results-fragment.xml"
    placeholder="webhelp.fragment.custom.search.engine.results"/>
</html-fragments>
```

10. Run the transformation with this publishing template selected.

**Note:**
A publishing template containing all the steps we described, except for the actual custom search engine implementation is available to download here. You can use it as a starting point.
How to Add a Link to PDF Documentation

It is possible to add a component in your WebHelp output that links to an external PDF resource. For example, it could link to the PDF equivalent of the documentation. This is achieved by configuring some transformation parameters and the link component is added in the header/breadcrumb stripe, next to the navigation links.

The transformation parameters used for generating a PDF link component in the WebHelp Responsive output are:

- `webhelp.pdf.link.url`: Specifies the target URL for the PDF link component.
- `webhelp.pdf.link.text`: Specifies the text for the PDF link component.
- `webhelp.pdf.link.icon.path`: Specifies the path or URL of the image icon to be used for the PDF link component. If not specified, a default icon is used.
- `webhelp.show.pdf.link`: Specifies whether or not the PDF link component is shown in the WebHelp Responsive output. Allowed values are: yes (default) and no.
- `webhelp.pdf.link.anchor.enabled`: Specifies whether or not the current topic ID should be appended as the name destination at the end of the PDF link. Allowed values are: yes (default) and no.

How to Add a Custom Component for WebHelp Output

This topic explains how to use several customization methods to define and implement a custom component for WebHelp output pages.

Predefined components

The WebHelp output is based on a set of HTML Page Layout Files (on page 1516) that define the default layout of the generated pages. Each layout file is made of a set of various components. Each component is described using an associated XML element that is processed at the generation time resulting in its associated component being included in the output pages.

Here are a few examples of predefined components: Logo, Title, Menu, Search Input, Topics Tiles, Topic Breadcrumb, Topic Content, Publication Table of Contents. A complete list with all the available components is available here: Layout of the Responsive Page Types (on page 1455).

For example, the page component that is used to define the Search Input field in the WebHelp HTML pages is defined as follows:

```xml
<!-- Search form -->
<whc:webhelp_search_input class="navbar-form wh_topic_page_search search" role="form"/>
```

At publishing time, the above component will be expanded into:
Customization Methods

The most common customization methods for the WebHelp Responsive output include:

- Apply custom CSS styles (on page 1542) to change the default layout and styles.
- Insert additional HTML content (on page 1544) using one of the available HTML Fragment Placeholder parameters (on page 1507).
- Extend the default processing using XSLT Extension Points (on page 1506).
- Configure available Transformation Parameters (on page 1605).

Use Case: Custom Link Component

For the subsequent procedure, suppose you have a DITA project for a User Manual and you also have various video demonstrations available on your website that supplement the documentation. You may want to link a video demonstration for a particular feature to its associated DITA topic in the WebHelp output.

You could simply add a link somewhere in your DITA topic, but this approach would not be very suitable for a printable (PDF) version of your User Manual. Thus, you need to include the link to the associated video demonstration only in the WebHelp output of your User Manual (and not the PDF version).

One way to link a video with its associated topic is to include its URL in the metadata section. For example:

```xml
<prolog>
  <metadata>
    <othermeta name="video-link" content="https://www.youtube.com/watch?v=zNmXFkWx08"/>
  </metadata>
</prolog>
```

Next, you need to instruct WebHelp to pick up the URL from the metadata and generate a link in a specific location of the HTML output page. You can achieve this by creating your own WebHelp custom component.
Creating a Custom Component

You can combine several of the available customization methods to define and implement your own WebHelp custom component.

**Figure 477. Custom Component**

![Diagram of HTML Fragment, XSLT Extension, and CSS](image)

To create a custom component that displays a link to the current topic's associated video tutorial, follow these steps:

1. Define your component. For example, it may have the following form:

   ```xml
   <comp:video-link xmlns:comp="http://example.com/custom-components"/>
   ```

   The component is an XML element that belongs to a custom defined namespace.

2. Insert the component in your topic pages. To do this, you will have to save the associated XML element in an HTML Fragment file (for example, named `video-link-fragment.xml`).

3. Reference the HTML Fragment file in your current Publishing Template's descriptor file (on page 1500) and associate it with an HTML Fragment placeholder that is available for the topic pages (webhelp.fragment.before.topic.toolbar in this case):

   ```xml
   <html-fragments>
       <fragment file="component/html-fragment/video-link-fragment.xml" placeholder="webhelp.fragment.before.topic.toolbar"/>
   </html-fragments>
   ```

   **Note:**
   The HTML Fragment file is referenced using a path relative to the Publishing Template root directory.

4. Create a custom XSLT file that processes the custom component and picks up the video URL available in the current topic's metadata and generates a link to the page that contains the video:

   ```xml
   <xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
       xmlns:xs="http://www.w3.org/2001/XMLSchema"
       xmlns:comp="http://example.com/custom-components"
       exclude-result-prefixes="xs comp"
       version="3.0">

   <!-- Custom component implementation -->
   ```
<xsl:template match="comp:video-link" mode="copy_template">
    <xsl:param name="ditaot_topicContent" tunnel="yes"/>
</xsl:template>

<!-- Look for a 'video-link' <meta> element in the current topic content -->
<xsl:variable name="videoLinkMeta" select="$ditaot_topicContent//*:meta[@name='video-link']"/>
<xsl:if test="exists($videoLinkMeta)">
    <div class="video-link-container">
        <a href="{$videoLinkMeta[1]/@content}" class="video-link" target="_blank" aria-label="Video">
            <span>Video</span>
        </a>
    </div>
</xsl:if>
</xsl:template>

The HTML content generated for your component will look like this:

```html
<div class="video-link-container">
    <a href="https://www.youtube.com/watch?v=zNmXfKWXw08" class="video-link" target="_blank" aria-label="Video">
        <span>Video</span>
    </a>
</div>
```

5. Reference the above XSL file in your Publishing Template's descriptor file using the XSLT extension point associated with the XSL module that generates an HTML file for each DITA topic:

```xml
<xslt>
    <extension file="component/xsl/video-link-impl.xsl" id="com.oxygenxml.webhelp.xsl.dita2webhelp"/>
</xslt>
```

6. Create a custom CSS file that contains the rules for styling the output for your component:

```css
@import url('https://fonts.googleapis.com/icon?family=Material+Icons');

.video-link-container {
    display: flex;
    align-items: center;
    flex-grow: 10;
    justify-content: flex-end;
}

.video-link {
}  
```
7. Reference the above CSS file in your Publishing Template's descriptor file:

```xml
<resources>
  <!-- .... -->
  <css file="component/css/video-link.css"/>
</resources>
```

**Result:** An icon that is a link to the video appears in the header stripe in the output page.

**Figure 478. Custom Link to Video Component**
Sample Publishing Template

A sample Publishing Template that contains all the above customizations is available here: https://github.com/oxygenxml/oxygen-publishing-template-samples/tree/master/templates/video-link-custom-component.

WebHelp Responsive Transformation Parameters

In addition to the common DITA-OT transformation parameters and the HTML-based Output Parameters, there are numerous other supported parameters that are specific to the WebHelp Responsive output.

Publishing Template Parameters

- **webhelp.publishing.template**
  Specifies the path to the ZIP archive (or root folder) that contains your custom WebHelp Responsive template.

  **Note:**
  The built-in templates are stored in the DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/templates folder.

  **Note:**
  Relative paths are resolved based on the current working directory.

- **webhelp.publishing.template.descriptor**
  Specifies the name of the descriptor to be loaded from the WebHelp Responsive template package. If it is not specified, the first encountered descriptor will be automatically loaded.

Custom Resource Parameters

- **webhelp.custom.resources**
  The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

- **webhelp.favicon**
  The file path that points to an image to be used as a favicon in the WebHelp output.

- **webhelp.logo.image.target.url**
  Specifies a target URL that is set on the logo image. When you click the logo image, you will be redirected to this address.

- **webhelp.logo.image**
  Specifies a path to an image displayed as a logo in the left side of the output header.

- **webhelp.logo.image.alt**
Specifies a value that will be set in the `@alt` attribute of the logo image. If the parameter is not specified, the `@alt` attribute will contain the publication title. Note that this parameter makes sense only in conjunction with the `webhelp.logo.image` parameter.

**Oxygen Feedback Parameter**

`webhelp.fragment.feedback`

You can integrate Oxygen Feedback with your WebHelp Responsive output to provide a comments area at the bottom of each page where readers can offer feedback. When you create an Oxygen Feedback site configuration, an HTML fragment is generated during the final step of the creation process and that fragment should be set as the value for this parameter.

**HTML Fragment Extension Parameters**

`webhelp.enable.html.fragments.cleanup`

Enables or disables the automatic conversion of HTML fragments to well-formed XML. If set to `true` (default), the transformation automatically converts non-well-formed HTML content to a well-formed XML equivalent. If set to `false`, the transformation will fail if at least one HTML fragment is not well-formed.

`webhelp.fragment.after.body`

This parameter can be used to display a given XHTML fragment after the body in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

`webhelp.fragment.after.body.main.page`

This parameter can be used to display a given XHTML fragment after the body in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

`webhelp.fragment.after.body.topic.page`

This parameter can be used to display a given XHTML fragment after the body in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

`webhelp.fragment.after.body.search.page`

This parameter can be used to display a given XHTML fragment after the body in the search results page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

`webhelp.fragment.after.body.terms.page`

This parameter can be used to display a given XHTML fragment after the body in the index terms page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

`webhelp.fragment.after.logo_and_title`
This parameter can be used to display a given XHTML fragment after the logo and title in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.search.input**

This parameter can be used to display a given XHTML fragment after the search field in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.main.page.search (deprecated)**

This parameter is deprecated. Use `webhelp.fragment.after.search.input.main.page` instead.

**webhelp.fragment.after.search.input.main.page**

This parameter can be used to display a given XHTML fragment after the search field in all the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.search.input.topic.page**

This parameter can be used to display a given XHTML fragment after the search field in all the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.search.input.search.page**

This parameter can be used to display a given XHTML fragment after the search field in all the search results page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.search.input.terms.page**

This parameter can be used to display a given XHTML fragment after the search field in all the index terms page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.toc_or_tiles**

This parameter can be used to display a given XHTML fragment after the table of contents or tiles in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.top_menu**

This parameter can be used to display a given XHTML fragment after the top menu in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.body**

This parameter can be used to display a given XHTML fragment before the page body in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.
webhelp.fragment.before.body.main.page
This parameter can be used to display a given XHTML fragment before the page body in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.body.topic.page
This parameter can be used to display a given XHTML fragment before the page body in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.body.search.page
This parameter can be used to display a given XHTML fragment before the page body in the search results page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.body.terms.page
This parameter can be used to display a given XHTML fragment before the page body in the index terms page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.logo_and_title
This parameter can be used to display a given XHTML fragment before the logo and title. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.search.input
This parameter can be used to display a given XHTML fragment before the search field in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.main.page.search (deprecated)
This parameter is deprecated. Use webhelp.fragment.before.search.input.main.page instead.

webhelp.fragment.before.search.input.main.page
This parameter can be used to display a given XHTML fragment before the search field in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.search.input.topic.page
This parameter can be used to display a given XHTML fragment before the search field in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.search.input.search.page
This parameter can be used to display a given XHTML fragment before the search field in the search page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.
This parameter can be used to display a given XHTML fragment before the search field in the search results page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.search.input.terms.page**

This parameter can be used to display a given XHTML fragment before the search field in the index terms page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.toc_or_tiles**

This parameter can be used to display a given XHTML fragment before the table of contents or tiles in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.top_menu**

This parameter can be used to display a given XHTML fragment before the top menu in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.footer**

This parameter can be used to display a given XHTML fragment as the page footer in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

⚠️ **Important:**

This parameter should only be used if you are using a valid, purchased license of Oxygen XML Editor (do not use it with a trial license).

**webhelp.fragment.head**

This parameter can be used to display a given XHTML fragment in the header section in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.head.main.page**

This parameter can be used to display a given XHTML fragment in the header section in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.head.topic.page**

This parameter can be used to display a given XHTML fragment in the header section in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.head.search.page**
This parameter can be used to display a given XHTML fragment in the header section in the search results page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.head.terms.page**

This parameter can be used to display a given XHTML fragment in the header section in the index terms page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.welcome**

This parameter can be used to display a given XHTML fragment as a welcome message (or title). The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.header**

This parameter can be used to display a given XHTML fragment after the header section in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.header.main.page**

This parameter can be used to display a given XHTML fragment after the header section in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.header.topic.page**

This parameter can be used to display a given XHTML fragment after the header section in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.header.search.page**

This parameter can be used to display a given XHTML fragment after the header section in the search results page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.header.terms.page**

This parameter can be used to display a given XHTML fragment after the header section in the index terms page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.search.input**

This parameter can be used to display a given XHTML fragment before the search field in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.
This parameter can be used to display a given XHTML fragment after the search field in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.main.content.area

This parameter can be used to display a given XHTML fragment before the main content section in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.main.content.area.main.page

This parameter can be used to display a given XHTML fragment before the main content section in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.main.content.area.topic.page

This parameter can be used to display a given XHTML fragment before the main content section in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.main.content.area.search.page

This parameter can be used to display a given XHTML fragment before the main content section in the search results page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.main.content.area.terms.page

This parameter can be used to display a given XHTML fragment before the main content section in the index terms page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.main.content.area

This parameter can be used to display a given XHTML fragment after the main content section in all types of pages. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.main.content.area.main.page

This parameter can be used to display a given XHTML fragment after the main content section in the main page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.main.content.area.topic.page

This parameter can be used to display a given XHTML fragment after the main content section in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.topic.toolbar

This parameter can be used to display a given XHTML fragment before the topic toolbar.
This parameter can be used to display a given XHTML fragment before the toolbar buttons above the topic content in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

**webhelp.fragment.after.topic.toolbar**

This parameter can be used to display a given XHTML fragment after the toolbar buttons above the topic content in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

**webhelp.fragment.before.topic.breadcrumb**

This parameter can be used to display a given XHTML fragment before the breadcrumb component in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

**webhelp.fragment.after.topic.breadcrumb**

This parameter can be used to display a given XHTML fragment after the breadcrumb component in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

**webhelp.fragment.before.publication.toc**

This parameter can be used to display a given XHTML fragment before the publication's table of contents component in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

**webhelp.fragment.after.publication.toc**

This parameter can be used to display a given XHTML fragment after the publication's table of contents component in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

**webhelp.fragment.before.topic.content**

This parameter can be used to display a given XHTML fragment before the topic's content in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

**webhelp.fragment.after.topic.content**

This parameter can be used to display a given XHTML fragment after the topic's content in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

**webhelp.fragment.before.feedback**

This parameter can be used to display a given XHTML fragment before the Oxygen Feedback commenting component in the topic page. The value of the parameter can be either a **well-formed** XHTML fragment or a path to a file that contains a **well-formed** XHTML fragment.

**webhelp.fragment.after.feedback**
This parameter can be used to display a given XHTML fragment after the Oxygen Feedback commenting component in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.before.topic.toc**

This parameter can be used to display a given XHTML fragment before the topic's table of contents component in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.after.topic.toc**

This parameter can be used to display a given XHTML fragment after the topic's table of contents component in the topic page. The value of the parameter can be either a well-formed XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

**webhelp.fragment.custom.search.engine.results**

This parameter can be used to replace the search results area with custom XHTML content. The value of the parameter is the path to an XHTML file that contains your custom content.

**webhelp.fragment.custom.search.engine.script**

This parameter can be used to replace WebHelp's built-in search engine with your own custom search engine. The value of the parameter is the path to an XHTML file that contains the scripts required for your custom search engine to run.

**Output Component Parameters**

**webhelp.default.collection.type.sequence**

Specifies if the sequence value will be used by default when the @collection-type attribute is not specified. This option is helpful if you want to have Next and Previous navigational buttons generated for all HTML pages. Allowed values are no (default) and yes.

**webhelp.merge.nested.topics.related.links**

Specifies if the related links from nested topics will be merged with the links in the parent topic. Thus the links will be moved from the topic content to the related links component and all of the links from the same group (for example, Related Tasks, Related References, Related Information) are merged into a single group. The default value is yes.

**webhelp.show.breadcrumb**

Specifies if the breadcrumb component will be presented in the output. The default value is yes.

**webhelp.show.changes.and.comments**

When set to yes, user comments, replies to comments, and tracked changes are published in the WebHelp output. The default value is no.

**webhelp.show.child.links**

Specifies if child links will be generated in the output for all topics that have subtopics. The default value is no.
**webhelp.show.full.size.image**

Specifies if responsive images that are displayed with a smaller dimension than their original size can be clicked to see an enlarged version of the image. The default value is *yes*.

**webhelp.show.indexterms.link**

Specifies if an icon that links to the index will be presented in the output. The default value is *yes*.

**webhelp.show.main.page.tiles**

Specifies if the tiles component will be presented in the main page of the output. For a *tree* style layout, this parameter should be set to *no*.

**webhelp.show.main.page.toc**

Specifies if the table of contents will be presented in the main page of the output. The default value is *yes*.

**webhelp.show.navigation.links**

Specifies if navigation links will be presented in the output. The default value is *yes*.

**webhelp.show.print.link**

Specifies if a print link or icon will be presented within each topic in the output. The default value is *yes*.

**webhelp.show.publication.toc**

Specifies if a table of contents will be presented on the left side of each topic in the output. The default value is *yes*.

**webhelp.show.topic.toc**

Specifies if a topic table of contents will be presented on the right side of each topic in the output. This table of contents contains links to each `<section>` within the current topic that contains an `@id` attribute and the section corresponding to the current scroll position is highlighted. The default value is *yes*.

**webhelp.show.top.menu**

Specifies if a menu will be presented at the topic of the main page in the output. The default value is *yes*.

**webhelp.publication.toc.hide.chunked.topics**

Specifies if the table of contents will contain links for *chunked* topics. The default value is *yes*.

**webhelp.publication.toc.links**

Specifies which links will be included in the table of contents. The possible values are:

- **chapter** (default) - The TOC will include links for the current topic, its children, its siblings, and its direct ancestor (including the direct ancestor's siblings), and the parent chapter.
- **topic** - The TOC will only include links for the current topic and its direct children.
- **all** - The TOC will include all links.
webhelp.publication.toc.tooltip.position

By default, if a topic contains a `<shortdesc>` element, its content is displayed in a tooltip when the user hovers over its link in the table of contents. This parameter controls whether or not this tooltip is displayed and its position relative to the link. The possible values are:

- **left** (default)
- **right**
- **top**
- **bottom**
- **hidden** - The tooltip will not be displayed.

webhelp.top.menu.depth

Specifies the maximum depth level of the topics that will be included in the top menu. The default value is 3. A value of 0 means that the menu has unlimited depth.

webhelp.topic.collapsible.elements.initial.state

Specifies the initial state of collapsible elements (tables with titles, nested topics with titles, sections with titles, index term groups). The possible values are `collapsed` or `expanded` (default value).

**Search-Related Parameters**

webhelp.search.japanese.dictionary

The file path of the dictionary that will be used by the *Kuromoji* morphological engine for indexing Japanese content in the WebHelp pages. The encoding for the dictionary must be `UTF8`.

webhelp.search.ranking

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the **Search** tab (default setting is `true`).

webhelp.search.stop.words.exclude

Specifies a list of words that will be excluded from the default list of *stop words* that are filtered out before the search processing. Use comma separators to specify more than one word (for example: `if,for,is`).

webhelp.sitemap.base.url

Base URL for all the `<loc>` elements in the generated `sitemap.xml` file. The value of a `<loc>` element is computed as the relative file path from the `@href` attribute of a `<topicref>` element from the *DITA map*, appended to this base URL value. The `<loc>` element is mandatory in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `sitemap.xml` file is not generated.

webhelp.enable.search.autocomplete
Specifies if the *Autocomplete* feature is enabled in the WebHelp search text field. The default value is *yes*.

**webhelp.search.enable-pagination**

Specifies whether or not search results will be displayed on multiple pages. Allowed values are *yes* or *no*.

**webhelp.search.index.elements.to.exclude**

Specifies a list of HTML elements that will not be indexed by the search engine. The value of the *@class* attribute can be used to exclude specific HTML elements from indexing. For example, the *div.not-indexed* value will not index all *<div>* elements that have a *@class* attribute with the value of *not-indexed*. Use a comma separator to specify more than one element.

**webhelp.search.page.numberOfItems**

Specifies the number of search results items displayed on each page. This parameter is only used when the *webhelp.search.enable.pagination* parameter is enabled.

**webhelp.search.stop.words.include**

Specifies a list of words that will be ignored by the search engine. Use a comma separator to specify more than one word.

**webhelp.sitemap.change.frequency**

The value of the *<changefreq>* element in the generated *sitemap.xml* file. The *<changefreq>* element is optional in *sitemap.xml*. If you leave this parameter set to its default empty value, then the *<changefreq>* element is not added in *sitemap.xml*. Allowed values: *<empty string>* (default), *always*, *hourly*, *daily*, *weekly*, *monthly*, *yearly*, *never*.

**webhelp.sitemap.priority**

The value of the *<priority>* element in the generated *sitemap.xml* file. It can be set to any fractional number between 0.0 (least important priority) and 1.0 (most important priority). For example, 0.3, 0.5, or 0.8. The *<priority>* element is optional in *sitemap.xml*. If you leave this parameter set to its default empty value, then the *<priority>* element is not added in *sitemap.xml*.

**webhelp.google.search.results**

A file path that specifies the location of a well-formed XHTML file containing the Google Custom Search Engine element *gcse:searchresults-only*. You can use all supported attributes for this element. It is recommended to set the *@linkTarget* attribute to *frm* for frameless (*iframe*) version of WebHelp or to *contentWin* for the frameset version of WebHelp. The default value for this attribute is *_blank* and the search results will be loaded in a new window. If this parameter is not specified, the following code will be used `<gcse:searchresults-only linkTarget="frm"></gcse:searchresults-only>`.

**webhelp.google.search.script**

A file path that specifies the location of a well-formed XHTML file containing the Custom Search Engine script from Google.
Publishing Speedup Parameters

**parallel**

A common parameter with other transformation types. When set to `true` (default value is `false`), the publishing pre-processing stages are run in parallel slightly improving the publishing time.

**store-type**

A common parameter with other transformation types. When set to `memory`, the processing stages use internal memory to store temporarily processed documents, thus decreasing the publishing time but slightly increasing the amount of internal memory used for the process. When publishing on Windows, setting this parameter can decrease the publishing times by about one-third.

**Note:**
The `fix.external.refs.com.oxygenxml` parameter is not supported when running the transformation from a command line. This parameter is normally used to specify whether or not the application tries to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references.

Parameters for Adding a Link to PDF Documentation in WebHelp Responsive Output

The following transformation parameters can be used to generate a PDF link component in the WebHelp Responsive output (for example, it could link to the PDF equivalent of the documentation):

**webhelp.pdf.link.url**

Specifies the target URL for the PDF link component.

**webhelp.pdf.link.text**

Specifies the text for the PDF link component.

**webhelp.pdf.link.icon.path**

Specifies the path or URL of the image icon to be used for the PDF link component. If not specified, a default icon is used.

**webhelp.show.pdf.link**

Specifies whether or not the PDF link component is shown in the WebHelp Responsive output. Allowed values are: `yes` (default) and `no`.

**webhelp.pdf.link.anchor.enabled**

Specifies whether or not the current topic ID should be appended as the name destination at the end of the PDF link. Allowed values are: `yes` (default) and `no`.

- Generating WebHelp Responsive Output *(on page 1532)*
- Setting DITA-OT Parameters
WebHelp Responsive XSLT-Import and XSLT-Parameter Extension Points

XSLT extension points can be used from either from an Oxygen Publishing Template or from a DITA-OT extension plug-in.

Extension Points from an Oxygen Publishing Template

The publishing template allows you to specify an XSLT extension point. The extension point will only affect the transformations that use the particular template.

Important:
While the publishing templates only support referencing one extension point at a time, you can use xslt:include or xslt:import to aggregate multiple modules.

For a specific example of how to use an extension in a publishing template, see: How to Use an XSLT Extension Point from a Publishing Template (on page 1582) topic.

Example:

```xml
<publishing-template>
  ...
  <webhelp>
    ...
    <xslt>
      <extension
          id="com.oxygenxml.webhelp.xsl.createMainPage"
          file="xsl/customMainPage.xsl"/>
    </xslt>
  </webhelp>
</publishing-template>
```

Extension Points from a DITA-OT Extension Plug-in

The DITA-OT plug-in installer adds an XSLT import statement in the default WebHelp XSLT so that the XSLT stylesheet referenced by the extension point becomes part of the normal build. You can use these extension points to override XSLT processing steps.

Example:

```xml
<plugin id="com.oxygenxml.webhelp.responsive.extension">
  <feature extension="com.oxygenxml.webhelp.xsl.dita2webhelp"
           file="xsl/fixup.xsl"/>
</plugin>
```

XSLT-Import Extension Points

The following extension points are supported:

com.oxygenxml.webhelp.xsl.dita2webhelp
Extension point to override the XSLT stylesheet (`dita2webhelp.xsl`) that produces an HTML file for each DITA topic. The location of this file is `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.responsive\xsl\dita2webhelp\dita2webhelp.xsl`.

**com.oxygenxml.webhelp.xsl.createMainPage**

Extension point to override the XSLT stylesheet (`createMainPage.xsl`) that produces the WebHelp Responsive main HTML page (`index.html`). The location of this file is `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.responsive\xsl\mainFiles\createMainPage.xsl`.

**com.oxygenxml.webhelp.xsl.createNavLinks**

Extension point to override the XSLT stylesheets that are used to generate navigation links in the WebHelp Responsive pages. These stylesheets can be found in the `navLinks` folder: `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.responsive\xsl\navLinks\`.

**com.oxygenxml.webhelp.xsl.createSearchPage**

Extension point to override the XSLT stylesheet (`createSearchPage.xsl`) that produces the WebHelp Responsive search HTML page (`search.html`). The location of this file is `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.responsive\xsl\mainFiles\createSearchPage.xsl`.

**com.oxygenxml.webhelp.xsl.createIndexTermsPage**

Extension point to override the XSLT stylesheet (`createIndextermsPage.xsl`) that produces the WebHelp Responsive index terms HTML page (`indexterms.html`). The location of this file is `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.responsive\xsl\mainFiles\createIndextermsPage.xsl`.

**com.oxygenxml.webhelp.xsl.createTocXML**

Extension point to override the XSLT stylesheet (`tocDita.xsl`) that produces the `toc.xml` file. This file contains information extracted from the `DITA map (on page 2966)` and it is mainly used to construct the WebHelp Table of Contents and navigational links. The path to this stylesheet is: `DITA-OT-DIR\plugins\com.oxygenxml.webhelp.responsive\xsl\navLinks\tocDita.xsl`.

**XSLT-Parameter Extension Points**

If your customization stylesheet declares one or more XSLT parameters and you want to control their values from the transformation scenario, you can use one of the following XSLT parameter extension points:

**com.oxygenxml.webhelp.xsl.dita2webhelp.param**

Use this extension point to pass parameters to the stylesheet specified using the `com.oxygenxml.webhelp.xsl.dita2webhelp` extension point (on page 1618).

**com.oxygenxml.webhelp.xsl.createMainPage.param**

Use this extension point to pass parameters to the stylesheet specified using the `com.oxygenxml.webhelp.xsl.createMainPage` extension point (on page 1619).
com.oxygenxml.webhelp.xsl.createNavLinks.param

Use this extension point to pass parameters to the stylesheet specified using the com.oxygenxml.webhelp.xsl.createNavLinks extension point (on page 1619).

com.oxygenxml.webhelp.xsl.createSearchPage.param

Use this extension point to pass parameters to the stylesheet specified using the com.oxygenxml.webhelp.xsl.createSearchPage extension point (on page 1619).

com.oxygenxml.webhelp.xsl.createIndexTermsPage.param

Use this extension point to pass parameters to the stylesheet specified using the com.oxygenxml.webhelp.xsl.createIndexTermsPage extension point (on page 1619).

com.oxygenxml.webhelp.xsl.createTocXML.param

Use this extension point to pass parameters to the stylesheet specified using the com.oxygenxml.webhelp.xsl.createTocXML extension point (on page 1619).

WebHelp Classic Output for DocBook

The WebHelp Classic variant is designed for desktop systems when feedback from users is not necessary and it is available for DocBook. You can also integrate a feedback system that provides the ability for your users to add comments in the output. This section contains information about configuring a WebHelp Classic system and customizing the output.

This type of WebHelp system can be generated by using one of the following transformation scenarios:

- DocBook WebHelp Classic (on page 1356).
- DocBook WebHelp Classic with Feedback (Deprecated) (on page 1356).

WebHelp Classic Output Layout and Features

Layout of the WebHelp Classic System Interface

The layout of the WebHelp Classic system consists of the following components:

Left Pane or Frame

This section on the left side of the help system includes the following tabs:

Content

A typical table of contents style presentation of your content. You can use the Expand all/Collapse all buttons to expand or collapse all the topics presented in the Table of Contents.
Note:
You can enhance the appearance of items in the Table of Contents. See the Customizing WebHelp Classic Output chapter (on page 1634) for more details.

Index

Presents the index terms for your content. If your content does not contain any <indexterm> elements, this tab is not generated.

Search Results

This tab is generated when the Search field is used. It presents the search results in the form of links to topics where the search terms are found, along with a rating scheme for each result. For more details, see the Search Feature section (on page 1624).

Upper Pane or Frame

The upper section of the help system includes the following features:

Search Field

Use this feature to perform searches in your content. When you enter search terms in this field, the results are displayed in the Search Results tab in the left section of the help system, along with a rating scheme for each result. For more details, see the Search Feature section (on page 1624).

Frames Option

Click on this option to display the output rendered in HTML frames.

Print Option

Opens a dialog box with various printing options and a print preview.

Navigation Links

You can navigate through the content of your output using the navigation links or arrows in the upper-right part of the page. These arrows allow you to move to the Parent topic, Previous topic, or Next topic. Links to the parent topics of the currently open topic are also presented at the top of the page.

Tip:
To hide the Parent, Next, and Previous links, you can edit the transformation scenario and set the value of the args.hide.parent.link parameter to yes.

Main Pane or Frame

The content of the help pages are rendered and displayed in this main section.
Figure 479. WebHelp Classic Output

WebHelp Classic with Feedback Enabled (Deprecated)

*Note:* See Deploying the Oxygen Feedback Comments Component *(on page 1627).*

The WebHelp Classic with Feedback variant also contains a Comments section at the bottom of each topic. This section is where you can interact with users through a comment system. For information about deploying a feedback-enabled system, see Deploying a PHP-based Feedback-Enabled System (Deprecated) *(on page 1627).*
To add a new comment, click the **Add New Comment** button, or click **Reply** to add a comment to an existing thread. You can click on the **Log in** button on the right side of this bar to be authenticated as a user and your user name will be included in any comments that you add. If you do not have a user name, you can click on the **Sign Up** button to create a new user.

After you log in, your name and user name are displayed in the **Comments** bar, along with the **Log off** and **Edit** buttons. Click the **Edit** button to open the **User Profile** dialog box where you can customize the following options:

- **Your Name** - You can use this field to edit the initial name that you used to create your user profile.
- **Your email address** - You can use this field to edit the initial email address that you used to create your profile.
- You can choose to receive an email in the following situations:
  - When a comment is left on a page that you commented on.
  - When a comment is left on any topic in the WebHelp Classic system.
  - When a reply is left to one of my comments.
• **New Password** - Allows you to enter a new password for your user account.

**Note:**
The **Current Password** field from the top of the **User Profile** is mandatory if you want to save the changes you make.

If you are an administrator, you can manage user information and comments. For more information, see Managing Users and Comments in a Feedback-Enabled System (Deprecated) (on page ).

**WebHelp Classic Search Engine**

**Search Rules**

Rules that are applied during a search include:

• You can use quotes to perform an exact search for multiple word phrases (for example, "grow flowers" will only return results if both words are found consecutively and exactly as they are typed in the search field). This type of search is known as a **phrase search**.

• **Boolean Search** is supported using the following operators: **and**, **or**, **not**. When there are two adjacent search terms without an operator, **or** is used as the default search operator (for example, **grow flowers** is the same as **grow or flowers**).

• The space character separates keywords (an expression such as **grow flowers** counts as two separate keywords).

• Words composed by merging two or more words with colon (":"), minus ("-"), underline ("_"), or dot ("." ) characters count as a single word.

• Your search terms should contain two or more characters (note that stop words will be ignored). This rule does not apply to CJK (Chinese, Japanese, Korean) languages.

• When searching for multi-word phrases in CJK (Chinese, Japanese, Korean) languages that often have multiple words appear in strings without a space separator, you need to add a space to separate the words. Otherwise, WebHelp will not find results. For example, Chinese uses a specialized character for space separators, but the current WebHelp implementation cannot detect such specialized characters, so to search for 开始之前 (it translates as "before you begin" or "before start"), you have to enter 开始之前 (notice the space between the second and third symbols) in the search field.

**5-Star Rating Mechanism and Sorting**

The **Search** feature is also enhanced with a rating mechanism that computes scores for every result that matches the search criteria. These scores are then translated into a 5-star rating scheme and the stars are displayed to the right of each result. The search results are sorted depending on the following:

• Search entries that satisfy the phrase search criterion are presented first.

• The number of keywords found in a single page (the higher the number, the better).

• The context (for example, a word found in a title, scores better than a word found in unformatted text).

The search ranking order, sorted by relevance is as follows:

- The search term is included in a meta keyword.
- The search term is in the title of the page.
Excluded Terms

To improve performance, the Search feature excludes certain stop words. For example, the English version of the stop words includes: a, an, and, are, as, at, be, but, by, for, if, in, into, is, it, no, not, of, on, or, such, that, the, their, then, there, these, they, this, to, was, will, with.

WebHelp Classic Search Results Tab

When you enter search terms in the Search field at the top of the help system, the results are displayed in the Search Results tab in the left section. When you click on a result in the Search Results tab, that result is displayed in the main pane with the search terms highlighted. If you press Enter with the Search field empty, the highlights are removed.

Figure 481. WebHelp Classic Search Results Tab
Missing Terms

If you enter multiple search terms (other than stop words), for any result that the search engine found at least one term but not one or more of the other terms, the Missing terms will be listed below each result.

Tag Element Scoring Values

HTML tag elements are also assigned a scoring value and these values are evaluated for the search results. For information about editing these values, see How to Change Element Scoring in Search Results (on page 1647).

Browser Compatibility

This output format is compatible with the most recent versions of the following common browsers:

- Edge
- Internet Explorer (deprecated)
- Chrome
- Firefox
- Safari
- Opera

Important:

Due to some security restrictions in certain browsers (Google Chrome and Internet Explorer), WebHelp Classic pages loaded from the local system (through URLs of the file:///... format) may not work properly. It is recommended that you load WebHelp Classic pages in Google Chrome or Internet Explorer only from a web server (with a URL such as http://your.server.com/webhelp/index.html or http://localhost/web_pages/index.html).

Warning:

Due to some restrictions in web browsers regarding JavaScript code, the frameless version (index.html start page) of the WebHelp Classic system should only be loaded from a web server (with a URL such as http://your.server.com/webhelp/index.html or http://localhost/web_pages/index.html). When loading WebHelp Classic pages from the local file system, the frameset version (index_frames.html start page) of the WebHelp Classic system should be used instead (file:///...).

Generating WebHelp Classic Output for DocBook

The publishing process can be initiated from a transformation scenario within Oxygen XML Editor/Author or from a command-line tool outside Oxygen XML Editor/Author.

Running from Oxygen XML Editor/Author

To publish DocBook content to WebHelp Classic output from a transformation scenario inside Oxygen XML Editor/Author, use one of the following procedures, depending on whether or not you want a feedback section in your output.
WebHelp Classic Output
To publish a DocBook document as a WebHelp Classic system, follow these steps:

1. Click the Configure Transformation Scenario(s) action from the toolbar (or the Document > Transformation menu).
2. Select the DocBook WebHelp Classic scenario from the DocBook 4 or DocBook 5 section.
3. Click Apply associated.

When the DocBook WebHelp Classic transformation is complete, the output is automatically opened in your default browser.

Automating the WebHelp Classic Output for DocBook
DocBook-based WebHelp output can be generated from an automated publishing process using a command-line tool outside of Oxygen XML Editor/Author. However, to do this, you must purchase an additional Oxygen XML WebHelp license.

Related Information:
Generating WebHelp Classic Output for DocBook

Deploying the Oxygen Feedback Comments Component
You can add a comments component in your WebHelp Classic output to provide a simple and efficient way for your community to interact and offer feedback. The comments component is contributed by Oxygen Feedback, a modern comment management system that can be integrated with your WebHelp Classic output to provide a comments area at the bottom of each WebHelp page where readers can add new comments or reply to existing ones.

Oxygen Feedback includes a modern, user-friendly administration interface where you can moderate comments, manage users, view statistics, and configure settings. It is very easy to integrate and there are no requirements for installing additional software.

An add-on is also available that contributes a Feedback Comments Manager view in Oxygen XML Editor/Author where the documentation team can see all the comments added in your WebHelp output. This means they can react to user feedback by making corrections and updating the source content without leaving the application.

Adding the Feedback System to WebHelp Classic Documentation

Prerequisite
To install and manage Oxygen Feedback, you will need to obtain a license for the product. This requires that you choose a subscription plan during the installation procedure. To see the subscription plans prior to installing the product, go to: https://www.oxygenxml.com/oxygen_feedback/buy_feedback.html.

Installation Procedure
1. Log in to your Feedback account from the administration login page (https://feedback.oxygenxml.com/login). You can click on Log in with Google or Log in with Facebook to create an account using your Google or Facebook credentials, or click the Sign Up tab to create an account using your name and email address.

2. Click the Add site button to create a site configuration. If you have not already selected a subscription plan, you will be directed to a page where you can choose from several options.

3. In the Settings page, enter a Name and Description for the site configuration. There are some optional settings that can be adjusted according to your needs. For more details, see the Site Settings topic. Click Continue.

4. In the Initial version page, enter the Base URL for your website (you can add additional URLs by clicking the Add button). You can also specify an Initial version if you want it to be something other than 1.0. If you do not plan to have multiple versions, leave the version as 1.0. For more details, see the Initial Version topic. Click Continue.

5. In the Installation page, choose a site generation option:
   a. If you will generate the documentation using a transformation scenario in Oxygen XML Editor/Author, select the Oxygen XML Editor option and continue with these steps:
      i. Copy the generated HTML fragment and click Finish.
      ii. Create an XML file (for example, feedback-install.xml) with the generated installation fragment.
      iii. In Oxygen XML Editor/Author, open the Configure Transformation Scenario(s) dialog box.
      iv. Select and duplicate the DocBook WebHelp Classic scenario (on page 1355).
      v. Go to the Parameters tab.
      vi. Set the webhelp.footer.file parameter to reference the path of the fragment file created earlier.
   
   b. If you will generate the documentation using a command-line script, select the Oxygen XML WebHelp option and continue with these steps:
      i. Copy the generated HTML fragment and click Finish.
      ii. Create an XML file (for example, feedback-install.xml) with the generated installation fragment.
      iii. Use the webhelp.footer.file parameter in your command-line script to specify the path to the file you just created. For example:

         ```
         docbook.bat -Dwebhelp.footer.file=c:\path\to\feedback-install.xml
         ```

6. [Optional] If you want the Oxygen Feedback comments component to fill the entire page width, contribute a custom CSS file (use the html.stylesheet parameter to reference it) that contains the following style rule:

   ```
   div.footer {
     float: none;
   }
   ```

For more details about Oxygen Feedback, how to configure settings, moderate comments, view statistics, and much more, see the Oxygen Feedback user guide.
Deploying a PHP-based Feedback-Enabled System (Deprecated)

Note:
See Deploying the Oxygen Feedback Comments Component (on page 1627).

System Requirements
The feedback-enabled WebHelp system requires a standard server deployment. You can request this from your server administrator and it requires the following system components:

- A Web server (such as Apache Web Server)
- A MySQL or MariaDB database server
- A database admin tool (such as phpMyAdmin)
- PHP Version 5.1.6 or later

The WebHelp system supports most of the recent versions of the following browsers: Chrome, Firefox, Edge, Safari, Opera.

Create WebHelp with Feedback Database
The system needs a database to store user details and the actual feedback, and a user added to it with all privileges. After this is created, you should have the following information:

- Database name
- Username
- Password

Exactly how you create the database and user depends on your web host and your particular needs.

Example:
The following procedure uses phpMyAdmin to create a MySQL database for the feedback system and a MySQL user with privileges for that database. The feedback system uses these credentials to connect to the database.

Using phpMyAdmin to create a database:

1. Access the phpMyAdmin instance running on your server.
2. Click Databases (in the right frame) and then create a database. You can give it any name you want (for example comments).
3. Create a user with connection privileges for this database.
4. Under localhost, in the right frame, click Privileges and then at the bottom of the page click the reload the privileges link.

Deploying the WebHelp with Feedback Output
If you have a web server configured with PHP and MySQL, you can deploy the WebHelp with Feedback output by following these steps:
1. Connect to your server using an FTP client.
2. Locate the home directory (from now on, referred to as DOCUMENT_ROOT) of your server.
3. Copy the transformation output folder into the DOCUMENT_ROOT folder.
4. Rename it to something relevant (for example, myProductWebHelp).
5. Open the output folder (for example, http://[YOUR_SERVER]/myProductWebHelp/). You are redirected to the installation wizard. Proceed with the installation as follows:
   a. Verify that the prerequisites are met.
   b. Click Start Installation.
   c. Configure the Deployment Settings section. Default values are provided, but you should adjust them as needed.

   **Tip:**
   You can change some of the options later. The installation creates a config.php file in [OXYGEN_WEBHELP_INSTALL_DIR]/feedback/resources/php/config/config.php where all your configuration options are stored.

   d. Configure the MySql Database Connection Settings section. Use the information (database name, username, password) from the Create WebHelp with Feedback Database section (on page ) to fill in the appropriate text boxes.

   **Warning:**
   Selecting the Create new database structure option will overwrite any existing data in the selected database, if it already exists. Therefore, it is useful the first time you install the WebHelp with Feedback system, but you do not want to select this option on subsequent deployments.

   e. If you are using a domain (such as OpenLDAP or Active Directory) to manage users in your organization, select the Enable LDAP Authentication option. This will allow you to configure the LDAP server, which will provide information and credentials for users who will access the WebHelp system. Also, this will allow you to choose which of the domain users will have administrator privileges.

   f. If the Create new database structure option is selected, the Create WebHelp Administrator Account section becomes available. Here you can set the administrator account data. The administrator is able to moderate new posts and manage WebHelp users.

   The same database can be used to store comments for multiple WebHelp with Feedback deployments. If a topic is available in multiple deployments and there are comments associated with it, you can choose to display the comments in all deployments that share the database. To do this, select the Display comments from other products option. In the Display comments from section, a list with the deployments sharing the same database is displayed. Select the deployments allowed to share common feedback.
Note:
You can restrict the displayed comments of a product depending on its version. If you have two products that use the same database and you restrict one of them to display comments starting from a certain version, the comments of the other product are also displayed from the specified version onwards.

g. Click Next Step.
h. Remove the installation folder from your web server.

Important:
When you publish subsequent iterations of your WebHelp with Feedback system, you will not upload the /install folder in the output, as you only need it uploaded the first time you create the installation. On subsequent uploads, you will just upload the other output files.

i. In your Web browser, go to your WebHelp with Feedback system main page.

Testing Your WebHelp with Feedback System
To test your system, create a user and post a comment. Check to see if the notification emails are delivered to your email inbox.

Note:
To read debug messages generated by the system:

1. Enable JavaScript logging by doing one of the following:
   - Open the log.js file, locate the var log= new Log(Level.NONE); line, and change the logging level to: Level.INFO, Level.DEBUG, Level.WARN, or Level.ERROR.
   - Append ?log=true to the WebHelp URL.
2. Inspect the PHP and Apache server log files.

Documentation Product ID and Version
When you run a WebHelp with Feedback transformation scenario, by default you are prompted for a documentation product ID and version number. This is needed when multiple WebHelp systems are deployed on the same server. Think of your WebHelp output as a product. If you have three different WebHelp outputs, you have three different products (each with their own unique documentation product ID). This identifier is included in a configuration file so that comments are tied to a particular output (product ID and version number).

Note:
The WebHelp with Feedback installation includes a configuration option (Display comments from other products) that allows you to choose to have comments visible in other specified products.
Refreshing the Content of a Feedback-Enabled System (Deprecated)

It is common to update the content of an existing installation of a WebHelp with Feedback system on a regular basis. In this case, reinstalling the whole system is not a viable option since it might result in the loss of the comments associated with your topics. Also, reconfiguring the system every time you want to refresh it may be time consuming.

Fortunately, you can refresh just the content without losing the comments or the initial system configuration. To do so, follow these steps:

1. Execute the transformation scenario that produces the WebHelp with Feedback output directory.
2. Go to the output directory (specified in the Output tab of the transformation scenario), locate the \feedback\resources\php\config\config.php file, and delete it.
3. Locate the \feedback\install directory and delete it.
4. Copy the remaining structure of the output folder and paste it into your WebHelp with Feedback system installation directory, overwriting the existing content.

Managing Users and Comments in a Feedback-Enabled System (Deprecated)

When you installed the WebHelp with Feedback system the first time (assuming the Create new database structure option was selected), you should have been prompted to create an administrator account (or a user named administrator was created by default). As an administrator, you have access to manage comments posted in your feedback-enabled WebHelp system. You can also manage the user information (such as role, status, or notification options).

To manage comments and user information, follow these steps:

1. At the bottom of each specific topic, there is a Comments navigation bar and on the right side there is a Log in button. Click this button and log in with your administrator credentials. This gives you access to an Admin Panel button.
2. Click the Admin Panel button to display an administration page.

Figure 482. Administrative Page

3. Use this page to manage the following options:

   Delete Orphaned Comments
Allows you to delete comments that are no longer associated with a topic in your WebHelp system.

**Delete Pending Users**

Allows you to delete user accounts that you do not wish to activate.

**View All Posts**

Allows you to view all the comments that are associated with topics in your WebHelp system.

**Export Comments**

Allows you to export all posts associated with topics in your WebHelp system into an XML file.

**Set Version**

Use this action to display comments starting with a particular version.

**Manage User Information**

To edit the details for a user, click on the corresponding row. This opens a window that allows you to customize the following information associated with the user:

- **Name**
  
  The full name of the user.

- **Level**
  
  Use this field to modify the privilege level (role) for the selected user. You can choose from the following:
  
  - **User** - Regular user, able to post comments and receive e-mail notifications.
  
  - **Moderator** - In addition to the regular User rights, this type of user has access to the Admin Panel where a moderator can view, delete, export comments, and set the version of the feedback-enabled WebHelp system.
  
  - **Admin** - Full administrative privileges. Can manage WebHelp-specific settings, users, and their comments.

- **Company**
  
  The name of the organization associated with the user.

- **E-Mail**
  
  The contact email address for the user. This is also the address where the WebHelp system sends notifications.

- **WebHelp Notification**
  
  When selected, the user receives notifications when comments are posted anywhere in your feedback-enabled WebHelp system.
Reply Notification

When selected, the user receives notifications when comments are posted as a reply to one of their comments.

Page Notification

When selected, the user receives notifications when comments are posted on a topic where they previously posted a comment.

Date

The date the user registered is displayed.

Status

Use this drop-down list to change the status of the user. You can choose from the following:

- **Created** - The user is created but does not yet have any rights for the feedback-enabled WebHelp system.
- **Validated** - The user is able to use the feedback-enabled WebHelp system.
- **Suspended** - The user has no rights for the feedback-enabled WebHelp system.

**Warning:**

The key used for identifying the page a comment is attached to is the relative file path to the output page. Since the output file and folder names mirror the source, any change to the file name (or its folder) in the source will affect the comments associated with that WebHelp page. If you change the file name or path, the comment history for that topic will become orphaned (a change to the topic ID does not affect the comment history).

Customizing WebHelp Classic Output

**Oxygen XML WebHelp** provides support for customizing the **WebHelp Classic** output to suit your specific needs. The **WebHelp Classic** type of output is designed for desktop systems and features a familiar **tri-pane** layout. You can use this system to publish DocBook documents. You can also integrate a feedback system to allow your users to add comments to your output.

To change the overall appearance of the **WebHelp Classic** output, you can use the visual **WebHelp Skin Builder tool** (on page 1635), which does not require knowledge of CSS language. If you are familiar with CSS and coding, you can style your WebHelp output through your own custom stylesheets. You can also customize your output by modifying option and parameters in the transformation scenario.

This section includes topics that explain various ways to customize your WebHelp system output, such as how to improve the appearance of the Table of Contents, add logo images in the title area, integrate with social media, add custom headers and footers, and much more.
Changing the Layout and Styles

This section contains some topics that explain how to customize the layout and style of your WebHelp Classic output using custom CSS, inserting custom HTML content, and more.

WebHelp Skin Builder

The WebHelp Skin Builder is a simple, easy-to-use tool, specially designed to assist users to visually customize the look and feel of the WebHelp output. It is implemented as an online tool hosted on the Oxygen XML website and allows you to experiment with various styles and colors over a documentation sample.

To be able to use the Skin Builder, you need:

- An Internet connection and unrestricted access to Oxygen XML website.
- A late version web browser.

To start the Skin Builder, use a web browser to go to https://www.oxygenxml.com/webhelp-skin-builder.

Skin Builder Layout

The left side panel of the Skin Builder is divided into 3 sections:

- **Actions** - Contains the following two buttons:
  - **Import** - Opens an Import CSS dialog box that allows you to load a CSS stylesheet and apply it over the documentation sample.
  - **Export** - Saves all properties as a CSS file.
- **Settings** - Includes a Highlight selection option that helps you identify the areas affected by a particular element customization.
  - When hovering an item in the customizable elements menu, the affected sample area is highlighted with a dotted blue border.
  - When an item in the customizable elements menu is selected, the affected sample area is highlighted with a solid red border.
- **Customize** - Provides a series of customizable elements organized under four main categories:
  - Header
  - TOC Area
  - Vertical Splitter
  - Content

For each customizable element, you can alter properties such as background color or font face. Any alteration made in the customizable elements menu is applied in real time over the sample area.
Creating a Customization Skin

1. You can start with one of the built-in skins or a CSS stylesheet applied over the sample using the Import button.
2. Use the elements in the Customize section to set properties that modify the look of the skin. By default, all customizable elements display a single property, but you can make more visible by clicking the Add button and choosing from the available properties.

Note:
If you want to revert a particular property to its initial value, click the Reset button.

3. When you are happy with the skin customizations you have made, click the Export button. All settings will be saved in a CSS file.

Apply a Customization Skin to a DocBook to WebHelp Classic Transformation Scenario

1. Start Oxygen XML Editor.
2. Load the DocBook file you want to produce as a WebHelp output.
3. In the Parameters tab, set the webhelp.skin.css parameter to point to the previously exported CSS.
4. To customize the logo, use the following parameters: webhelp.logo.image and webhelp.logo.image.target.url.
5. Run the transformation to obtain the WebHelp output.

For more information about using the WebHelp Skin Builder, watch our video demonstration:

https://www.youtube.com/embed/32PGX–PQx0

How to Use CSS Styling to Customize WebHelp Output

The most common way to customize the look and style of your WebHelp output is to use custom CSS styling. This method can be used to make small, simple styling changes or more advanced, precise changes. To implement the styling in your WebHelp output, you simply need to create the custom CSS file and reference it in your transformation scenario or script. This custom file will be the final CSS to be applied so its content will override the styles in the other pre-existing CSS files.

Using the CSS Inspector to Identify Content for Custom CSS File

You can use your browser's CSS inspector to identify the pertinent code in the current CSS files and you can even make changes directly in the CSS inspector to test the results so that you know exactly what content to use in your custom CSS file.

In most popular browsers (such as Chrome, Firefox, and Edge), you can access the CSS inspector by using F12 or by selecting Inspect Element (or simply Inspect) from the contextual menu.
Referencing the Custom CSS Using Oxygen XML Editor/Author

To use a custom CSS to style WebHelp output and use a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Create your custom CSS file.
2. Edit the WebHelp transformation scenario and open the Parameters tab. Set the `html.stylesheet` parameter to the path of your custom CSS file.
3. Run the WebHelp transformation scenario to generate the output.

Referencing the Custom CSS Using a Script Outside of Oxygen XML Editor/Author

To use a custom CSS to style WebHelp output and use a script outside of Oxygen XML Editor/Author (on page 1626), follow this procedure:

1. Create your custom CSS file.
2. Reference your custom CSS file. Use the `html.stylesheet` parameter in your transformation script and set its value to the path of your custom CSS file.
3. Execute the transformation script.

How to Add Custom HTML Content in WebHelp Classic Output

You can add custom HTML content in the WebHelp Classic output by inserting it in a well-formed XML file that will be referenced in the transformation. This content may include references to additional JavaScript, CSS, and other types of resources, or such resources can be inserted inline within the HTML content that is inserted in the XML file.

Using Oxygen XML Editor/Author

To include custom HTML content in the WebHelp Classic output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:
1. Insert the HTML content in a well-formed XML file considering the following notes:

   - **Well-Formedness** - If the content of the file is not XML Well-formed (on page 726), (or fragments are not well-formed), the transformation will fail.

     A common use case is if you want to include several `<script>` or `<link>` elements. In this case, the XML fragment has multiple root elements and to make it well-formed, you can wrap it in an `<html>` element. This element tag will be filtered out and only its children will be copied to the output documents. Similarly, you can wrap your content in `<head>`, `<body>`, `<html/head>`, or `<html/body>` elements.

   - **Referencing Resources in the XML File** - You can include references to local resources (such as JavaScript or CSS files) by using the built-in `${oxygen-webhelp-output-dir}` macro to specify their paths relative to the output directory:

     ```html
     <html>
     <script type="text/javascript" src="${oxygen-webhelp-output-dir}/js/test.js"/>
     <link rel="stylesheet" type="text/css"
          href="${oxygen-webhelp-output-dir}/css/test.css"/>
     </html>
     ```

     To copy the referenced resources to the output directory, follow the procedure in: How to Copy Additional Resources to Output Directory (on page 1646).

   - **Inline JavaScript or CSS Content**

     **JavaScript**:

     ```javascript
     /* Include JavaScript code here. */
     
     function myFunction() {
       return true;
     }
     ```

     **CSS**:

     ```css
     /* Include CSS style rules here. */
     
     *{
       color:red
     }
     ```

     **Note:**

     If you have special characters (for example, ``, `<`) that break the well-formedness of the XML fragment, it is important to place the content inside an XML comment.
[Important] XML comment tags (both the start and end tags) must be on lines by themselves. If they are on the same line as any of the script's content, it will likely result in a JavaScript error.

```html
<script type="text/javascript">
<!--
/* Include JavaScript code here. */

function myFunction() {
    return true;
}
-->
</script>
```

2. Edit the WebHelp Classic transformation scenario.

3. Go to the Parameters tab.

4. Edit the value of the webhelp.head.script parameter and set it to reference the URL of the XML file created in step 1. Your additional content will be included at the end of the head element of your output document.

Note:
If you want to include the content in the body element, use the webhelp.body.script parameter instead.

5. Click OK to save the changes and run the transformation scenario.

Using a Script Outside of Oxygen XML Editor/Author

Important:
Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated.

To include custom HTML content in the WebHelp Classic output using a script outside of Oxygen XML Editor/Author (on page 1626), follow this procedure:
1. Insert the HTML content in a well-formed XML file considering the following notes:

- **Well-Formedness** - If the content of the file is not *XML Well-formed (on page 726)*, (or fragments are not well-formed), the transformation will fail.

A common use case is if you want to include several `<script>` or `<link>` elements. In this case, the XML fragment has multiple root elements and to make it well-formed, you can wrap it in an `<html>` element. This element tag will be filtered out and only its children will be copied to the output documents. Similarly, you can wrap your content in `<head>`, `<body>`, `<html/head>`, or `<html/body>` elements.

- **Referencing Resources in the XML File** - You can include references to local resources (such as JavaScript or CSS files) by using the built-in `${oxygen-webhelp-output-dir}` macro to specify their paths relative to the output directory:

```html
<html>
  <script type="text/javascript" src="${oxygen-webhelp-output-dir}/js/test.js"/>
  <link rel="stylesheet" type="text/css"
        href="${oxygen-webhelp-output-dir}/css/test.css" />
</html>
```

To copy the referenced resources to the output directory, follow the procedure in: How to Copy Additional Resources to Output Directory *(on page 1646)*.

- **Inline JavaScript or CSS Content**:

  **JavaScript**:

```html
<script type="text/javascript">
  /* Include JavaScript code here. */

  function myFunction() {
    return true;
  }
</script>
```

  **CSS**:

```html
<style>
  /* Include CSS style rules here. */

  *{
    color:red
  }
</style>
```

**Note:**

If you have special characters (for example, `&`, `<`) that break the well-formedness of the XML fragment, it is important to place the content inside an XML comment.
[Important] XML comment tags (both the start and end tags) must be on lines by themselves. If they are on the same line as any of the script's content, it will likely result in a JavaScript error.

```html
<script type="text/javascript">
<!--
/* Include JavaScript code here. */

function myFunction() {
    return true;
}
-->
</script>
```

2. Use the `webhelp.head.script` parameter in your transformation script and set its value to reference the URL of the XML file created in step 1. Your additional content will be included at the end of the `head` element of your output document.

Note:
If you want to include the content in the `body` element, use the `webhelp.body.script` parameter instead.

3. Execute the transformation script.

Related Information:
How to Copy Additional Resources to Output Directory (on page 1646)

How to Change Number Styles for Ordered Lists

Ordered lists (```<ol>```s) are usually numbered in XHTML output using numerals. If you want to change the numbering to alphabetical, follow these steps:

1. Define a custom `outputclass` value and set it as an attribute of the ordered list, as in the following example:

```xml
<ol outputclass="number-alpha">
    <li>A</li>
    <li>B</li>
    <li>C</li>
</ol>
```

2. Add the following code snippet in a custom CSS file:

```css
ol.number-alpha{
    list-style-type:lower-alpha;
}
```
3. Edit the WebHelp transformation scenario and open the **Parameters** tab. Set the `html.stylesheet` parameter to the path of your custom CSS file.

4. Run the transformation scenario.

**How to Change the Icons in a WebHelp Classic Table of Contents**

You can change the icons that appear in a WebHelp Classic table of contents by assigning new image files in a custom CSS file. By default, these icons are defined with the following CSS codes (the first example is the icon that appears for a collapsed menu and the second for an expanded menu):

```
.hasSubMenuClosed{
  background: url('../img/book_closed16.png') no-repeat;
  padding-left: 16px;
  cursor: pointer;
}
```

```
.hasSubMenuOpened{
  background: url('../img/book_opened16.png') no-repeat;
  padding-left: 16px;
  cursor: pointer;
}
```

**Using Oxygen XML Editor/Author**

To assign other icons and use a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Create a custom CSS file that assigns your desired icons to the `.hasSubMenuClosed` and `.hasSubMenuOpened` properties.

```
.hasSubMenuClosed{
  background: url('TOC-my-closed-button.png') no-repeat;
}
```

```
.hasSubMenuOpened{
  background: url('TOC-my-opened-button.png') no-repeat;
}
```

2. It is recommended that you store the image files in the same directory as the default icons (`/OXYGEN_INSTALL_DIR/frameworks/docbook/xsl/com.oxygenxml.webhelp.classic/oxygen-webhelp/resources/img`).

3. Edit the WebHelp transformation scenario and open the **Parameters** tab. Set the `html.stylesheet` parameter to the path of your custom CSS file.

4. Run the WebHelp transformation scenario to generate the output.
Using a Script Outside of Oxygen XML Editor/Author

Important:

Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated.

To assign other icons and use a script outside of Oxygen XML Editor/Author (on page 1626), follow this procedure:

1. Create a custom CSS file that assigns your desired icons to the .hasSubMenuClosed and .hasSubMenuOpened properties.

   ```css
   .hasSubMenuClosed{
     background: url('TOC-my-closed-button.png') no-repeat;
   }
   
   .hasSubMenuOpened{
     background: url('TOC-my-opened-button.png') no-repeat;
   }
   ```

2. It is recommended that you store the image files in the same directory as the default icons (DocBook XSL directory)\com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\img\).

3. Reference your custom CSS file. Use the html.stylesheet parameter in your transformation script and set its value to the path of your custom CSS file.

4. Execute the transformation script.

How to Customize the Appearance of Selected Items in the Table of Contents

The appearance of selected items in the table of contents of WebHelp Classic output can be enhanced.

For example, to highlight the background of the selected item, follow these steps:

1. Locate the toc.css file in the following directory: DocBook XSL directory)\com.oxygenxml.webhelp.classic\oxygen-webhelp\resources\css.

2. Edit that CSS file, find the menuItemSelected class, and change the value of the background property.

3. Run the transformation.
Note:
You can also overwrite the same value from your own custom CSS and then specify the path to your CSS in the transformation scenario by using the `html.stylesheet` parameter and set its value to the path of your custom CSS file.

Adding Graphics and Media Resources
This section contains topics that explain how to add media resources to the published WebHelp Class output or to the output directory.

How to Add a Favicon in WebHelp Systems
You can add a custom favicon to your WebHelp output by simply using a parameter in the transformation scenario to point to your favicon image. This is available for DocBook WebHelp output using the WebHelp Classic transformation.

Using Oxygen XML Editor/Author
To add a favicon to your WebHelp output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Edit the WebHelp transformation scenario and open the Parameters tab.
2. Locate the `webhelp.favicon` parameter and enter the file path that points to the image that will be used as the favicon.
3. Run the transformation scenario.

Result: Browsers that provide favicon support will display the favicon (typically in the browser's address bar, in the list of bookmarks, and in the history).

Using a Script Outside of Oxygen XML Editor/Author

Important:
Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated.

To add a favicon to your WebHelp output using a script outside of Oxygen XML Editor/Author, follow this procedure:
1. Specify the file path that points to the image that will be used as the **favicon** using the `webhelp.favicon` parameter.
2. Execute the transformation script.

**Result:** Browsers that provide **favicon** support will display the **favicon** (typically in the browser's address bar, in the list of bookmarks, and in the history).

### How to Add a Logo Image in the Title Area

You can customize **WebHelp Classic** output to include a logo in the title area. It will be displayed before the publication title. You can also specify a URL that can be used to send users to a specific website when they click the logo image.

This customization can be done using a transformation scenario from within **Oxygen XML Editor/Author** or using a command-line script outside of **Oxygen XML Editor/Author**.

#### Using **Oxygen XML Editor/Author**

To add a logo in the title area of your WebHelp output using a transformation scenario from within **Oxygen XML Editor/Author**, follow this procedure:

1. Edit a **WebHelp Classic** transformation scenario, then open the **Parameters** tab.
2. Specify the path to your logo in the `webhelp.logo.image` parameter.
3. If you also want to add a link to your website when you click the logo image, set the URL in the `webhelp.logo.image.target.url` parameter.
4. Run the transformation scenario.

#### Using a Script Outside of **Oxygen XML Editor/Author**

**Important:**

Running WebHelp transformations from a script outside of **Oxygen XML Editor/Author** requires an additional license and some additional setup:

- You must have a valid license for the **Oxygen XML WebHelp Plugin** ([https://www.oxygenxml.com/buy_webhelp.html](https://www.oxygenxml.com/buy_webhelp.html)).
- The **Oxygen XML WebHelp Plugin** must be installed and integrated.

To add a logo in the title area of your WebHelp output using a script outside of **Oxygen XML Editor/Author**, follow this procedure:

1. Specify the path to your logo using the `webhelp.logo.image` parameter.
2. If you also want to add a link to your website when you click the logo image, set the URL using the `webhelp.logo.image.target.url` parameter.
3. Execute the transformation script.
How to Add Videos in DocBook WebHelp Classic Output

You can insert references to videos in your DocBook topics and then publish them to WebHelp Classic output. The videos can be played directly in all HTML5-based outputs, including WebHelp systems.

To add videos in the WebHelp Classic output generated from DocBook documents, follow these steps:

1. Edit the DocBook document and reference the video using a `<mediaobject>` element, as in the following example:

   ```xml
   <mediaobject>
     <videoobject>
       <videodata fileref="http://www.youtube.com/watch/v/VideoName"/>
     </videoobject>
   </mediaobject>
   ```

2. Apply a WebHelp transformation scenario to obtain the output.

How to Copy Additional Resources to Output Directory

You can copy additional resources (such as JavaScript, CSS or other resources) to the output directory of a WebHelp system by using the `webhelp.custom.resources` parameter.

Using Oxygen XML Editor/Author

To copy additional resources to the output directory using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Place all your resources in the same directory.
2. Edit the WebHelp transformation scenario, then open the Parameters tab.
3. Edit the value for the `webhelp.custom.resources` parameter and set it to the absolute path of the directory in step 1.
4. Click OK to save the changes to the transformation scenario.
5. Run the transformation scenario.

Result: All files from the new directory will be copied to the root of the WebHelp output directory.

Using a Script Outside of Oxygen XML Editor/Author

⚠️ Important:

Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated.
To copy additional resources to the output directory using a script outside of Oxygen XML Editor/Author (on page 1626), follow this procedure:

1. Place all your resources in the same directory.
2. Specify the absolute path to that directory using the webhelp.custom.resources parameter.
3. Execute the transformation script.

**Result:** All files from the new directory will be copied to the root of the WebHelp output directory.

### How to Add MathML Equations in WebHelp Output

Currently, only Firefox can render MathML equations embedded in the HTML code. MathJax is a solution to properly view MathML equations embedded in HTML content in a variety of browsers.

If you have DocBook content that has embedded MathML equations and you want to properly view the equations in published HTML output types (such as WebHelp), you need to add a reference to the MathJax script in the head element of all HTML files that have the equation embedded.

For example:

```html
<script type="text/javascript" src="https://cdnjs.cloudflare.com/ajax/libs/mathjax/2.7.1/MathJax.js?config=TeX-AMS-MML_HTMLorMML"

> </script>
```

**Result:** The equation should now be properly rendered in the WebHelp output for other browsers.

### Searching the Output

This section contains topics that explain how to customize some of the search features in WebHelp Classic output.

### How to Change Element Scoring in Search Results

The WebHelp Search feature is enhanced with a rating mechanism that computes scores for every page that matches the search criteria. HTML tag elements are assigned a scoring value and these values are evaluated for the search results. The WebHelp directory includes a properties file that defines the scoring values for tag elements and this file can be edited to customize the values according to your needs.

To edit the scoring values of HTML tag element for enhancing WebHelp search results, follow these steps:

1. Edit the scoring properties file for DocBook WebHelp systems ([DocBook XSL directory] \com.oxygenxml.webhelp.classic\indexer\scoring.properties). The properties file includes instructions and examples to help you with your customization.

The values that can be edited in the scoring.properties file:
2. Save your changes to the file.
3. Re-run your WebHelp transformation.

How to Index Japanese Content in WebHelp Classic

To optimize the indexing of Japanese content in WebHelp pages, the Lucene Kuromoji Japanese analyzer can be used. This analyzer is included in the Oxygen XML Editor/Author installation kit.

Using Oxygen XML Editor/Author

To activate the Japanese indexing in your WebHelp output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Set the language for your content to Japanese. Edit a DocBook to WebHelp transformation scenario and in the Parameters tab, set the value of the l10n.gentext.default.language parameter to ja.
2. Run the WebHelp transformation scenario to generate the output.

Using a Script Outside of Oxygen XML Editor/Author

Important:
Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:
You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).

The Oxygen XML WebHelp Plugin must be installed and integrated.

To activate the Japanese indexing in your WebHelp output using a script outside of Oxygen XML Editor/Author, follow this procedure:

1. Set the language for your content to Japanese. Use the l10n.gentext.default.language parameter in your transformation script and set its value to ja.
2. Execute the transformation script.

Related Information:
How to Localize the Interface of DocBook to WebHelp Classic Output (on page 1649)

Localization in WebHelp Classic Output

This section contains topics that explain the localization support for DocBook WebHelp Classic transformations.

How to Localize the Interface of DocBook to WebHelp Classic Output

Static labels that are used in the WebHelp output are kept in translation files in the [DocBook XSL directory]/com.oxygenxml.webhelp.classic/oxygen-webhelp/resources/localization folder. Translation files have the strings-lang1-lang2.xml name format, where lang1 and lang2 are ISO language codes. For example, the US English text is kept in the strings-en-us.xml file.

To localize the interface of the WebHelp output for DocBook transformations, follow these steps:

1. Look for the strings-[lang1]-[lang2].xml file in [DocBook XSL directory]/com.oxygenxml.webhelp.classic/oxygen-webhelp/resources/localization directory (for example, the Canadian French file would be: strings-fr-ca.xml). If it does not exist, create one starting from the strings-en-us.xml file.
2. Translate all the labels from the above language file. Labels are stored in XML elements that have the following format: <str name="Label name">Caption</str>.
3. Make sure that the new XML file that you created in the previous two steps is listed in the file [DocBook XSL directory]/com.oxygenxml.webhelp.classic/oxygen-webhelp/resources/localization/strings.xml. For example, a Canadian French file would be listed as: <lang xml:lang="fr-ca" filename="strings-fr-ca.xml">.
4. Edit any of the DocBook to WebHelp transformation scenarios (with or without feedback) and set the l10n.gentext.default.language parameter to the code of the language you want to localize (for example, fr-ca for Canadian French).
5. Run the transformation scenario to produce the WebHelp output.
How to Activate Support for Right-to-Left (RTL) Languages

To activate support for RTL (right-to-left) languages in WebHelp output, set the `@xml:lang` attribute with the corresponding attribute value:

- `ar-eg` - Arabic
- `he-il` - Hebrew
- `ur-pk` - Urdu

Integrating Social Media and Google Tools in the WebHelp Classic Output

Oxygen XML Editor includes support for integrating some of the most popular social media sites in WebHelp output.

How to Add a Facebook Like Button in WebHelp Classic Output

It is possible to integrate Facebook™ into your WebHelp Classic output and the widget will appear in the footer sections of your WebHelp page.

Using Oxygen XML Editor/Author

To add a Facebook™ Like widget to your WebHelp output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Go to the Facebook Developers website.
2. Fill-in the displayed form, then click the Get Code button.
3. Copy the two code snippets and paste them into a `<div>` element inside an XML file called `facebook-widget.xml`. Make sure you follow these rules:
   - The file must be well-formed.
   - The code for each `<script>` element must be included in an XML comment.
   - The start and end tags for the XML comment must be on a separate line.

The content of the XML file should look like this:

```xml
<div id="facebook">
  <div id="fb-root"/>
  <script>
    <!--
    (function(d, s, id) {
      var js, fjs = d.getElementsByTagName(s)[0];
      if (d.getElementById(id)) return;
      js = d.createElement(s); js.id = id;
      js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
      fjs.parentNode.insertBefore(js, fjs);
    }(d, s, 'facebook'));
  </script>
</div>
```
4. In Oxygen XML Editor/Author, click the Configure Transformation Scenario(s) action from the toolbar (or the Document > Transformation menu).

5. Select an existing WebHelp Classic transformation scenario (depending on your needs, it may be with or without feedback) and click the Duplicate button to open the Edit Scenario dialog box.

6. Switch to the Parameters tab and edit the webhelp.footer.file parameter to reference the facebook-widget.xml file that you created earlier.

7. Click Ok and run the transformation scenario.

Using a Script Outside of Oxygen XML Editor/Author

Important:
Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated.

To add a Facebook™ Like widget to your WebHelp output using a script outside of Oxygen XML Editor/Author (on page 1626), follow this procedure:

1. Go to the Facebook Developers website.
2. Fill-in the displayed form, then click the Get Code button.
3. Copy the two code snippets and paste them into a <div> element inside an XML file called facebook-widget.xml. Make sure you follow these rules:
   - The file must be well-formed.
   - The code for each <script> element must be included in an XML comment.
   - The start and end tags for the XML comment must be on a separate line.

   The content of the XML file should look like this:

```xml
<div id="facebook">
    <div id="fb-root"/>
    <script>
        <!--
        (function(d, s, id) {
            var js, fjs = d.getElementsByTagName(s)[0];
```
4. Use the `webhelp.footer.file` parameter in your transformation script and set its value to reference the `facebook-widget.xml` file that you created earlier.

5. Execute the transformation script.

How to Add Tweet Button in WebHelp Classic Output

It is possible to integrate Twitter into your WebHelp Classic output and the widget will appear in the footer section of your WebHelp page.

Using Oxygen XML Editor/Author

To add a Twitter™ Tweet widget to your WebHelp Classic output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Go to the Tweet button generator page.
2. Fill in the displayed form. The Preview and code area displays the code that you will need.
3. Copy the code snippet displayed in the Preview and code area and paste it into a `<div>` element inside an XML file called `tweet-button.xml`. Make sure you follow these rules:
   - The file must be well-formed.
   - The code for each `<script>` element must be included in an XML comment.
   - The start and end tags for the XML comment must be on a separate line.

The content of the XML file should look like this:

```xml
<div id="twitter">
  <a href="https://twitter.com/share" class="twitter-share-button">Tweet</a>
  <script>
    !--
    function (d, s, id) {
      var js, fjs = d.getElementsByTagName(s)[0], p = /^http:/i.test(d.location) ? 'https': 'http';
      if (!d.getElementById(id)) {
        js = d.createElement(s);
        js.id = id;
        js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
        fjs.parentNode.insertBefore(js, fjs);
      }
      (document, 'script', 'facebook-jssdk');
    }
    -->
  </script>
</div>
```
4. In Oxygen XML Editor/Author, click the ⌁ Configure Transformation Scenario(s) action from the toolbar (or the Document > Transformation menu).

5. Select an existing WebHelp transformation scenario (depending on your needs, it may be with or without feedback) and click the Duplicate button to open the Edit Scenario dialog box.

6. Switch to the Parameters tab and edit the webhelp.footer.file parameter to reference the tweet-button.xml file that you created earlier.

7. Click Ok and run the transformation scenario.

Using a Script Outside of Oxygen XML Editor/Author

⚠️ Important:
Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated.

To add a Twitter™ Tweet widget to your WebHelp Classic output using a script outside of Oxygen XML Editor/Author (on page 1626), follow this procedure:

1. Go to the Tweet button generator page.
2. Fill in the displayed form. The Preview and code area displays the code that you will need.
3. Copy the code snippet displayed in the Preview and code area and paste it into a `<div>` element inside an XML file called tweet-button.xml. Make sure you follow these rules:
   - The file must be well-formed.
   - The code for each `<script>` element must be included in an XML comment.
   - The start and end tags for the XML comment must be on a separate line.

The content of the XML file should look like this:

```xml
<div id="twitter">
  <a href="https://twitter.com/share" class="twitter-share-button">Tweet</a>
</div>
```
4. Use the \texttt{webhelp.footer.file} parameter in your transformation script and set its value to reference the \texttt{tweet-button.xml} file that you created earlier.

5. Execute the transformation script.

How to Integrate Google Analytics in WebHelp Classic Output

You can use \textit{Google Analytics} to track and report site data for your \textit{WebHelp Classic} output.

Using Oxygen XML Editor/Author

To integrate \textit{Google Analytics} into your WebHelp Classic output using a transformation scenario from within \textit{Oxygen XML Editor/Author}, follow this procedure:

1. Create a new \textit{Google Analytics account} (if you do not already have one) and log on.
2. Choose the Analytics solution that best fits the needs of your website.
3. Follow the on-screen instructions to obtain a \textit{Tracking Code} that contains your \textit{Tracking ID}. A \textit{Tracking Code} looks like this:

\begin{verbatim}
<script>
(function(i,s,o,g,r,a,m){i['GoogleAnalyticsObject']=r;i[r]=i[r]||function(){
(i[r].q=i[r].q||[]).push(arguments)},i[r].l=1*new Date();a=s.createElement(o),
m=s.getElementsByTagName(o)[0];a.async=1;a.src=g;m.parentNode.insertBefore(a,m)
}(window,document,'script','//www.google-analytics.com/analytics.js','ga'));

ga('create', 'UA-XXXXXXXX-X', 'auto');
ga('send', 'pageview');
</script>
\end{verbatim}
4. Save the Tracking Code (obtained in the previous step) in a new XML file called `googleAnalytics.xml`. Note that the file should only contain the tracking code.

5. In Oxygen XML Editor/Author, click the [Configure Transformation Scenario(s)] action from the toolbar (or the Document > Transformation menu).

6. Select an existing WebHelp transformation scenario (depending on your needs, it may be with or without feedback) and click the Duplicate button to open the Edit Scenario dialog box.

7. Switch to the Parameters tab and edit the `webhelp.footer.file` parameter to reference the `googleAnalytics.html` file that you created earlier.

8. Click OK and run the transformation scenario.

**Using a Script Outside of Oxygen XML Editor/Author**

**Important:**

Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated.

To integrate Google Analytics into your WebHelp Classic output using a script outside of Oxygen XML Editor/Author (on page 1626), follow this procedure:

1. Create a new Google Analytics account (if you do not already have one) and log on.

2. Choose the Analytics solution that best fits the needs of your website.

3. Follow the on-screen instructions to obtain a Tracking Code that contains your Tracking ID. A Tracking Code looks like this:

```xml
<script>
  (function(i,s,o,r,a,m){i['GoogleAnalyticsObject']=r;i[r]=i[r]||function(){
  (i[r].q=i[r].q||[]).push(arguments)},i[r].l=1*new Date();a=s.createElement(o),
m=s.getElementsByTagName(o)[0];a.async=1;a.src=g;m.parentNode.insertBefore(a,m)
 })(window,document,'script','//www.google-analytics.com/analytics.js','ga');

  ga('create', 'UA-XXXXXXXX-X', 'auto');
  ga('send', 'pageview');
</script>
```

4. Save the Tracking Code (obtained in the previous step) in a new XML file called `googleAnalytics.xml`. Note that the file should only contain the tracking code.

5. Use the `webhelp.footer.file` parameter in your transformation script and set its value to reference the `googleAnalytics.html` file that you created earlier.

6. Execute the transformation script.
How to Integrate Google Search in WebHelp Classic Output

It is possible to integrate the Google Search Engine into your WebHelp Classic output and you can specify where you want the results to appear in your WebHelp page.

Using Oxygen XML Editor/Author

To integrate the Google Search Engine into your WebHelp output using a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Go to the Google Custom Search Engine page using your Google account.
2. Select the Create a custom search engine button.
3. Follow the on-screen instructions to create a search engine for your site. At the end of this process you should obtain a code snippet that looks like this:

   ```html
   <script>
   (function() {
   var cx = '000888210889775888983:8mn4k_mf-yg';
   var gcse = document.createElement('script');
   gcse.type = 'text/javascript';
   gcse.async = true;
   var s = document.getElementsByTagName('script')[0];
   s.parentNode.insertBefore(gcse, s);
   })();
   </script>
   ```

4. Save the script into a well-formed HTML file called googlecse.html.
5. In Oxygen XML Editor/Author, click the Configure Transformation Scenario(s) action from the toolbar (or the Document > Transformation menu).
6. Select an existing WebHelp Responsive transformation scenario (depending on your needs, it may be with or without feedback) and click the Duplicate button to open the Edit Scenario dialog box.
7. Switch to the Parameters tab and edit the webhelp.google.search.script parameter to reference the googlecse.html file that you created earlier.
8. You can also use the webhelp.google.search.results parameter to choose where to display the search results.
   a. Create an HTML file with the following content:

   ```html
   <div class="gcse-searchresults-only" data-autoSearchOnLoad="true" data-queryParameterName="searchQuery"></div>
   ```
   (you must use the HTML5 version for the GCSE). For more information about other supported attributes, see Google Custom Search: Supported Attributes.
b. Set the value of the `webhelp.google.search.results` parameter to the file path of the file you just created. If this parameter is not specified, the following code is used:

```html
<div class="gcse-searchresults-only" data-autoSearchOnLoad="true" data-queryParameterName="searchQuery"></div>
```

9. Click **Ok** and run the transformation scenario.

### Using a Script Outside of Oxygen XML Editor/Author

**Important:**

Running WebHelp transformations from a script outside of **Oxygen XML Editor/Author** requires an additional license and some additional setup:

- You must have a valid license for the **Oxygen XML WebHelp Plugin** ([https://www.oxygenxml.com/buy_webhelp.html](https://www.oxygenxml.com/buy_webhelp.html)).
- The **Oxygen XML WebHelp Plugin** must be installed and integrated.

To integrate the **Google Search Engine** into your WebHelp Classic output using a script outside of **Oxygen XML Editor/Author** (on page 1626), follow this procedure:

1. Go to the **Google Custom Search Engine page** using your Google account.
2. Select the **Create a custom search engine** button.
3. Follow the on-screen instructions to create a search engine for your site. At the end of this process you should obtain a code snippet that looks like this:

```javascript
(function () {
    var cx = '00088821088977588983:8mn4x_mf-yg';
    var gcse = document.createElement('script');
    gcse.type = 'text/javascript';
    gcse.async = true;
    var s = document.getElementsByTagName('script')[0];
    s.parentNode.insertBefore(gcse, s);
})();
```

4. Save the script into a well-formed HTML file called `googlecse.html`.
5. Use the `webhelp.google.search.script` parameter in your transformation script and set its value to reference the `googlecse.html` file that you created earlier.
6. You can also use the `webhelp.google.search.results` parameter to choose where to display the search results.
   a. Create an HTML file with the following content:
      ```html
      <div class="gcse-searchresults-only" data-autoSearchOnLoad="true" data-queryParameterName="searchQuery"></div> (you must use the HTML5 version for the GCSE).
      For more information about other supported attributes, see Google Custom Search: Supported Attributes.
      b. Set the value of the `webhelp.google.search.results` parameter to the file path of the file you just created. If this parameter is not specified, the following code is used:
      ```html
      <div class="gcse-searchresults-only" data-autoSearchOnLoad="true" data-queryParameterName="searchQuery"></div>.
      ```
    7. Execute the transformation script.

Miscellaneous Customization Topics

This section contains miscellaneous topics about how to customize the WebHelp Classic output.

How to Disable Caching in WebHelp Classic Output

In cases where a set of WebHelp Classic pages need to be updated on a regular basis to deliver the latest version of the documentation, the WebHelp pages should always be requested from the server upon reloading it in a Web browser on the client side, rather than re-using an outdated cached version in the browser.

To disable caching in WebHelp Classic output, follow this procedure:

1. Edit the following file:
   ```plaintext
   [OXYGEN_INSTALL_DIR]\frameworks\docbook\xsl\com.oxygenxml.webhelp.classic\xsl\createMainFiles.xsl.
   ```
2. Locate the following template in the XSL file:
   ```xml
   <xsl:template name="create-toc-common-file">
   ```
   and add the following code snippet:

   ```html
   <meta http-equiv="Pragma" content="no-cache" />
   <meta http-equiv="Expires" content="-1"/>
   ```

   **Note:**
   The code should look like this:

   ```html
   <html>
   <head>
   <xsl:if test="$withFrames">
   <base target="contentwin"/>
   </xsl:if>
   <meta http-equiv="Content-Type" content="text/html; charset=utf-8"/>
   <!-- Disable caching of WebHelp pages in web browser. -->
   <meta http-equiv="Pragma" content="no-cache" />
   <meta http-equiv="Expires" content="-1"/>
   ....
   ```
3. Save your changes to the file.
4. Re-run your WebHelp transformation scenario.

How to Publish WebHelp Classic Output on a SharePoint Site

Since WebHelp output must be published locally, on the same machine where the WebHelp process is running, to publish your files directly to a SharePoint library you need to map a network drive to connect to SharePoint and change your file extensions to .aspx, as described in the steps below.

Using Oxygen XML Editor/Author

To publish WebHelp Classic output on a SharePoint site and use a transformation scenario from within Oxygen XML Editor/Author, follow this procedure:

1. Map a network drive to connect to your SharePoint library. For more information, see: https://support.microsoft.com/en-us/kb/2616712.
2. Edit the WebHelp transformation scenario and open the Parameters tab. Set the html.ext parameter to .aspx.
3. Run the WebHelp transformation scenario to generate the output.

Using a Script Outside of Oxygen XML Editor/Author

Important:
Running WebHelp transformations from a script outside of Oxygen XML Editor/Author requires an additional license and some additional setup:

- You must have a valid license for the Oxygen XML WebHelp Plugin (https://www.oxygenxml.com/buy_webhelp.html).
- The Oxygen XML WebHelp Plugin must be installed and integrated.

To publish WebHelp Classic output on a SharePoint site and use a script outside of Oxygen XML Editor/Author (on page 1626), follow this procedure:

1. Map a network drive to connect to your SharePoint library. For more information, see: https://support.microsoft.com/en-us/kb/2616712.
2. Use the html.ext parameter in your transformation script and set its value to .aspx.
3. Execute the transformation script.

DITA to PDF Output Customization

Oxygen XML Editor provides support for generating PDF output using transformation scenarios for certain types of documents (for example, DITA, DocBook, TEI, and JATS) and Oxygen XML Editor supports several
different types of processors. There are numerous ways to customize the published output to fit your specific needs.

**CSS-based DITA to PDF Customization**

Oxygen XML Editor comes bundled with a **DITA-OT CSS-based PDF Publishing Plugin** for transforming DITA maps or single topics to PDF, while styling the resulting output using CSS. It is the base of two types of transformation scenarios:

**DITA Map Transformation Type (DITA Map PDF - based on HTML5 & CSS)**

This transformation type converts DITA maps to PDF using a CSS-based processing engine and HTML5 as an intermediate format. For this transformation, the `pdf-css-html5` transtype is used. Because the structure of the HTML5 intermediate format resembles the one used in WebHelp output, it is possible to reuse parts of your CSS file you developed for a WebHelp customization.

**Single Topic Transformation Type (DITA PDF - based on HTML5 & CSS)**

This transformation type converts a single DITA topic to PDF using a CSS-based processing engine and HTML5 as an intermediate format. For this transformation, the `pdf-css-html5-single-topic` transtype is used. This transformation is derived from the DITA Map PDF - based on HTML5 & CSS transformation type but applies on a single topic.

**Related Information:**
- DITA Map PDF - based on HTML5 & CSS Transformation *(on page 1347)*
- DITA PDF - based on HTML5 & CSS Transformation *(on page 2864)*

**Overview**

This section contains topics that provide a basic overview of the **DITA-OT CSS-based PDF Publishing Plugin**, technical details, and some additional resources to help you with your customizations.

**Tip:**
For more information and some tips in regard to publishing DITA documents to PDF using CSS, watch our Webinars: Transforming DITA documents to PDF using CSS, Part 1 – Page Definitions, Cover Page and PDF Metadata and Transforming XML and HTML documents to PDF using CSS, Part 2 – Lists, Tables and Images.

**Resources**

Customizing the PDF output requires knowledge of CSS, Paged Media, and DITA. The following list provides some resources to help you:

• **CSS Paged Media** - This is a part of the CSS specification that shows how to organize your publication in pages, how to use headers/footers, page breaks, and other page-related issues. The specification is available here: [https://www.w3.org/TR/CSS2/page.html](https://www.w3.org/TR/CSS2/page.html). Also, there is a set of hands-on examples in the Oxygen PDF Chemistry user guide: [https://www.oxygenxml.com/doc/ug-chemistry/](https://www.oxygenxml.com/doc/ug-chemistry/).

• **DITA** - You will need a basic understanding of DITA elements, attributes, and structure. A good resource is *The DITA Style Guide - Best Practices for Authors* by Tony Self. It is available at: [www.ditastyle.com](http://www.ditastyle.com) and: [https://www.oxygenxml.com/dita/styleguide/webhelp-feedback/Artefact/c_DITA_Authoring_Concepts.html](https://www.oxygenxml.com/dita/styleguide/webhelp-feedback/Artefact/c_DITA_Authoring_Concepts.html). You can find all the details for every DITA element on OASIS website: [http://docs.oasis-open.org/dita/v1.2/os/spec/DITA1.2-spec.html](http://docs.oasis-open.org/dita/v1.2/os/spec/DITA1.2-spec.html).

DITA-OT DAY 2017: Using CSS to Style PDF Output

**Supported Processors**

The **DITA-OT CSS-based PDF Publishing Plugin** supports the following CSS processors:

• **Oxygen PDF Chemistry** - This is recommended processor because the built-in CSS files were fine-tuned for this processor. For example, metadata extraction *(on page 1725)* only functions with this processor. If the plugin is started from an Oxygen XML Editor/Author distribution, a Chemistry installation is not needed.

**Technical Details**

It has the following transformation types:
- pdf-css-html5 *(DITA Map PDF - based on HTML5 & CSS transformation)* - CSS styling applied over a merged HTML5 document (the merged DITA map converted to HTML5).
- pdf-css-html5-single-topic *(DITA PDF - based on HTML5 & CSS transformation)* - CSS styling applied over a merged HTML5 document (the merged DITA topic converted to HTML5).

This is how it works:

1. It expands all the topic references into a temporary clone of the map, resolving keys and reused content. For the single topic transformation the result is a file with the keys and content resolved.
2. It generates a structure for the table of contents and index. The result is a merged map with all the references resolved. When transforming a single topic, the TOC and Index are not added to the merged file, this includes only the contents of the topic.

3. Then it post-processes the merged map. It fixes some of the structure in the TOC and index, moves the frontmatter and backmatter to the correct places, transforms any change tracking and review processing instructions to elements that can be styled later, etc. The result is another merged map.
Note:
In the single topic transformation type (DITA PDF - based on HTML5 & CSS), these steps are simplified.

4. The merged DITA map or topic is transformed to a single HTML5 file.

The generated HTML elements copy the class attributes from the original DITA elements. In this way you can either use selectors that were designed for DITA structure, or ones for the HTML structure - see: Reusing the Styling for WebHelp and PDF Output (on page 1809). This step can apply customization XSLT extension points (on page 1683) that change the default processing.

5. In the last phase, it uses a collection of CSS files to style the merged map. References to the CSS files are collected from the publishing template (on page 1673).
Increasing Memory Allocation for Java

If you are working with a large project with extensive metadata or key references, you may need to increase the amount of memory that is allocated to the Java process that performs the publishing.

When the Transformation is Started from Oxygen

To alter the memory allocation setting from the transformation scenario, follow these steps:

1. Open the Configure Transformation Scenario(s) dialog box.
2. Select your transformation scenario, then click Edit.
3. Go to the Advanced tab.
4. Locate the JVM Arguments and increase the default value. For instance, to set 2 gigabytes as the maximum amount of memory, you can use: -Xmx2g. If you do not specify the -Xmx value in this field, by default, the application will use a maximum of 512 megabytes when used with a 32-bit Java Virtual Machine and one gigabyte with a 64-bit Java Virtual Machine.

Note:
This memory setting is used by both the DITA-OT process and the Chemistry CSS processor.

When the Transformation is Started from the Command Line

There can be two situations where an out of memory error can be triggered:

- From the DITA-OT basic processing (the preparation of the merged XML document).
- From the Chemistry PDF CSS processor (the transformation of the merged XML document to PDF).

To solve both of them, you can change the value of the ANT_OPTS environment variable from a command line for a specific session.

Example: To increase the JVM memory allocation to 1024 MB for a specific session, issue the following command from a command prompt (depending on your operating system):

- **Windows**
  
  ```
  set ANT_OPTS=%ANT_OPTS% -Xmx1024M
  ```

- **Linux/macOS X**
  
  ```
  export ANT_OPTS=$ANT_OPTS -Xmx1024M
  ```

Tip:
To persistently change the memory allocation, change the value allocated to the ANT_OPTS environment variable on your system.

If the Chemistry PDF CSS processor fails with an Out Of Memory Error, try adding the baseJVMArgLine parameter to the DITA-OT command line. For example:

```
-DbaseJVMArgLine=-Xmx984m
```
### Transformation Parameters

This list includes the most common customization parameters that are available in the **DITA Map PDF - based on HTML5 & CSS** transformation scenario. Other standard DITA-OT parameters were omitted for clarity, but they are still supported.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Allowed Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>args.allow.external.coderefs</td>
<td>Enables the inclusion of code files that are located outside the DITA map folder hierarchy, referenced using the DITA <code>&lt;coderef&gt;</code> element. Allowed values are <strong>yes</strong> or <strong>no</strong> (default).</td>
<td></td>
</tr>
<tr>
<td>args.chapter.layout</td>
<td>Specifies whether chapter-level TOCs are generated for bookmaps. When set to <strong>MINITOC</strong>, a small section with links is added at the beginning of each chapter. The default is <strong>BASIC</strong>. For details, see: <em>Table of Contents on a Page (Mini TOC)</em> <em>(on page 1763)</em>. Allowed values:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>BASIC</strong> - No chapter TOC is created.</td>
<td>• <strong>MINITOC</strong> - A chapter-level TOC will be generated.</td>
</tr>
<tr>
<td></td>
<td>• <strong>MINITOC-BOTTOM-LINKS</strong> - A chapter-level TOC will be generated, with the links under the chapter description.</td>
<td></td>
</tr>
<tr>
<td>args.css</td>
<td>You can use this to specify a list of CSS URLs to be used in addition to those specified in the <strong>dita.css.list</strong> parameter or publishing template. The files must have URL syntax and be separated using semicolons.</td>
<td></td>
</tr>
<tr>
<td>args.css.param.*</td>
<td>You can use this parameter pattern to set attributes on the root of the merged map. This means you can activate specific CSS rules from your custom CSS using custom attributes. For examples, see: <em>Styling Through Custom Parameters</em> <em>(on page 1833)</em>.</td>
<td></td>
</tr>
<tr>
<td>args.css.param.numbering</td>
<td>You can use this parameter to change the numbering of the first-level topics (chapters) and nested topics. Allowed values:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>shallow</strong> - Only the topics from the first level will be numbered (chapters). This is the default.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>deep</strong> - All the topics from the map will be numbered (nested topics up to level 3).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>deep-chapter-scope</strong> - Similar to deep, but in addition, the page numbers, figures, and table numbers are reset at the start of each first-level topic (chapter). The table and figure titles (and the links to them) are prefixed with the chapter numbers. The generic cross reference links contain both the first-level topic (chapter) numbers and the page numbers to avoid ambiguity.</td>
<td></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>--------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td><code>args.css.param.numbering-sections</code></td>
<td>Controls whether or not the sections are included in the table of contents. When set to <strong>yes</strong> (sections are included), they are numbered according the numbering scheme set by the <code>args.css.param.numbering</code> parameter.</td>
<td></td>
</tr>
<tr>
<td><code>args.css.param.show-on-page-lbl</code></td>
<td>Controls whether or not the links will have an <strong>on page NN</strong> label after them. This parameter has different defaults, depending on the transformation type. For map transformations (<strong>pdf-css-html5</strong> trans type), the default is <strong>yes</strong>. For topic transformations (<strong>pdf-css-html5-single-topic</strong> trans type), the default is <strong>no</strong>.</td>
<td></td>
</tr>
<tr>
<td><code>args.css.param.title.layout</code></td>
<td>Changes the structure of the title element. In the output, the title area consists of two parts: one is the number of the chapter (and optionally, the sections number), and one is the title text. This parameter allows a switch between normal text flow (in-line flow) and a table layout where the number is placed in one cell and the text in the other (to avoid wrapping text under the chapter number).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>normal</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>table</strong> (avoid wrapping text under counter)</td>
<td></td>
</tr>
<tr>
<td><code>args.draft</code></td>
<td>Specifies whether or not the content of <code>&lt;draft-comment&gt;</code> and <code>&lt;required-cleanup&gt;</code> elements is included in the output.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Allowed values:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>no</strong> (default) - No draft information is shown in the output.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>yes</strong> - The draft information is shown in the output.</td>
<td></td>
</tr>
<tr>
<td><code>args.figurelink.style</code></td>
<td>Specifies how cross references to figures are styled in output. Allowed values:</td>
<td></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>----------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>args.gen.task.lbl</td>
<td>Specifies whether or not to generate headings for sections within task topics. Allowed values: YES or NO (default). When set to YES, headings such as &quot;About this task&quot;, &quot;Before you begin&quot;, &quot;Procedure&quot;, or &quot;What to do next&quot;, are shown in the task contents.</td>
<td></td>
</tr>
<tr>
<td>args.hyph.dir</td>
<td>Specifies the directory that contains custom hyphenation dictionaries. For more details see: Hyphenation (on page 1789).</td>
<td></td>
</tr>
<tr>
<td>args.input</td>
<td>Specifies the main DITA map file for your documentation project.</td>
<td></td>
</tr>
<tr>
<td>args.keep.output.debug.files</td>
<td>Specifies whether or not the debug files generated during the transformation should be kept in the output folder. Allowed values: YES (default) or NO.</td>
<td></td>
</tr>
<tr>
<td>args.output.base</td>
<td>Specifies the name of the output file without a file extension. By default, the name of the PDF file is derived from the name of the DITA map file. This parameter allows you to override it.</td>
<td></td>
</tr>
<tr>
<td>args.tablelink.style</td>
<td>Specifies how cross references to tables are styled in output. Allowed values:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• NUMBER - Only the number of the tables will be shown in links.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• TITLE - Only the title of the tables will be shown in links.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• NUMTITLE (default) - Both the title and number of the tables will be shown in links.</td>
<td></td>
</tr>
<tr>
<td>clean.temp</td>
<td>Specifies whether or not the DITA-OT deletes the files in the temporary directory after it finishes a build. Allowed values: yes (default) or no.</td>
<td></td>
</tr>
<tr>
<td>css.processor.path.antenna-house</td>
<td>Path to the Antenna House executable file that needs to be run to generate the PDF (for example, C:\path\to\AHFCmd.exe on Windows).</td>
<td></td>
</tr>
<tr>
<td>css.processor.path.chemistry</td>
<td>Path to the Oxygen PDF Chemistry executable file that needs to be run to generate the PDF (for example, C:\path\to\chemistry.bat on Windows). If this parameter is not set, the plugin will use the system's PATH environment variable to locate and start Oxygen PDF Chemistry.</td>
<td></td>
</tr>
<tr>
<td>css.processor.path.prince</td>
<td>Path to the Prince executable file that needs to be run to generate the PDF (for example, C:\path\to\prince.exe on Windows).</td>
<td></td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
<td></td>
</tr>
<tr>
<td><code>css.processor.type</code></td>
<td>Specifies the processor to use for the transformation. Allowed values: chemistry (default), antenna-house, or prince.</td>
<td></td>
</tr>
<tr>
<td><code>default.language</code></td>
<td>Specifies the default language for source documents. Examples: fr, de, zh, etc. Depending on the transformation type, the actual number of supported languages can vary, see: Localization (on page 1797).</td>
<td></td>
</tr>
<tr>
<td><code>drop.block.margins.at.page.boundary</code></td>
<td>Specifies that the top and bottom margins associated with a block element should be discarded when the block is at the top or bottom of the page. Allowed values: YES (default) or NO.</td>
<td></td>
</tr>
<tr>
<td><code>editlink.ditamap.edit.url</code></td>
<td>Use this parameter to add an Edit link next to the topic title in the WebHelp output. When a user clicks the link, the topic is opened in Oxygen XML Web Author or Content Fusion where they can make changes that can be saved to a file server. The value should be set as the edit URL of the main DITA map used for publishing your output. The easiest way to obtain the URL is to open the map in Web Author or Content Fusion and copy the URL from the browser’s address bar.</td>
<td></td>
</tr>
<tr>
<td><code>editlink.additional.query.parameters</code></td>
<td>You can use this optional parameter to add additional parameters to be appended to each generated edit link. Each parameter must start with &amp; (for example: &amp;tags-mode=no-tags).</td>
<td></td>
</tr>
<tr>
<td><code>editlink.remote.ditamap.url</code> (deprecated)</td>
<td>Use this parameter in conjunction with editlink.web.author.url to add an Edit link next to the topic title in the PDF output. When a user clicks the link, the topic is opened in Oxygen XML Web Author where they can make changes that can be saved to a file server. The value should be set as the custom URL of the main DITA map. For example, a GitHub custom URL might look like this: <a href="https://getFileContent/oxygenxml/userguide/master/UserGuide.ditamap">https://getFileContent/oxygenxml/userguide/master/UserGuide.ditamap</a>.</td>
<td></td>
</tr>
<tr>
<td><code>editlink.web.author.url</code> (deprecated)</td>
<td>This parameter needs to be used in conjunction with editlink.remote.ditamap.url to add an Edit link next to the topic title in the PDF output. When a user clicks the link, the topic is opened in Oxygen XML Web Author where they can make changes that can be saved to a file server. The value should be set as the URL of the Web Author installation. For example: <a href="https://www.oxygenxml.com/oxygen-xml-web-author/">https://www.oxygenxml.com/oxygen-xml-web-author/</a>.</td>
<td></td>
</tr>
<tr>
<td><code>enable.latin.glyph.substitutions</code></td>
<td>When set to yes (default), glyph substitution is enabled (if the particular font supports it). This applies to Latin-based scripts only (the substitutions are always enabled in other types of scripts). If you encounter problems rendering or copying accented glyphs (i.e. umlauts or other diacritics), it might be helpful to set this parameter to no to disable the font glyph substitutions. Another example of a case when you might need to disable the substitutions is a situation where an ac-</td>
<td></td>
</tr>
</tbody>
</table>
Oxygen XML Editor 23.1 | 11 - Publishing | 1669

cented character cannot be mapped to a compound glyph, resulting in the glyph not being rendered in the PDF output.

**Warnings:**

- Disabling substitutions also disables Latin ligatures.
- Disabling substitutions is not recommended unless absolutely necessary. It is better practice to use another font if you can find one that does not have the rendering issues.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>figure.title.placement</td>
<td>Controls the title placement of the figures, relative to the image. Possible values include <strong>top</strong> (default) and <strong>bottom</strong>.</td>
</tr>
<tr>
<td>fix.external.refs.com.oxygenxml</td>
<td>The DITA Open Toolkit usually has problems processing references that point to locations outside of the processed DITA map directory. This parameter is used to specify whether or not the application should try to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references. The fix has no impact on your edited DITA content. Allowed values: <strong>true</strong> or <strong>false</strong> (default).</td>
</tr>
<tr>
<td>hide.frontpage.toc.index.glossary</td>
<td>When set to <strong>yes</strong>, the generated structures (table of contents, index list, front page, etc.) are removed from the output. The default is <strong>no</strong>.</td>
</tr>
<tr>
<td>pdf.version</td>
<td>Use this parameter to specify the version of the produced PDF. It has no impact on the set of PDF features used by the engine, but may be used to signal a compatibility level to the PDF readers. The default is <strong>1.5</strong>.</td>
</tr>
<tr>
<td>show.changes.and.comments</td>
<td>When set to <strong>yes</strong>, the user comments, colored highlights and tracked changes are shown in the output.</td>
</tr>
<tr>
<td>show.changes.and.comments.as.changebars</td>
<td>When set to <strong>yes</strong> (default) and the <strong>show.changes.and.comments</strong> parameter is also set to <strong>yes</strong>, the user comments and tracked changes are shown as change bars in the PDF output. This parameter can be used in conjunction with the <strong>show.changes.and.comments.as.pdf.sticky-notes</strong> parameter to choose whether the change bars are displayed in footnotes or sticky notes. You can override this from your customization CSS (on page 1693).</td>
</tr>
<tr>
<td>show.changes.and.comments.as.pdf.sticky.notes</td>
<td>When set to <strong>yes</strong> (default) and the <strong>show.changes.and.comments</strong> parameter is also set to <strong>yes</strong>, the user comments and tracked changes are shown in the PDF output as sticky note annotations. When set to <strong>no</strong>, the comments and tracked changes are left in the document model.</td>
</tr>
</tbody>
</table>
and are styled by the default CSS rules as footnotes. You can override this from your customization CSS (on page 1693).

**show.changed.text.in.pdf.sticky.notes.content**

When set to **yes** (default) and both the `show.changes.and.comments` and `show.changes.and.comments.as.pdf.sticky.notes` parameters are also set to **yes**, the inserted and deleted text is shown in the sticky note annotations. When set to **no**, only the inserted and deleted labels are shown in the annotations (this is useful for search scope).

**show.image.map.area.numbers**

When set to **yes**, a counter for each area from the image map will be displayed over the image, near the defined shape. The default is **no**.

**show.image.map.area.shapes**

When set to **yes**, each of the image map area shapes will be displayed with a translucent fill over the image. You can use this to debug your image maps. The default is **no**.

**store-type**

Setting this parameter to **memory** will increase the processing speed and thus, could help decrease the publishing time.

**table.title.placement**

Controls the placement of the title for tables. Possible values include **top** (default) and **bottom**.

**table.title.repeat**

Specifies whether or not a table caption should repeat on other pages when the table spans onto multiple pages. The caption is not repeated for tables nested in lists or other tables. Allowed values are **yes** (default) or **no**.

**use.css.for.embedded.svg**

When set to **yes** (default), the CSS files specified in the publishing template or by the `args.css` parameter are also applied on embedded SVG elements. Allowed values are **yes** and **no**.

**use.navtitles.in.all.links**

Specifies whether a `<navtitle>` defined in a topic or a topic reference should be used as the display name for all links or only in the table of contents. Allowed values are **yes** and **no** (default).

**parallel**

Specifies whether or not certain pre-processing tasks should be run in parallel. Setting this parameter to **true** may add a small increase to the publishing speed. Allowed values are: **true** and **false** (default).

The following parameters can be used to specify a publishing template:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pdf.publishing.template</code></td>
<td>Specifies the path to the folder containing the custom PDF template.</td>
</tr>
<tr>
<td><code>pdf.publishing.template.descriptor</code></td>
<td>Specifies the name of the descriptor file to be loaded from the PDF template folder or package. If it is not specified, the first encountered descriptor file will be loaded.</td>
</tr>
</tbody>
</table>

The following parameter is available on all DITA transformations when using the **Oxygen Publishing Engine**:
args.disable.security.checks  
Specifies whether or not to load external entities that are not solved through catalogs. For security reasons, the default is no.

Allowed values:
- yes
- no (default)

The following parameters are only available for the **DITA PDF - based on HTML5 & CSS** single DITA topic transformation scenario (pdf-css-html5-single-topic trans type):

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>args.root.map</td>
<td>Specifies the path of the root map file used to expand the key references in the published topic.</td>
</tr>
<tr>
<td>args.enable.root.map.key.processing</td>
<td>Indicates whether or not the keys should be processed using the root map parameter.</td>
</tr>
</tbody>
</table>

**Console Logging**

To activate the logging of the last processing stage, involving the usage of the Chemistry processor to generate the PDF from the merged HTML, use the `-verbose` DITA-OT parameter from the command line.

**Note:**
When the transformation is started from an Oxygen application, this parameter is automatically set.

**License Key**

**Chemistry License**

If you have an Oxygen PDF Chemistry license key, you will be able to generate PDF output that is not stamped with the Chemistry logo image.

To install your Chemistry license key:

- If you are using the version of Chemistry that comes bundled in Oxygen XML Editor/Author, save the license key text in a file with the name `licensekey.txt` and place it in the `DITA-OT-DIR/plugins/com.oxygenxml.pdf.css/lib/oxygen-pdf-chemistry` folder.
- If you are using another Chemistry installation, make sure you place the `licensekey.txt` file in that folder.
Oxygen Publishing Engine License

If you have purchased a license for the Oxygen Publishing Engine, you will be able to produce both PDF and WebHelp output without any restrictions.

To install your Oxygen Publishing Engine license key, save the license key text in a file with the name licensekey.txt and place it in the DITA-OT-DIR folder.

Publishing Templates

An Oxygen Publishing Template defines all aspects of the layout and styles for output obtained from the following transformation scenarios:

• WebHelp Responsive
• DITA Map PDF - based on HTML5 & CSS

It is a self-contained customization package stored as a ZIP archive or folder that can easily be shared with others. It provides the primary method for customizing the output.

Some possible customization methods include:

• Add additional template resources to customize the output (such as logos, Favicon, or CSS files).
• Extend the default processing by specifying one or more XSLT extension points.
• Specify one or more transformation parameters to customize the output.
• Customize various aspects of the output through simple CSS styling.
• For WebHelp Responsive output, change the layout of the main page or topic pages by customizing which components will be displayed and where they will be positioned in the page.

The following graphics are possible sample structures for Oxygen Publishing Template packages:

Template Descriptor

For information about creating and customizing publishing templates, and how to adjust the WebHelp and PDF output through CSS styling and other customization methods, watch our Webinar: Creating Custom Publishing Templates for WebHelp and PDF Output. The Webinar slides and sample project are also available from that webpage.

Related Information:
How to Create a Publishing Template (on page 1535)
How to Edit a Packed Publishing Template (on page 1537)
How to Add a Publishing Template to the Publishing Templates Gallery (on page 1537)
How to Share a Publishing Template (on page 1683)

Publishing Template Package Contents for PDF Customizations

An Oxygen Publishing Template for PDF output must contain a template descriptor file and at least one CSS file, and may contain other resources (such as graphics, XSLT files, etc.). All the template resources can be
stored in either a ZIP archive or in a folder. It is recommended to use a ZIP archive because it is easier to share with others.

**Template Descriptor File**

Each publishing template includes a descriptor file that defines the meta-data associated with template. It is an XML file with certain elements that defines all the resources included in a template (such as CSS files, images, and transformation parameters).

The template descriptor file must have the `.opt` file extension and must be located in the templates’ root folder.

A PDF template descriptor might look like this:

```xml
<publishing-template>
  <name>Flowers</name>

  <pdf>
    <tags>
      <tag>purple</tag>
      <tag>light</tag>
    </tags>

    <preview-image file="flowers-preview.png"/>

    <resources>
      <css file="flowers.css"/>
    </resources>

    <parameters>
      <parameter name="figure.title.placement" value="top"/>
    </parameters>
  </pdf>
</publishing-template>
```

**Tip:**

It is recommended to edit the template descriptor in Oxygen XML Editor/Author because it provides content completion and validation support.

**Template Name and Description**

Each template descriptor file requires a `<name>` element. This information is displayed as the name of the template in the transformation scenario dialog box.

Optionally, you can include a `<description>` and it displayed when the user hovers over the template in the transformation scenario dialog box.
<publishing-template>
    <name>Flowers</name>
    <description>Flowers themed light colored template</description>
  ...
</publishing-template>

**Template Author**

Optionally, you can include author information in the descriptor file and it displayed when the user hovers over the template in the transformation scenario dialog box. This information might be useful if users run into an issue or have questions about a certain template.

If you include the `<author>` element, a `<name>` is required and optionally you can include `<email>`, `<organization>`, and `<organizationUrl>.

```xml
<publishing-template>
  ...
  <author>
    <name>John Doe</name>
    <email>jdoe@example.com</email>
    <organization>ACME</organization>
    <organizationUrl>http://www.example.com/jdoe</organizationUrl>
  </author>
  ...
</publishing-template>
```

**PDF Element**

The `<pdf>` element contains various details about the template and its resources that define the PDF output. It is a required element if you intend on using a DITA Map to PDF transformation scenario. The elements that are allowed in this `<pdf>` section specify the template tags (on page 1676), template preview image (on page 1676), resources (on page 1676) (such as CSS files), transformation parameters (on page 1677), or XSLT extensions (on page 1677).

```xml
<pdf>
  <tags>
    ...
  </tags>
  <preview-image file="MyPreview.png"/>

  <resources>
    ...
  </resources>

  <parameters>
    ...
  </parameters>
</pdf>
```
**Template Tags**

The `<tags>` section provides meta information about the template (such as color theme). Each tag is displayed at the top of the Templates tab window in the transformation scenario dialog box and they help the user filter and find particular templates.

```xml
<publishing-template>
  ...
  <pdf>
    <tags>
      <tag>purple</tag>
      <tag>light</tag>
    </tags>
  </pdf>
</publishing-template>
```

**Template Preview Image**

The `<preview-image>` element is used to specify an image that will be displayed in the transformation scenario dialog box. It provides a visual representation of the template to help the user select the right template. The image dimensions should be 200 x 115 pixels and the supported image formats are: JPEG, PNG, or GIF.

You can also include an `<online-preview-url>` element to specify the URL of a published sample of your template. This will display an **Online preview** icon in the bottom-right corner of the image in the transformation scenario dialog box and if the user clicks that icon, it will open the specified URL in their default browser.

```xml
<publishing-template>
  ...
  <pdf>
    ...
    <preview-image file="ashes/ashes-tree.png"/>
    <online-preview-url>https://www.example.com/samples/tiles/ashes</online-preview-url>
  </pdf>
</publishing-template>
```

**Template Resources**

The `<resources>` section of the descriptor file specifies a set of resources (CSS files) that are used to customize various components in the generated output. These resources will be copied to the output folder during the transformation process. At least one CSS file must be included (using the `<css>` element).

```xml
<publishing-template>
  ...
  <pdf>
    ...
    <resources>
      <css file="css/custom_styles.css"/>
      <css file="css/custom_fonts.css"/>
    </resources>
  </pdf>
</publishing-template>
```
Transformation Parameters

You can also set one or more transformation parameters in the descriptor file.

```xml
<publishing-template>

...</pdf>

<parameters>

<parameter name="show.changes.and.comments" value="yes"/>

</parameters>

</pdf>
```

The following information can be specified in the `<parameters>` element:

**Parameter name**

The name of the parameter. It may be one of the transformation parameters listed in the Parameters tab of the DITA Map PDF - based on HTML5 & CSS transformation scenario or a DITA-OT PDF-based output parameter.

**Parameter Value**

The value of the parameter. It should be a relative path to the template root folder for file paths parameters.

**Parameter Type**

The type of the parameter: **string** or **filepath**. The **string** value is default.

After creating a publishing template (on page 1679) and adding it to the templates gallery (on page 1682), when you select the template in the transformation scenario dialog box, the Parameters tab will automatically be updated to include the parameters defined in the descriptor file. These parameters are displayed in italics.

XSLT Extension Points

The publishing templates support one or more XSLT extension points. They can be specified using the `<xslt>` element in the descriptor file using the following structure:
For more information about the available extension points, see: XSLT Extensions for PDF Transformations (on page 1683).

Combining PDF and WebHelp Responsive Customizations in a Template Package

An Oxygen Publishing Template package can contain both a PDF and WebHelp Responsive customization in the same template package and you can use that same template in both types of transformations. The template descriptor file can define the customization for both types by including both a `<webhelp>` and `<pdf>` element and some of the resources can be reused. Resources referenced in elements in the `<webhelp>` element will only be used for WebHelp transformations, and resources referenced in the elements in the `<pdf>` element will only be used in PDF transformations.
How to Create a Publishing Template

To create a customization, you can start from scratch or from an existing template, and then adapt it according to your needs.

Creating a Template Starting from Scratch

To create a new Oxygen Publishing Template, follow these steps:

1. Create a folder that will contain all the template files.
2. In Oxygen XML Editor/Author, open the new document wizard (use File > New or the New toolbar button), then choose the Publishing Template Descriptor template.
Figure 485. Choosing the Publishing Template Descriptor Document Template

3. Save the .opt file into your customization directory.
4. Open the .opt file in the editor and customize it to suit your needs.

Creating a Template Starting from an Existing Template

If you are using a WebHelp Responsive or DITA Map PDF - based on HTML5 & CSS transformation, the easiest way to create a new Oxygen Publishing Template (on page 2969) is to select an existing template in the transformation scenario dialog box and use the Save template as button to save that template into a new template package that can be used as a starting point.

To create a new Oxygen Publishing Template, follow these steps:

1. Open the transformation scenario dialog box and select the publishing template you want to export and use as a starting point.
2. Optional: You can set one or more transformation parameters from the Parameters tab and the edited parameters will be exported along with the selected template. You will see which parameters will be exported in the dialog box that is displayed after the next step.
3. Click the Save template as button.
   
   Step Result: This opens a template package configuration dialog box that contains some options and displays the parameters that will be exported to your template package.
4. Specify a name for the new template.
5. Optional: Specify a template description.
6. **Optional:** The same publishing template package can contain both a WebHelp Responsive and PDF customization and you can use the same template in both types of transformations ([DITA Map WebHelp Responsive](/DITA-Map-WebHelp-Responsive) or [DITA Map to PDF - based on HTML5 & CSS](/DITA-Map-to-PDF-based-on-HTML5-CSS)). You can use the Include WebHelp customization and Include PDF customization options to specify whether your custom template will include both types of customizations.

7. **Optional:** For WebHelp Responsive customizations, you can select the Include HTML Page Layout Files option if you want to copy the default HTML Page Layout Files ([on page 1516](/HTML-Page-Layout-Files)). They are helpful if you want to change the structure of the generated HTML pages.

8. In the **Save as** field, specify the name and path of the ZIP file where the template will be saved.

9. **Step Result:** A new ZIP archive will be created on disk in the specified location with the specified name.

For more information about creating and customizing publishing templates, watch our video demonstration:

https://www.youtube.com/embed/zNmXfKWXwO8

**Related Information:**

- Publishing Template Package Contents for PDF Customizations ([on page 1673](/Publishing-Template-Package-Contents-for-PDF-Customizations))
- Publishing Template Package Contents for WebHelp Responsive Customizations ([on page 1500](/Publishing-Template-Package-Contents-for-WebHelp-Responsive-Customizations))

### How to Edit a Packed Publishing Template

To edit an existing Oxygen Publishing Template ([on page 2969](/Oxygen-Publishing-Template)) package, follow these steps:

1. Unzip the ZIP archive associated with the Oxygen Publishing Template in a separate folder.
2. Link the folder associated with the template in the Project view.
3. Using the Project view, you can modify the resources (CSS, JS, fonts) within the Oxygen Publishing Template folder to fit your needs.
4. Open the publishing template descriptor file (.opt extension) in the editor and modify it to suit your needs.
5. **Optional:** Once you finish your customization, you can archive the folder as a ZIP file.

**Related Information:**

- Publishing Template Package Contents for PDF Customizations ([on page 1673](/Publishing-Template-Package-Contents-for-PDF-Customizations))
- Publishing Template Package Contents for WebHelp Responsive Customizations ([on page 1500](/Publishing-Template-Package-Contents-for-WebHelp-Responsive-Customizations))

### How to Use a Publishing Template in a PDF Transformation

**From Oxygen XML Editor/Author**

A publishing template can be used for PDF output from the DITA Map PDF - based on HTML5 & CSS transformation scenario (or from the DITA PDF - based on HTML5 & CSS transformation scenario).
The **Templates** tab in the transformation scenario dialog box displays all the templates that are available in your template gallery. To use a particular template in the transformation scenario, simply select it from this tab and then continue configuring the transformation using the other tabs to suit your needs.

To add the publishing template to your templates gallery, follow these steps:

1. Open the transformation scenario dialog box by editing a **DITA Map PDF - based on HTML5 & CSS** transformation (or a **DITA PDF - based on HTML5 & CSS** transformation scenario).
2. In the **Templates** tab, click the **Configure Publishing Templates Gallery** link to.
   
   **Step Result:** This will open the preferences page.
3. Click the **Add** button and specify the location of your template directory.
   
   **Step Result:** Your template directory is now added to the **Additional Publishing Templates Galleries** list.
4. Click **OK** to return to the transformation scenario dialog box.

**Result:** All the templates contained in your template directory will be displayed in the preview pane along with all the built-in templates.

### From Command Line

You can use the simpler form, meaning you only use the `pdf.publishing.template` parameter to point to the `*.opt` (publishing template) file:

```
dita.bat
   --input=map\test.ditamap
   "-Dpdf.publishing.template=full_path_to_template_dir/my_template.opt"
   --format=pdf-css-html5
   ...
```

Or use the two parameters to indicate the folder containing the publishing templates and the name of the publishing template file relative to that folder:

```
dita.bat
   --input=map\test.ditamap
   "-Dpdf.publishing.template=full_path_to_template_dir"
   "-Dpdf.publishing.template.descriptor=my_template.opt"
   --format=pdf-css-html5
   ...
```

**Tip:**

You can also start the `dita` process by passing it a **DITA OT Project File**. Inside the project file you can specify as parameters for the **webhelp-responsive** transformation type the WebHelp-related parameters.
How to Share a Publishing Template

To share a publishing template with others, following these steps:

1. Copy your template in a new folder in your project.
2. Go to Options > Preferences > DITA > Publishing and add that new folder to the list.
3. Switch the option as the bottom of that preferences page to Project Options.
4. Share your project file (.xpr).

XSLT Extensions for PDF Transformations

Since PDF output is primarily obtained by running XSLT transformations over the DITA input files, one customization method would be to override the default XSLT templates that are used by the PDF transformation.

The pdf-css-html5 transformation type uses two stages to transform the merged DITA map (the one that aggregates all the topics) to HTML5:

1. **Stage 1**: Makes some changes on the merged map (on page 1695) and the result is a modified merged map. This stage can be altered by implementing the com.oxygenxml.pdf.css.xsl.merged2merged XSLT extension point. This extension overrides the stylesheets found in the following folder: DITA-OT-DIR\plugins\com.oxygenxml.pdf.css\xsl\merged2merged.

   **Note:**
   Use this when you need to filter DITA content.

2. **Stage 2**: Transforms the merged map (on page 1695) to HTML5 and the result is a single HTML document. This stage can be altered by implementing the com.oxygenxml.pdf.css.xsl.merged2html5 XSLT extension point. This extension overrides the stylesheets found in the following folder: DITA-OT-DIR\plugins\com.oxygenxml.pdf.css\xsl\merged2html5.

   **Note:**
   Use this when you need to change the HTML structures generated for a specific DITA element.

These extension points can be used either from a Publishing Template or a DITA-OT extension plugin.

How to Use XSLT Extension Points for PDF Output from a Publishing Template

The examples in this section demonstrate how to use XSLT extension points from an Oxygen Publishing Template.
How to Style Codeblocks with a Zebra Effect

Suppose you want your codeblocks to have a particular background color for one line, and another color for the next line. One advantage of this coloring technique is that you can clearly see when text from the codeblock is wrapped.

This effect can be done by altering the HTML5 output, creating a div for each line from the code block, then styling them.

To add this functionality using an Oxygen Publishing Template, follow these steps:

1. If you have not already created a Publishing Template, you need to create one. For details, see How to Create a Publishing Template (on page 1679).
2. Link the folder associated with the publishing template to your current project in the Project view.
3. Using the Project view, create an xslt folder inside the project root folder.
4. In this folder, create an XSL file (for example, named merged2html5Extension.xsl) with the following content:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
xmlns:xs="http://www.w3.org/2001/XMLSchema"
exclude-result-prefixes="xs"
version="2.0">

<xsl:template match="*[contains(@class, ' pr-d/codeblock ')]">
  <div class='zebra'>
    <xsl:analyze-string regex="\n" select=".">
      <xsl:matching-substring/>
      <xsl:non-matching-substring>
        <div><xsl:value-of select="."/></div>
      </xsl:non-matching-substring>
    </xsl:analyze-string>
    </div>
  </xsl:template>
</xsl:stylesheet>
```

5. Open the template descriptor file (on page 1674) associated with your publishing template (the .opt file) and set the XSLT stylesheet created in the previous step with the com.oxygenxml.pdf.css.xsl.merged2html5 XSLT extension point:

```xml
<publishing-template>
  ...
  <pdf>
    ...
  </pdf>
  <xslt>
    <extension
      id="com.oxygenxml.pdf.css.xsl.merged2html5"
      ...>
```
6. Create a **css** folder in the publishing template directory. In this directory, save a custom CSS file with rules that style the **codeblock** structure. For example:

```css
div.zebra {
    font-family: courier, fixed, monospace;
    white-space: pre-wrap;
}
div.zebra > *:nth-of-type(odd){
    background-color: silver;
}
```

7. Open the **template descriptor file** *(on page 1674)* associated with your **publishing template** *(the .opt file)* and reference your custom CSS file in the **resources** element:

```xml
<publishing-template>
  ...
  <pdf>
    ...
    <resources>
      <css file="css/custom.css"/>
    </resources>
  </pdf>
</publishing-template>
```

8. Edit the **DITA Map PDF - based on HTML5 & CSS** transformation scenario.

9. In the **Templates** tab, click the **Choose Custom Publishing Template** link and select your template.

10. Click **OK** to save the changes and run the transformation scenario.

### How to Remove the Related Links Section

Suppose that you want the related links sections to be removed from the PDF output.

To add this functionality using an **Oxygen Publishing Template**, follow these steps:

1. If you have not already created a Publishing Template, you need to create one. For details, see **How to Create a Publishing Template** *(on page 1679).*
2. Link the folder associated with the publishing template to your current project in the **Project** view.
3. Using the **Project** view, create an **xslt** folder inside the project root folder.
4. In this folder, create an XSL file *(for example, named merged2mergedExtension.xsl)* with the following content:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    exclude-result-prefixes="xs"
    version="2.0">
```
5. Open the template descriptor file (on page 1674) associated with your publishing template (the .opt file) and set the XSLT stylesheet created in the previous step with the com.oxygenxml.pdf.css.xsl.merged2merged XSLT extension point:

```xml
<publishing-template>
  ...
  <pdf>
    ...
    <xslt>
      <extension
        id="com.oxygenxml.pdf.css.xsl.merged2merged"
        file="xslt/merged2mergedExtension.xsl"/>
    </xslt>
  </pdf>
</publishing-template>
```

6. Edit the DITA Map PDF - based on HTML5 & CSS transformation scenario.

7. In the Templates tab, click the Choose Custom Publishing Template link and select your template.

8. Click OK to save the changes and run the transformation scenario.

How to Wrap Words in Markup

Suppose you want compound words that contain hyphens (or any other criteria) to be wrapped with inline elements (such as the HTML `<code>` element).

To add this functionality using an Oxygen Publishing Template, follow these steps:

1. If you have not already created a Publishing Template, you need to create one. For details, see How to Create a Publishing Template (on page 1679).
2. Link the folder associated with the publishing template to your current project in the Project view.
3. Using the Project view, create an xslt folder inside the project root folder.
4. In this folder, create an XSL file (for example, named `merged2htmlExtension.xsl`) with the following content:

```xml
<xsl:template match="text()">
  
  <xsl:variable name="txt">
    <xsl:next-match />
  </xsl:variable>

  <xsl:analyze-string regex="(\w|\-)+" select="$txt">
    <xsl:matching-substring>
      <!-- A word -->
      <xsl:choose>
```
5. Open the template descriptor file (on page 1674) associated with your publishing template (the .opt file) and set the XSLT stylesheet created in the previous step with the com.oxygenxml.pdf.css.xsl.merged2merged XSLT extension point:

```xml
<publishing-template>
  ...
  <pdf>
    ...
    <xslt>
      <extension
        id="com.oxygenxml.pdf.css.xsl.merged2merged"
        file="xslt/merged2mergedExtension.xsl"/>
    </xslt>
  </pdf>
</publishing-template>
```

6. Edit the DITA Map PDF - based on HTML5 & CSS transformation scenario.
7. In the Templates tab, click the Choose Custom Publishing Template link and select your template.
8. Click OK to save the changes and run the transformation scenario.

**How to Convert Definition Lists into Tables**

Suppose you want your definitions lists (<dl>) to be displayed as tables in your PDF output.

To add this functionality using an Oxygen Publishing Template, follow these steps:

1. If you have not already created a Publishing Template, you need to create one. For details, see How to Create a Publishing Template (on page 1679).
2. Link the folder associated with the publishing template to your current project in the Project view.
3. Using the Project view, create an xslt folder inside the project root folder.
4. In this folder, create an XSL file (for example, named `merged2html5Extension.xsl`) with the following content:

```xml
<xsl:template match="*[contains(@class, ' topic/dl ')]">
  <xsl:call-template name="setaname"/>
  <xsl:apply-templates select="*[contains(@class, ' ditaot-d/ditaval-startprop ')]
    mode="out-of-line"/>
  <table>
    <xsl:call-template name="commonattributes"/>
    <xsl:call-template name="setid"/>
    <xsl:apply-templates/>
  </table>
  <xsl:apply-templates select="*[contains(@class, ' ditaot-d/ditaval-endprop ')]
    mode="out-of-line"/>
</xsl:template>

<xsl:template match="*[contains(@class, ' topic/dlentry ')]">
  <tr>
    <xsl:call-template name="commonattributes"/>
    <xsl:call-template name="setidaname"/>
    <xsl:apply-templates/>
  </tr>
</xsl:template>

<xsl:template match="*[contains(@class, ' topic/dd ') | 
  *[contains(@class, ' topic/dt ']">
  <td>
    <xsl:call-template name="commonattributes"/>
    <xsl:call-template name="setidaname"/>
    <xsl:apply-templates select="../*[contains(@class, ' ditaot-d/ditaval-startprop ')]
      mode="out-of-line"/>
    <xsl:apply-templates/>
    <xsl:apply-templates select="../*[contains(@class, ' ditaot-d/ditaval-endprop ')]
      mode="out-of-line"/>
  </td>
</xsl:template>
```

5. Open the template descriptor file (on page 1674) associated with your publishing template (the `.opt` file) and set the XSLT stylesheet created in the previous step with the `com.oxygenxml.pdf.css.xsl.merged2html5` XSLT extension point:

```xml
<publishing-template>
  ...
</publishing-template>
```
6. Edit the DITA Map PDF - based on HTML5 & CSS transformation scenario.
7. In the Templates tab, click the Choose Custom Publishing Template link and select your template.
8. Click OK to save the changes and run the transformation scenario.

How to Use XSLT Extension Points for PDF Output from a DITA-OT Plugin

The examples in this section demonstrate how to use XSLT extension points from a DITA-OT plugin.

How to Style Codeblocks with a Zebra Effect

Suppose you want your codeblocks to have a particular background color for one line, and another color for the next line. One advantage of this coloring technique is that you can clearly see when text from the codeblock is wrapped.

This effect can be done by altering the HTML5 output, creating a `<div>` for each line from the code block, then styling them.

To add this functionality using a DITA-OT plugin, follow these steps:

1. In the `DITA-OT-DIR\plugins\` folder, create a folder for this plugin (for example, `com.oxygenxml.pdf.custom.codeblocks`).
2. Create a `plugin.xml` file (in the folder you created in step 1) that specifies the extension point and your customization stylesheet. For example:

```xml
<plugin id="com.oxygenxml.pdf.custom.codeblocks">
  <feature extension="com.oxygenxml.pdf.css.xsl.merged2html5"
    file="custom_codeblocks.xsl"/>
</plugin>
```

3. Create your customization stylesheet (for example, `custom_codeblocks.xsl`) with the following content:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:xm="http://www.w3.org/2001/XMLSchema"
  exclude-result-prefixes="xs"
  version="2.0">

  <xsl:template match="*[contains(@class, ' pr-d/codeblock ')]">
    <div class='zebra'>
      <xsl:analyze-string regex="\n" select="."/>
    </div>
  </xsl:template>
</xsl:stylesheet>
```
4. Use the **Run DITA-OT Integrator** transformation scenario *(on page 1352)* found in the **DITA Map** section in the **Configure Transformation Scenario(s)** dialog box.

5. Create a custom CSS file with rules that style the *codeblock* structure. For example:

```css
div.zebra {
    font-family: courier, fixed, monospace;
    white-space: pre-wrap;
}
div.zebra > *:nth-of-type(odd){
    background-color: silver;
}
```

6. Edit a **DITA Map PDF - based on HTML5 & CSS** transformation scenario and reference your custom CSS file (using the `args.css` parameter).

7. Run the transformation scenario.

**How to Remove the Related Links Section**

Suppose you want the related links sections to be removed from the PDF output.

To add this functionality using a DITA-OT plugin, follow these steps:

1. In the **DITA-OT-DIR\plugins\** folder, create a folder for this plugin (for example, `com.oxygenxml.pdf.custom.codeblocks`).

2. Create a **plugin.xml** file (in the folder you created in step 1) that specifies the extension point and your customization stylesheet. For example:

   ```xml
   <plugin id="com.oxygenxml.pdf.custom.related.links">
     <feature extension="com.oxygenxml.pdf.css.xsl.merged2merged">
       file="custom_related_links.xsl"/>
   </plugin>
   ```

3. Create your customization stylesheet (for example, `custom_related_links.xsl`) with the following content:

   ```xml
   <?xml version="1.0" encoding="UTF-8"?>
   <xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
                   xmlns:xs="http://www.w3.org/2001/XMLSchema"
                   exclude-result-prefixes="xs"
                   version="2.0">
   ```
4. Use the Run DITA-OT Integrator transformation scenario (on page 1352) found in the DITA Map section in the Configure Transformation Scenario(s) dialog box.

5. Run the DITA Map PDF - based on HTML5 & CSS transformation scenario.

Sample Use-cases: Using XSLT and CSS for PDF Transformations

This section includes examples that can be used as a starting point for various customizations using XSLT and CSS.

How to Use a Bullet Instead of Numbers for Tasks Containing a Single Step

If a DITA Task only contains one step (<step> element), you probably want it to be rendered like an unordered list (displayed with a bullet instead of a number).

```xml
...<steps>
   <step>
      <cmd>The step</cmd>
   </step>
</steps>...
```

Should be rendered as:

- The step

Instead of:

1. The step

To achieve this, you need to create an XSLT template that adds a special @outputclass attribute (with its value set to single) for the single step, then you need to match this attribute from the CSS and change its aspect.

1. In the customization XSL, add:

```xml
<xsl:template match="*[contains(@class, ' topic/related-links ')]">
   <!-- Remove. -->
</xsl:template>
</xsl:stylesheet>

<xsl:template match="*[contains(@class, ' task/step ')]*[count(../*[contains(@class, ' task/step ')]) = 1]">
   <xsl:copy>
      <xsl:copy-of select="@*"/>
      <xsl:attribute name="outputclass" select="concat(@outputclass, ' single ')"/>
      <xsl:apply-templates/>
   </xsl:copy>
</xsl:template>
```
2. In your customization CSS (on page 1693), add:

```
*([outputclass = single]) {
  list-style-type: circle !important;
  margin-left: 2em;
}
```

How to Use XSLT Extension Points for PDF Output from a Publishing Template (on page 1683)

DITA-OT Extension Points

The DITA-OT CSS-based PDF Publishing Plugin supports DITA-OT extension points that can be used to expand the functionality of the transformation. The extension points are defined in the plugin.xml file. For more information, see DITA Open Toolkit Extension Points.

Related Information:
XSLT Extensions for PDF Transformations (on page 1683)

How to Contribute a Custom CSS to the Transformation from a DITA-OT Plugin

This topic is intended for publishing architects/developers that need to deploy a customized DITA-OT.

Usually, the CSS styles can be passed to the transformation by referencing the CSS files using the args.css parameter. However, there are cases where you want to add some sort of "built-in" CSS that is applied in conjunction with the publishing template or CSS files referenced in the transformation.

For this, you need to use the com.oxygenxml.pdf.css.init extension point and set the value of the extension.css ANT property to the path of the custom CSS file:

1. In your plugin.xml file, add:

```
<feature extension="com.oxygenxml.pdf.css.init" file="init.xml"/>
```

2. Create a file named init.xml with the following ANT content:

```
<root>
  <property name="extension.css"
    value="${dita.plugin.[com.my.plugin.id].dir}/css/my-custom.css"/>
  <!-- add here more init stuff if needed -->
</root>
```
Customizing PDF Output Using CSS

The publishing process is driven by a customization CSS.

Tip:
If you use the default Chemistry processor in Oxygen XML Editor/Author, you can use LESS instead of CSS. In this case, the customization files should have the .less extension.

To change the styling of the output for the DITA Map PDF - based on HTML5 & CSS and the DITA PDF - based on HTML5 & CSS transformation scenarios:

1. Create the CSS file that will contain all of your customizations. It is recommended to create this file in your project directory so you can edit it easily.
2. Add your custom CSS rules. As a good starting point you can:
   - Check the various topics in this section for assistance with specific types of customizations.
   - Use the Oxygen Styles Basket (on page 1694) to generate basic selectors for common content.
3. For linking the CSS file, you have two options:
   - Create a publishing template, create the customization CSS file inside the template folder, and link it to the publishing template descriptor. For assistance, see Publishing Templates (on page 1497).
   - Choose an existing publishing template, then edit the scenario and set the full path to the custom CSS file as the value of the args.css parameter. The rules from custom CSS will override the rules from the template CSS files.
4. Run the transformation scenario.

Tip:
For more information and some tips in regard to publishing DITA documents to PDF using CSS, watch our Webinar: Transforming DITA documents to PDF using CSS, Part 1 – Page Definitions, Cover Page and PDF Metadata.
Oxygen Styles Basket

The Oxygen Styles Basket is a handy free-to-use web-based visual tool that helps you to fine-tune the CSS file that is used to customize your PDF or WebHelp output. You simply pick and mix aspects from galleries to add and adjust the rules in your custom CSS file.

It is based on galleries that you can use to pick and mix styling aspects to create a custom look and feel. Various different types of aspects can be selected to be integrated in the CSS stylesheet (such as fonts, tables, lists, spacing, code). It is also possible to re-upload a previously generated CSS for further customization.

You can see the results of your changes in the Preview pane or you can click the See Results toolbar button to see the results in a generated preview version of either PDF or WebHelp output. When you are finished with your customization, you can Download the results as a CSS file or a Publishing Template Package that you can use in your transformation process.

Debugging the CSS

If you notice that some of the CSS properties were not applied as expected, some of the tips offered in this topic might help you with the debugging process.
Merged Map File
Depending on the type of transformation, one or more merged map files are created at some point during the transformation stages. These files could be used to help debug unexpected results.

1. The first thing you should try is to check the file structure of the merged map file. This can be found in the out/pdf-css directory and it has the .merged.html file extension (you will also find a .merged.xml file that aggregates the entire ditamap structure). You can open the HTML files in Oxygen XML Editor/Author to examine the structure. Optionally, you can use the pretty print feature (Format and Indent) to make the structure easier to read.

2. Check that the CSS selectors are written correctly against the document structure.

3. If you still cannot identify the problem, then inspect how the styles are applied (you can try any of the methods listed below).

Inspecting the Applied Styles Using the Chrome Browser
To inspect the applied CSS styles using Chrome:

1. Open the file ending in .merged.html.
2. Click on the element you want to inspect.
3. Activate the Chrome Developer Tools by using > More Tools > Developer Tools, or press CTRL +SHIFT+I.
4. Activate the Rendering pane by using > More Tools > Rendering:
5. In the **Rendering** pane, select **print** from the **Emulate CSS media** section. This will activate the CSS selectors enclosed in @media print {...}.

   ![Table of Options](image)

<table>
<thead>
<tr>
<th>Animations</th>
<th>Console</th>
<th>Rendering</th>
</tr>
</thead>
<tbody>
<tr>
<td>- Paint flashing</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- Highlights areas of the page (green) that need to be repainted</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- Layer borders</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- Shows layer borders (orange/olive) and tiles (cyan)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- FPS meter</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- Plots frames per second, frame rate distribution, and GPU memory</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- Scrolling performance issues</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
   |   - Highlights elements (teal) that can slow down scrolling, including touch

   ![CSS Emulation](image)

   **Emulate CSS media**
   - Forces media type for testing print and screen styles

   ![CSS Selector](image)

   **print**

   **Note:**
   This allows you to debug the styling of elements, table of contents, and index, but not the styles of the page margin boxes (headers, footers) or page breaks.

   ![Tip](image)

   **Tip:**
   In the left pane of the **Developer Tools** interface, you can inspect elements and their styles in the **Elements** tab. You can click on any of the links to display the applied CSS files in the **Styles** tab in the right pane. Editing the styles in that pane results in a live preview of how the change will affect the output.

   ![Caution](image)

   **CAUTION:**
   Do not modify the built-in rules directly in the CSS files from the **Oxygen XML Editor/Author** installation. Instead, copy the rules to your own customization CSS.

---

**Inspecting the Applied Styles Using Oxygen XML Editor/Author**

**To inspect styles:**

1. In **Oxygen XML Editor/Author**, open the file ending in `.merged.html`.
2. *[Optional]* From the **Styles** toolbar, choose the **+ Print Ready** entry. This will activate certain CSS selectors enclosed in @media print {...}.
3. Click on the element you want to style. Use the **Inspect Styles** action from the Contextual Menu. A specialized **CSS Inspector** view will show the built-in CSS rules.
Tip:
With this file open in Author mode, it might be helpful to switch the Tags Display Mode to Full Tags with Attributes. You might be able to identify the selector you need to style without using the CSS Inspector view.

Note:
This allows you to debug styling of elements, but not of the page margin boxes (headers, footers) or page breaks.

CAUTION:
Do not modify the built-in rules directly in the CSS files from the Oxygen XML Editor/Author installation. Instead, copy the rules to your own customization CSS.

Other techniques
These are some other techniques you may find useful:

- Add background and borders properties to the specific CSS rule. If they do not appear in the output then there is a problem with the rule selector.
- Try to use the !important notation to the property that is not applied, or make the selector more specific (you can add more parent selectors).
- To figure out how the elements are mapped to PDF, you can use this fragment in the customization CSS:

```
* {
    border: 1pt solid blue !important;
}

*:before(1000) {
    content: oxy_name() !important;
    color: orange;
}

*:before(999) {
    content: "[ class= "' attr(class) "] " !important;
    color: orange;
}
```

This will show the element name, its class attribute, and will paint a blue border around each of the elements in the output. It will not show the page margin boxes or some content elements that were hidden.
How to Speed up CSS Development and Debugging

You can speed up your CSS development considerably by not invoking the entire pipeline of transforming your DITA maps to PDF. Instead, you can use the merged map (on page 1695) and transform it directly to PDF.

1. Transform your DITA Map to PDF using the DITA Map PDF - based on HTML5 & CSS transformation scenario.
2. Open the merged file (on page 1695) (*.merged.html) that is located in the output directory in the editor.
3. Configure an XML to PDF transformation with CSS scenario. Do not set CSS files here since the merged file already contains pointers to the stylesheets. This scenario uses the Chemistry CSS processor.
4. Optional: Enable the output of the CSS processor using the following preferences page: Options > Preferences > XML > PDF Processors > CSS Processor.

Now you can make incremental changes to the CSS stylesheet and quickly see the results by transforming the merged file directly.

**Fastpath:**
If your changes involve only element styling, with no specific paged media CSS rules and properties, you can simply open the merged file in a browser (such as Chrome or Firefox) and refresh at each CSS change, as shown in: Debugging the CSS (on page 1694).

How to Write XPath Expressions

This topic contains some guidelines for writing XPath expressions. They are used to extract the content from the merged DITA map document.

This is an example where the product name meta-information is placed before the front page title:

```xml
[*[class~="front-page/front-page-title"]:before {  
    text-align: left;  
    content: oxy_xpath("//*[contains(@class, 'topic/prodname')]/text()")[1];  
    display:block;  
}
```

**Notes:**

- Do not use the DITA element names directly. You must use the DITA @class attribute instead, as these attributes are propagated to the merged elements (including HTML `<div>` elements) while the element names can be lost. By using the class selectors, you also cover DITA specializations.
- Use the `[1]` XPath predicate to select the first value from the document. For example, `oxy_xpath("//*[contains(@class, 'topic/prodname')]/text()"[1])`. The meta-information
might be copied multiple times in the output, inherited by the `<topicref>` elements, so you can get many more values than expected.

- Do not use strings as values for the pseudo-elements content, as the string values are not supported for pseudo-elements. Instead, use the XPath directly.
- Use the Oxygen XPath Builder view to test the XPath expressions.

Related Information:
How to Debug XPath Expressions (on page 1699)

How to Debug XPath Expressions

You can use the content extracted from the document using the `oxy_xpath` function in your pseudo-elements (:before, :after) or in string-set variables.

For example, the following XPath finds the publication author, set in the DITA map:

```xml
<map>
  <title>The Art of Bike Repair</title>
  <topicmeta>
    <author>John Doe</author>
  </topicmeta>
  ...

:root {
  string-set: author oxy_xpath('//*[contains(@class, "front-page/front-page")]/*[contains(@class, "map/topicmeta")]/*[contains(@class, "topic/author")]//text()');
}
```

To debug an XPath expression:

1. Read the XPath Expressions Guidelines (on page 1698).
2. Begin by transforming your document using your customization CSS.
3. In the output folder, you will find a [MAP_NAME].merged.html file (or if you are using the DITA Map PDF - based on HTML5 & CSS transformation, a [MAP_NAME].merged.html file).
4. Open the merged file in the Oxygen XML Editor/Author.
5. Activate the XPath Builder view (Window > Show View > XPath/XQuery Builder).
6. Paste your XPath expression and click the Execute XPath button. Check if it returns the expected results.

The XPath builder has a function that allows it to display the document path of the current element from the editor (⚙️, Settings drop-down menu > Update on cursor move). Alternatively, you can right-click the element in the merged document and select the Copy XPath action, then paste it in the XPath builder.
Default Page Definitions

All page definitions are found in: [PLUGIN_DIR]css/print/p-pages-and-headers.css.

**Note:**
This is listed solely for illustration purposes, as the plugin might use something different.

There are pages for the default page, chapter page, front matter page, back matter page, blank pages, index page, and large tables page.

**Default Page**

The default page imposes a header that contains the publication title, chapter, and section title. They alternate on the left or right side of the page:

```xml
@page :left {
    @top-left {
        content: string(maptitle) string(parttitle) string(chaptertitle) string(sectiontitle) " |
        counter(page);
        font-size:8pt;
    }
}

@page :right{
    @top-right {
        content: string(maptitle) string(parttitle) string(chaptertitle) string(sectiontitle) " |
        counter(page);
        font-size:8pt;
    }
}
```

**Tip:**
To override the default rules defined for named pages (such as chapter or table of contents), you need to use more specific page rules that contain the page name:

```xml
@page :left, table-of-contents:left, chapter:left {
    @top-left {
        content: "...";
    }
}
```
Chapter Page

This is inherited from the default page. The chapter page is associated to the topics marked as chapters, usually direct children of the map. It clears the header from the first page of each chapter.

```xml
@page :right, table-of-contents: :right, chapter: :right{
    @top-right {
        content: "...";
    }
}
```

Front Matter and Back Matter page

The bookmap front matter and back matter page. It clears the headers.

```xml
@page matter-page {
    @top-left-corner    { content:none }
    @top-left           { content:none }
    @top-center         { content:none }
    @top-right          { content:none }
    @top-right-corner   { content:none }
    @bottom-left-corner { content:none }
    @bottom-left        { content:none }
    @bottom-center      { content:none }
    @bottom-right       { content:none }
    @bottom-right-corner{ content:none }
}
```
Blank Pages

The following example clears the header for the blank pages that may be created by a page-break-before, page-break-after, or by using double side pagination (on page 1770):

```xml
@page :blank{
  @top-left {
    content: none;
  }
  @top-right {
    content: none;
  }
}
```

Index Page

The page that contains the index terms (appears only if there are such items in your topics). It uses a lower roman page number in the footer:

```xml
@page index {
  @top-left-corner    { content: none }
  @top-left           { content: none }
  @top-center         { content: none }
  @top-right          { content: none }
  @top-right-corner   { content: none }
  @bottom-left-corner { content: none }
  @bottom-left        { content: none }
  @bottom-center      { content: counter(page, lower-alpha) }
  @bottom-right       { content: none }
  @bottom-right-corner{ content: none }
}
@media oxygen-chemistry {
  @page index {
    column-count: 2;
    column-fill: auto;
  }
}
```

When transformed, the page layout is spread on two columns.

Large Tables Page

The big tables are placed on a rotated page, with orientation landscape:

```xml
@page landscape-page :right {
  size: landscape;
  @top-left {
```
```css
.content: none
}
@top-center {
    content: none
}
@top-right {
    content: none
}

@right-bottom {
    content: string(maptitle) string(parttitle) string(chapertitle) string(sectiontitle) " | " counter(page);
    font-size: 8pt;
    transform: rotate(90);
    vertical-align: middle;
    text-align: right;
}

@page landscape-page :left {
    size: landscape;

    @top-left {
        content: none
    }
    @top-center {
        content: none
    }
    @top-right {
        content: none
    }
    @right-top {
        content: string(maptitle) string(parttitle) string(chapertitle) string(sectiontitle) " | " counter(page);
        font-size: 8pt;
        transform: rotate(90);
        vertical-align: middle;
        text-align: left;
    }
}
```
Page Size

This is where you can find information on how the page sizes are defined.

Page Size - Built-in CSS rules

The {PLUGIN_DIR}/css/print/p-page-size.css file contains the default page rules. It uses the US-LETTER size (8.5 X 11 inches). The content of this file is:

```css
@page {
    padding-top: 0.2em;
    padding-bottom: 0.2em;
    size: us-letter;
    margin: 1in;
}
```

Note:
This is listed solely for illustration purposes, as the plugin might use something different.

How to Change the Page Size

Suppose you want to publish using the standard A4 page size, with a margin of 2cm.

In your customization CSS (on page 1693), use:

```css
@page {
    size: A4;
    margin: 2cm;
}
```

If you need different margins depending on the page side:

```css
@page {
    size: A4;
    margin: 2cm;
}
@page :left{
    margin-right: 4cm;
}
@page :right{
    margin-left: 4cm;
}
```

This would only increase the gutter margins or the inside margins needed for binding of the final book. The other margins would remain 2cm.
How to Change the Page Orientation

Suppose you want to publish on a landscape page orientation. The default is portrait, so you need to change it by using the size property. This will contain both the physical measurements and the orientation. In your customization CSS (on page 1693), use:

```css
@page {
    size: us-letter landscape;
}
```

How to Change the Page Settings for a Specific Element

Suppose your publication mainly uses a portrait page orientation, but there are some topics that have wide images. To avoid having the images bleed outside of the page, you could use a wider page setting (landscape).

1. Mark the topic with an `@outputclass` attribute and give it a distinct value (for example, `wide`), you can set the attribute on the root element of the topic or on the `<topicref>` element from the map.

   ```
   Note:
   The `@outputclass` values from the `<topicref>` automatically propagate to the root of the topic from the merged map (on page 1695).
   ```

2. In your customization CSS (on page 1693), match the output class and associate it with a named page. In the following example, the page has a landscape orientation and small margins. This technique works for any element (e.g. a table or list) not just for a topic.

   ```css
   @page wide-page {
       size: letter landscape;
       margin: 0.5in;
   }

   *[outputclass = 'wide'] {
       page: wide-page !important;
   }
   ```

   ```
   Note:
   The `!important` rule is necessary to override the default page settings.
   ```

Page Headers and Footers

The page headers and footers use the string sets defined for publication, chapter, and section titles. These string-sets are defined in the numbering CSS (on page 1746):

```html
parttitle
```
Set to the title of the current part (only for DITA bookmaps that use parts).

**chaptertitle**

Set to the title of the current chapter (Shallow and Deep numbering).

**sectiontitle**

Set to the title of each section (Deep numbering only).

To see where the default page rules are defined, see: Default Page Definitions (on page 1700).

Although you may define string sets in your customization CSS, you need to take into account the fact that the string-set CSS property is not additive, and matching the same elements will end up breaking the current definitions. A very common use-case is to match the title element that is also used in the default CSS. The best approach, in this case, is to take a look at the rules from the numbering CSS (on page 1746), copy the ones dealing with string sets to your customization, then alter the property definition by adding your definition to the existing ones (and not removing the existing ones).

Related Information:

Numbering (on page 1746)

Page Headers and Footers - Built-in CSS

The headers and footers are part of the page definitions. To see how the default page layouts are defined, see: Default Page Definitions (on page 1700).

How to Position Text in the Headers and Footers

By default, the name of the publication and chapter titles are placed in the top-left or top-right page margin boxes:

```css
@page :left {
    @top-left {
        content: string(maptitle) string(parttitle) string(chaptertitle) string(sectiontitle) " |
        " counter(page);
    }
}

@page :right{
    @top-right {  
        content: string(maptitle) string(parttitle) string(chaptertitle) string(sectiontitle) " |
        " counter(page);
    }
}  
```

If you want to change this, you should use the content CSS properties of other page margin boxes, and inhibit the ones in the above content. For example, to set the chapter title in the page top left corner, you can use:
@page :left {
  @top-left {
    content: none;
  }
  @top-left-corner {
    content: string(maptitle) string(parttitle) string(chaptertitle) string(sectiontitle) " |
    white-space: nowrap;
    text-align: left;
  }
}

@page :right {
  @top-right {
    content: none;
  }
  @top-right-corner {
    content: string(maptitle) string(parttitle) string(chaptertitle) string(sectiontitle) " |
    white-space: nowrap;
    text-align: right;
  }
}

Note:
The corner page margin boxes are fixed and limited as the available space. Above, the `text-align` and `white-space` properties are used to make the text bleed out of these boxes towards the center of the page. If you plan to add an image or artwork background, you should consider using the technique described in: How to Decorate the Header by Using a Background Image on the Entire Page (on page 1716).

How to Change the Size of Headers and Footers

This is directly related to the page margins and size.

The headers and footers are placed in the so-called page margin boxes, a series of rectangular areas residing in the page margins.

To affect the margins of all page definitions, you may use the following rule:

```xml
@page {
  margin-top: 3cm !important;
  margin-bottom: 3cm !important;
  margin-left: 2cm !important;
}
```
If you want to affect only a specific page, like the first page from chapters for instance, you must use more specific page selectors. See the Default Page Definitions (on page 1700) for details.

Note that the page margin boxes fill the entire page margin. This means the margin-top, for example, dictates the height of the @top-left-corner, @top-left, @top-center, @top-right, @top-right-corner margin boxes. These cannot have margins on themselves, so to change the position of the content inside them, you must use padding properties:

```css
@page {
  @top-left {
    content: "...",
    padding: 1cm;
  }
}
```

How to Change the Font of the Headers and Footers

To change the font for all the headers and footers, in your customization CSS (on page 1693), add a CSS rule similar to this:

```css
@page {
  font-size: 12pt;
  font-family: "Arial";
}
```

**Important:**
These settings apply to all page margin boxes, but not to the text inside the page.

If you want to change the settings only for a specific page type (for example, the table of contents), use the name of the page:

```css
@page table-of-contents {
  font-size: 12pt;
  font-family: "Arial";
}
```

Related Information:
How to Change the Header of the Table of Contents (on page 1761)
How to Change Header Text for Each Topic

It is possible to dynamically change the header depending on the content in a topic. The following example assumes that the data to be presented in the header is located in the metadata section of each topic. One way is to specify it in the DITA map is by using the `<topicmeta>` element for the `<topicref>` topic reference:

```xml
...  
<topicref href="topics/installing.dita">
  <topicmeta>
    <data name="header-data" value="ID778-3211"/>
  </topicmeta>
...  
```

In the above example, there is set of key value pairs with the name `header-data`. This information is automatically copied into the content in the merged map file (on page 1695), like this:

```xml
<topic ... >
  <title class="- topic/title ">Installing</title>
  <shortdesc class="- topic/shortdesc ">You install components to make them available for your solution.</shortdesc>
  <prolog class="- topic/prolog ">
    ...
  ...
  <data class="- topic/data" name="header-data" value="ID778-3211"/>
  ...
```

This information can be extracted from the CSS:

```css
/* Define the string set variable that contains the text extracted from the data element */
*[class ~="topic/topic"] *[class ~="topic/data"][name="header-data"] {  
  string-set: hdrstr attr(value);
}

/* Using the value='none' stops applying the image. */
*[class ~="topic/topic"] *[class ~="topic/data"][name="header-data"][value="none"] {  
  string-set: hdrstr ";
}

/* Use the string set variable in one of the page margin boxes. */
@page chapter {
  @top-left-corner {
    content: string(hdrstr);
  }
}
```
Notes:

The string set is applied to all pages that follow the data element, until another data element changes it:

```
...<topicref href="topics/installing.dita">
  <topicmeta>
    <data name="header-data" value="ID778-3211"/>
  </topicmeta>
</topicref>
<topicref href="..."> <!-- Uses the same value -->
  <topicref href="..."> <!-- Uses the same value -->
  <topicref href="..."> <!-- Uses the same value -->
  <topicref href="topics/change.dita">
    <topicmeta>
      <data name="header-data" value="ID990-3200"/>
    </topicmeta>
  </topicref>
  <topicref href="..."> <!-- The string set is changed now -->
  <topicref href="..."> <!-- The string set is changed now -->
  <topicref href="..."> <!-- The string set is changed now -->
```

To clear the text, use the `none` value:

```
...<topicref href="..."> <!-- The string set is void now -->
```

How to Change Header Images for Each Chapter

It is possible to dynamically change an image in the header depending on the chapter. For this, you need to define an image reference in the metadata section of each chapter. One way is to specify it in the DITA map by using the `<topicmeta>` element for the `<chapter>` topic reference:

```
...<chapter href="topics/installing.dita">
  <topicmeta>
    <data name="header-image" value="img/installing.png"/>
  </topicmeta>
...```

In the above example, there is set of key value pairs with the name `header-image`. The `img/installing.png` is an image reference relative to the DITA map URI. This information is automatically copied into the content in the merged map file (on page 1695), like this:
Installing

You install components to make them available for your solution.

This information can be picked up from CSS:

```css
/* Define the string set variable that contains an URL */
*[class ~="topic/topic"] *[class ~="topic/data"]*[name="header-image"] {
    string-set: imgst oxy_url(oxy_xpath('/*/@xtrf'), attr(value));
}

/* Using the value='none' stops applying the image. */
*[class ~="topic/topic"] *[class ~="topic/data"]*[name="header-image"]*[value="none"] {
    string-set: imgst "";
}

/* Use the string set variable in one of the page margin boxes. */
@page chapter {
    @top-left-corner {
        content: string(imgst);
        font-size:0; /* remove the font ascent and descent */
    }
}
```

Details: The `@value` attribute is used to build a URL relative to the URI of the DITA map. To determine the base URI of the DITA map, the `@xtrf` attribute was used from the root element of the merged map document, extracted using the `oxy_xpath` function.

Notes:

- The image is always aligned vertically to the middle of available space from the page margin box.
- Make sure you use an image of the correct size. For example, if you want to place the image in the top-left corner of the page, assuming the top and left page margins are 1 in, then make sure the image is a square having a size of 1 in.
- The image is applied to all pages that follow the data element, until another data element changes it:

```xml
...<chapter href="topics/installing.dita">
```
To clear the image, use the `none` value:

```xml
...<data name="header-image" value="none"/>
...
```

### How to Add a Multi-line Copyright Notice to the Footer

Suppose you want to add a footer with the following two lines of text at the end of each page that is shown on the right side:

© 2017 - My Company Ltd  
All rights reserved

For this, you need to specify a rule that matches all the right pages and adds that content in the bottom-center. In your customization CSS (on page 1693), add the following CSS rule:

```css
@page :right {  
  @bottom-center {  
    content: "© 2017 - My Company Ltd \A All rights reserved";
    font-size: 0.5em;
    color: silver;
  }
}
```
How to Add a Group of Topics to the Footer

To create a footer that contains the content of several topic files, but only on the last page, there are two possible approaches:

**Method 1: Using the position:fixed CSS Property**

1. Group all the footer topics under a single parent topic, under the last topic from your DITA map. For example, you can have the following map structure:

   ```
   ...
   End topic
   Footer container topic
       Footer content topic 1
       Footer content topic 2
   ```

2. Add an @outputclass=footer on the <topic> root element of the footer container topic, or on its <topicref> in the map.

3. Use the CSS position: fixed property to position this topic to the bottom of the page:

   ```
   *[outputclass ~^"footer"] { 
     position: fixed;
     
     bottom: 0.5in;
     left: 0.5in;
     
     width:5in;
     height:200pt;
   }
   ```
**Note:**

Make sure the width and height are enough for the content of the footer to fit. Be careful because the content might bleed out of the page. Use bottom and left values to position the block in the page.

---

**Method 2: Using the float:footnote CSS Property**

The second approach would be to declare the footer block as a footnote. Assuming the same DITA Map structure as above, you can use the following CSS fragment:

```css
*{outputclass ~="footer"} {  
  float:footnote;
}

*{outputclass ~="footer":footnote-call{  
  color:transparent;
  font-size:0;
}

*{outputclass ~="footer":footnote-marker{  
  color:transparent;
  font-size:0;
}
```

**Note:**

Use transparent colors and/or zero size font to avoid the display of the footnote counters.

---

**How to Add a Background Image to the Header**

A common use-case is to add a background image to one of the page corners.

```css
@page :left {  
  @bottom-left-corner{  
    content: " ";  
    background-image:  
    url('https://www.oxygenxml.com/resellers/resources/OxygenXMLEditor_icon.svg');  
    background-repeat:no-repeat;
    background-position:50% 50%;
  }
}
```

**Important:**

Always specify a `content` property. If not, the page margin box will not be generated.
Another use-case is to use the \texttt{@top-left} or \texttt{@top-right} page margin boxes. These boxes have an automatic layout and they can be very small if they have no content. If there is no text to be placed over the image, use a series of non-breaking spaces (\texttt{\A0}) to increase the box width as in the following example (alternatively, you can use the technique described in How to Decorate the Header by Using a Background Image on the Entire Page (on page \pageref{1716})).

\begin{verbatim}
@page: left {
  @top-left{
    content: \A0\A0\A0\A0\A0\A0\A0\A0\A0\A0\A0;
    background-image: url('https://www.oxygenxml.com/resellers/resources/OxygenXMLEditor_icon.svg');
    background-repeat:no-repeat;
    background-position:50% 50%;
  }
}
\end{verbatim}

\textbf{Note:}  
You can use raster image formats (such as PNG or JPEG), but it is best to use vector images (such as SVG or PDF). They scale very well and produce better results when printed. In addition, the text from these images is searchable and can be selected (if the glyphs have not been converted to shapes) in the PDF viewer.

  \end{itemize}
\end{enumerate}

\section*{How to Add a Link in Headers and Footers}

\textbf{Method 1: Using an SVG Link Attribute}

It is possible to add a link inside the document header (or footer) by using the \texttt{<a>} element inside an SVG document. For example, suppose you have the following SVG document named \texttt{custom.svg}:

\begin{verbatim}
<svg viewBox="0 0 100 40" xmlns="http://www.w3.org/2000/svg">
    <text x="10" y="25">PDF Chemistry</text>
  </a>
</svg>
\end{verbatim}

This creates an SVG link with \texttt{PDF Chemistry} displayed as its text (the content of the \texttt{<text>} element).
Note:
If you just want to add a link without text, you can define a rectangle that contains the link instead of text.

To display the link, you just need to set your SVG file as the content of one of the page margin boxes:

```css
@page {
  @top-left {
    content: url("custom.svg");
  }
}
```

**Method 2: Using the CSS `-oxy-link` Property**

It is also possible to add a link inside the document header (or footer) by using the `-oxy-link` property on the `@page` margin box declaration. The entire page margin box will behave as a link and will be clickable.

```css
@page {
  @top-left {
    content: "Link";
    -oxy-link: "https://www.oxygenxml.com/";
    color: blue;
  }
}
```

**How to Decorate the Header by Using a Background Image on the Entire Page**

If you want to precisely position artwork and the page margin boxes are not sufficient, it is possible to use a background image for the entire page.

This technique consists of creating an image (SVG is the best since it is a vector image) as wide as the page that would contain the logo and placing other decorations at the desired locations. This offers the best results and the position of the artwork does not depend on the page margin contents.

**Example:**

```css
@page :left, chapter: left, chapter:first: left {
  background-image: url('img/page_background_image_with_logos_and_artwork_for_left_page.svg');
  background-repeat: no-repeat;
  background-position: 50% 50%;
}
```

For a list of all the possible page names, see: Default Page Definitions (on page 1700).

**Related Information:**

- How to Add a Background Image for the Cover (on page 1737)
How to Style a Part of the Text from the Header

If you need to style a fragment of text (for example, a company slogan) with certain colors or font styles, you have several options:

• Use an SVG image as the background for a page margin box or for the entire page. See: How to Add a Background Image to the Header (on page 1714).

• Use the `oxy_label` constructor. This is a function that creates a text label with a set of styles.

```css
@page {
  @top-right {
    content: oxy_label(text, "My Company", styles, "color:red; font-size: larger;")
      ,
    oxy_label(text, "Product", styles, "color:blue;
      text-decoration:underline;"));
  }
}
```

You can combine the `oxy_label` with `oxy_xpath`, to extract and style a piece of text from the document:

```css
content: oxy_label(text, oxy_xpath("/some/xpath"), styles, "color:blue; "));```

**Note:**
These functions work only with the Chemistry CSS processor.

**Note:**
You cannot use `string()` inside an `oxy_label()`. As a workaround, to apply styling on the dynamic text retrieved by a `string()` function you can define some overall styles for the entire page margin box and then use the `oxy_label` to style differently the static text.

```css
@page {
  @top-right {
    color: red;
    content: oxy_label(text, "My Company", styles, "color:black")
      ,
    string(chaptertitle); /* This inherits the styling from @top-right*/
  }
}
```

• Use two adjacent page margin boxes, and style them differently:

```css
@page {
  @top-center {
    content: "First part";
    color: red;
    text-align:right;
  }
}
```
How to Simplify the Header (Keep Only the Chapter Title)

The headers display information such as *map title, part title, chapter title,* and *section title,* ending in the page number.

```css
.content: string(maptitle) string(parttitle) string(chaptertitle) string(sectiontitle) " | " counter(page);
```

This might be too much if you have long titles. The solution is to override the default header content.

In your *customization CSS (on page 1693),* add the following CSS rule:

```css
@page :left {
  @top-left {
    content: string(chaptertitle) " | " counter(page);
  }
}
@page :right {
  @top-right {
    content: string(chaptertitle) " | " counter(page);
  }
}
```

⚠️ **Important:**

Some of the CSS default page rules are more important. If you see that the content does not change:

- Try to also specify the name of the page, to increase the specificity of the rules:

  ```css
  @page :left, table-of-contents:left, chapter:left {
    ...
  }
  @page :right, table-of-contents:right, chapter:right {
    ...
  }
  ```

- Add an `!important` classifier just before the semi-colon.
How to Change the Header Separators (Between Sections and Chapter Titles)

There are some strings defined for part, chapter, and sections. Each of these strings start with the " | " character as a separator. For example, in the header of a page, you may find a sequence of strings:

My Publication | Introduction | Getting Started

1. "My Publication" is the value of the `maptitle` string.
2. "Introduction" is the value of the `chaptertitle` string.
3. "Getting Started" is the value of the `sectiontitle` string.

There might be cases where you want to change this separator. You will need to recompose the header content using the above string sets. Suppose you want to use " - " as a separator. In your customization CSS (on page 1693), add the following CSS rule:

```css
*[class =~ "topic/topic"][is-part] > *[class =~ "topic/title"] {
    string-set: parttitle " - " counter(part, upper-roman) " - " content(), chaptertitle ""; /* Avoid propagating a past chapter title on a new part */
}
*[class =~ "topic/topic"][is-chapter]:not([is-part]) > *[class =~ "topic/title"] {
    string-set: chaptertitle " - " counter(chapter) " - " content();
}
```

If you enabled the deep numbering for chapters and subsections (on page 1750), then use:

```css
/*
* Alter the string sets that are shown in the header of the page.
*/
*[class =~ "map/map"]*[p|numbering~='deep'] *[class =~ "topic/topic"][is-part] > *[class =~ "topic/title"] {
    string-set: parttitle " - " counter(part, upper-roman) " - " content(), chaptertitle ""; /* Avoid propagating a past chapter title on a new part */
}
*[class =~ "map/map"]*[p|numbering~='deep'] *[class =~ "topic/topic"][is-chapter]:not([is-part]) > *[class =~ "topic/title"] {
    string-set: chaptertitle " - " counter(chapter) " - " content(), sectiontitle "";
}
*[class =~ "map/map"]*[p|numbering~='deep'] *[class =~ "topic/title"] {
    string-set: chaptertitle " - " counter(chapter) " - " content();
}
```
How to Change the Header Styling Depending on Page Side

To modify the styling of the default page headers, add the following CSS rule in your customization CSS (on page 1693):

```
@page :left {
    @top-left {
        color:navy;
        font-style:italic;
    }
    @top-right {
        color:red;
    }
}
```

If you intend to modify just the headers of the table of contents, use the table-of-contents page rule selector:

```
@page table-of-contents: left {
    @top-left {
        color:navy;
        font-style:italic;
    }
    @top-right {
        color:red;
    }
}
```

How to Use XPath Computed Data or Images in the Header or Footer

A very simple approach is to use the oxy_xpath directly in the content property:

```
@page front-page {
    @top-center {
        content: "Created: " oxy_xpath('//*[@class[contains(@class, "topic/created ")]][1]');
    }
}
```

Example 1: Compute the Number of Words

The following example computes the number of words from the publication. It counts all the words, including the ones from the TOC, but does not take the static labels into account:

```
@page front-page {
    @bottom-center {
```
**Example 2: Retrieve Image from a Document and Insert it in the Header**

Another example is to use an image from the document in the publication header:

```xml
<bookmeta>
  <metadata>...
    <data name="cover">
      <image href="product-cover.png" outputclass="cover-image"/>
    </data>
  ...
</metadata>
</bookmeta>
```

```css
@page {
  @top-center {
    content: url("oxy_xpath('//*[contains(@outputclass, "cover-image")]//@href")");
  }
}
```

If the URL returned by `oxy_xpath` is not absolute, it is considered to be relative to the CSS file. To obtain an absolute URL from one relative to the XML document, you can use in the XPath expression functions like `resolve-uri` and `document-uri`:

```css
@page {
  @top-center {
    content: url(oxy_xpath("resolve-uri('//*[contains(@outputclass, 'cover-image')]//@href),
                        document-uri('//'))");
  }
}
```
Example 3: Insert the Current Date in the Footer

Another example is to use the `oxy_xpath` function to compute the current date and insert it in the publication footer:

```xml
@page {
    @bottom-left {
        content: oxy_xpath('current-date()');
    }
}
```

Example 4: Picking up Metadata from the Original Map

Another example is to use the `oxy_xpath` function to extract the title, or any other element text value from the original processed DITA map file. For this, you can use the `@xtrf` attribute that is set on the root element of the merged map. This attribute contains the URL of the input map.

```xml
:root{
    string-set: maptitle oxy_xpath('document(@xtrf)/*[contains(@class, " map/map ")/*/contains(@class, " topic/title ")]/text()');
}
```

How to Add a Line Under the Header

There are two ways to add a horizontal line under the header.

Method 1: Add a Border in the Page Margin Boxes

To add a horizontal line that would stretch across the width of the page, add a bottom border to each of the 5 margin boxes in the top side of the page (`top-left-corner, top-left, top-center, top-right, top-right-corner`).

If you consider that the space between the header and the bottom border is too large, you could also change the alignment by adding a `vertical-align: bottom;` declaration in the page margin boxes.

For example, if you need to set some text as a header in the top-left margin box and insert a horizontal line under it, the customization CSS would look something like this:

```xml
@page chapter, chapter:first:left:right, front-page{

    padding-top: 1em;

    @top-left {
        content: "Custom header";
    }
```
color: gray;
border-bottom: 1px solid black;
vertical-align: bottom;
}

@top-center{
  content: " ";
  border-bottom: 1px solid black;
  vertical-align: bottom;
}

@top-right{
  content: " ";
  border-bottom: 1px solid black;
  vertical-align: bottom;
}

@top-right-corner{
  content: " ";
  border-bottom: 1px solid black;
  vertical-align: bottom;
}

@top-left-corner{
  content: " ";
  border-bottom: 1px solid black;
  vertical-align: bottom;
}

Note:
The padding-top: 1em; is used to avoid the border at the bottom of the header that joins with the page content.

Method 2: Use a Background Image

An alternative method is to add a horizontal line/border under an existing header (or in any other part of the page) using an SVG image, as described in How to Add a Background Image to the Header (on page 1714).

How to Change the Headings Using a Parameter

Suppose you need to change the headings of your publication by specifying a static text in a parameter.

First, establish a name for your parameter (it must start with the args.css.param. prefix). For example, you could name it args.css.param.heading.text. It will have the text value that you will pass when starting the
transformation. This parameter does not have to be registered anywhere as it will be automatically recognized and passed as an XML attribute on the root of the merged file, as specified in Styling Through Custom Parameters (on page 1833).

Next, alter your customization CSS to make use of the parameter value. In the example below, the text is placed in the central part of the header:

```css
@page front-page, table-of-contents, chapter {
  @top-center{
    content: oxy_xpath("/*/heading.text");
  }
}
```

Note:
You can use any XPath 2.0 here. It will be executed in the context of the merged map document, so you can collect data from it. You can use if/then/else expressions if your parameter is a switch.

The text does not affect the first pages from the page sequences because the built-in CSS page rules (on page 1700) clear the content from the headers. If you need the text content on all pages, you might consider adding an !important keyword after the content property value, or increase the specificity of the page selectors, like this:

```css
  @top-center{
    ...
  }
}
```

Another use case is to alter the string-sets that are used in the headers (not the headers directly), as it is explained here: How to Use XPath Computed Data or Images in the Header or Footer (on page 1720). You can use this technique to alter the chapter titles as in the following example:

```css
*[class = "map/map"][numbering="deep"]
  *[class = "topic/topic"][is-chapter]:not([is-part]) >
    *[class = "topic/title"] {
      string-set:
        chaptertitle * | "" counters(chapter-and-sections, ".") * " - "
        oxy_xpath("/*/heading.text") content() ,
        sectiontitle "";
    }
```
Metadata

DITA has a solid vocabulary for specifying metadata. There are `<prolog>` elements in the topics, and `<topicmeta>`, `<bookmeta>` elements in the bookmaps. They can be used to define authors, dates, audiences, organizations, etc. See: https://www.oxygenxml.com/dita/1.3/specs/archSpec/base/metadata-in-maps-and-topics.html

It is up to you to decide where this information should be presented, in the PDF content or in the PDF document properties.

Metadata - XML Fragment

In the merged map file (on page 1695), the metadata section is placed inside the `<oxy:front-page>` element. This is different from the original placement in the map or bookmap (after the title), but allows for the usage of information from it in the title page.

Bookmaps

This is an example of a section taken from a merged bookmap. It only contains some of the possible metadata elements. The `<bookmeta>` metadata section is inherited from `<topicmeta>`:

```xml
         xmlns:opentopic-index="http://www.idiominc.com/opentopic/index" cascade="merge"
         ditaarch:DITAArchVersion="1.3">

    <bookmeta xmlns:dita-ot="http://dita-ot.sourceforge.net/ns/201007/dita-ot"
               class="- map/topicmeta bookmap/bookmeta">
      <author class="- topic/author">Howe Tuduit</author>
      <bookid class="- topic/data bookmap/bookid">
        <isbn class="- topic/data bookmap/isbn">071271271X</isbn>
        <booknumber class="- topic/data bookmap/booknumber">SG99-9999-00</booknumber>
        <maintainer class="- topic/data bookmap/maintainer">
          <organization class="- topic/data bookmap/organization">ACME Tools</organization>
          <person class="- topic/data bookmap/person"/>
        </maintainer>
      </bookid>
      <bookrights class="- topic/data bookmap/bookrights">
        ...
      </bookrights>
      <bookowner class="- topic/data bookmap/bookowner">

      </bookmeta>

  </oxy:front-page>
</bookmap>
```
For the **DITA Map PDF - based on HTML5 & CSS** transformation type, the merged map is further processed resulting in a collection of HTML5 `<div>` elements. These elements preserve the original DITA `@class` attribute values and add a new value derived from the DITA element name.
Maps

The maps have a more simple structure, they use the `<topicmeta>` element for metadata sections. This is also a simplified example, as there may be many more elements in the metadata section:

```xml
<map xmlns:ditaarch="http://dita.oasis-open.org/architecture/2005/"
     xmlns:opentopic-index="http://www.idiominc.com/opentopic/index"
     cascade="merge" class="- map/map ">
  ditaarch:DITAArchVersion="1.3">
  ...
</map>

  ...
</oxy:front-page>

For the DITA Map PDF - based on HTML5 & CSS transformation type, the merged map is further processed resulting in a collection of HTML5 `<div>` elements. These elements preserve the original DITA `<class>` attribute values and add a new value derived from the DITA element name.

```xml
     xmlns:opentopic-index="http://www.idiominc.com/opentopic/index"
     cascade="merge" class="- map/map ">
  ditaarch:DITAArchVersion="1.3">
  ...
</div>

<div class=" front-page/front-page front-page">
  ...
</div>

<div class="- map/topicmeta topicmeta">
  ...
</div>

<div class="- topic/author author"/>
  Dan C
</div>

<div class="- topic/metadata metadata">
  ...
</div>

<div class="- topic/prodinfo prodinfo">
  ...
</div>

<div class="- topic/prodname prodname">
  oXygen PDF CSS DITA Plugin
</div>

</div>

<div class="- topic/audience audience"/>
```
Metadata - Built-in CSS rules

The `{PLUGIN_DIR}/css/print/p-meta.css` file contains the rules that extract metadata.

How to Create a Searchable PDF

To make a PDF searchable, you need to add some `<keyword>` or `<indexterm>` elements inside bookmaps, maps, or topics. Most of the search engines will parse the resulting document and extract those keywords and create a search base.

**Note:**

Both `<keyword>` and `<indexterm>` elements can be combined inside the `<keywords>` element. They will be equally processed by the search engine.

In the generated PDF, keywords are displayed in the Document Properties.

**Bookmaps**

If you want your keywords to appear inside a bookmap, you need to define them inside the `<bookmeta>` element:

```xml
<bookmap>
  ...
  <bookmeta>
    <keywords>
      <keyword>web server</keyword>
      <keyword>hard disk</keyword>
    </keywords>
  </bookmeta>
</bookmap>
```

**Maps**

If you want your keywords to appear inside a map, you need to define them inside the `<topicmeta>` element:

```xml
<map>
  ...
  <topicmeta>
    <keywords>
      <keyword>flowers</keyword>
      <indexterm>care and preparation</indexterm>
      <keyword>seasons</keyword>
    </keywords>
  </topicmeta>
</map>
```
Topics
If you want your keywords to appear inside one or more topics, you need to define them inside the `<prolog>` element:

```xml
<topic>
  ...
  <prolog>
    <metadata>
      <keywords>
        <indexterm>iris</indexterm>
      </keywords>
    </metadata>
  </prolog>
</topic>
```

**Warning:**
Keywords must be at map level or at topic level, you cannot combine them.

How to Add the Publication Audience to the Custom PDF Metadata
The audience element indicates the users the publication is addressing. This can be placed inside a `<topicmeta>` element in a `<map>` as in the following example:

```xml
<map>
  ...
  <topicmeta>
    ...
    <audience type="programmer" job="programming" experiencelevel="expert"/>
  </topicmeta>
</map>
```

To collect the `@type` attribute, add the following in your customization CSS *(on page 1693)*:

```css
*[^map/*] > [*[^map/topicmeta]] > *[^^topic/audience]] {
  -oxy-pdf-meta-custom: "Audience" attr(type);
}
```

**Note:**
It is best to use the class selector (such as `[^map/*]`) instead of `topicmeta` to cover cases where the elements are specialized (for instance, in a bookmap the `bookmeta` is a `topicmeta`, so your selector will also function for bookmaps, not only simple maps.

**Note:**
The selector begins with `map` to choose the `<topicmeta>` that is a direct child of the map, not other `<topicmeta>` elements from other `<topicref>` elements.

The metadata is displayed in the **Custom** tab of the **Document Properties** dialog box from Acrobat Reader:
How to Show Metadata in the Cover Page

Suppose you need to present the **Author** and the **ISBN** (when it exists) just under the publication title and suppose your bookmap contains:

```xml
<bookmap id="taskbook">
  <booktitle>
    <booklibrary>Retro Tools</booklibrary>
    <mainbooktitle>Product tasks</mainbooktitle>
    <booktitlealt>Tasks and what they can do</booktitlealt>
  </booktitle>
  <bookmeta>
    <author>Howe Tuduit</author>
    <critdates>
      <created date="1/1/2015"/>
      <revised modified="3/4/2016"/>
      <revised modified="3/5/2016"/>
    </critdates>
  </bookmeta>
</bookmap>
```
The entire `<booktitle>` element content is displayed on the first page of the PDF, so if you need to add the information after it, in your customization CSS (on page 1693), add the following CSS rules:

```
*{class ~="bookmap/booktitle"]:after {
    display: block;
    content: "by " oxy_xpath("//*[contains(@class, " bookmap/bookmeta ")]/*/contains(@class, " topic/author "))/text()");
    margin-top: 4em;
    text-align: center;
    color: gray;
}
*{class ~="bookmap/booktitle"]:after(2) {
    display: block;
    content: oxy_xpath("if(//*[contains(@class, " bookmap/isbn ")] then concat("ISBN ", //*[contains(@class, " bookmap/isbn ")]//text() else "")");
    text-align: center;
    color: gray;
}
```

The following CSS extensions were used in this example:

- **oxy_xpath** - Executes an XPath expression and returns a string content. Use this whenever you need to extract data from elements other than the one matched by the CSS rule selector.
- **:after(N)** - Creates more than one after pseudo-element. The argument value represents how far the generated content is from the real content. In the example above, the content of the :after is closer to the title (upper) than the content of the :after(2).

Note:
The attr() CSS function can also be used but is limited to extracting attribute values from the matched element.

**Generating Synthetic Pages for Metadata.**

Suppose you need to show this information on a page that follows the title page, instead of on the title page. In this case, you need to prepare a named page and place the content in it. In your customization CSS (on page 1693), add the following CSS rules:

```
@page page-for-meta {
    background-color: yellow; /* Just to see it better*/
@top-left-corner {
    content:""; /* Remove the default header */
```
How to Show Metadata in the Header or Footer

The header and footer are composed of page margin boxes that can be populated with static text by using string-sets.

If you need to add some of the map metadata to the header of the front page (for example, the creation date), add the following CSS rules in your customization CSS (on page 1693):

```css
*[class =~ "bookmap/booktitle"]:after {
  page: page-for-meta;
}
*[class =~ "bookmap/booktitle"]:after(2) {
  page: page-for-meta;
}
```

```css
@page front-page {
  @top-center {
    content: "Created: " string(mapcreated);
  }
}
```

**Note:**

The `front-page` is the name of a page that used to present the element with the class "front-page/front-page". The above page rule is combined with the default styles.

How to Remove or Change the PDF Keywords

The keywords defined in the prolog sections of topics are automatically collected and set as PDF keywords. These are shown by the readers in the PDF document properties window.
If you need to remove them, you can use the following CSS snippet in your customization CSS *(on page 1693)*:

```css
:root {
  -oxy-pdf-meta-keywords:"";
}
```

To change them, if you have a hard-coded list, you just enumerate each of them in the property content, separating them with comma:

```css
:root {
  -oxy-pdf-meta-keywords:"alpha, beta, gamma";
}
```

If you need to extract them by other criteria from the merged map, you can use the `oxy_xpath()` function instead of the hard-coded list.

### How to Remove the PDF Publication Title Property

The title defined in the PDF reader is automatically collected from the map's main title.

If you want to display the map name instead of the title, you can use one of the following rules in your customization CSS *(on page 1693)*:

```css
/*
 * Titles (maps).
 */
*[class ~~ "front-page/front-page-title"] *[class ~~ "topic/title"]:not([class ~='bookmap/booktitle']) {
  -oxy-pdf-meta-title: unset;
}
```

```css
/*
 * Titles (bookmaps).
 */
*[class ~~ "front-page/front-page"] *[class ~~ "bookmap/booktitle"] > *[class ~='bookmap/mainbooktitle'] {
  -oxy-pdf-meta-title: unset;
}
```

### How to Change the PDF Publication Title Property

The `<title>` element of a bookmap is quite complex and contains elements for the book library and an alternate title:

```xml
<booktitle>
  <booklibrary>Retro Tools</booklibrary>
  <mainbooktitle>Main Book Title</mainbooktitle>
</booktitle>
```
For the publication title, the built-in CSS uses only the content of the `<mainbooktitle>`. If you want to collect all of the text from the `<booktitle>`, you can add the following rule to your customization CSS (on page 1693):

```
:root {
  -oxy-pdf-meta-title: oxy_xpath('//*[contains(@class, "bookmap/booktitlealt")]')[1]/text();
  -oxy-pdf-meta-description: "";
}
```

An XPath expression is used to collect all the `<booktitlealt>` elements from the merged map, select the first one, then use its text.

The built-in CSS uses the `<booktitle> as the PDF description. In the example above, this property is cleared since it was moved as a title.

### How to Use a Key Value from the Map in the CSS

To use a key value in the CSS, the key must be referenced from the content (either a topic or map).

If you do not have it referenced, you may force a reference by using the `<topicmeta>` or `<bookmeta>` section of your map and a `<data>` element. This has no effect on the published content, but allows the CSS rules to use its content.

```
<bookmeta>
  ....
  <data keyref="my_key"/>
  ....
</bookmeta>
```

This is expanded in the merged HTML file to:

```
<div class="- map/topicmeta bookmap/bookmeta topicmeta bookmeta">
  ...
  <div keyref="my_key" class="- topic/data data">
    <div class="- topic/keyword keyword">KEY VALUE</div>
  </div>
  ...
</div>
```

Suppose that you need the expanded key value in the footer of the publication. You can define a string-set on this `<data>` element:

```
*[class = "topic/data"]|keyref="my_key"] {
  string-set: key-string content(text);
}
@page {
  @bottom-left {
```
Oxygen XML Editor 23.1

### Content

```
content: "My key is: " string(key-string) !important;
}
```

Or you can use the value from a :before pseudo-element, like the one for the title:

```
*[class ~= "topic/title"]:before {
  content: oxy_xpath("//*[contains(@class, 'topic/data')][@keyref = 'my_key']//text()");
}
```

Another use-case is to use the key as a source for a custom PDF document property:

```
*[class ~= "topic/data"][@keyref="my_key"] {
  -oxy-pdf-meta-custom: attr(keyref) content(text);
}
```

### Cover (Title) Page

Customizing the cover page is one of the most requested customization requests.

### Cover Page - XML Fragment

The **merged map file** (*on page 1695*) contains the `<oxy:front-page>` element, as a child of the root element. This contains the metadata and an `<oxy:front-page-title>` element with the title structure.

```
<bookmap xmlns:ditaarch="http://dita.oasis-open.org/architecture/2005/" ...>
    <bookmeta xmlns:dita-ot="http://dita-ot.sourceforge.net/ns/201007/dita-ot" ...
      </bookmeta>
    <oxy:front-page-title>
      <booktitle xmlns:dita-ot="http://dita-ot.sourceforge.net/ns/201007/dita-ot"
        class="- topic/title bookmap/booktitle">
        <booklibrary class="- topic/ph bookmap/booklibrary " class="Retro Tools"></booklibrary>
      </booktitle>
      <booktitlealt class="- topic/ph bookmap/mainbooktitle " class="Tasks"></booktitlealt>
    </oxy:front-page-title>
  </oxy:front-page>
</bookmap>
```

For the **DITA Map PDF - based on HTML5 & CSS** transformation type, the merged map is further processed resulting in a collection of HTML5 `<div>` elements. These elements preserve the original DITA `<class>` attribute values and add a new value derived from the DITA element name.

```
<div class="- map/map bookmap/bookmap bookmap" ...
  <div class="- front-page/front-page front-page">
    <div class="- map/topicmeta bookmap/bookmeta boometa" ...
```
Cover Page - Built-in CSS rules

The element with the class `front-page/front-page` is associated with a page named `front-page` with no headers or footers. The front page title is styled with a bigger font. The built-in CSS rules are in `[PLUGIN_DIR]/css/print/p-front-page.css`.

```plaintext
@media print {

  *[class~="front-page/front-page"] { 
    page: front-page; 
  }

  /* Prevents the front-page title margin collapsing */
  *[class~="front-page/front-page"]:before(1000) { 
    display:block; 
    content:\A; 
    font-size:0; 
  }

  *[class~="front-page/front-page-title"] { 
    display:block; 
    text-align:center; 
    margin-top:3in; 
    font-size:2em; 
    font-family:arial, helvetica, sans-serif; 
    font-weight:bold; 
  }

  @page front-page { 
    @top-left-corner { content:none } 
    @top-left { content:none } 
    @top-center { content:none } 
    @top-right { content:none } 
    @top-right-corner { content:none } 
  }
```
How to Add a Background Image for the Cover

The simplest way is to create an SVG image as large as the entire physical page and set it as the background for the front-page. This makes it easy to accomplish a good positioning of the graphical elements or artwork. In the foreground, you can place text fragments using a series of :after pseudo-elements bound to the front page title.

To set the size to an SVG image, you should specify the @width and @height attributes on the <svg> root element using specified unit values (in, cm, etc.) This should be enough only if all the coordinates from your drawing have unit identifiers.

If you are using unit-less coordinates in your drawing like the following:

```svg
text points="17.78 826.21 577.51 ...."
```

Next, make sure you also specify the @viewBox attribute on the <svg> root element that defines the abstract rectangle that contains the drawing:

```svg
<svg xmlns="http://www.w3.org/2000/svg" width="8.5in" height="11in" viewBox="0 0 600 850">
```

The following SVG document has the @width, @height, and @viewBox attributes. The width and height have physical units (in inches), while the view box and rectangle coordinates are unit-less.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE svg PUBLIC "-//W3C//DTD SVG 1.1//EN"
  "http://www.w3.org/Graphics/SVG/1.1/DTD/svg11.dtd">
<svg xmlns="http://www.w3.org/2000/svg" width="8.5in" height="11in" viewBox="0 0 110 110">
  <desc>A gradient as big as a page.</desc>
  <defs>
    <linearGradient id="lc" x1="0%" y1="0%" x2="0%" y2="100%"
                     spreadMethod="pad">
      <stop offset="0%" stop-color="#00DD00" stop-opacity="1"/>
      <stop offset="100%" stop-color="#00AA00" stop-opacity="1"/>
    </linearGradient>
  </defs>
</svg>
```
This example shows a gradient. It is the size of a US-LETTER page and can be used in a publication using this page size.

Note:
You can use raster image formats (such as PNG or JPEG), but it is best to use vector images (such as SVG or PDF). They scale very well and produce better results when printed. In addition, the text from these images is searchable and can be selected (if the glyphs have not been converted to shapes) in the PDF viewer.

In your customization CSS (on page 1693), add the following:

```css
@page front-page {
    background-image: url("us-letter.svg");
    background-position: center;
    background-repeat: no-repeat;
    background-size: 100% 100%;
}
```

For smaller artworks, you can use `background-position` with percentage values to position and center the artwork (for example, a company logo):

```css
@page front-page {
    background-image: url("company-logo.svg");
    background-position: 50% 5%; /* The first is the alignment on the X axis, the second on the Y axis. */
    background-repeat: no-repeat;
}
```

Note:
The text from the SVG or PDF background images is searchable in the PDF reader.

How to Use Different Background Cover Images Based on Bookmap or Map Info

It is common to use the same CSS file for customizing multiple publications, and you may need to set a different cover for each of them. The solution is to use an XPath expression to extract some information from the document, and based on that, select the SVG images.
The backslash (\) is used to continue the expression string on the subsequent lines (there should be no spaces after it). For more use cases solved using XPath, see: Metadata (on page 1725).

How to Change Styling of the Cover Page Title

Match the front page title element in your customization CSS (on page 1693) based on its class attribute:

```css
*{class =~ "front-page/front-page-title"} {  
  margin-top: 1in;  
  font-size: 3em;  
}
```

⚠️ Important:
Make sure the sum of the top and bottom margins and paddings for this element do not exceed the physical dimension of the page. If this happens, an extra blank page may appear before the cover page. Usually, it is enough to specify only the top margin.

How to Add Text to the Cover Page

If you need to add arbitrary text to the cover page, you can use the front page title element as an anchor and add as many blocks of text as you need after it, and style them differently.

In your customization CSS (on page 1693), add the following:

```css
*{class =~ "front-page/front-page-title"}:after(1) {  
  display:block;  
  content: "DRAFT VERSION";  
  font-size: large;  
  color: red;  
  text-align:center;  
}
```

```css
*{class =~ "front-page/front-page-title"}:after(2) {  
  /* add more styles */
}  
```
The result is:

To use content from the document, you can use the `oxy_xpath` function in the `content` property. For a more complex example, including the generation of a new page for the synthetic `:after` elements, see: How to Show Metadata in the Cover Page (on page 1730).

Related Information:
- How to Show Metadata in the Cover Page (on page 1730)

**How to Place Cover on the Right or Left Side**

In your customization CSS (on page 1693), add the following CSS rules:

```css
*{[class ~="front-page/front-page"]{
    page-break-before: left;
}
```

**Note:**

This will create an empty page at the beginning of the publication, moving the cover content on the needed side.

For more information, see: Oxygen PDF Chemistry: Controlling Page Breaks.

Related Information:
- Double Side Pagination (on page 1770)
How to Add a Specific Number of Empty Pages After the Cover Page

In your customization CSS (on page 1693), add the following CSS rules:

```css
@page my-blank-page {
    /* Hide the page numbers */
    @top-left {content: none;
    @top-right {content: none;
}

*[class ~='front-page/front-page']:after(1){
    page:my-blank-page;
    display:block;
    content: '\2002';
    color:transparent;
    page-break-after:always;
}

*[class ~='front-page/front-page']:after(2){
    page:my-blank-page;
    display:block;
    content: '\2002';
    page-break-after:always;
}

*[class ~='front-page/front-page']:after(3){
    page:my-blank-page;
    display:block;
    content: '\2002';
    page-break-after:always;
}
```

Note:
The \2002 character is a space that is not shown on the pages, but gives a value for the content property.

How to Force an Odd or Even Number of Pages in a Chapter (on page 1771)

How to Add a Copyright Page after the Map Cover (Not for Bookmaps)

Regular DITA maps do not have the concept of a copyright notice. This is available only in the DITA bookmap structure.
If you are constrained to using a regular map and you need to add a copyright page between the front cover and the TOC, use the following technique:

In your customization CSS (on page 1693), declare a new page layout:

```css
@page copyright-notice-page {
    @top-left {
        content: none; /* Clear the headers for the copyright page */
    }
    @top-right {
        content: none;
    }
}
```

The element with the class `front-page/front-page` element contains the title of the publication and generates the cover page. A synthetic :after element is created that follows this element and it is placed on a different page.

```css
*[class="front-page/front-page"]:after{
    display: block;
    page: copyright-notice-page; /* Moves the synthetic element on a new page. */
    margin-top: 90%; /* use margins to position the text in the page */
    margin-left: 5em;
    margin-right: 5em;
    content: "Copyright 2018-2019 MyCorp Inc. \A All rights reserved";
    text-align: center; /* More styling */
    color: blue;
}
```

If you need to add more content as blocks, use the :after(2), :after(3) pseudo-elements:

```css
*[class="front-page/front-page"]:after(2){
    display: block;
    page: copyright-notice-page; /* Continue on the same page as the first ':after'. */
    content: "Some more styled text";
    color: red;
}
```

If you want to extract information from the document, use the `oxy_xpath()` function. For example, if the copyright info is stored in the map like this:

```xml
<map ...>
    <topicmeta>
```

then use this:

```xml
 *[class =~ "front-page/front-page"]:after(3) { 
    display: block;
    page: copyright-notice-page;
    content: 
    "Year: "
    oxy_xpath('//*[contains(@class, " front-page/front-page ")/*[contains(@class, " map/topicmeta ")/*[contains(@class, " topic/copyright ")/*[contains(@class, " topic/copyryear ")]/@year']
    "
    "\A Holder: "
    oxy_xpath('//*[contains(@class, " front-page/front-page ")/*[contains(@class, " map/topicmeta ")/*[contains(@class, " topic/copyright ")/*[contains(@class, " topic/copyrholder ")]/text()']
    color: green;
  }
```

How to Debug XPath Expressions (on page 1699)

How to Remove the Cover Page and TOC

If you need to hide or remove the cover page, the table of contents or other structures, match the elements with a "front-page/front-page" and "toc/toc" classes in your customization CSS (on page 1693):

```xml
 *[class =~ 'map/map'] > *[class =~ 'toc/toc'] { 
    display: none !important;
  }
 *[class =~ 'map/map'] > *[class =~ 'front-page/front-page'] { 
    display: none !important;
  }
 *[class =~ 'topic/topic'][is-chapter] { 
    -oxy-page-group: auto;
  }
```
Oxygen XML Editor 23.1 | 11 - Publishing | 1744

Front Matter and Back Matter
The front matter is a series of topics that are usually placed after the cover page and before the TOC or the
content.
The back matter is a series of topics that are usually placed after the content of the book.

Front Matter and Back Matter - XML Fragment
In the merged map file (on page 1695), the frontmatter topic references are wrapped in a <frontmatter>
element that has the class bookmap/frontmatter. Then, the referenced content is marked with the attribute @isfrontmatter="true":
<bookmap xmlns:ditaarch="http://dita.oasis-open.org/architecture/2005/" ...>
<oxy:front-page class="- front-page/front-page ">
...
</oxy:front-page>
class="- toc/toc ">
...
<frontmatter xmlns:dita-ot="http://dita-ot.sourceforge.net/ns/201007/dita-ot"
class="- map/topicref bookmap/frontmatter ">
...
<topicref class="- map/topicref " href="#unique_1" type="concept">
...
</frontmatter>
</opentopic:map>
<concept
class="- topic/topic concept/concept "
is-frontmatter="true"
topicrefclass="- map/topicref bookmap/bookabstract " ...>

For the DITA Map PDF - based on HTML5 & CSS transformation type, the merged map is further processed
resulting in a collection of HTML5 <div> elements. These elements preserve the original DITA @class attribute
values and add a new value derived from the DITA element name.
<div xmlns:ditaarch="http://dita.oasis-open.org/architecture/2005/" ...>
<div class=" front-page/front-page front-page">
...
</div>
<div class="- toc/toc toc">
<div class="- map/topicref bookmap/frontmatter topicref frontmatter">
<div href="#unique_2" type="topic" class="- map/topicref topicref">
...
</div>
</div>


Note:
The process also applies for the backmatter topic references inside a `<backmatter>` element with the `bookmap/backmatter` class and referenced content with the `@is-backmatter="true"` attribute both in the merged map and merged HTML files.

Front Matter and Back Matter - Built-in CSS
The built-in CSS rules are in `[PLUGIN_DIR]/css/print/p-bookmap-frontmatter-backmatter.css`. By default, it associates the top-level topics that do not represent chapters to a `matter-page` style of page layout. Each child topic starts on a new page.

Related Information:
Page Headers and Footers (on page 1705)

How to Remove Page Breaks Between Front Matter Child Topics
If you do not like the fact that all the topics that enter a bookmap frontmatter start on a new page, you can disable this by using the following rules in your customization CSS (on page 1693):

```css
*[^class ~="map/map"] > *[^class ~="topic/topic"] [is-frontmatter] {
    page-break-before: auto;
}
```

How to Style the Front Matter and Back Matter Topics

Style all the Topics with the Same Aspect
All the topics referenced from the `<frontmatter>` and `<backmatter>` bookmap elements are formatted using the `matter-page` as defined in Default Page Definitions (on page 1700). In the merged file, the `<backmatter>` and `<frontmatter>` elements are omitted, and their child topic content is matched using a CSS rule like the one below:

```css
*[^class ~="map/map"] > *[^class ~="topic/topic"] [is-backmatter],
*[^class ~="map/map"] > *[^class ~="topic/topic"] [is-frontmatter] {
    page: matter-page;
    ...
}
```
Style the Topics Depending on Their Role

There might be cases when you need to distinguish between certain types of topics that have different roles in your publication:

- Preface
- Notice
- Abstract
- Copyright

These are referenced from the DITA map by specialized `<topicref>` elements, with different class attribute values.

The class attribute values are then passed by the transformation process onto the corresponding topic elements from the merged map content. For example, a topic that was referenced by a `<preface>` map element now has a "bookmap/preface" value in its `@topicrefclass` attribute:

```xml
<topic
    class="- topic/topic"
    id="unique_1"
    topicrefclass="- map/topicref bookmap/preface" .. >
...;
</topic>
```

This can be used to match and apply various styling choices, or even a particular page layout:

```css
@page preface-page {
    background-color:silver;
    @top-center{
        content: "Custom Preface Header";
    }
}

*[class ~="topic/topic"][@topicrefclass ~="bookmap/preface"] {
    page: preface-page;
}
```

Numbering

The topics in this section contain some technical details in case you need to fine-tune the way the numbering works.

Numbering - Built-in CSS

The built-in CSS rules are in:

- [PLUGIN_DIR]/css/print/p-numbering-shallow.css
- [PLUGIN_DIR]/css/print/p-numbering-deep.css
The first CSS (shallow) contains rules that add a "Chapter NN" before the first-level topics from the publication, the second one (deep) contains rules that add a deep structure of counters on all topics referenced from the map (at any level), the third one (chapter-scope) creates a chapter scope-oriented numbering (meaning that the numbering for pages, tables, figures, and links to them are reset for each chapter), and the last one is similar to the third except that page numbers do not reset. For more details, see Numbering Types (on page 1750).

Numbering - Input XML Fragments

The numbering affects multiple logical parts of your publication, the table of contents, headers/footers, chapter titles, figures and tables titles:

The Table of Contents

The table of contents is a tree of `<topicref>` elements.

```xml
<map xmlns:ditaarch="http://dita.oasis-open.org/architecture/2005/"
     xmlns:oxy="http://www.oxygenxml.com/extensions/author"
     class=" front-page/front-page ">
    ...
</oxy:front-page>
<opentopic:map xmlns:opentopic="http://www.idiominc.com/opentopic" class=" toc/toc ">
    <title class="- topic/title ">Publication Title</title>

    <topicref is-chapter="true" class="- map/topicref ">
        <topicmeta class="- map/topicmeta">
            <navtitle href="#unique_1" class="- topic/navtitle">Overview</navtitle>
        </topicmeta>
    </topicref>

    <topicref class="- map/topicref ">
        <topicmeta class="- map/topicmeta" data-topic-id="dcpp_resources">
            <navtitle href="#unique_2" class="- topic/navtitle">Resources</navtitle>
        </topicmeta>
    </topicref>

    ...
</opentopic:map>
```
Note:
The `<opentopic:map>` element contains the effective table of contents structure.

Note:
The TOC items are the elements with the class `- map/topicref`.

Note:
The ones identified as chapters have the `@is-chapter` attribute set.

For the **DITA Map PDF - based on HTML5 & CSS** transformation type, the merged map is further processed resulting in a collection of HTML5 `<div>` elements. These elements preserve the original DITA `@class` attribute values and add a new value derived from the DITA element name.

```html
<div class="- map/map map">
  ...
  <div class=" front-page/front-page front-page">
    ...
  </div>
  <div class=" toc/toc toc">
    <div class="- topic/title title">Publication Title</div>
    <div is-chapter="true" class="- map/topicref topicref">
      <div class="- map/topicmeta topicmeta">
        <div href="#unique_1" class="- topic/navtitle navtitle">Overview</div>
        ...
      </div>
      <div class="- map/topicref">
        <div class="- map/topicmeta" data-topic-id="dcpp_resources">
          <div href="#unique_2" class="- topic/navtitle">Resources</div>
          ...
        </div>
      </div>
    </div>
  </div>
  ...
</div>
```

The **Header and Footers**

These are based on string sets generated for the titles. The complete set of strings is defined in: `[INSTALLATION_DIR]/css/print/p-pages-and-headers.css`. 
The CSS rules that build the string sets are matching the map title from the front page and the titles from the content.

```
  <oxy:front-page-title>
    <title class="- topic/title ">Publication Title</title>
  </oxy:front-page-title>
</oxy:front-page>
```

For the **DITA Map PDF - based on HTML5 & CSS** transformations:

```
<div class=" front-page/front-page front-page">
  <div class=" front-page-title/front-page-title front-page-title">
    <div class="- topic/title title ">
      Publication Title
    </div>
  </div>
</div>
```

The main content is organized as follows:

```
<map xmlns:ditaarch="http://dita.oasis-open.org/architecture/2005/" ...>
  ...
  <opentopic:map xmlns:opentopic="http://www.idiominc.com/opentopic">
    ...
  </opentopic:map>

  <topic is-chapter="true" oid="dcpp_overview">
    <title class="- topic/title ">Overview</title>
    <body class="- topic/body ">
      ...
    </body>
  </topic>

  <topic class="- topic/topic " id="unique_2" oid="dcpp_resources">
    <title class="- topic/title ">Resources</title>
    ...
  </topic>

  <topic class="- topic/topic " id="unique_2" oid="dcpp_parameters">
    <title class="- topic/title ">Parameters</title>
    ...
  </topic>
</map>
```

For the **DITA Map PDF - based on HTML5 & CSS** transformations:

```
<div class=" map/map map" ...>
  ...
  <div class=" toc/toc toc"
```
<div is-chapter="true" oid="dcpp_overview" class="- topic/topic topic">
  <div class="- topic/title title">Overview</div>

  ... 
  
  </div>

  <div class="- topic/topic topic" id="unique_2" oid="dcpp_resources">
    <div class="- topic/title title">Resources</div>
    
    ... 
  
  </div>

  <div class="- topic/topic topic" id="unique_2" oid="dcpp_parameters">
    <div class="- topic/title title">Parameters</div>
    
    ... 
  
  </div>

</div>

Note:
The topic content comes after the <opentopic:map> element.

Note:
The child topics are the elements that have the class - topic/topic included in the parents.

Note:
The ones identified as chapters have the @is-chapter attribute set.

The Titles of Chapters
The titles from the content are children of the topics:

<topic class="- topic/topic " id="unique_2" oid="dcpp_parameters">
  
  <title class="- topic/title ">Parameters</title>
  
  ... 

</topic>

For the DITA Map PDF - based on HTML5 & CSS transformations:

<div class="- topic/topic topic" id="unique_2" oid="dcpp_parameters">
    <div class="- topic/title title ">Parameters</div>
    
    ... 

</div>

Note:
The title elements have the class: - topic/title. The actual element name can be different.
Numbering Types

The type of numbering that appears in your publication is controlled by the `args.css.param.numbering` parameter.

This parameter activates various sets of CSS rules from the built-in CSS. By default, only the first-level topics (the chapters) are numbered (shallow numbering). The following values are accepted:

<table>
<thead>
<tr>
<th>Value</th>
<th>Chapters</th>
<th>Sections/Nested Topics</th>
<th>Figures &amp; Tables</th>
<th>Pages</th>
</tr>
</thead>
<tbody>
<tr>
<td>shallow</td>
<td>numbered</td>
<td>no</td>
<td>counted from the start of the publication</td>
<td>from the start of the publication</td>
</tr>
<tr>
<td>deep</td>
<td>numbered</td>
<td>numbered</td>
<td>counted from the start of the publication</td>
<td>from the start of the publication</td>
</tr>
<tr>
<td>deep-chapter-scope</td>
<td>numbered</td>
<td>numbered</td>
<td>numbering is restarted at the beginning of each chapter, adds the chapter number in their titles (and in the links to them), and in the list of tables and list of figures sections</td>
<td>restarted at the beginning of each chapter</td>
</tr>
<tr>
<td>deep-chapter-scope-no-page-reset</td>
<td>numbered</td>
<td>numbered</td>
<td>numbering is restarted at the beginning of each chapter, adds the chapter number in their titles (and in the links to them), and in the list of tables and list of figures sections</td>
<td>from the start of the publication</td>
</tr>
</tbody>
</table>

Note:
When using any of the deep numbering types, no distinction is made between sections and nested topics. For example, if a topic contains two sections, followed by another nested topic, the sections will be numbered with 1 and 2, and the nested topic with 3.

Notice:
The `deep-chapter-scope` and `deep-chapter-scope-no-page-reset` values are only available for the DITA Map PDF - based on HTML5 & CSS transformation scenario.

Examples

Shallow
Each chapter (or first-level topic) is numbered, but sections/nested topics are not numbered. Figures, tables, and pages are numbered sequentially from the start of the publication and they do not reset.

Chapter 1. First Chapter
- Page 1
  - Topic
    - Section
      - Table 1
      - Table 2
  - Topic
    - Section
      - Page 2
      - Table 3

Chapter 2. Second Chapter
- Page 3
  - Topic
    - Table 4
    - Table 5
  - Topic
    - Page 4

It will result in the following content inside the PDF:

Chapter 1. Introduction..............................................................1
Chapter 2. Care and Preparation......................................................2
  Pruning............................................................................2
  Garden Preparation................................................................3
Chapter 3. Flowers by Season.........................................................4
  Spring Flowers......................................................................4
    Iris...............................................................................4
    Snowdrop.......................................................................6
...

List of Figures
  Figure 1: Iris

List of Tables
  Table 1: Flowers

Deep

All chapters (or first-level topics) and sections/nested topics are numbered (these are also prefixed with the chapter number). Figures, tables, and pages are numbered sequentially from the start of the publication and they do not reset.
1. First Chapter
   Page 1
   Topic 1.1
   Table 1
   Topic 1.2
   Table 2
   Page 2
   Table 3
2. Second Chapter
   Page 3
   Topic 2.1
   Table 4
   Table 5
   Topic 2.2
   Page 4

It will result in the following content inside the PDF:

1. Introduction..................................................................................3
2. Care and Preparation....................................................................4
   2.1. Pruning............................................................................4
   2.2. Garden Preparation.........................................................5
3. Flowers by Season.........................................................................6
   3.1. Spring Flowers..............................................................6
       3.1.1. Iris.......................................................................6
       3.1.2. Snowdrop..........................................................8
       ...

List of Figures
   Figure 1: Iris

List of Tables
   Table 1: Flowers

Deep Chapter Scope

Each chapter (or first-level topic) is independent (so it can be read separately, as a separate part of your publication). The sections/nested topics, pages, figures, and table counters (and links to them) restart at each chapter. The general cross reference links also display the chapter number before the page number to clearly specify the target.
Each chapter (or first-level topic) is independent (so it can be read separately, as a separate part of your publication). The sections/nested topics, figures, and table counters (and links to them) restart at each chapter, but the page numbers do not reset. The generic cross reference links contain only the page number.
It will result in the following content inside the PDF:

1. Introduction......................................................................3
2. Care and Preparation..............................................................4
   2.1. Pruning.......................................................................4
   2.2. Garden Preparation............................................................5
3. Flowers by Season.................................................................6
   3.1. Spring Flowers.................................................................6
      3.1.1. Iris......................................................................6
      3.1.2. Snowdrop...............................................................8
...

   Figure 3-1: Iris

List of Tables
   Table 2-1: Flowers

Tip:
When using deep numbering, if you want to exclude sections from being numbered, see How to Exclude Topic Sections from Numbering (on page 1).

How to Remove the 'Chapter NN' Prefix from Table of Contents and Content.

If you are using the shallow numbering CSS (this is the default), and you want to hide the "Chapter" prefix, use the following rules in your customization CSS (on page 1693):

For the TOC:
For the titles in the content, change the content of the title :before (this example just uses the chapter number):

```css
*{[class =~ "topic/topic"]}{is-chapter:not([is-part])} > *{[class =~ "topic/title"]}{:before} {
  content: counter(chapter) ". " !important;
}
```

How to Activate Continuous Page Numbering

The page numbers are reset to one of two cases:

- On the first topic that follows the TOC.
- On the first topic from the index.

To avoid the page counter from being reset, use the following rules in your customization CSS (on page 1693):

```css
*{[class =~ "map/map"]} > *{[class =~ "toc/toc"]} + *{[class =~ "topic/topic"]},
*{[class =~ "index/groups"]} {
  counter-reset: none;
}
```

The index page also changes the format of the page numbers to lower alpha characters. To switch to decimal characters, use:

```css
@page index {
  @bottom-center {
    content: counter(page, decimal)
  }
}
```

How to Use Part, Chapter, and Subtopics Numbers in Links

This topic is applicable if you have enabled deep numbering (on page 1750). Suppose you have a link in the third chapter that points to a paragraph in the second subtopic of the first chapter and you need this structural information (1.2) presented to the user, just after the link text. To do this, you can use the target-counters CSS function to extract the entire context of the counters from the target. The chapter-and-sections built-in counter is already updated with both the chapter number and the nested topics:

```css
*{[class =~ "topic/xref"]}{:after} {
  content: target-counters(attr(href), chapter-and-sections, ":") !important;
}
```
This counter does not include the part number, so take care when linking between parts (you may consider adding the target part number explicitly):

```
*{[class ~= "topic/xref"]:after {  
    content: "[" target-counter(attr(href), part, upper-roman) "/" target-counters(attr(href), chapter-and-sections, ".") "]!important;
    color:blue;
}}
```

Related Information:

Numbering Types (on page 1750)

**How to Include Topic Sections in TOC**

To include topic sections in the table of contents, set the `args.css.param.numbering-sections transformation parameter (on page 1665)` to `yes`. In this case, they are numbered according the numbering scheme set by the `args.css.param.numbering parameter (on page 1750)`. If you want to prevent topic sections from being numbered in your output, set the value of the `args.css.param.numbering-sections` parameter to `no`.

**Table of Contents**

The table of contents is a hierarchy of topic titles with links to the topic content.

For plain maps, the TOC is automatically generated. For DITA bookmaps, you will need to add a `<toc>` element in the `<booklists>` element (inside the `<frontmatter>`):

```
<bookmap>
  ...
  <frontmatter>
    <booklists>
      <toc/>
      <figurelist/>
      <tablelist/>
    </booklists>
  </frontmatter>
  ...
  ...
```

Table of Contents on a Page (Mini TOC) (on page 1763)

List of Tables/Figures (on page 1768)

Index (on page 1776)
Table of Contents - XML Fragment

In the merged map file (on page 1695), the `<opentopic:map>` contains a hierarchy of `<topicref>` elements, or other elements (such as `<chapter>` or `<part>`) that are specializations of `<topicref>`.

Each of the `<topicref>` elements include a metadata section that includes the topic title.

```xml
<bookmap ...

<oxy:front-page> ...
<oxy:front-matter> ...

<opentopic:map xmlns:opentopic="http://www.idiominc.com/opentopic" class="- toc/toc ">

  <oxy:toc-title xmlns:oxygen="http://www.oxygenxml.com/extensions/author" empty="true"
      class="- toc/title ">

    <booktitle class="- topic/title bookmark/booktitle ">
      <booklibrary class="- topic/ph bookmark/booklibrary ">Retro Tools</booklibrary>
      <mainbooktitle class="- topic/ph bookmark/mainbooktitle ">Tasks</mainbooktitle>
      <booktitlealt class="- topic/ph bookmark/booktitlealt ">Product Tasks</booktitlealt>
    </booktitle>

  </oxy:toc-title>

  <chapter is-chapter="true"
      class="- map/topicref bookmark/chapter " href="#unique_5" type="topic">
    <topicmeta class="- map/topicmeta " data-topic-id="installing">
      <navtitle href="#unique_5" class="- topic/navtitle ">Installing</navtitle>

    </topicmeta>

    <topicref class="- map/topicref " href="#unique_6" type="task">
      <topicmeta class="- map/topicmeta " data-topic-id="installstorage">
        <navtitle href="#unique_6" class="- topic/navtitle ">Installing</navtitle>

      </topicmeta>

    </topicref>

  </chapter>
```

For the DITA Map PDF - based on HTML5 & CSS transformation type, the merged map is further processed resulting in a collection of HTML5 `<div>` elements. These elements preserve the original DITA `@class` attribute values and add a new value derived from the DITA element name.
Note:

The `<oxy:toc-title>` element is used as a placeholder for the name of the TOC. For instance, you can use the string "Contents", specified on a pseudo-element, in the CSS.

Table of Contents - Built-in CSS

The built-in CSS rules are in: `[PLUGIN_DIR]/css/print/p-toc.css`.
How to Increase TOC Depth

By default, only the first three levels of topics are displayed in the Table of Contents of the PDF output.

The CSS rule (see Table of Contents - Built-in CSS (on page 1759)) that hides topics on higher levels is:

```css
/* Hide sections below level 3. */
*[class "map/topicref"] {display: none;}
```

If you want to increase the TOC depth so that topic references on level 3 or higher are visible, you can overwrite this rule in your customization CSS like this:

```css
*[class "map/topicref"] {display: block;}
```

How to Style the Table of Contents Entries

Note:
Each of the items from the table of contents is an element that has the `map/topicref` class.

The following example uses the italic font for the label and changes the color and style of the connecting line between the title and the page number.

In your customization CSS (on page 1693), add the following two selectors:

```css
/* The toc item label - the topic title */
*[class "map/topicref"] *[class "topic/navtitle"] {font-style: italic; color: navy;}

/* The dotted line between the topic name and the page number. */
*[class "map/topicref"] *[class "topic/navtitle"]:after {content: leader('-') target-counter(attr(href), page);}
```
And if you need to alter the indent of the nested table of content items, use the following selector:

```css
*[class = "map/topicref"] *{class = "map/topicref"} {
  margin-left: 1em;
}
```

The numbers can be styled like this:

```css
*[class = "map/topicref"] > *{class = "map/topicmeta"}:before,
*[class = "map/topicref"]
  > *{class = "map/topicmeta"} > *{class = "topic/navtitle"}:before{
    color:blue;
}
```

The following is an example of customizing the font size for the items representing chapters. The chapters are level one topics and are marked in the merged DITA document TOC with the attribute `@is-chapter`.

```css
*[class = "map/topicref"]@[is-chapter = "true"] > *{class = "map/topicmeta"} > *{class
  = "topic/navtitle"}{
  font-size:2em;
}
```

### How to Change the Header of the Table of Contents

In the built-in CSS, there is a page named `table-of-contents`. The default is to have the word ‘Contents’ in its header (this is localized, using the `toc-header` string defined in the `p-18n.css`) alternating in the left or right side of the header:

```css
@page table-of-contents:left {
  @top-left {
    content: string(toc-header) " | " counter(page, lower-roman);
    font-size: 8pt;
  }
}
```

```css
@page table-of-contents:right {
  @top-right {
    content: string(toc-header) " | " counter(page, lower-roman);
    font-size: 8pt;
  }
}
```

If you need to change this string, or change the color, you should use the following `@page` selectors as a starting point in your customization CSS *(on page 1693)*:
How to Make the Table of Contents Start on an Odd Page

In your customization CSS (on page 1693), add the following snippet for the `table-of-contents` page:

```css
@page table-of-contents {
  -oxy-initial-page-number: auto-odd;
}
```

Related Information:
Double Side Pagination (on page 1770)

How to Display a Topic Before the Table of Contents

To display a topic before the `table-of-contents` page, follow these steps:

1. Make sure the topic is referenced on the first level in the DITA map.
2. Set the `@outputclass` to `before-toc` on the `<topicref>`.

```xml
<topicref href="pathToMyTopic" outputclass="before-toc"/>
```

Result: When the PDF is processed, the topic will automatically appear before the table of contents.

Related Information:
Controlling the Publication Content (on page 1834)

How to Display Short Descriptions in the TOC

To display the short descriptions from the topics in the table of contents, you need to make the `<shortdesc>` element visible.
The following example only makes the short descriptions associated with the chapters visible. The chapters are level one topics and are marked in the merged DITA document TOC with the attribute @is-chapter.

In your customization CSS (on page 1693), add the following CSS selector:

```css
*[class ~="map/topicref"] [is-chapter="true"] > *[class ~="map/topicmeta"] > *[class ~="map/shortdesc"] { display:block; /* The default is none - the shortdesc is hidden. */ color:gray; }
```

**Note:**

If you need all the TOC item short descriptions to be visible, remove the [is-chapter] condition.

### How to Remove Entries from the TOC

To remove entries from the table of contents, set the @toc="no" attribute on the topicrefs from the map that need to be removed. This is sometimes desirable for the topics listed in the frontmatter or backmatter when using a bookmap.

### How to Hide the TOC

To hide the TOC, you have multiple options:

- Use a DITA bookmap instead of a DITA map, and omit the <toc> element from the <booklists>. An example bookmap can be found in the DITA 1.3 Spec. This is the best approach.
- Use the transformation parameter: `hide.frontpage.toc.index.glossary` (on page 1669).
- Use a `display:none` property to hide the element that contains the TOC structure, and also remove it from the PDF bookmarks tree:

```css
*[class ~="map/map"] > *[class ~="toc/toc"] { display:none; }
*[class ~="map/map"] > *[class ~="toc/toc"] > *[class ~="toc/title"]{
 bookmark-label: none;
 -ah-bookmark-label: none;
}
```

**Related Information:**

Transformation Parameters (on page 1665)

### Table of Contents on a Page (Mini TOC)

To add a mini table of contents for each chapter, you need to:
• Use DITA bookmaps instead of regular maps.
• Set the `args.chapter.layout` transformation parameter to either of the following values: **MINITOC** or **MINITOC-BOTTOM-LINKS**.

**Note:**
If the chapter does not have child topics, it will not have a mini TOC in the PDF output.

**Layout for MINITOC**
This table of contents is positioned between the chapter title and the chapter child topics. It consists of a list of links pointing to the child topics, positioned in the left side of the page, and a description in the right side. This content is collected from the topic file referenced by the chapter `<topicref>` in the map.

### Chapter 1. Introduction

<table>
<thead>
<tr>
<th>Topics:</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>About this framework.</td>
<td>The DITA Open Toolkit, or DITA-OT for short, is a set of Java-based, open-source tools that provide processing for content authored in the Darwin Information Typing Architecture</td>
</tr>
<tr>
<td>Description</td>
<td>The DITA Open Toolkit documentation provides information about installing, running, configuring and extending the toolkit</td>
</tr>
</tbody>
</table>

**About this framework.**
The framework is DITA.

**Description**
The framework is composed by a large set of modules.

**Layout for MINITOC-BOTTOM-LINKS**
This table of contents is positioned between the chapter title and the chapter child topics. It consists of a chapter description and list of links pointing to the child topics, under the description. This description is collected from the topic file referenced by the chapter `<topicref>` in the map.
Chapter 1. Introduction

DITA Open Toolkit, or DITA-OT for short, is a set of Java-based, open-source tools that provide processing for content authored in the Darwin Information Typing Architecture.

The DITA Open Toolkit documentation provides information about installing, running, configuring and extending the toolkit.

Topics:

- About this framework.
- Description

About this framework.

The framework is DITA.

Description

The framework is composed by a large set of modules.

The above chapter example has the following DITA map fragment:

```xml
<chapter href="topics/chapter-introduction.dita">
  <topicref href="topics/introduction-about.dita" />
  <topicref href="topics/introduction-description.dita" />
</chapter>
```

The `chapter-introduction.dita` file provides the description content that is in the right side of the page. The children `<topicref>` elements generate the mini TOC links.

### Table of Contents for Chapters (Mini TOC) - XML Fragment

In the merged XML file, the mini TOC is built from a related links section and some `<div>` elements that wrap the entire mini TOC and the description area.

- **chapter/minitoc**
  
  Wraps the entire structure, including the content of the chapter `<topicref>`.

- **chapter/minitoc-links**
  
  Wraps the `<related-links>` element. Note that the label of the related links list is internationalized.

- **chapter/minitoc-desc**
Contains the entire content of the topic file referenced by the chapter `<topicref>` element in the map.

```
<div class="- topic/div chapter/minitoc">
  <div class="- topic/div chapter/minitoc-links">
    <linklist class="- topic/linklist">
      <desc>
        <ph class="- topic/ph chapter/minitoc-label">Topics:</ph>
      </desc>
      <link class="- topic/link " href="#unique_2" type="topic" role="child">
        <linktext class="- topic/linktext">About this framework.</linktext>
      </link>
      <link class="- topic/link " href="#unique_3" type="topic" role="child">
        <linktext class="- topic/linktext">Description</linktext>
      </link>
    </linklist>
  </div>
</div>
```

When using the `pdf-css-html5` transformation, this structure is converted to a set of HTML elements, preserving the class values:

```
<div class="- topic/div chapter/minitoc div minitoc">
  <div class="- topic/div chapter/minitoc-links div minitoc-links">
    <nav role="navigation" class="- topic/related-links related-links">
      <div class="- topic/linklist linklist linklistwithchild">
        <div class="- topic/desc desc">
          <span class="- topic/ph chapter/minitoc-label ph minitoc-label">Topics:</span>
        </div>
        <ul class="linklist">
          <li>
            <a href="#unique_2" type="topic" role="child">About this framework.</a>
          </li>
          <li>
            <a href="#unique_3" type="topic" role="child">Description</a>
          </li>
        </ul>
      </div>
    </nav>
</div>
```
DITA Open Toolkit, or DITA-OT for short, is a set of Java-based, open-source tools that provide processing for content authored in the Darwin Information Typing Architecture.

The DITA Open Toolkit documentation provides information about installing, running, configuring and extending the toolkit.

Table of Contents for Chapters (Mini TOC) - Built-in CSS

The built-in CSS rules are in: [PLUGIN_DIR]/css/print/p-chapters-minitoc.css.

How to Style the Table of Contents for Chapters (Mini TOC)

Suppose that you do not want the links and the chapter description to be side by side, but instead place the links above the description. Also, you may choose to remove the label above the links and put all the links in a colored rectangle with decimal numbers before them.

In your customization CSS (on page 1693), add the following selectors:

```css
/* Change from inline to blocks to stack them one over the other. */

*[class~="chapter/minitoc-desc"],
```
Related Information:

How to Speed up CSS Development and Debugging (on page 1698)

List of Tables/Figures

To activate these:

1. The map must be a DITA bookmap.
2. There must be a `<figurelist>` or `<tablelist>` in the frontmatter or backmatter. In the following example, both of the lists are added just after the table of contents (the `toc` element is the placeholder where the table of contents will be created):

```xml
<frontmatter>
  <booklists>
    <toc/>
    <figurelist/>
  </booklists>
</frontmatter>
```
How to Set a Header for a List of Tables/Figures

Suppose you want to set the headline "Figure List" on the second and subsequent pages associated to a list of figures and something similar for a list of tables.

Start by associating pages to the list of figures and tables from the merged file:

```xml
*{class~="placeholder/tablelist"} { 
  page:tablelist;
  color:green;
}
*{class~="placeholder/figurelist"}{ 
  page:figurelist;
  color:green;
}
```

**Note:**
The "placeholder/tablelist" is the class name of the output generated from the `<tablelist>` bookmap element.

Then define the pages:

```xml
@page figurelist { 
  @top-left { content: none; } 
  @top-center { content: "Figure List"; } 
  @top-right { content: none; } 
}
@page figurelist:first { 
  @top-left { content: none; } 
  @top-center { content: none; } 
  @top-right { content: none; } 
}
@page tablelist { 
  @top-left { content: none; } 
  @top-center { content: "Table List"; } 
  @top-right { content: none; } 
}
```
@page tablelist:first {
    @top-left { content: none; }
    @top-center { content: none; }
    @top-right { content: none; }
}

How to Remove the Numbers Before a List of Tables or Figures

Suppose you need to remove the "Figure NN" prefix before each entry of a list of figures.

An entry in the generated list of figures from the merged map looks like this:

```xml
<entry class="- listentry/entry " href="#unique_6_Connect_42_fig_rjy_spn_xgb">
  <prefix class="- listentry/prefix ">Figure</prefix>
  <number class="- listentry/number ">4</number>
  <title class="- topic/title ">This is another figure</title>
</entry>
```

For the HTML merged map, the element names are all `<div>` elements but they have the same class.

So, to hide the label and the number, use:

```css
*[^class~="listentry/prefix"],
*[^class~="listentry/number"] {
  display:none;
}
```

This works for both a list of tables and list of figures since the structure of each entry is the same.

To make it more specific (for example, to apply it only for the list of figures), you can add the selector:

```css
*[^class~="placeholder/figurelist"] *[^class~="listentry/prefix"],
*[^class~="placeholder/figurelist"] *[^class~="listentry/number"] {
  display:none;
}
```

Double Side Pagination

By default, the processor generates pages that are mirror images (the right page has the header on the right side, the left pages have the header on the left side). The chapters follow one another with no constraint on the page side.

Note:

For a plain DITA map, the chapters are the `<topicref>` elements that are placed on the first level. For bookmaps, the chapters are the topics referenced by a `<chapter>` element.
This section contains information about how to position the start of the chapters on an odd folio number. Some of the CSS rules given here as examples are already listed in: [INSTALLATION_DIRECTORY]/css/print/p-optional-double-side-pagination.css. You may choose to import this file from your customization CSS (on page 1693).

How to Start Chapters on Odd Pages

A common use case is to arrange the chapters of the publication to start on an odd page number.

In your customization CSS (on page 1693), add the following:

```css
@page chapter {
-oxy-initial-page-number: auto-odd;
}
@page table-of-contents {
-oxy-initial-page-number: auto-odd;
}
```

Supported values for `oxy-initial-page-number` include: auto, auto-even, auto-odd, or a number.

How to Style the Empty (Blank) Pages

By making the chapters start on an odd page, the CSS processor might add blank pages to the previous page sequence as padding.

To style those blank pages add the following code in your customization CSS (on page 1693):

```css
@page chapter:blank, table-of-contents:blank {
@top-left      { content: none; }
@top-center    { content: none; }
@top-right     { content: none; }
@bottom-left   { content: none; }
@bottom-center { content: none; }
@bottom-right  { content: none; }
}
```

**Note:**
This just removes the headers and footers, but you can use a background image or a header with "Intentionally left blank" text.

Related Information:
How to Add a Background Image for the Cover (on page 1737)
How to Force an Odd or Even Number of Pages in a Chapter

Another use case is to specify a number of pages for a section. Suppose that you have a table of contents that follows the cover page and you need to have an even number of pages. Hence, the next chapter would start on an even page.

In your customization CSS (on page 1693), use the -oxy-force-page-count property with an even value:

```css
@page table-of-contents {
  -oxy-force-page-count: even;
}
```

Supported values for -oxy-force-page-count include: even, odd, end-on-even, end-on-odd, auto, no-force.

How to Style the First page of a Chapter

You can use the :first page rule selector to control how the first page of a chapter looks. Suppose that you have defined the following layout for your default page and you want to put the publication title (the `maptitle` string) on the header of the first page (instead of the chapter name that is displayed on this page):

In your customization CSS (on page 1693), add the following:

```css
@page chapter:first {
  @top-right-corner { content: string(maptitle); }
  @top-left { content: none; }
}
```

Multiple Column Pages

This section contains information about how to handle pages that have multiple columns.

How to Use a Two Column Layout

Change Layout for Predefined Pages.

First you need to identify which of the pages need to be changed. Pages are already defined for the cover page, table of contents, chapter content, and others. The complete list is here: Default Page Definitions (on page 1700).

Next, add the column-count and column-gap properties to that page. For example:

```css
@page chapter{
  column-count:2;
  column-gap:1in;
}
```

If you need some of the elements to expand on all the columns, use the column-span:all CSS property. The next snippet makes the chapter titles span both columns:
Limitation:
You cannot use multiple column configurations on the same page. Oxygen XML Editor only takes the `column-count` and `column-gap` properties into account if they are set on `@page` rules, not on elements from the content.

Change Layout for a Specific Topic.
If you need to have a different column layout just for one topic, you can use the following technique:

1. Define an `outputclass` on the topic root element.

   `<topic outputclass="two_columns" ...`

2. Define a CSS rule that changes the `page` property for the matching element.

   `*[class ~="two_columns"],
   *[outputclass ~="two_columns"]{
     page: two_column_page !important;
   }`

Tip:
In the selector, use the `class` attribute for the HTML transformation, or `outputclass` for the direct transformation, or leave them both if you are not sure.

Note:
The topics from the first level use the `chapter` page. You must use `!important` because the built-in rules are more specific and you need to override the `page` property.

3. Define a page layout.

   `@page two_column_page {
     column-count: 2;
   }`

Note that the topic will be separated from other sibling topics with different page layouts by page breaks.

Related Information:
Page Formatting in Oxygen PDF Chemistry
PDF Bookmarks

The PDF Bookmarks are used to generate a hierarchical structure similar to a table of contents in a specialized view of your PDF Reader.

By default, the titles defined in the topics are used as bookmark labels.

PDF Bookmarks - Built-in CSS

The PDF bookmarks are generated by matching the titles from the topics in the content. The built-in CSS rules are in: `[PLUGIN_DIR]/css/print/p-bookmarks.css`.

How to Change the Bookmark Labels using the Navigation Title

To change the bookmark labels, you can specify a navigation title in a DITA map or topic.

This will be used as the bookmark label instead of the topic title in the table of contents and the bookmark views. There are two possibilities to do specify it:

1. Place a `<navtitle>` element in the topic reference in the DITA map:

   ```xml
   ... 
   <topicref href="topics/my_topic.dita" locktitle="yes">
     <topicmeta>
       <navtitle>Introduction</navtitle>
     </topicmeta>
   </topicref>
   ...
   
   Note:
   As a best practice, a @locktitle attribute with the value ‘yes’ is needed to activate the navigation title. The plugin applies the navigation title even if the attribute is missing.
   ```

2. Place a `<navtitle>` element in the topic, as a title alternative.

   ```xml
   <topic id="other_topic" xml:lang="en-us">
     <title>Normal Title</title>
     <titlealts>
       <navtitle>Navigation Title</navtitle>
     </titlealts>
     <body>
     ...
   </topic>
   ```

How to Control the Depth of the Sections From the PDF Bookmarks.

By default, the PDF bookmarks are generated for up to 7 levels. If you need to limit them (for example to 2 levels), you can use the following CSS rules in your customization CSS (on page 1693):
These rules clear the labels generated by the titles starting with the depth 3 (the topic nesting level is given by the selectors *[class="topic/topic"]).

**How to Specify the Open/Closed PDF Bookmark State**

If you want to specify the initial state for the bookmarks (opened/expanded or closed/collapsed), you can use the `bookmark-state` property in your customization CSS (on page 1693).

For example, to specify that all bookmarks for the first three levels are opened (expanded) in the initial state, use:

```
*[class="topic/topic"] > *[class="topic/title"],
*[class="topic/topic"] *[class="topic/topic"] > *[class="topic/title"],
*[class="topic/title"] {
    bookmark-state: open;
}
```

**How to Remove the Numbering From the PDF Bookmarks**

By default, the PDF bookmark labels are generated while taking the text set before the chapters titles into account. Since this usually contains the part, chapter, or section numbers, the PDF Bookmarks will make use of them.

The solution is to remove the `content(before)` from the `bookmark-label`, leaving just the `content(text)`.

In your customization CSS (on page 1693), add the following CSS rules:

```
*[class="topic/topic"] > *[class="topic/title"] {
    bookmark-label: content(text);
    -ah-bookmark-label: content();
}
```
Important:
This is a simple example that does not use the possible navigation titles, just the content of the <title> element. Copy and modify the built-in CSS for the full CSS rule that matches the <title> and <titlealts> elements:

*{class="topic/topic"}:has(*{class="topic/titlealts"}) > *{class="topic/title"} {...}

Related Information:
Numbering (on page 1746)

Index
The content of an <indexterm> element is used to produce an index entry in the generated index. You can nest <indexterm> elements to create multi-level indexes. The content is not output as part of the topic content, only as part of the index tree.

To add an index to your publication, you just need to add <indexterm> elements inside the <prolog> section (inside a <metadata> element):

```
<title>The topic title.</title>
<prolog>
  <metadata>
    <keywords>
      <indexterm>Installing <indexterm>Water Pump</indexterm></indexterm>
    </keywords>
  </metadata>
</prolog>
<body>
....
```

or in the content itself:

```
... 
<p>Open the lid then turn the body pump to the right.<br/>
<indexterm>Installing <indexterm>Water Pump</indexterm></indexterm>
</p>...
```

If you are using a bookmap, you need to specify where the index list should be presented (for instance in the backmatter of the book. Technically, it is possible to also add it to the frontmatter, but this is unusual). This is done using an <indexlist> element in the <booklists> element (inside the <backmatter>):

```
<bookmap>
...
  <chapter href="tasks/troubleshooting.dita">
...</chapter>
...</bookmap>
```
For plain maps, the index list is automatically added at the end of the publication, with no need to modify the map.

Index - XML Fragment

In the merged map file (on page 1695), the structure that holds the index tree is the `<opentopic-index:index.groups>` element.

```
<map class="- map/map ">
    <oxy:front-page>
        ...
    </oxy:front-page>
    <opentopic:map xmlns:opentopic="http://www.idiominc.com/opentopic">
        ...
    </opentopic:map>
    <topic class="- topic/topic ">
        <title class="- topic/title ">Request Support</title>
        ...
    </topic>
    <opentopic-index:index.groups id="d16e5548">
        ...
    </opentopic-index:index.groups>
</map>
```

Each of the groups contain:

- A label, the starting letter ("T" in the following example).
- A tree of `<opentopic-index:index.entry>` elements.

```
<opentopic-index:index.group>
    <opentopic-index:index.label>T</opentopic-index:index.label>
    <opentopic-index:index.entry value="table of contents">
        <opentopic-index:formatted-value>table of contents</opentopic-index:formatted-value>
        <opentopic-index:refID value="table of contents:">
            <oxy:index-link xmlns:oxy="http://www.oxygenxml.com/extensions/author">
```
Each of the entries contain:

- The formatted value (`<opentopic-index:formatted-value>`).
- A link to the publication content (`<opentopic-index:refID>`/`<oxy:index-link>`).
- Possibly other child entries.

For the **DITA Map PDF - based on HTML5 & CSS** transformation type, the merged map is further processed resulting in a collection of HTML5 `<div>` elements. These elements preserve the original DITA `@class` attribute values and add a new value derived from the DITA element name.
The index group content becomes:

```xml
<map>
  <div class="index/group group">
    <div class="index/label label">T</div>
    <div class="index/entry entry">
      <div class="index/formatted-value formatted-value">table of contents</div>
      <div class="index/refid refid">
        <div class="index/link link" href="#d16e3988">[d16e3988]</div>
      </div>
    </div>
    <div class="index/entry entry">
      <div class="index/formatted-value formatted-value">change header</div>
      <div class="index/refid refid">
        <div class="index/link link" href="#d16e4176">[d16e4176]</div>
      </div>
    </div>
    <div class="index/entry entry">
      <div class="index/formatted-value formatted-value">style</div>
      <div class="index/refid refid">
        <div class="index/link link" href="#d16e4120">[d16e4120]</div>
      </div>
    </div>
  </div>
</map>
```

Index - Built-in CSS

All index styling is found in: `[PLUGIN_DIR]css/print/p-index.css`.

How to Style the Index Page Title and the Grouping Letters

In your customization CSS (on page 1693), add the following CSS rules:

```css
* [class ~="index/groups"] * [class ~="index/group"] * [class ~="index/label"] {
  font-size: 1.5em;
  color: navy;
}
```
How to Style the Index Terms Labels

In your customization CSS (on page 1693), add the following CSS rule:

```css
*[^class ~='index/groups']>*[^class ~='index/formatted-value'] {  
  font-style: oblique;
  color: gray;
}
```

The result is:
How to Add Filling Dots Between the Index Labels and the Page Numbers

Suppose you want the leader CSS content to generate a row of dots. It is necessary that the parent entry has the text justified.

In your customization CSS (on page 1693), add the following CSS rule:

```css
/* Hide the sequences of links that actually do not contain links. */
*[class="index/group"] *[class="index/entry"] > *[class="index/refid"]{
  display: none;
}
*[class="index/group"] *[class="index/entry"] >
  *[class="index/refid"]:has(*[class="index/link"]){
    display: inline;
}
*[class="index/group"] *[class="index/entry"] {
  text-align: justify;
}
*[class="index/group"] *[class="index/entry"] > *[class="index/refid"]:before{
  content: leader('.');
}
```

The output now contains the dots:
How to Change the Index Page Number Format and Reset its Value

The page number is reset at the beginning of the index page by the built-in CSS rule:

```css
* [class ~="index/groups"] { 
  counter-reset: page 1;
}
```

If you want to start the page counter from a different initial number, just change the value of this counter. For example, to continue the normal page counting, use:

```css
* [class ~="index/groups"] { 
  counter-reset: none;
}
```

If you need to style the page number differently (for example, using decimals), add the following CSS rule in your customization CSS (on page 1693):

```css
@page index { 
  @bottom-center { content: counter(page, decimal) }
}
```

How to Impose a Table-like Index Layout

In case you need to place the index labels and links on the same line but with some extra alignment constraints, you can use inline blocks to give the index a table-like appearance:
You need to place the elements that have the following class on the same line:

- **index/formatted-value**
  - This is the text of the index term.

- **index/refid**
  - This element contains a list of links.

A fixed width is used for the formatted value and the links container (almost half of the available width). To achieve the index hierarchical layout, set progressive padding to the formatted value text.

In your customization CSS *(on page 1693)*, add the following CSS rule:

```css
/* Hide the sequences of links that actually do not contain links. */

* {[
    class~="index/formatted-value",
    class~="index/refid"
]}
  display:inline-block;
}

* {[
    class~="index/formatted-value"
]}
  width:45%;
}
* {[
    class~="index/refid"
]}
  width:45%;
}
To avoid bleeding of the index term label, you may need to mark it as being hyphenated:
To activate hyphenation, see: How to Enable Hyphenation for Entire Map (on page 1791).

**Footnotes**

Footnotes are pieces of information placed at the bottom of the page. A footnote has a number that is left in the content (the footnote call) and the same value placed before the footnote text (the footnote marker).

**Footnotes - Built-in CSS**

Footnote properties are defined in [PLUGIN_DIR]css/print/p-foot-notes.css.

**How to Change Style of the Footnote Markers and Footnote Calls**

To bold the footnotes numbers and use some colors, add the following rules to your customization CSS (on page 1693):

```css
*[class ~='topic/fn']:footnote-call {
  font-weight: bold;
  color:red;
}

*[class ~='topic/fn']:footnote-marker {
  font-weight: bold;
  color:red;
}
```

Related Information:
https://www.oxygenxml.com/doc/ug-chemistry/topics/ch_footnotes.html

**How to Add a Separator Above the Footnotes**

The `@footnote` part of a `@page` declaration controls the style of the separator between the page content and the footnotes. For the content, you should set a leader. The leader uses a letter or a line style to fill the entire width of the page.

```xml
@page {
  margin:0.5in;
  ....
  @footnote {
    content: leader(solid);
    color:silver;
  }
}
```

To create a dotted line, you can use the dot character: leader(‘.’). Other commonly used characters are: “-“ (dash) and “_” (underscore).
How to Reset the Footnotes Counter

There are cases where you want to reset the footnote counter.

For example, if you need to reset it at the beginning of each chapter, add the following rules to your customization CSS (on page 1693):

```css
*[class =~ "bookmap/chapter"],
*[class =~ "topic/topic"]\[is-chapter\] {
  counter-reset: footnote 1;
}
```

Or you can mark any element with an `@outputclass` value, match that value, and reset the counter at any point in your counter:

```xml
<p outputclass="reset-footnotes"/>
```

Page Breaks

The page breaks can be controlled in multiple ways:

1. **By creating an `@page` and assigning it to an element** will create a page break between this element and the sibling elements that have a different page.

2. **Using the CSS properties:** `page-break-before`, `page-break-after`, or `page-break-avoid`.

3. **In your DITA topic, set the `@outputclass` attribute on the topic root (or any element) to contain one of the `page-break-before`, `page-break-after`, or `page-break-avoid` values.** If you want to control the page breaking from the DITA map, use the `@outputclass` attribute on the `<topicref>`, with any of the values mentioned above.

Related Information:

- Double Side Pagination (on page 1770)
- Oxygen PDF Chemistry: Controlling Page Breaks

Page Breaks - Built-in CSS

Page break properties are used in: `[PLUGIN_DIR]css/print/p-page-breaks.css`.

How to Avoid Page Breaks in Lists and Tables

To avoid splitting elements over two pages, you can use the `page-break-inside` CSS property. For example, if you want to impose this on tables and lists, then add the following rules to your customization CSS (on page 1693):
**Note:**

Since the task steps are inherited from `topic/ol`, they will also not be split over two separate pages. However, if you want to allow this, add the following CSS rule:

```
* [class ~= "task/steps"] {
  page-break-inside: auto;
}
```

**Note:**

Another way to do this is to mark the element with an `@outputclass` set to `page-break-avoid`.

---

### How to Force a Page Break Before or After a Topic or Another Element

If you want to force a page break **before all** the second-level topics (for example, sections in chapters that are usually kept flowing one after another without page breaks), add the following in your customization CSS (on page 1693):

```
* [class ~= "map/map"] > * [class ~= "topic/topic"] > * [class ~= "topic/topic"] {
  page-break-before: always;
}
```

If you want to force a page break **for a specific topic**, mark the topic (or any other element you need to control page breaking for) with an `@outputclass` attribute set to one of these values:

- **page-break-before**
  
  Use this for a page break before the marked element.

- **page-break-after**
  
  Use this for a page break after the marked element.

- **page-break-avoid**
  
  Use this to avoid page breaks inside the marked element.

For example, to force a page break before a certain topic, use:
Note:
You can set the output class on the `<topicref>` element from the DITA map instead of the `<topic>` element. In this way you can reuse the topic in another context where the page breaking is not necessary.

You can also control page breaking for lists, paragraphs, or any other block type elements. The following example avoids page breaks inside an ordered list:

```
<ol outputclass="page-break-avoid" ...
```

How to Add a Blank Page After a Topic

If you want to add a new blank page after a topic, add the following rules to your customization CSS (on page 1693).

Style the separating blank page:

```
@page topic-separating-page{
  @top-left {
    content: "";
  }
  @top-right {
    content: "";
  }
  @top-center {
    content: "This page is blank";
  }
}
```

Associate this page to the :after pseudo-element of the topic:

```
*[class="topic/topic"][outputclass="add-separator-page"]:after {
  content: " ";
  display: block;
  page: topic-separating-page;
}
```

In the XML content, on the `<topic>` element, set the `@outputclass` to the `add-separator-page` value.

```
<topic outputclass="add-separator-page"> ... </topic>
```

The :after pseudo-element will be created next to the topic content and will be placed on the topic-separating-page.

Use the page margin box selectors to override the default content from the headers/footers.
Note:
You can set the output class on the `<topicref>` element from the DITA map instead of the `<topic>` element. This allows you to reuse the topic in another context where the page breaking is not necessary.

How to Enforce a Number of Lines from Paragraphs that Continue in Next Page

In typography, an orphan is the first line of a paragraph that appears alone at the bottom of a page (the paragraph continues on a subsequent page), while a widow is the last line of a paragraph that appears alone at the top of a page. The default is 2 for each of them. You can control this number by adding the following to your customization CSS (on page 1693):

```
:root {
  widows:4;
  orphans:4;
}
```

Note:
As a difference from the W3C standard, the widows and orphans CSS properties are applied to lists as well (the default is 2). This means that a list that spans consecutive pages will have either zero or at least 2 lines on each of the pages.

How to Avoid Page Breaks Between Top-Level Topics (Chapters)

If you plan to publish a simple map with just one level of topics (such as a list of topics), then the automated page breaks between these topics might not be desired.

In this case, you can use the following CSS snippet to disable the page breaks between chapters:

```
*[class =~ "topic/topic"]{is-chapter} {
  -oxy-page-group:auto;
}
```

Related Information:
Oxygen PDF Chemistry User Guide: Chapter Page Placement and Styling

Hyphenation

Hyphenation specifies how words should be hyphenated when text wraps across multiple lines.

The transformation plugin uses the capabilities of the PDF Chemistry processor to perform hyphenation.

Hyphenation Dictionaries

The Oxygen XML Editor provides built-in hyphenation patterns for the following languages:
The built-in hyphenation pattern license terms are listed in the XML files in the `[CHEMISTRY_INSTALL_DIR]/config/hyph` folder. Most of them comply with the LaTeX distribution policy.

### Installing New Hyphenation Dictionaries

Oxygen XML Editor uses the TeX hyphenation dictionaries converted to XML by the OFFO project: [https://sourceforge.net/projects/offo/](https://sourceforge.net/projects/offo/).

The `.xml` files allow you to access the licensing terms and you can use them as a starting point to create customized dictionaries (see How to Alter a Hyphenation Dictionary (on page 1791)).

The `.hyp` files are the compiled dictionaries that the Oxygen XML Editor actually uses.

One simple way to add more dictionaries:

1. Download and extract the `offo-hyphenation-compiled.zip` file. This file is a bundle of many dictionary files.
2. Copy the `fop-hyph.jar` file to the `[OXYGEN_INSTALL_DIR]/lib` directory.
3. If you just need a single dictionary, place the `.hyp` or `.xml` file in the `[OXYGEN_INSTALL_DIR]/config/hyph` directory (create that directory if it is missing).
How to Alter a Hyphenation Dictionary

You can copy the dictionaries you need to change in another directory, then use the `-hyph-dir` parameter to refer them inside your transformation.

Each file is named with the language code and has the following structure:

```xml
<hyphenation-info>
  <hyphen-min before="2" after="3"/>

  <exceptions>
    o-mni-bus
    ...
  </exceptions>

  <patterns>
    préémi3nent.
    proémi3nent.
    surémi3nent.
    ...
  </patterns>

</hyphenation-info>
```

To change the behavior of the hyphenation, you can modify either the patterns or the exceptions sections:

**exceptions**

Contains the list of words that are not processed using the patterns, each on a single line. Each of the words should indicate the hyphenation points using the hyphen ("-"), with "-" using the hyphenation ("-"), character. If a word does not contain this character, it will not be hyphenated.

For example, `o-mni-bus` will match the `omnibus` word and will indicate two possible hyphenation points.

**Note:**

Compound words (i.e. e-mail) cannot be controlled by exception words.

**patterns**

Contains the list of patterns, each on a single line. A pattern is a word fragment, not a word. The numbers from the patterns indicate how desirable a hyphen is at that position.

For example, `tran3s2act` indicates that the possible hyphenation points are "tran-s-act" and the preferable point is the first one, having the higher score of "3".
How to Enable Hyphenation for Entire Map

To enable hyphenation for your entire map:

1. Make sure you set an `@xml:lang` attribute on the root of your map, or set the `default.language` parameter in the transformation.
2. In your customization CSS (on page 1693), add:

   ```css
   :root {
     hyphens: auto;
   }
   ```

3. To except certain elements from being hyphenated, use `hyphens: none`. The following example excludes the `<keyword>` elements from being hyphenated:

   ```css
   *[class ~="topic/keyword"] {
     hyphens: none;
   }
   ```

How to Enable/Disable Hyphenation for Tables

To enable hyphenation for your entire map:

1. Make sure you set an `@xml:lang` attribute on the root of your map or your table elements.
2. The built-in CSS already has the following rule defined that activates hyphenation:

   ```css
   *[class ~="topic/table"] {
     hyphens: auto;
   }
   ```

   **Note:**

   To disable table hyphenation, add the following in your customization CSS (on page 1693):

   ```css
   *[class ~="topic/table"] {
     hyphens: none;
   }
   ```

3. To prevent certain elements from being hyphenated, use `hyphens: none`. The following example excludes the `<keyword>` elements from being hyphenated:

   ```css
   *[class ~="topic/keyword"] {
     hyphens: none;
   }
   ```

How to Disable Hyphenation for a Word

To disable hyphenation for a specific word, there are several possible approaches:
• If the word is a compound (like "T-shirt") and you want to keep it on the same line, you have two options:

**Manual Approach**

Wrap the word in an inline element with the @outputclass attribute set. In the CSS, change its style to white-space:nowrap. For example:

```xml
.. <ph outputclass="no-hyphenation">T-shirt</ph>...
```

```css
*[outputclass ~="no-hyphenation"] {  
  white-space: nowrap;
}
```

**Automatic Approach**

A better alternative to this is to write an XSLT extension that matches the text nodes and performs automatic markup (to see an example, go to How to Wrap Words in Markup (on page 1686) in the XSLT Extensions for PDF Transformations (on page 1683) section). Then match the compound-word class the same as in the previous example:

```css
*[outputclass ~="compound-word"] {  
  white-space: nowrap;
}
```

**Another Alternative**

In all the compound words from your documentation, replace the hyphen ("-") with a non-breaking hyphen character ำ (or XML notation $\#{2011}$).

Then change the autocorrect settings (on page 164) to automatically replace the compound word with its equivalent. For example: "T-shirt" would be replaced with "T'][$u2011]shirt".

• If the word is not a compound, you have two options:
  ◦ Use one of the approaches listed above.
  ◦ Alter the hyphenation dictionaries as explained in: How to Alter a Hyphenation Dictionary (on page 1791).

**Accessibility**

By default, the PDF documents produced using this plugin are partially accessible in the sense that most of the paragraphs, tables, lists, headers, and footers are tagged automatically so a PDF reader can use this information to present the content.

**Related Information:**

Oxygen PDF Chemistry: Accessibility

**Accessibility - Built-in CSS**

Accessibility properties are defined in $[PLUGIN_DIR]css/print/p-accessibility.css.$
How to Create Fully Accessible Documents

To make your documents fully accessible (PDF/UA1), do the following:

1. In your customization CSS (on page 1693), specify fonts for all elements and for all page margin boxes. There should be no text that falls back to the basic provided fonts (Times, Courier, etc.). For instance, you can use:

   ```
   :root { font-family: Arial }
   @page {
     @top-left {font-family: Arial }
     ...
   }
   ```

2. Specify an `@alt` attribute with a description on any image, or better, use the `<alt>` DITA element.

3. Change the Chemistry invocation from the `build.xml` file, adding the argument `-pdf-ua`. There are two targets to change: `chemistry` and `chemistry.embedded`.

Fonts

Fonts are an important part of the publication. Your font selection should take into consideration both design and the targeted ranges of characters.

To use them in the customization CSS (on page 1693):

- You can place the font files in the same folder as your CSS and use a `@font-face` definition to reference them.
- You can use web fonts (for example, Google Fonts), and import the CSS snippet into your CSS.
- You can use system fonts.

All these techniques are explained in: Oxygen PDF Chemistry User Manual: Fonts.

How to Avoid Characters Being Rendered as #

When the processor renders text with a font that does not include certain characters, those characters are replaced with the # symbol.

To prevent this, make sure you use the proper font.

As an example, suppose the right arrow character is used in a definition list like this:

```
<dlentry>
  <dt>&#8594;</dt>
  <dd><ph>This is the right arrow.</ph></dd>
</dlentry>
```

If the font does not include this character, the output will look something like this:

```
#
This is the right arrow.
```
To fix this, use a fallback font. For example, if you use *Times New Roman* for the entire publication, you could add *Symbol* as the fallback font. In your *customization CSS* *(on page 1693)*, add:

```css
*{[^class =~ "topic/dlentry"] {  
  font-family: "Times New Roman", Symbol;
}}
```

**Tip:**

On Windows, one simple way to determine the font needed to display the text is to copy the text fragment that has rendering problems from the DITA source document and paste it into Microsoft WordPad or Word. It will automatically select a font capable of rendering the text. Simply click on the text to see the name of the font from the "Font" ribbon toolbar. Then you can use it as a fallback font in the CSS. Make sure there are no licensing restrictions on that particular font.

### How to Set Fonts in Titles and Content

Suppose that in your *customization CSS* *(on page 1693)*, you have defined your font (for example, *Roboto*) using a Google web font:

```css
@import url('https://fonts.googleapis.com/css?family=Roboto');
```

You can force a font on all elements, then style the ones that need to be different. The advantage of this method is that you do not need to trace all elements that have a font family defined in the built-in CSS files, you just reset them all.

In your *customization CSS* *(on page 1693)*, add an `!important` rule that associates a font to all the elements from the document:

```css
*{
  font-family:"Roboto" !important;
}
```

**Note:**

If you want to use the `:root` selector instead of the `*` sector, without the `!important` qualifier, the elements that have a predefined font specified in the built-in CSS will keep that font. If your content uses non-Latin glyphs, it is possible that the built-in fonts do not render them.

Next, identify the selectors for the elements that need to be styled with a different font than the one associated above. For information on how to do this, see: [Debugging the CSS *(on page 1694)*](#).

For example, if you want the titles or the pre-formatted text to have a different font from the rest, matched by the above `*` selector, you need to use more specific CSS selectors:

```css
*[^class="front-page/front-page-title"],  
[^class="topic/title"] {  
  font-family: Arial !important;
}
```
How to Use Fonts for Asian Languages

For Asian languages, you must use a font or a sequence of fonts that cover the needed character ranges. If the characters are not found, the # symbol is used.

When you specify a sequence of fonts, if the glyphs are not found in the first font, the next font is selected, and so on until one is found that includes all the glyphs. A common font sequence for Asian languages is as follows:

```css
font-family: Calibri, SimSun, "Malgun Gothic", "Microsoft JhengHei";
```

To apply this font sequence, see: How to Set Fonts in Titles and Content (on page 1795).

Some of the Asian fonts do not have italic, bold, or bold-italic variants. In this case, you may use the regular font file with multiple font face definitions to simulate (synthesize) the missing variants. You need to use the `-oxy-simulate-style:yes` CSS property in the font face definition as explained in: Using Simulated/Synthetic Styles in Oxygen Chemistry.

**How to Use Asian Fonts in Linux**

For Asian languages on Linux distributions, PDF Chemistry automatically uses DejaVu and Noto CJK as fallback fonts for Serif, Sans-Serif, and Monospace content.

⚠️ **Warning:**

On some distributions, the Noto CJK fonts are not available. In this case, you need to install them using the system package manager:

- `fonts-noto-cjk` on Debian family distributions (e.g. Ubuntu).
- `google-noto-cjk-fonts` on Red Hat family distributions (e.g. CentOS).

**How to Add a New Asian Font**

If you want to add a specific font for Asian languages, you need to declare it inside your customization CSS (on page 1693). The following example uses the Noto Sans Tamil font-family:

```css
/* Font Declaration */
@font-face {
}
Localization

The DITA Map PDF - based on HTML5 & CSS transformation type supports a large number of languages for customizing localization. In this type of transformation, the intermediary merged DITA map is transformed to HTML5 using the DITA-OT built-in support, so the customization of the internationalization (the labels for chapters, parts, figures, tables, notes, etc.) can be achieved by following the DITA-OT recommendations: Customizing Generated Text.

It is recommended that you do this customization on a DITA-OT distribution deployed outside of the Oxygen installation. Otherwise, you will lose the customization when upgrading Oxygen. You can contact the Oxygen support team to ask for the Oxygen Publishing Engine package.

Supported Languages (HTML5 and CSS)

There are over 20 supported languages. For the full list of supported languages (and their codes), see https://www.dita-ot.org/3.2/topics/globalization-languages.html.

How to Select a Language (HTML5 and CSS)

There are two ways to switch the labels to a specific language:

- Alter the DITA maps and/or topics to have the `@xml:lang` attribute set on the root element with one of the supported values (i.e. "fr", "de", "zh", "ru").
- If changing the files is not an option, you can alter the value of the `default.language` transformation parameter to the desired language code.
How to Add Support for a New Language

If the list of supported languages does not include the language you need, you can create a custom dictionary. The DITA-OT documentation offers a good insight on how to do it: https://www.dita-ot.org/3.2/topics/plugin-addgeneratedtext.html

In addition to that, you need to alter CSS files. Some of the labels come from CSS files located in the [PLUGIN_DIR]/css/print/i18n/ directory.

You should use one of the files as a template, copy its rules to your customization CSS (on page 1693), and then translate the labels. Make sure you also change the :lang selector to match your language code.

Comments, Highlights, and Tracked Changes

The comments and tracked changes can be made visible in the PDF output by setting the show.changes.and.comments transformation parameter to yes.

Figure 487. Chemistry Annotations in Acrobat Reader

By default, they are shown as PDF text annotations (sticky notes). These are graphical markers in the document content and are also listed in the Comments section when opening the output file in Acrobat Reader.

Note: Comments with the Mark as Done flag selected appear with a check mark in the Comments section and with a Completed label (John Doe Completed).

To avoid rendering the elements as PDF annotations and show them as footnotes instead, you can use the show.changes.and.comments.as.pdf.sticky.notes transformation parameter set to no.

The comments and changes are included in the merged map file (on page 1695) either as XML elements (<oxy-insert>, <oxy-delete>, <oxy-comment>, <oxy-attributes>) in the case of the XML merged map, or as HTML elements with similar classes (oxy-insert, oxy-delete, oxy-comment, oxy-attributes) in the case of the HTML merged map. Sub-elements contain meta-information about each change.
Tip:
These elements are automatically recognized and transformed in PDF annotations when using Chemistry as PDF processor.

Note:
The inserted text, deleted text, and deleted markup are included in the sticky notes, you can change this behavior by using the `show.changed.text.in.pdf.sticky.notes.content` parameter (on page 1670).

Related Information:
- Transformation Parameters (on page 1665)
- Debugging the CSS (on page 1694)

Comments and Tracked Changes - XML Fragment

This section contains information about how each type of tracked change is structured in the merged map XML file (on page 1695).

Insertions

For an insertion type of tracked change, the structure that defines the insertion details is inside the `range` (`<oxy-range-start>` to `<oxy-range-end>`), the inserted text is highlighted by an `<oxy-insert-hl>` element, and the details are stored in the `<oxy-insert>` element.

```xml
<oxy:oxy-range-start id="sc_1" hr_id="1"/>

  <oxy:oxy-insert href="#sc_1" hr_id="1">
    <oxy:oxy-author>dan</oxy:oxy-author>
    <oxy:oxy-content>insert</oxy:oxy-content>
    <oxy:oxy-date>2018/03/15</oxy:oxy-date>
    <oxy:oxy-hour>09:38:29</oxy:oxy-hour>
    <oxy:oxy-tz>+02:00</oxy:oxy-tz>
  </oxy:oxy-insert>

  <oxy:oxy-insert-hl>This is an insert!!</oxy:oxy-insert-hl>

<oxy:oxy-range-end hr_id="1"/>
```

Comments

Similar to insertions, comments are defined in a `range` (`<oxy-range-start>` to `<oxy-range-end>`), the comment details is in the `<oxy-comment>` element, and the highlighted content is wrapped in the `<oxy-comment-hl>` element.
Note:
Comments that are marked as done have a flag="done" attribute:

Attribute changes
The attribute changes are more complex. The range is empty, and is directly above the affected element (the one that has modified attributes). The <oxy-attributes> element contains details about multiple attribute changes, each stored in the <oxy-attributed-change> element.

```
<oxy:oxygen-range-start id="sc_3" hr_id="3"/>
<oxy:oxygen-end hr_id="3"/>
<oxy:oxygen-attributes href="#sc_3" hr_id="3"/>

<oxy:oxygen-attribute-change type="inserted" name="platform">
  <oxy:oxygen-author>dan</oxy:oxygen-author>
  <oxy:oxygen-current-value>windows</oxy:oxygen-current-value>
  <oxy:oxygen-date>2018/03/15</oxy:oxygen-date>
  <oxy:oxygen-hour>10:05:04</oxy:oxygen-hour>
  <oxy:oxygen-tz>+02:00</oxy:oxygen-tz>
</oxy:oxygen-attribute-change>
....
<oxy:oxygen-attribute-change type="removed" name="audience">
  ....
</oxy:oxygen-attribute-change>
</oxy:oxygen-attributes>
```
Deletions

For a deletion, there are some elements that define the start and end of the deletion, and the highlighted text is wrapped in the `<oxy-delete-hl>` element.

```xml
<oxy:oxy-range-start id="sc_2" hr_id="2"/>
<oxy:oxy-delete-hl> This is a deleted text. </oxy:oxy-delete-hl>
<oxy:oxy-range-end hr_id="2"/>
```

There is a structure that offers details about the deletion change, using the `<oxy-delete>` element. This is linked to the above deletion range by the same ID value:

```xml
<oxy:oxy-delete href="#sc_2" hr_id="2">
  <oxy:oxy-author>dan</oxy:oxy-author>
  <oxy:oxy-content><image href="../img/ex.gif"></oxy:oxy-content>
  <oxy:oxy-date>2018/03/14</oxy:oxy-date>
  <oxy:oxy-hour>11:38:06</oxy:oxy-hour>
  <oxy:oxy-tz>+02:00</oxy:oxy-tz>
</oxy:oxy-delete>
```

Colored Highlights

To show some text as highlighted with a background color:

```xml
<oxy:oxy-color-hl color="rgba(140,255,140,50)">Some colored text.</oxy:oxy-color-hl>
```

Comments and Tracked Changes - HTML Fragment

This section contains information about how each type of tracked change is structured in the merged map HTML file (on page 1695).

Insertions

For an insertion type of tracked change, the structure that defines the insertion details is inside a range (oxy-range-start to oxy-range-end), the inserted text is highlighted by a `<span>` element with the class oxy-insert-hl, and the details are stored in a `<span>` element with the oxy-insert class.

```xml
<oxy:oxy-color-hl color="rgba(140,255,140,50)">Some colored text.</oxy:oxy-color-hl>
```

```xml
<oxy:oxy-range-start id="sc_1" hr_id="1"/>
<oxy:oxy-insert href="#sc_1" hr_id="1">
  <oxy:oxy-author>dan</oxy:oxy-author>
  <oxy:oxy-content>insert</oxy:oxy-content>
  <oxy:oxy-date>2018/03/15</oxy:oxy-date>
  <oxy:oxy-hour>09:38:29</oxy:oxy-hour>
  <oxy:oxy-tz>+02:00</oxy:oxy-tz>
</oxy:oxy-insert>
```

```xml
</span>
```
<span class="oxy-insert-hl">This is an insert!!</span>

Comments

Similar to insertions, comments are defined in a range (oxy-range-start to oxy-range-end), the comment details in an element with the class oxy-comment, and the highlighted content is wrapped in the oxy-comment-hl element.

<element>
  <span class="oxy-range-start" id="sc_1" hr_id="1"/>
  <span class="oxy-comment" href="#sc_1" hr_id="1">
    <span class="oxy-author">dan</span>
    <span class="oxy-comment-text">This is a comment.</span>
    <span class="oxy-date">2018/03/15</span>
    <span class="oxy-hour">09:56:59</span>
    <span class="oxy-tz">+02:00</span>
  </span>
  The commented text.
</element>

Note:

Comments that are marked as done have a flag="done" attribute:

<element>
  <span class="oxy-comment" href="#sc_6" hr_id="6" flag="done">
    <span class="oxy-author">dan</span>
    <span class="oxy-current-value">windows</span>
  </span>
</element>

Attribute changes

The attribute changes are more complex. The range is empty, and is directly above the affected element (the one that has modified attributes). The element with the class oxy-attributes contains details about multiple attribute changes, each stored in an element with the class oxy-attribute-change.

<element>
  <span class="oxy-range-start" id="sc_3" hr_id="3"/>
  <span class="oxy-range-end" hr_id="3"/>
  <span class="oxy-attributes" href="#sc_3" hr_id="3">
    <span class="oxy-attribute-change" type="inserted" name="platform">
      <span class="oxy-author">dan</span>
      <span class="oxy-current-value">windows</span>
    </span>
  </span>
</element>
Deletions

For a deletion, there are some elements that define the start and end of the deletion, and the highlighted text is wrapped in an element with the class oxy-delete-hl.

```xml
<element>
  ....
  <span class="oxy-attribute-change" type="removed" name="audience">
    ....
  </span>
  ....
</element>
```

There is a structure that offers details about the deletion change, using the element with the class oxy-delete. This is linked to the above deletion range by the same ID value:

```xml
<element>
  <span class="oxy-delete" href="#sc_2" hr_id="2">
    <span class="oxy-author">dan</span>
    <span class="oxy-content"><image href="../img/ex.gif"></span>
    <span class="oxy-date">2018/03/14</span>
    <span class="oxy-hour">11:38:06</span>
    <span class="oxy-tz">+02:00</span>
  </span>
</element>
```

Colored Highlights

To show some text as highlighted with a background color:

```xml
<element>
  <span class="oxy-color-hl" color="rgba(140,255,140,50)">Some colored text.</span>
</element>
```

Comments and Tracked Changes - Built-in CSS

The built-in CSS that controls the way tracked changes and comments are displayed is found in: [PLUGIN_DIR]css/print/p-side-notes.css.

How to Style Changed or Commented Text

To style the highlighted text from the document content, use the oxy-comment-hl element (or oxy-delete-hl, oxy-insert-hl, respectively, by local name or class name):
oxy-comment-hl,
.oxy-comment-hl {  
  color:magenta;
}

Note:  
The class name selector is useful when using the DITA Map PDF - based on HTML5 & CSS or DITA PDF - based on HTML5 & CSS transformation scenarios.

If you want to change the small labels that define the affected start and end ranges (they are a number formatted like "[n] .. [/n]" where n is the number of the change), you can use the following selectors:

oxy-range-start:before,  
.oxy-range-start:before {  
  display:inline;  
  content:'[ ' attr(hr_id) ' ]' ;  
  color:red;  
}

oxy-range-end:before,  
.oxy-range-end:before {  
  display:inline;  
  content:' [ ' attr(hr_id) ' ] ' ;  
  color:red;  
}

Use `display:none` if you want to hide them.

If you want to change the background color of the comment footnote (assuming you set the `show.changes.and.comments.as.pdf.sticky.notes` transformation to `no`), add the following snippet in your customization CSS (on page 1693):

oxy-comment,  
.oxy-comment {  
  background-color:inherit;  
  border:2pt solid yellow;  
}

Similarly, you can style the other footnotes for `<oxy-attributes>`, `<oxy-delete>`, and `<oxy-insert>` elements.

How to Hide Tracked Change Footnotes

This topic is relevant if you have set the `show.changes.and.comments.as.pdf.sticky.notes` transformation parameter to `no`, and therefore the changes are shown as footnotes instead of PDF annotations.
In some cases, when your document contains a lot of tracked changes, you may need to hide the footnotes associated with the insertions, deletions, or attribute changes. Using the following example, the deletions and insertions are hidden, but the comments remain visible. In your customization CSS (on page 1693), add:

```css
oxy-attributes, oxy-delete, oxy-insert{
    float:none;
    display:none;
}
```

**Troubleshooting**

This section contains information about fixing various change tracking, highlights and comments publishing problems.

**Highlights are Spanning Unexpectedly to the End of the Page**

**Problem**

Tracked changes and highlights span beyond what is expected.

**Cause**

If the change tracking insertions, comments, or highlights span over an area that is larger than expected, the markup that signals their end is missing.

**Solution**

To fix this, open the topic where the highlights start and check if the XML processing instructions that define the end of the highlighted interval are correct. The intervals are defined as follows:

For highlights:

```xml
<?oxy_custom_start type="oxy_content_highlight" color="140,255,140"?>
<?oxy_custom_end>
```

For comments:

```xml
<?oxy_comment_start author="dan" timestamp="20201102T092905+0200" comment="Test"?>
<?oxy_comment_end>
```

For inserted text:

```xml
<?oxy_insert_start author="dan" timestamp="20201102T093034+0200"?>
<?oxy_insert_end>
```

Make sure all the ending processing instructions are located before the root element end tag.
Draft Watermarks

A watermark is an image displayed as the background of a printed document and it is faded enough to keep the publication text readable. Draft watermarks are used to indicate that a document is under construction or has not yet been approved.

How to Add a Draft Watermark on All Pages

To add a draft watermark to all of your publication pages, you can use the following page selector in your customization CSS (on page 1693):

```css
@page {
    background-image: url("draft.svg");
    background-position: center;
    background-repeat: no-repeat;
    background-color: inherit;
}
```

If you have already set a background image for other pages (for example, the front-page or table-of-contents), the above selector won't change them, as they are more specific.

The best practice is to use a different draft.css CSS file that imports the customization CSS where the rest of the style changes reside. If you need to publish the content as a draft, use the draft.css in your transformation scenario, otherwise directly reference the customization CSS (on page 1693).

Related Information:
Images and Figures (on page 1815)

How to Add a Draft Watermark Depending on Metadata

Suppose you want to apply a Draft watermark until your DITA bookmap is approved and the map is approved when an `<approved>` element has been added to the metadata section (for example, in the `bookmeta/bookchangehistory` element).

```xml
<bookmeta>
    <author>John</author>
    <critdates>
        <created date="1/1/2015"/>
        <revised modified="3/4/2016"/>
        <revised modified="3/5/2016"/>
    </critdates>
    <bookchangehistory>
        <approved/>
    </bookchangehistory>
</bookmeta>
```
Use **oxy_xpath** every time you need to probe the value from an element other than the one matched by the CSS selector, and test the expression on the merged HTML file using the **Oxygen XPath Builder** view.

You can either use a page selector that imposes the draft watermark on the entire page surface (recommended):

```xml
@page {
    background-image: url(oxy_xpath('if (/bookmeta/bookchangehistory/approved) then "" else "../../../../images/draft-watermark.png" '));
    background-position: center;
    background-repeat: no-repeat;
    background-color: inherit;
}
```

or use an element selector that restricts the watermark image only to the page area covered by that element:

```xml
:root, body{
    /* same as properties above */
}
```

The **body** selector is used here in case you want to apply the **DITA Map PDF - based on HTML5 & CSS** transformation type. You can use another element selector to target a specific part of your publication (for example, marking only the tables as drafts).

**Related Information:**

- Metadata *(on page 1725)*
- How to Debug XPath Expressions *(on page 1699)*

**Flagging Content**

In DITA, you can mark certain content to flag it or draw attention to it. This is done by defining a flag in a DITAVAL file.

You can attach the DITAVAL file to the DITA map using the `<ditavalref>` element in the map, or by specifying it in the `args.filter` transformation parameter.

In the following example, all the elements that have the attribute `@product` set to `YourProd` is flagged to have a purple background:

```xml
<val>
    ...
    <prop action="flag" att="product" val="YourProd" bgcolor="purple"/>
    ...
</val>
```
Related Information:
- Change Bars
- DITAVAL Elements

**How to Flag Content Using Change Bars**

As an example, to add a *change bar* (revision mark) for particular content, you can use the following in the DITAVAL file:

```xml
<val>
  <revprop action="flag"
    changebar="color:blue;style:solid;width:2pt;offset:1.25mm;placement:start" val="new"/>
</val>
```

This would result in any content that is marked with `<rev new>` having a blue change bar.

**How to Flag Content Using Images**

You can mark the elements that match a specific profiling condition using images (one for the start, one for the end). The image references are relative to the DITAVAL file.

```xml
<val>
  <prop action="flag"
    att="product" val="MyProd"
    backcolor="blue"
    color="yellow">

    <startflag imageref="startflag.jpg">
      <alt-text>This is the start of my product info</alt-text>
    </startflag>

    <endflag imageref="endflag.jpg">
      <alt-text>This is the end of my product info</alt-text>
    </endflag>

  </prop>
</val>
```

**Styling the Content**

If you need to change the styles of the elements from the topic contents, you should create a customization [CSS](on page 1693) and then add CSS rules. To create the CSS rules, you can use the development tools described in [Debugging the CSS](on page 1694).
Reusing the Styling for WebHelp and PDF Output

If you are using the pdf-css-html5 transformation type, then the generated HTML5 document that is later converted to PDF is very similar to the generated HTML5 pages from the WebHelp Responsive output.

This is an output example from the WebHelp transformation:

```html
<h1 class="title topic/title1" id="ariaid-title2">Care and Preparation</h1>
<div class="body">
  <p class="shortdesc">When caring ...</p>
  <p class="p">When caring for your flower garden you want ...</p>
</div>
```

And the same example from the PDF transformation (note the additional emphasized class values):

```html
<h1 class="- topic/title title topic/title1" id="ariaid-title2">Care and Preparation</h1>
<div class="- topic/body body">
  <p class="- topic/shortdesc shortdesc">When caring ...</p>
  <p class="- topic/p p">When caring for your flower garden you want ...</p>
</div>
```

It makes sense to reuse the same CSS rules you developed for one transformation type to the other. The main rule is to use the short class names instead of the long ones. For example, to style the short descriptions with italic font, use:

```css
.shortdesc {
  font-style: italic;
}
```

The rule of thumb is that if you have a CSS rule that successfully styles an element in WebHelp, it should apply without any modification in the PDF output.

**Titles**

Titles can be styled by matching the `topic/title` class attribute.

```css
*{class="topic/title"] { 
  color:navy;
}
```

**How to Avoid Wrapping the Title Text Without Indentation**

By default, the chapter/section number is on the same line as the title text. If the title is too long, the text wraps to the next line without any indentation.

```
4.5.5 This is a long title
text that wraps.
```

If you want the wrapped text to include indentation, you need to set the value of the `args.css.param.title.layout` transformation parameter to `table`. This results in the chapter/section number being placed in one cell while the rest of the title content is in another cell with wrapped text and it is displayed with an indent:
4.5.5 This is a long title
text that wraps.

Equations
This processor supports MathML equations.

How to Change the Font of MathML Equations
Suppose that you need to change the font of MathML equations from the documentation, and also add some padding. The MathML fragments are wrapped in elements that have the class `equation-d/equation-block` or `equation-d/equation-inline`, so you can match them with:

```css
*[class ~="equation-d/equation-block"],
*[class ~="equation-d/equation-inline"]{
  font-family:"courier new";
  font-size:1.5em;
  padding:1em;
}
```

Note:
An equation can be rendered using multiple classes of fonts (e.g. the serif, sans serif, monospace, fraktur, and doublestruck classes. Depending on each of the equation symbols, a class is selected for it. The font specified in the CSS rule (as in the preceding example), applies only to the serif class. However, if a symbol codepoint is not covered by the currently selected class fonts, it falls back to the font specified in the CSS.

Attention:
Some of the fonts may not be supported. In that case, a default serif font is used.

Lists
You can style the list item markers or other properties.

Note:
The lists are treated differently than ordinary block elements in the sense that their margins are not collapsed with the margins of the neighboring blocks or lists. This is also visible for nested lists.

How to Style the List Markers
For the media print, the default CSS rules for the list items use the :marker pseudo-class.

```css
@media print {
  *[class="topic/li"]:marker {
```
To eliminate the bold font weight for the items form ordered lists then add the following rules to your customization CSS (on page 1693):

```css
*[^class="topic/li"]::marker {
  font-weight: normal;
}
```

For the unordered lists:

```css
*[^class="topic/ul"]::marker {
  font-weight: normal;
}
```

## How to Continue List Numbering

It is possible to continue the numbering of an ordered list even when the content is split on multiple `<ol>` elements.

You just need to define an `@outputclass` attribute on the lists where numbering should continue:

```xml
<ol @outputclass="continue">
  <li>Third Item</li>
</ol>
```

Then set the following content inside your CSS customization:

```css
*[^class="topic/ol"] {
  counter-reset: list-counter;
}

*[^class="topic/ol"][@outputclass="continue"] {
  counter-reset: none;
}

*[^class="topic/ol"] > *[^class="topic/li"] {
```
How to Change the Numbering System of Ordered Lists

It is possible to change all lists to have a different numbering system and there are several methods that can be used to achieve this.

**Use the list-style-type CSS Property.**

The Chemistry engine supports the following types: decimal, decimal-leading-zero, lower-roman, upper-roman, lower-latin, upper-latin, lower-alpha, upper-alpha.

```
*[^class~="topic/ol"] {  
  list-style-type: lower-roman;
}
```

**Change the Content of the :marker CSS Pseudo-Element.**

The following example emulates the Cyrillic numbering for the list items for an ordered list that has the @outputclass attribute set to cyrillic:

```
Important:
This example will work only for lists up to 28 items. You will have to extend it for longer lists!
```

```
*[^class~="topic/ol"][outputclass~="cyrillic"] > *[^class~="topic/li"]:marker {  
  width:3em;
}
```

```
*[^class~="topic/ol"][outputclass~="cyrillic"] > *[^class~="topic/li"]:nth-of-type(1):marker{ content:"а" }
*[^class~="topic/ol"][outputclass~="cyrillic"] > *[^class~="topic/li"]:nth-of-type(2):marker{ content:"б" }
*[^class~="topic/ol"][outputclass~="cyrillic"] > *[^class~="topic/li"]:nth-of-type(3):marker{ content:"в" }
*[^class~="topic/ol"][outputclass~="cyrillic"] > *[^class~="topic/li"]:nth-of-type(4):marker{ content:"г" }
*[^class~="topic/ol"][outputclass~="cyrillic"] > *[^class~="topic/li"]:nth-of-type(5):marker{ content:"д" }
*[^class~="topic/ol"][outputclass~="cyrillic"] > *[^class~="topic/li"]:nth-of-type(6):marker{ content:"е" }
```
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"ж"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"з"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"и"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"к"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"л"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"м"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"н"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"о"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"п"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"р"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"с"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"т"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"у"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"ф"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"х"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"ц"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"ч"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"ш"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"щ"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"э"} *
*[class =~ "topic/ol"] [outputclass =~ "cyrillic"] > *{content:"ю"} *
Links

Links allow the users to navigate through the documentation.

How to Remove 'on page NNN' Link Label

For printed material, it is usually desirable for the links to display a label after the text content (such as "on page 54"). This makes it easier the user to identify the target page. However, if the produced PDF is not printed and is intended only for electronic use, this label may create clutter and make the document harder to read. To eliminate this label, add the following in your customization CSS (on page 1693):

```css
* [class = "topic/xref"] [href]:after,
* [class = "topic/link"] [href]:after {
  content: none !important;
}
```

Another use-case is to remove the labels only from links shown in tables cells, and leave the others as they are. For this, you could use a more specific selector:

```css
* [class = "topic/entry"] * [class = "topic/xref"] [href]:after{
  content: none !important;
}
```

How to Change Link Styles

Suppose you want the links to be bold and with an underline. In your customization CSS (on page 1693), add this snippet:

```css
* [class = "topic/xref"] [href]:after,
* [class = "topic/link"] [href]:after {
  font-weight: bold;
  text-decoration: underline;
}
```

How to Hide Descriptions in Related Links Sections

The link descriptions that come from DITA relationship tables or related link elements within topics, are structured in the merged map (on page 1695) like this:

```xml
<related-links class="- topic/related-links ">
  <linkpool class="- topic/linkpool ">
    <link class="- topic/link ">
```
... role="friend" scope="local" type="topic">
    &lt;linktext class="- topic/linktext ">Salvia</linktext>
    &lt;desc class="- topic/desc ">The salvia plant</desc>
  &lt;/link>
&lt;/linkpool>
...
&lt;/related-links>

If you need to hide these descriptions, add the following code in your customization CSS (on page 1693):

```
*[class ~="topic/link"] > *[class ~="topic/desc"] {
    display: none;
}
```

Images and Figures

Images are an important part of a publication.

Note:

You can use raster image formats (such as PNG or JPEG), but it is best to use vector images (such as SVG or PDF). They scale very well and produce better results when printed. In addition, the text from these images is searchable and can be selected (if the glyphs have not been converted to shapes) in the PDF viewer.

Images - Built-in CSS

Image properties are defined in [PLUGIN_DIR]css/print/p-figures-images.css.

```
*[class ~="topic/image"] {
    prince-image-resolution: 96dpi;
    -ah-image-resolution: 96dpi;
    image-resolution: 96dpi;
    max-width: 100%;
}
```

How to Fix Image Bleeding - Control Image Size

Sometimes the images may be too big for the page. The built-in CSS rules specify a maximum size for images, limiting to the width of the parent block. But if the parent block is itself too wide and bleeds out of page, you might consider specifying a length.

In your customization CSS (on page 1693), add the following snippet:

```
*[class ~="topic/image"] {
    ...
```
Pay attention to images that have an image map (on page 1820) associated. The built-in rules set the max-width: auto for them to avoid scaling. Otherwise, it would cause a misalignment between the image and its clickable areas. These images are best to have a @width and @height attribute.

How to Change Image Resolution

This is a technique to change the size of all raster images from your documentation. It will not work for vector images, such as PDF or SVG.

The default resolution is 96dpi, just as in a web browser. If the default resolution is not good (suppose you need a higher pixel density of 300dpi), you can change it by adding the following in your customization CSS (on page 1693):

```
* [class ~="topic/image"] {
  prince-image-resolution: 300dpi;
  -ah-image-resolution: 300dpi;
  image-resolution: 300dpi;
}
```

**Important:**

The above selector does not apply to images from the `<imagemap>` element. You can use the selector for that purpose:

```
* [class =>'ut-d/imagemap'] > * [class =>'topic/image'] {
  ...
}
```

Make sure you verify the area shapes to match the new image boundaries. The pixels specified in the image map area coordinates are always 1/96 in. For more details, see: How to Use Image Maps (on page 1820).

How to Place Big Images on Rotated Pages

Very wide images may bleed out of the page. One solution for this is to use landscape pages for these wide images.

In your customization CSS (on page 1693), add:

```
* [class='="topic/image"] [outputclass='land'] {
  page: landscape-page;
}
```

Setting the attribute @outputclass = 'land' on the table element will force the table on a new landscape page.
Another solution is to set an \texttt{@outputclass} attribute on the image, then create a rule that matches it, and associate a landscape page for it.

**How to Place a Text and Image Side by Side**

If you need to align text and an image side by side, you can use the following technique:

1. Organize your text and image under a \texttt{<div>} element like this:

   ```
   ... 
   <div outputclass="side-by-side">
     <p> This will be in the left side, the next figure in the right. </p>
     <fig>
       <image href="cactus.jpeg"/>
     </fig>
   </div>
   ... 
   ```

   \textbf{Note:}
   
   You can use the \texttt{@outputclass} attribute to mark the \texttt{<div>} elements that have this special layout.

2. In your customization CSS (on page 1693), add:

   ```
   *[outputclass ~="side-by-side"] > *[class ~="topic/p"] {
     display:inline-block;
     width: 45%;
   }
   
   *[outputclass ~="side-by-side"] > *[class ~="topic/fig"] {
     display:inline-block;
     width: 45%;
   }
   ```

   The image should fill the entire width of the parent \texttt{<fig>} element:

   ```
   *[outputclass ~="side-by-side"] > *[class ~="topic/fig"] > *[class ~="topic/image"] {
     width:100%;
   }
   ```

   By default, the bottom of the image is on the same line as the text baseline. If you want the text and the image to be aligned at the top, add these lines:

   ```
   *[outputclass ~="side-by-side"] > *[class ~="topic/p"] {
     vertical-align:top;
   }
   ```

   ```
   *[outputclass ~="side-by-side"] > *[class ~="topic/fig"] {
   ```
How to Control the Image Size in Complex Static Content

It is common to have text and images mixed together in a :before or :after pseudo-element. For example, for notes you may have both artwork and text:

```css
*[class ~= "topic/note"]::before {
    content: url('note.png') "Some text";
}
```

If you want to change the size of the image, you have two options:

- Use the `image-resolution` CSS property:

  ```css
  *[class ~= "topic/note"] {
      image-resolution:300dpi;
  }
  ```

- Separate the image from the text and apply the width and height CSS properties only on the image, using the width and height properties. You could use multiple :before pseudo-elements for that, considering that the farthest content presented before the actual content of an element is matched by the :before with the highest number in the brackets:

  ```css
  *[class ~= "topic/note"]:before(2) {
      content: url('note.png')
      width:0.5in;
  }
  ```

  ```css
  *[class ~= "topic/note"]:before(1) {
      content: "Some text";
  }
  ```

How to Center Images

DITA defines a `@placement` attribute for the `<image>` elements. The implicit value is `inline`. Suppose that you need to center the images that have the placement set to `break` (for example, they are not on the same line with other content and the images from the `<fig>` element).

In your customization CSS (on page 1693), add:
How to Change/Reset the Figure Numbering

Note:
This topic is applicable for the DITA Map PDF - based on HTML5 & CSS DITA PDF - based on HTML5 & CSS transformation types.

There are cases when you need to change the aspect of the figure counter that is shown before the figure titles. By default, the figure titles are formatted like this:

Figure NN. Lore Ipsum Title

NN is the number of the figure that starts being counted from the beginning of the publication.

One use-case is to have the NN counter be incremented only within one chapter (for example, the first chapter contains "Figure 1" and "Figure 2", and the second chapter starts over with "Figure 1" instead of incrementing to "Figure 3").

You should reset the figure counter on each topic marked as chapter, then hide the label from the figure <figcaption> (this is an HTML element generated by the XSL transformation), and create another label using a :before selector on the <figcaption>.

[*class = "topic/topic"][is-chapter] {  
  counter-reset: figcount;
}
How to Fix Missing Images

If your images are not accessible, you may receive an error message in the transformation console like this:

```
Image not found. URI:file:/path/to/my/image
```

This is usually because they are in a folder that is not in the folder subtree of the transformed map or topic. To solve this, you can set the following transformation parameter: `fix.external.refs.com.oxygenxml=true`.

How to Use Image Maps

To use the DITA `<imagemap>` element in a PDF transformation, follow this procedure:

1. Start by determining the width and height of your image in CSS *pixels* and specify it on the `<image>` element using the `@width` and `@height` attributes.

   **Notes:**
   - A CSS *pixel* is $1/96$ in, so if the image is created at a 96dpi resolution, one dot from the image is one pixel in the CSS space. If your image is displayed at another resolution *(on page 1816)*, then it is adjusted accordingly (for example, 192dpi results in two dots from the image being equal to one pixel in the CSS space).
   - You can use other CSS units, including percentages. The percentages are solved relative to the image size and represent a way of creating *responsive* image maps.

   **Warning:**
   - If you publish the content for both PDF and HTML web output, make sure you only use *pixels*, as some browsers only support these units.

   **Example:**
   - Suppose you have a very large image that is 6400x4800 dots, but you want to make it fit in a box of 640x480 CSS *pixels*. In the following snippet, this is done by specifying the width and height attributes. The areas must use coordinates relative to these values.
2. In the map element, add areas (each with a shape and a set of coordinates):

```html
<imagemap>
  <image href="../images/Gear_pump_exploded.png"
    id="gear_pump_exploded"
    width="640"
    height="480">
    <alt>Gear Pump</alt>
  </image>

  <area>
    <shape>circle</shape>
    <coords>172, 265, 14</coords>
    <xref href="parts/bushings.dita#bushings_topic/bushings"
      format="dita">Bushings</xref>
  </area>

  <area>
    <shape>poly</shape>
    <coords>568, 81, 576, 103, 468, 152, 455, 130</coords>
    <xref href="parts/drive-shaft.dita#drive_shaft_topic/drive_shaft"
      format="dita">Drive Shaft</xref>
  </area>

  ...
</imagemap>
```

The type of areas are the ones defined in the HTML standard: circle, poly, rect, default. For more details, see: https://html.spec.whatwg.org/multipage/image-maps.html#the-area-element.

3. Verify how the shapes look in the output. You can make the shapes visible by one of the following methods:

- Using the `show.image.map.area.numbers` and `show.image.map.area.shapes` transformation parameters.
- Adding a CSS snippet to your customization. The shapes have the `image-map-shape` class, the bullet around the image map number (`image-map-number`), and the text inside the bullet (`image-map-number-text`). To make them translucent yellow:

```css
.image-map-shape{
  fill: yellow;
  fill-opacity: 0.5;
  stroke-opacity: 0.5;
}
```
How to Hide the Image Map Links List

Below every image map, a list of links that point to the image map targets is displayed. This list can be hidden from the final output by using the following CSS selector:

```
.imagemap--areas {
  display: none;
}
```

How to Use SVG Syntax Diagrams

The DITA `<syntaxdiagram>` element is supported by the PDF transformation. To use SVG syntax diagrams, follow this procedure:

1. Download the latest version of the `svg-syntaxdiagrams` plugin, unzip it, and copy all the folders into your `DITA-OT-DIR\plugins` folder (they all start with "com.").
2. Open a command prompt inside `DITA-OT-DIR\bin` and run the `dita install` command.
3. You can now add your custom `<syntaxdiagram>` element in your topic, as in the following example:

```
<syntaxdiagram id="syntaxdiagram_ok4_clk_xnb">
  <title>CopyFile</title>
  <groupseq><kwd>COPYF</kwd></groupseq>
  <groupcomp><var>input-filename</var><kwd>*INFILE</kwd></groupcomp>
  <groupseq><var>output-filename</var><kwd>*OUTFILE</kwd></groupseq>
  <groupchoice><var>input-filename</var><kwd>*INFILE</kwd></groupchoice>
  <groupchoice><var>output-filename</var><kwd>*OUTFILE</kwd></groupchoice>
</syntaxdiagram>
```

4. Run the DITA Map PDF - based on HTML5 & CSS (or DITA PDF - based on HTML5 & CSS) transformation.

**Warning:**
If you are not publishing the content for the first time, you may need to delete the `out/` and `temp/` folders to see the syntax diagram correctly in the `.merged.html` file.

**Result:** The PDF is generated and the syntax diagram is displayed as a referenced SVG file like this:
Tables

Tables are widely used in technical documentation. This section contains information about the CSS rules that are used to style them and how to fix some problems.

Tables - Built-in CSS

There is a combination of CSS files that address tables:

- [PLUGIN_DIR]/css/core/-table-html-cals.css
- [PLUGIN_DIR]/css/print/p-tables.css

How to Handle Wide Tables - Page Rotation

Some of the tables can have a large number of columns. In this case, the table may bleed out of the page. One solution is to use landscape pages for these tables.

Setting the attribute `@orient` = 'land' on the table element will force the table on a new landscape page.

Another solution is to use automatic detection of wide tables (5 or more columns):

```css
*[class~="topic/table"] > *[class~="topic/tgroup"]{cols='5'},
*[class~="topic/table"] > *[class~="topic/tgroup"]{cols='6'},
*[class~="topic/table"] > *[class~="topic/tgroup"]{cols='7'},
*[class~="topic/table"] > *[class~="topic/tgroup"]{cols='8'}
{
  page: landscape-page;
  max-width: 100%;
  page-break-before: avoid;
}
```

**Note:**
The landscape-page page layout is defined in the [PLUGIN_DIR]/css/print/p-pages-and-headers.css.

If you want to rotate the entire topic that contains the big table, use:

```css
*[class~="topic/table"] > *[class~="topic/tgroup"]{cols='5'},
*[class~="topic/table"] > *[class~="topic/tgroup"]{cols='6'},
*[class~="topic/table"] > *[class~="topic/tgroup"]{cols='7'},
*[class~="topic/table"] > *[class~="topic/tgroup"]{cols='8'}
{
  max-width: 100%;
  table-layout:auto;
}
```
How to Fix Text Bleeding From Table Cells

Slim tables or tables that have many columns make the text from the cells be confined to a small horizontal space. Sometimes this causes long words to bleed outside the cell boundaries.

By default, the built-in CSS automatically activates the hyphenation for the text inside tables as long as your topics have the language specified.

In case the text is still bleeding outside the boundaries, you can also use the `overflow-wrap` property to force the word to break:

```css
*{class ~="topic/table"}{
  overflow-wrap: break-word;
}
```
How to Avoid a Table Exceeding the Page Width

The DITA specification indicates that tables should have a fixed layout. This can be done in two different ways:

1. **Using proportional or relative measures** - It includes percent values and shares values (i.e. "3\*" or "12\*").
2. **Using fixed measures** - It includes all the values followed by units (i.e. \textit{in}, \textit{pt}, \textit{px}, and others).

**Important:**
Although the specification allows you to combine these values, it is strongly recommended that you only use one method at a time. Combining both methods could lead to a table exceeding the page width and will make the content unreadable.

How to Enable the Automatic Table Layout

It is possible to automatically arrange the table layout directly from the customization CSS (on page 1693) by simply adding this:

```css
*[class~="topic/tgroup"] {
  table-layout:auto !important;
}
```

This will help you to obtain a more optimal arrangement of the cells inside your table.

If you want to control which table will use this layout, you can set the \texttt{@outputclass} attribute on the \texttt{<table>} element:

```xml
<table outputclass='auto_tbl'> ... </table>
```

Then, in the CSS, use a rule that matches the \texttt{@outputclass}:

```css
*[class="topic/table"][@outputclass='auto_tbl'] > *[class="topic/tgroup"] {
  table-layout:auto !important;
}
```

**Important:**
Make sure the tables have no column width specified.

How to Rotate Content from a Table Cell

There are cases where you want to style the first column as a kind of table header, with vertical text.
There is an important thing to remember: you can rotate an element from a table cell, but not the cell itself. So, your DITA table cell should contain a `<div>` or a `<p>` element that will be rotated. The cell has to be marked somehow so that it can be matched from the CSS. One way is to set an `@outputclass` attribute on it, another will be to mark the table and then match the first entries from it.

```xml
<row>
  ...
  <entry outputclass="rotated">
    <p>Rotated</p>
  </entry>
  ...
</row>
```

In your customization CSS (on page 1693), use the following rule that matches the child of the entry:

```css
*[class ~="topic\row"] > *[class ~="topic\entry"][outputclass ~="rotated"] {
  width: 1em; /* This gives the table column its width. It is the height of the rotated element - assuming it contains just one line. */
  padding-top: 14em; /* Increase this until the entire vertical text fits into the cell. */
}

*[outputclass ~="rotated"] > * {
  transform: rotate(-90deg) !important;
  width: 1em; /* This also gives the table column its width. */
  height: 1em; /* This is the effective width after rotation. */
  border: 1pt solid red; /* Just for debug */
  background-color: yellow; /* Just for debug */
  hyphens: manual; /* Disable hyphenation, to force the text extend out of the small bounds - the parent rotated entry has enough padding to accommodate it. */
  padding: 0;
  margin: 0;
}
```

The padding and margins are set to zero to clear any space that may come from other rules. The width is required - it will become the height of the cell.

### How to Add Horizontal Lines to a Choice Table

To add horizontal lines that separate the options within a `<choicetable>`, you can use borders set on each of the rows. The following CSS styles the top header and the first column with some background colors. In a choice table, the first column represents the choice labels.

```css
*[class="task\choptionhd"],
*[class="task\choptionhd"],
*[class="task\chdeschd"],
*[class="task\choption"] {
```
Note:
Using the frame attribute on the choice table will make these selectors apply partially. Please make sure you are designing your customization CSS taking into account all possible values for the frame attribute.

How to Remove the Table NN Label

For the DITA Map PDF - based on HTML5 & CSS transformation scenario, the label for a table's title is wrapped in a span element with the class: `table--title-label`.

```html
<table ...>
...
<caption class="- topic/title title tablecap">
  <span class="table--title-label">Table</span>
  <span class="table--title-label-number">1. </span>
  <span class="table--title">The title of the table</span>
</caption>
...
```

To hide it, set its display to none:

```css
.table--title-label {
  display:none;
}
```

For the direct transformation, use:
How to Center Tables

You can center the tables by using margins `auto`, while the table caption (title) can be centered using the `text-align` property:

```
*{class =~ "topic/table"} {
  margin-left:auto;
  margin-right:auto;
  width: 50%;
  border: 1pt solid blue;
}
*{class =~ "topic/table"} *{class =~ "topic/title"} {
  text-align:center;
}
```

How to Add Stripes to a Table

To create a striped look for your tables, you can use the following CSS rules:

```
/* Header background and foreground */
*{class =~ "topic/table"}[outputclass =~ "stripes"] > *{class =~ "topic/thead"} > *{class =~ "topic/row"} { 
  background-color: blue;
  color:white;
}

/* A default background for the entire table body */
*{class =~ "topic/table"}[outputclass =~ "stripes"] > *{class =~ "topic/tbody"} { 
  background-color: #eeeeee;
}

/* Color for the stripes */
*{class =~ "topic/table"}[outputclass =~ "stripes"] > *{class =~ "topic/tbody"} > *{class =~ "topic/row"}:nth-child(odd) { 
  background-color: cyan;
}

/* Border for the cells */
*{class =~ "topic/table"}[outputclass =~ "stripes"] *{class =~ "topic/entry"} { 
```
The above rules assume that tables that are to be painted with stripes are marked with an `@outputclass` attribute:

```
<table outputclass="stripes">...
</table>
```

If you want to make all tables look the same, you can ignore this attribute and remove the `[outputclass =~ "stripes"]` simple selector from the above rules.

**CAUTION:**
Applying stripes and thin cell borders can cause rendering issues in the PDF renderer on screen display devices. For more information, see How to Fix Disappearing Thin Lines or Cell Borders (on page 1839).

**Code Blocks**

Code blocks are used to render section of programming code.

**How to Enable Code Syntax Highlighting**

This topic refers only to the DITA Map PDF - based on HTML5 & CSS transformation type.

You can use syntax highlighting to make it easier to read your code snippets by displaying each type of code in different colors and fonts. In the DITA topics, set the `@outputclass` attribute on the `<codeblock>` elements to one of these values:

- `language-bourne`
- `language-c`
- `language-cpp`
- `language-csharp`
- `language-css`
- `language-ini`
- `language-java`
- `language-javascript`
- `language-json`
- `language-lua`
- `language-perl`
- `language-php`
- `language-python`
- `language-ruby`
- `language-sql`
- `language-xml`
- `language-xquery`
For example, for a java snippet:

```xml
<codeblock outputclass="language-java">
    for (int i=0; i <100; i++) {
        // do something
    }
</codeblock>
```

The resulting HTML fragment in the merged HTML5 document is:

```html
<pre class="+ topic/pre pr-d/codeblock pre codeblock language-java"
xml:space="preserve">

<em class="hl-comment" style="color:#006400">// do something</em>
</pre>
```

And in the output, it will be rendered as:

```
for (int i=0; i <100; i++) {
    // do something
}
```

Changing the Colors for the Syntax Highlighting

As you can see in the above example, the HTML elements `<span>` and `<strong>` are used to color the content. Since they have a `@style` attribute set, the overriding properties need to be marked with `!important`.

Suppose you want to color the keywords in red and the comments in blue. To do so, add the following to your customization CSS (on page 1693):

```css
.hl-keyword {
    color: red !important;
}
.hl-comment {
    color: blue !important;
}
```

How to Disable Line Wrapping in Code Blocks

By default, code blocks have the content wrapped to avoid the bleeding of long lines out of the page. To avoid wrapping, add the following in your customization CSS (on page 1693):
For the DITA Map PDF - based on HTML5 & CSS transformation type, the best solution to distinguish between lines is to leave them wrapped, but color each line with a different background (zebra coloring). An example is provided here: XSLT Extensions for PDF Transformations (on page 1683).

**How to Deal with Unwanted Returns in Code Blocks**

There are cases where the source file contains long lines of code that need to continue onto the next line in the rendered PDF (to wrap visually).

When the user copies the block from the PDF reader, they get two separated lines. This means that the command fails when users copy it from the PDF to the command-line terminal (because it comes in as two commands).

For example, the command:

```bash
$gist = ls -l * | count -n | some more
```

May be rendered in the PDF on two lines:

```bash
$gist = ls -l * | count -n
| some more
```

And this is invalid when used in the terminal.

There is no CSS workaround for this, but to manually format the command line, add a line continuation character like this:

```bash
$gist = ls -l * | count -n \
| some more
```

**Note:**

For Linux/macOSX, the continuation character is the backslash \. For Windows, this is the shift character ^.

The command-line processor will now recognize that the first line is continuing on to the next one.

**Notes**

Notes contain an additional piece of information that calls attention to particular content. They may have various types (tip, caution, danger, restriction, important, warning).

For information on how to add and manage mixed content before the note icons and labels, see How to Control the Image Size in Complex Static Content (on page 1818).

**How to Change Note Icons**

The recommended icon format is SVG.
To change the default icons for notes that do not have a `@type` attribute, add the following rule to your customization CSS (on page 1693):

```css
div.note > span.note__title{
    background-image:url("../img/note.svg") !important;
}
```

For a note with a `@type` attribute set to `warning`, `caution`, or `trouble`, add the following corresponding CSS rule:

```css
div.warning > span.note__title{
    background-image:url("../img/warning.svg") !important;
}
div.caution > span.note__title{
    background-image:url("../img/caution.svg") !important;
}
div.trouble > span.note__title{
    background-image:url("../img/troubleshooting.svg") !important;
}
```

### Abbreviated Forms

When using the `<abbreviated-form>` element in your content, it is possible to style the subsequent occurrences differently than the first occurrence. To achieve this, add something similar to the following rule in your customization CSS (on page 1693):

```css
a:has(dfn[@class ~="abbreviated-form"]){
    color:oxygen(xpath("let $cdf:= dfn return if (preceding::dfn[@keyref = $cdf/@keyref]) then 'black' else 'red'"));
    text-decoration:oxygen(xpath("let $cdf:= dfn return if (preceding::dfn[@keyref = $cdf/@keyref]) then 'none' else 'underline'"));
}
```

This example would render the first occurrence with a red color and an underline, while the subsequent occurrences would be rendered with a black color and no underline.

### Trademarks

Trademarks are used to specify legally registered words and they are often used in technical documentation. To specify a trademark, your DITA content could use a structure similar to this:

```xml
<tm tmtype="tm">My Product Name</tm>
```

Depending on the value of the `tmtype` attribute, a different symbol is appended to the text: (®, ™, or ℠).

The structure of the merged HTML document the CSS will apply to is:
How to Style the Trademark Element Text

To change the style of the entire trademark text, you can match the `topic/tm` class like this:

```css
*[class ~="topic/tm"] {
    font-weight: bold;
}
```

How to Style the Trademark Symbol

To change the aspect of the trademark symbol, you can use the `topic/tmmark` class. Usually, common fonts already render these symbols smaller and with superscript by default. The following example does it from the CSS:

```css
*[class ~="topic/tmmark"] {
    vertical-align: super;
    font-size: smaller;
}
```

Styling Through Custom Parameters

You can activate parts of your CSS by using custom transformation parameters that start with the `args.css.param.` prefix.

These parameters are recognized by the publishing pipeline and are forwarded as synthetic attributes on the root element of the merged map. The last part of the parameter name will become the attribute name, while the value of the parameter will become the attribute value. The namespace of these synthetic attributes is: `http://www.oxygenxml.com/extensions/publishing/dita/css/params`.

When using the DITA Map PDF - based on HTML5 & CSS or the DITA PDF - based on HTML5 & CSS transformations, the generated attribute will be in no namespace.

Notes:

- Make sure the name of your custom parameter does not conflict with an attribute name that may already exist on the root element.
- Use only Latin alphanumeric characters for parameter names.
- You can set multiple styling parameters at the same time.

How to Limit the Depth of the TOC Using a Parameter

In the following example, a custom parameter is used to switch from a full depth table of contents to a flat one that shows only the titles of the first-level topics (such as chapters, notices, or the preface).
The custom parameter is:

```
args.css.param.only-chapters-in-toc="yes"
```

The CSS that hides the topicrefs at level 2 or more:

```
:root[only-chapters-in-toc='yes'] *[class !="toc/toc"]
    > *[class !="map/topicref"] > *[class !="map/topicref"] {
        display:none;
    }
```

The :root[a]only-chapters-in-toc='yes'] selector makes the rule activate only when the attribute is set.

**How to Change the Page Size Using a Parameter**

In the following example, a custom parameter is used to modify the page size. The parameter is defined in the transformation scenario as:

```
args.css.param.page-size="A4"
```

Then in the CSS, the attribute value is extracted and used as follows:

```
@page {
    size: oxy_xpath('/ctx/@*[local-name()="page-size"][1]');
}
```

**How to Change the Cover Page Using a Parameter**

In the following example, a custom parameter is used to set the path of the cover page. The parameter points to an image by using its URL and is defined in the transformation scenario as:

```
args.css.param.cover-page="file:/path/to/cover-page.svg"
```

Then in the CSS, the attribute value is extracted and used as follows:

```
@page front-page {
    background-image: url(oxy_xpath('/ctx/@*[local-name()="cover-page"][1]'));
}
```

**Controlling the Publication Content**

Using a plain DITA map, the transformation will produce a publication with a front page, a table of contents, chapters with content, and an index at the end. This is appropriate for most cases, but there are use cases where some adjustments are necessary. For example, if you want to do one of the following:

- Remove the TOC or index.
- Add a glossary.
- Change the position of the TOC or the index relative to the sibling topics.
- Add a preface, frontmatter, or backmatter with copyright notices, abstracts, list of tables, list of figures, etc.
All of these can be achieved using a DITA bookmap.

A bookmap has a more elaborate structure than a regular map. You should start by defining the title structure, with a main title and alternative title:

```xml
<!DOCTYPE bookmap PUBLIC "-//OASIS//DTD DITA BookMap//EN" "bookmap.dtd">
<bookmap id="taskbook">
  <booktitle>
    <mainbooktitle>Publication Title</mainbooktitle>
    <booktitlealt>A very short description of the publication</booktitlealt>
  </booktitle>
</bookmap>
```

Then you may define a frontmatter. For this, you can link the topics that need to appear before the main content. You can also define the location where the table of contents will be placed. In the example below, it appears between the `abstract.dita` and `foreword.dita` topics:

```xml
<frontmatter>
  <topicref href="topics/abstract.dita"/>
  <booklists>
    <toc/>
  </booklists>
  <topicref href="topics/foreword.dita"/>
</frontmatter>
```

**Note:**
To remove the TOC from the publication, just omit the `<toc>` element from the `<booklists>` element.

Next, the topics are grouped into chapters:

```xml
...<chapter href="topics/installation.dita" />
...```

At the end, you could define the structure of the backmatter. Just like for the frontmatter, you can include some topics and some generated content (such as the index). In the example below, the glossary is defined to come after the index, followed by a list of figures and list of tables. At the very end, there is a topic with some thank you notes.

```xml
<backmatter>
  <topicref href="topics/conclusion.dita"/>
  <booklists>
    <indexlist/>
  </booklists>
  <glossarylist>
    <topicref href="topics/xp.dita" keys="xp" print="yes"/>
    <topicref href="topics/anti_lock_braking_system.dita" keys="abs" print="yes"/>
  </glossarylist>
</backmatter>
```
As you can see, the bookmap offers much better control over the final content of the publication. It also offers more options in controlling the metadata that will go into the PDF (see the Metadata (on page 1725) topic).

**How to Omit the Front Page, TOC, Glossary, Index for a Plain DITA Map**

For a plain DITA map, there are no elements that allow you to control if and where to place the generated content such as the title page, table of contents, list of tables, glossary, or index. For the most common use-case, when you want to hide them all and just keep the content, you can use the transformation parameter hide.frontpage.toc.index.glossary. See: Transformation Parameters (on page 1665).

**Related Information:**
- How to Remove Entries from the TOC (on page 1763)
- How to Hide the TOC (on page 1763)

**How to Make Chapters Look Like Individual Publications**

*Note:*

This topic is only applicable for the DITA Map PDF - based on HTML5 & CSS transformation scenario.

Sometimes you want to make each chapter independent (i.e. it can be read separately, as a separate part of your publication). For this, you need the page counter, figure, and table counters to restart at each chapter. You can control this by using the args.css.param.numbering (on page 1746) command-line parameter.

In addition to numbering, you can force the creation of a chapter TOC (on page 1763).

**Troubleshooting**

This section contains information about fixing various change tracking, highlights and comments publishing problems.

**Failed to Run Pipeline: The Entity Cannot Be Resolved Through Catalogs**

**Problem**

You can get a Failed to run pipeline error message that looks something like this:

```
Failed to run pipeline: The entity SOME_ENTITY cannot not be resolved through catalogs.
For security reasons files that are not listed in the DITA-OT catalogs and are not located in the DITA-OT directory are not read
```
**Cause**

This happens when the security checks that are implemented in the default transformation have blocked the reading of files that are not part of the DITA-OT ([Oxygen Publishing Engine](https://www.oxygenxml.com/products/publishing-engine)) installation directory and not part of the transformed DITA map.

**Solution**

If the origin of the transformed content is known and trusted, you can disable these checks by setting the `args.disable.security.checks` transformation parameter to `yes`.

**The format-date() XPath Function Does not Respect the Specified Locale**

**Problem**

Formatting a date using another language code, as in this example:

```xml
<title:before { content: oxy_xpath('format-date(current-date(), "[Mn] [Y]", "ru", (), ())'); }
```

results in an output like: `[Language: en]september 2019`, with the date being formatted in English.

**Cause**

The XPath expressions are evaluated using the Saxon HE processor. This processor does not support languages other than English ([https://sourceforge.net/p/saxon/mailman/message/26849522/](https://sourceforge.net/p/saxon/mailman/message/26849522/)).

**Solution**

As a solution, you can either switch to a more language-neutral format that avoids the months names:

```xml
<title:before { content: oxy_xpath('format-date( current-date(), "[M] [Y]", "en", (), ())'); }
```

or you can use a more complex XPath expression like this:

```xml
<title:before { content: oxy_xpath("let $cm:= format-date(current-date(), 'MNN') \ return concat( \ if ($cm= 'January') then  'JAN' else \ if ($cm= 'February') then  'FEB' else \ if ($cm= 'March') then  'MAR' else \ unset($cm)");
```
if ($cm= 'April') then 'APR' else \\
if ($cm= 'May') then 'MAY' else \\
if ($cm= 'June') then 'JUNE' else \\
if ($cm= 'July') then 'JUL' else \\
if ($cm= 'August') then 'AUG' else \\
if ($cm= 'September') then 'SEPT' else \\
if ($cm= 'October') then 'OCT' else \\
if ($cm= 'November') then 'NOV' else '' \\
\, \\
' ,' \\
format-date(current-date(), '[Y0001]') \\
); 
}

Make sure the entire expression is rendered blue in the CSS editor. Replace the capitalized month names with the translation in the desired language.

**Error Parsing CSS File - Caused by a Networking Problem**

**Problem**

My custom styles are not applied and in the transformation results console, I get an error containing one of the following: I/O exception, Unknown host, Error parsing.

**Cause**

One of the CSS files contains references to resources from another website that is currently inaccessible. These resources may include:

- Fonts
- Images
- Other CSS files
Note:
If you exported one of the built-in publishing templates from the transformation scenario dialog, it is possible that the associated CSS files use an imported Google Font.

Remedy

1. Check your proxy settings (ask the system administrator for help).
2. If the server is still inaccessible from the transformation process, download the remote resources using a web browser, save them in the customization CSS file folder, and refer them directly from your CSS.

Note:
If the problem is caused by a remote font, see Using Local Fonts.

Glossary Entries Referenced Using 'glossref' are not Displayed

Problem
I have a `<glossgroup>` that contains multiple `<glossentry>` elements and all the entries are referenced using `<glossref>` elements inside my map. When I add an `<abbreviated-form>` element linked to one of my `<glossentry>` elements (using a `@keyref`), the entry is not resolved in the PDF output.

Solution
Make sure every `<glossentry>` has an `@id`. Then, for each `<glossentry>`, declare a `<glossref>` element like this:

```xml
<glossref href="concepts/glossary.dita#flowers.genus" print="yes" keys="genus"/>
```

Important:
For bookmaps, the `<glossref>` elements should be declared in a separate ditamap.

How to Fix Disappearing Thin Lines or Cell Borders

Problem
There are cases where thin lines disappear from the PDF viewer at certain zoom levels.

Cause
This is caused by the limited resolution of the display, while a printer has a superior resolution and there should be no problem printing thin lines on paper.

Solution
If the primary PDF target is the display, then you have to use thicker lines in your CSS customization (for example, avoid using 1px and use 1pt or larger instead).
If you are using Adobe Acrobat Reader, then you can enhance the display of thin lines. This behavior can be changed by going to Edit > Preferences > Page Display > Enhance Thin Lines. Deselecting this option makes thin lines displayed as a row of gray pixels (through antialiasing) and they do not disappear. You can experiment by selecting and deselecting the option.

**XSL FO-based DITA to PDF Customization**

Oxygen XML Editor comes bundled with the DITA Open Toolkit that provides a mechanism for converting DITA maps (on page 2966) to PDF output. Oxygen XML Editor includes a built-in DITA Map PDF - based on XSL-FO transformation scenario (on page 1349) that converts DITA maps to PDF using an xsl:fo processor.

There are several methods that can be used to customize DITA to PDF output:

- Create a customization directory that contains your customized files and reference that directory in the PDF transformation scenario (using the customization.dir parameter).
- Creating a DITA Open Toolkit plugin that adds extensions to the PDF output. More details can be found in the DITA Open Toolkit Documentation.

**Tip:**

Some sample plugins are available on GitHub that could help you to get started with creating a plugin:

- Sample Plugin: DITA-OT PDF Customization Plugin for Oxygen User Manual
- Sample Plugin: DITA-OT PDF2 - Generate Numbers Before Topic's Title

**Using a Customization Directory**

One way to customize the PDF output generated by the DITA Map PDF - based on XSL-FO transformation scenario (on page 1349) is to create a dedicated folder to store customized files. With this approach, you will copy the contents of the built-in customization directory to a new directory where you can customize the files according to your needs and reference the new directory using the customization.dir parameter in the transformation scenario. The biggest advantage of this method is that the contents of your customization directory will remain unaffected when the DITA-OT is upgraded.

**How to Create a Customization Directory**

Follow this procedure to create a customization directory:

1. Copy all the entire DITA-OT-DIR\plugins\org.dita.pdf2\Customization directory to another location where you have write access.
2. Modify any of the files in whatever way necessary to achieve your specific goal. For inspiration, see Embedding a Company Logo (on page 1841) for a specific example of how you can modify contents of the directory to embed a logo in the output.
3. Edit the DITA Map PDF - based on XSL-FO transformation scenario (on page 1349), go to the Parameters tab, and set the customization.dir parameter to point to the location of your customization directory.

Automatic PDF plugin customization generator by Jarno Elovirta.
DITA-OT Documentation - PDF Customization Plugin

Embedding a Company Logo

The following procedure explains how to embed a company logo image in the front matter of the book.

1. Create a customization directory (on page 1840) (if you have not already done so).
2. Create a \cfg\common\artwork directory structure in your customization directory and copy your logo to that directory (for example, \C:\Customization\common\artwork\logo.png).

   Important:
   Make sure that your logo image is named: logo.png.

3. Rename Customization\catalog.xml.orig to: Customization\catalog.xml.
4. Open the catalog.xml in Oxygen XML Editor and uncomment this line:
   <!--uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/-->
   It now looks like this:
   <uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/>

5. Rename the file Customization\fo\xsl\custom.xsl.orig to: C:\Customization\fo\xsl\custom.xsl.
6. Open the custom.xsl file in Oxygen XML Editor and create the template called createFrontCoverContents for DITA-OT 3.6.

   Tip:
   You can copy the same template from DITA-OT-DIR\plugins\org.dita.pdf2\xsl\fo\front-matter.xsl and modify it in whatever way necessary to achieve your specific goal. This new template in the custom.xsl file will override the same template from DITA-OT-DIR\plugins\org.dita.pdf2\xsl\fo\front-matter.xsl.

Example:
For example, the custom.xsl could look like this:
<?xml version='1.0'?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:fo="http://www.w3.org/1999/XSL/Format"
    version="2.0">

<xsl:template name="createFrontCoverContents">
    <!-- set the title -->
    <xsl:apply-templates select="$map/*/contains(@class,' topic/title ')[1]"/>

    <!-- set the subtitle -->
    <xsl:apply-templates select="$map/*/contains(@class,' bookmap/bookmeta ')"/>

    <!-- Load the image logo -->
    <xsl:apply-templates select="$map/*[contains(@class,' topic/sliderbyn')]">
        <fo:block xsl:use-attribute-sets="__frontmatter__owner">
            <xsl:apply-templates select="$map/*[contains(@class,' bookmap/mainbooktitle ')]"/>
        </fo:block>
    </xsl:apply-templates>
</xsl:template>
</xsl:stylesheet>
7. Edit the **DITA Map PDF - based on XSL-FO** transformation scenario *(on page 1349)*, go to the **Parameters** tab, and set the **customization.dir** parameter to point to the location of your customization directory.

**Tip:**
For other specific examples, see **DITA-OT 3.x Documentation - Customizing PDF Output**.

**Related Information:**
Using a Customization Directory *(on page 1840)*

### Customizing the Header and Footer in PDF Output

The XSLT stylesheet `DITA-OT-DIR/plugins/org.dita.pdf2/xsl/fo/static-content.xsl` contains templates that output the static header and footers for various parts of the PDF such as the prolog, table of contents, front matter, or body.

The templates for generating a footer for pages in the body are called `insertBodyOddFooter` or `insertBodyEvenFooter`.

These templates get the static content from resource files that depend on the language used for generating the PDF. The default resource file is `DITA-OT-DIR/plugins/org.dita.pdf2/cfg/common-vars/en.xml`. These resource files contain variables (such as `Body odd footer`) that can be set to specific user values.

Instead of modifying these resource files directly, they can be overwritten with modified versions of the resources in a PDF customization directory.

1. Create a customization directory *(on page 1840)* (if you have not already done so).
2. Locate the stylesheets and templates listed above in your customization directory and modify them in whatever way necessary to achieve your specific goal.

**Tip:**
For more information and examples, see the **Oxygen PDF Customization Plugin project on GitHub**.

3. Edit the **DITA Map PDF - based on XSL-FO** transformation scenario *(on page 1349)*, go to the **Parameters** tab, and set the **customization.dir** parameter to point to the location of your customization directory.
Adding a Watermark to PDF Output

To add a watermark to the PDF output of a DITA Map PDF - based on XSL-FO transformation scenario (on page 1349), follow this procedure:

1. Create a customization directory (on page 1840) (if you have not already done so).
2. Create a `cfg\common\artwork` directory structure in your customization directory and copy your watermark image to that directory (for example, `C:\Customization\cfg\common\artwork\watermark.png`).
3. Rename the `Customization\catalog.xml.orig` file to: `Customization\catalog.xml`.
4. Open the `catalog.xml` in Oxygen XML Editor and uncomment this line:

   ```xml
   <!--uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/>-->
   ```

   The uncommented line should look like this:

   ```xml
   <uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/>
   ```

5. Rename the file: `Customization\fo\xsl\custom.xsl.orig` to: `Customization\fo\xsl\custom.xsl`.
6. Open the `Customization\fo\xsl\custom.xsl` file in Oxygen XML Editor to overwrite two XSLT templates:
   - The first template is located in the XSLT stylesheet `DITA-OT-DIR\plugins\org.dita.pdf2\xsl\fo\static-content.xsl`. Override by copying the original template content in the `custom.xsl` and specifying a watermark image for every page in the PDF content, using a `block-container` element that references the watermark image file:

   ```xml
   <fo:static-content flow-name="odd-body-header">
     <fo:block-container absolute-position="absolute">
       <fo:block-container absolute-position="absolute">
         top="-2cm" left="-3cm" width="21cm" height="29.7cm"
         background-image="\{concat($artworkPrefix, 'Configuration/OpenTopic/cfg/common/artwork/watermark.png')\}"
         >
       </fo:block-container>
       <fo:block/>
     </fo:block-container>
   </fo:static-content>
   ```

   ```xml
   <xsl:call-template name="insertVariable">
     <xsl:with-param name="theVariableID" select="'Body odd header'"/>
     <xsl:with-param name="theParameters"/>
     <prodname>
       <xsl:value-of select="$productName"/>
     </prodname>
   </xsl:call-template>
   ```
• The second template to override is located in the XSLT stylesheet DITA-OT-DIR\plugins\org.dita.pdf2\xsl\fo\commons.xsl and is used for styling the first page of the output. Override it by copying the original template content in the custom.xsl and adding the block-container element that references the watermark image file:

```xml
<xsl:template name="createFrontMatter_1.0">
  <fo:page-sequence master-reference="front-matter"
xsl:use-attribute-sets="__force__page__count">
    <xsl:call-template name="insertFrontMatterStaticContents"/>
    <fo:flow flow-name="xsl-region-body">
      <fo:block-container absolute-position="absolute"
top="-2cm" left="-3cm" width="21cm" height="29.7cm"
background-image="{concat($artworkPrefix,'Configuration/OpenTopic/cfg/common/artwork/watermark.png')}">
        <fo:block/>
      </fo:block-container>
      <fo:block xsl:use-attribute-sets="__frontmatter">
        <!-- set the title -->
      </fo:block>
    </fo:flow>
  </fo:page-sequence>
</xsl:template>
```
7. Edit the DITA Map PDF - based on XSL-FO transformation scenario (on page 1349), go to the Parameters tab, and set the customization.dir parameter to point to the location of your customization directory.

Related Information:
Adding a Watermark in DITA Map to XHTML Output (on page 2883)

Adding an Edit Link in PDF Output to Launch Oxygen XML Web Author

You can embed Edit links in the DITA Map PDF output that will automatically launch a particular document in Oxygen XML Web Author. A reviewer can then simply click the link and they will be redirected to the Oxygen XML Web Author editing page with that particular file open and editable.

To embed an Edit link in the DITA Map PDF output, follow these steps:
1. Edit a **DITA Map PDF - based on XSL-FO** transformation scenario *(on page 1349)* and open the **Parameters** tab.

2. Set values for the following parameters:
   - **editlink.ditamap.edit.url** - The URL of the DITA map used to publish your content. The easiest way to obtain the URL is to open the map in Web Author and copy the URL from the browser’s address bar.
   - **editlink.additional.query.parameters** - Optional query parameters to be appended to each generated edit link. Each parameter must start with & (e.g. &tags-mode=no-tags).

3. Run the transformation scenario.

**Result:** In the PDF output, all topics will have an **Edit** link to the right side of the title and clicking the link will launch that particular document in Oxygen XML Web Author.

### Force Page Breaks Between Two Block Elements in PDF Output

Suppose that in your DITA content you have two **block elements** *(on page 2964)*, such as two paragraphs:

```xml
<p>First para</p>
<p>Second para</p>
```

and you want to force a page break between them in the PDF output.

Here is how you can implement a DITA Open Toolkit **plugin** *(on page 2969)* that would achieve this:

1. Define your custom processing instruction that marks the place where a page break should be inserted in the PDF, for example:

   ```xml
   <p>First para</p>
   <processing-instruction('pagebreak')>
   <p>Second para</p>
   ```

2. Locate the **DITA Open Toolkit** distribution and in the *plugins* directory create a new **plugin** folder (for example, `DITA-OT-DIR/plugins/pdf-page-break`).

3. In this new folder, create a new **plugin.xml** file with the following content:

   ```xml
   <plugin id="com.yourpackage.pagebreak">
   <feature extension="package.support.name" value="Force Page Break Plugin"/>
   <feature extension="package.support.email" value="support@youremail.com"/>
   <feature extension="package.version" value="1.0.0"/>
   <feature extension="dita.xsl.xslfo" value="pageBreak.xsl" type="file"/>
   </plugin>
   ```

   The most important feature in the **plugin** is that it will add a new XSLT stylesheet to the XSL processing that produces the PDF content.

4. In the same folder, create an XSLT stylesheet named **pageBreak.xsl** with the following content:

   ```xml
   <xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
                   xmlns:fo="http://www.w3.org/1999/XSL/Format" version="1.0">
   <xsl:template match="processing-instruction('pagebreak')">...
   ```
Set a Font for PDF Output Generated with FO Processor

When a DITA map (on page 2966) is transformed to PDF using an FO processor and it contains some Unicode characters that cannot be rendered by the default PDF fonts, a font that is capable of rendering these characters must be configured and embedded in the PDF result.

The settings that must be modified for configuring a font for the built-in FO processor are detailed in Add a Font to the Built-in FO Processor - Advanced Version (on page 1423).

DITA-OT PDF Font Mapping

The DITA-OT contains a file DITA-OT-DIR/plugins/org.dita.pdf2/cfg/fo/font-mappings.xml that maps logical fonts used in the XSLT stylesheets to physical fonts that will be used by the FO processor to generate the PDF output.

The XSLT stylesheets used to generate the XSL-FO output contain code like this:
The font-family is defined to be `monospace`, but `monospace` is just an alias. It is not a physical font name. Therefore, another stage in the PDF generation takes this `monospace` alias and looks in the `font-mappings.xml`.

If it finds a mapping like this:

```xml
<aliases>
  <alias name="monospace">Monospaced</alias>
</aliases>
```

then it looks to see if the `monospace` has a `logical-font` definition and if so, it will use the `physical-font` specified there:

```xml
<logical-font name="Monospaced">
  <physical-font char-set="default">
    <font-face>Courier New, Courier</font-face>
  </physical-font>
</logical-font>
```

**Important:**

If no alias mapping is found for a font-family specified in the XSLT stylesheets, the processing defaults to `Helvetica`.

Related Information:
http://www.elovirta.com/2016/02/18/font-configuration-in-pdf2.html

---

**Adding Libraries to the Built-in FO Processor (DITA-OT)**

Starting with Oxygen XML Editor version 20.0, both hyphenation and PDF image support are enabled by default in the built-in DITA-OT FO processor. For older version of Oxygen XML Editor, use the following procedures to enable such support.

**Adding Hyphenation Support for DITA-OT Transformation Scenarios**

1. Download the pre-compiled JAR (on page 2967) from OFFO.
2. Edit the DITA-OT transformation scenario and switch to the Advanced tab.
3. Click the Libraries button and add the path to the `fop-hyph.jar` library.

**Adding Support for PDF Images**

1. Download the `fop-pdf-images JAR` libraries.
2. Edit the DITA-OT transformation scenario and switch to the Advanced tab.
3. Click the Libraries button and add the path to the libraries.
Adding Support for CGM Images

1. Go to the JCGM page and download the jcgm-image-0.1.1.jar and jcgm-core-0.2.0.jar libraries.
2. Edit the DITA-OT transformation scenario and switch to the Advanced tab.
3. Click the Libraries button and add the path to the libraries.

Debugging DITA PDF Transformations

To debug a DITA PDF transformation scenario, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98), go to XML > XML Catalog, click Add, and select the file located at DITA-OT-DIR/plugins/org.dita.pdf2/cfg/catalog.xml.
2. Open the map in the DITA Maps Manager (on page 2662) and create a DITA Map PDF - based on XSL-FO transformation scenario.
3. Edit the scenario, go to the Parameters tab and change the value of the clean.temp parameter to no.
4. Run the transformation scenario.
5. Open the stage1.xml file located in the temporary directory and format and indent (on page 514) it.
6. Create a transformation scenario for this XML file by associating the topic2fo_shell_fop.xsl stylesheet located at DITA-OT-DIR/plugins/org.dita.pdf2/xsl/fo\topic2fo_shell_fop.xsl. If you are specifically using the RenderX XEP or Antenna House FO processors to build the PDF output, you should use the XSL stylesheets topic2fo_shell_xep.xsl or topic2fo_shell_axf.xsl located in the same folder.

Note:
For validation purposes, you need to add the main debugged stylesheet (usually topic2fo_shell_fop.xsl) to the Main Files folder (on page 386) in the Project view.

7. In the transformer drop-down menu, select the Saxon EE XSLT processor (the same processor used when the DITA-OT transformation is executed).
8. Click the Parameters button and set the locale parameter with the value en_GB and the customizationDir.url parameter to point either to your customization directory or to the default DITA-OT customization directory. Its value should have a URL syntax like this: file:///c:/path/to/DITA-OT-DIR/plugins/org.dita.pdf2/cfg.
9. If your XSLT stylesheet uses Java extensions, you need to reference the extra JAR libraries by clicking the Extensions button and add the libraries in the resulting dialog box. For example, if you have enabled the show.changes.and.comments parameter, you need to add the following JAR library for the parameter to have an effect: DITA-OT\plugins\com.oxygenxml.common\lib\oxygen-dita-publishing-xslt-extensions.jar.
10. Apply the transformation to continue the debugging process.
DocBook to PDF Output Customization

When the default layout and output of the DocBook to PDF transformation needs to be customized, follow these steps:

   You could start from a copy of the file \[DocBook XSL directory]/fo/titlepage.templates.xml (for example, \[OXYGEN-INSTALL-DIR]/frameworks/docbook/xsl/fo/titlepage.templates.xml) and customize it. More information about the spec file can be found here.

2. Generate a new XSLT stylesheet from the title spec file from the previous step.
   Apply \[DocBook XSL directory]/template/titlepage.xsl to the title spec file. The result is an XSLT stylesheet (for example, mytitlepages.xsl).

3. Import mytitlepages.xsl in a DocBook customization layer.
   The customization layer is the stylesheet that will be applied to the XML document. The mytitlepages.xsl should be imported with an element like this:
   
   ```xml
   <xsl:import href="dir-name/mytitlepages.xsl"/>
   ```

4. Insert a logo image in the XML document.
   The path to the logo image must be inserted in the book/info/mediaobject structure of the XML document.

5. Apply the customization layer to the XML document.
   A quick way is to duplicate the transformation scenario DocBook PDF that is included with Oxygen XML Editor and set the customization layer in the XSL URL property of the scenario (on page 1362).

Related Information:

- Video demonstration for creating a DocBook customization layer in Oxygen XML Editor.
12. Working with XPath Expressions

XPath is a language for addressing specific parts of a document. XPath models an XML document as a tree of nodes. An XPath expression is a mechanism for navigating through and selecting nodes from the document. An XPath expression is, in a way, analogous to an SQL query used to select records from a database.

**Note:**
If an XPath expression is run over a JSON document, it is converted to XML and the XPath is executed over the converted XML document.

There are various types of nodes, including element nodes, attribute nodes, and text nodes. XPath defines a way to compute a string-value for each type of node.

XPath defines a library of standard functions for working with strings, numbers and boolean expressions.

**Examples:**
- `child::*` - Selects all children of the root node.
- `./name` - Selects all elements having the name "name", descendants of the current node.
- `/catalog/cd[price>10.80]` - Selects all the `<cd>` elements that have a price element with a value larger than 10.80.

To find out more about XPath, see [http://www.w3.org/TR/xpath](http://www.w3.org/TR/xpath).

**Related Information:**
- Content Completion in XPath Expressions *(on page 832)*
- Find/Replace in Multiple Files *(on page 400)*
- Find/Replace Dialog Box *(on page 395)*

**XPath Toolbar**

XPath is a query language for selecting nodes from an XML document. To use XPath expressions effectively, you need a good understanding of the XPath Core Function Library.

**XPath Toolbar**

Oxygen XML Editor provides an XPath toolbar to let you query XML documents fast and easy using XPath expressions.
The XPath toolbar includes the following features:

**XPath version chooser drop-down menu**

You can choose the XPath version from the drop-down menu available in the left side of the toolbar. Available options include **XPath 1.0**, **XPath 2.0**, **XPath 2.0 SA**, **XPath 3.1**, **XPath 3.1 SA**.

**Note:**
The **XPath 2.0 SA** and **XPath 3.1 SA** options have some limitations. These options only offer information about the beginning part of the matching result. For example, if you search for an element, it will only highlight the start tag.

**Warning:**
Oxygen XML Editor uses Saxon to execute XPath 3.1 expressions, but implements a part of the 3.1 functions. When using a function that is not implemented, Oxygen XML Editor can return a compilation error.

**XPath scope menu**

Oxygen XML Editor allows you to define a scope for the XPath operation to be executed. You can choose where the XPath expression will be executed:

- **Current file** - Currently selected file only.
- **Project** - All the files in the project.
- **Selected project resources** - The files selected in the project.
- **All opened files** - All files that are opened in the application.
- **Current DITA Map hierarchy** - All resources referenced in the currently selected **DITA map** that is open in the **DITA Maps Manager view** (on page 2662).
- **Opened archive** - Files that are opened in the **Archive Browser view** (on page 1861).
- **Working sets** - The selected working sets (on page 2972).

At the bottom of the scope menu the following scope configuration actions are available:

- **Configure XPath working sets** - Allows you to configure and manage collections of files and folders, encapsulated in logical containers called working sets (on page 2972).
- **XPath file filter** - You can filter the files from the selected scope that will have the XPath expression executed. By default, the XPath expression will be executed only on XML or JSON files, but you can also define a set of patterns that will filter out files from
the current scope. If you select the **Include archive** option, the XPath expression will be also executed on the files in any archive (including EPUB and DocX) found at the current scope.

**History drop-down list**

The XPath combo box keeps a history of the last 15 expressions that were used so that you can easily choose them again.

**Settings menu**

The following actions are available in this drop-down menu:

- **XPath update on cursor move**
  
  When selected and you navigate through a document, the XPath expression corresponding to the XML node at the current cursor position is displayed. For JSON documents, it displays the XPath expression for the current property.

- **Evaluate XPath as you type**
  
  When you select this option, the XPath expression you are composing is evaluated in real time.

  ![Note:]
  
  This option and the automatic validation are disabled when you edit huge documents (on page 433) or when the scope is other than **Current file**.

- **XPath Options**

  Opens the Preferences page of the currently selected processing engine.

- **Switch to XPath Builder View**

  Opens the XPath Builder view (on page 1854).

  ![Note:]
  
  During the execution of an XPath expression, the XPath toolbar displays a **Stop** button. Use this button to stop the XPath execution.

When you type expressions longer than 60 characters, a dialog box opens that offers you the possibility to switch to the XPath Builder view (on page 1854).

**Related Information:**

XPath Expression Results View (on page 1858)
XPath Builder View

The XPath/XQuery Builder view allows you to compose complex XPath expressions and execute them over the currently edited XML document. For XPath 2.0 / 3.1, you can use the `doc()` function to specify the source file that will have the expressions executed. When you connect to a database, the expressions are executed over that database. If you are using the XPath/XQuery Builder view and the current file is an XSLT document, Oxygen XML Editor executes the expressions over the XML document in the associated scenario.

Note:
If an XPath expression is run over a JSON document, it is converted to XML and the XPath is executed over the converted XML document.

If the view is not displayed, it can be opened by selecting it from the Window > Show View menu. You can also open it simply by pressing the Switch to XPath Builder View button that is located on the XPath toolbar (on page 1852).

The upper part of the view contains the following actions:

**XPath version chooser drop-down menu**
A drop-down menu that allows you to select the type of the expression you want to execute. You can choose between:

- XPath 1.0 (Xerces-driven)
- XPath 2.0, XPath 2.0 SA, XPath 3.1, XPath 3.1 SA, Saxon-HE XQuery, Saxon-PE XQuery, or Saxon-EE XQuery (all of them are Saxon-driven)
- Custom connection to XML databases that can execute XQuery expressions

Note:
The results returned by XPath 2.0 SA and XPath 3.1 SA have a location limited to the line number of the start element (there are no column information and no end specified).

Note:
Oxygen XML Editor uses Saxon to execute XPath 3.1 expressions. Since Saxon implements a part of the 3.1 functions, when using a function that is not implemented, Oxygen XML Editor returns a compilation error.

**Execute XPath button**
Use this button to start the execution of the XPath or XQuery expression you are editing. The result of the execution is displayed in the Results view (on page 508).

**Favorites button**
 Allows you to save certain expressions that you can later reuse. To add an expression as a favorite, click this button and enter a name for it. The star turns yellow to confirm that the expression was saved. Expand the drop-down menu next to the star button to see all your favorites. Oxygen XML Editor automatically groups favorites in folders named after the method of execution.

**History drop-down menu**

Keeps a list of the last 15 executed XPath expressions. Use the Clear history action from the bottom of the list to remove them.

**Settings drop-down menu**

Contains the following three options:

- **Update on cursor move**
  When selected and you navigate through a document, the XPath expression corresponding to the XML node at the current cursor position is displayed. For JSON documents, it displays the XPath expression for the current property.

- **Evaluate as you type**
  When you select this option, the XPath expression you are composing is evaluated in real time.

**Note:**

This option and the automatic validation are disabled when you edit huge documents (on page 433) or when the scope is other than Current file.

- **Options**
  Opens the Preferences page of the currently selected processing engine.

**XPath scope menu**

Oxygen XML Editor allows you to define a scope for the XPath operation to be executed. You can choose where the XPath expression will be executed:

- **Current file** - Currently selected file only.
- **Project** - All the files in the project.
- **Selected project resources** - The files selected in the project.
- **All opened files** - All files that are opened in the application.
- **Current DITA Map hierarchy** - All resources referenced in the currently selected DITA map that is open in the DITA Maps Manager view (on page 2662).
- **Opened archive** - Files that are opened in the Archive Browser view (on page 1861).
- **Working sets** - The selected working sets (on page 2972).

At the bottom of the scope menu the following scope configuration actions are available:
• **Configure XPath working sets** - Allows you to configure and manage collections of files and folders, encapsulated in logical containers called working sets *(on page 2972).*

• **XPath file filter** - You can filter the files from the selected scope that will have the XPath expression executed. By default, the XPath expression will be executed only on XML or JSON files, but you can also define a set of patterns that will filter out files from the current scope. If you select the Include archive option, the XPath expression will be also executed on the files in any archive (including EPUB and DocX) found at the current scope.

**Figure 489. XPath/XQuery Builder View**

While you edit an XPath or XQuery expression, Oxygen XML Editor assists you with the following features:

• **Content Completion Assistant (on page 2965)** - It offers context-dependent proposals and takes into account the cursor position in the document you are editing. The set of functions proposed by the Content Completion Assistant also depends on the engine version. Select the engine version from the drop-down menu available in the toolbar.
• Syntax Highlighting - Allows you to identify the components of an expression. To customize the colors of the components of the expression, open the Preferences dialog box (Options > Preferences) (on page 98) and go to Editor > Syntax Highlight (on page 195).
• Automatic validation of the expression as you type.

Note:
When you type invalid syntax, a red serrated line underlines the invalid fragments.

• Function signature and documentation balloon, when the cursor is located inside a function.

The usual edit actions (Cut, Copy, Paste, Select All, Undo, Redo) are available in the contextual menu of the top editable part of the view.

Related Information:
XPath Expression Results View (on page 1858)

XPath Expression Results View

When you run an XPath expression, Oxygen XML Editor displays the results of its execution in the Results view (on page 508).

This view contains the following columns:

• Description - The result that Oxygen XML Editor displays when you run an XPath expression.
• XPath location - The path to the matched node.
• Resource - The name of the document that you run the XPath expression on.
• System ID - The path to the document itself.
• Location - The location of the result in the document.

To arrange the results depending on a column, click its header. To group the results by their resource, or by their system ID, right-click the header of any column in the Results view and select Group by "Resource" or Group by "System ID". If no information regarding location is available, Oxygen XML Editor displays Not available in the Location column. Oxygen XML Editor displays the results in a valid XPath expression format.

- /node[value]/node[value]/node[value] -

The Results view also includes various toolbar and contextual menu actions. For more information, see Results View (on page 508).

Example:
The following snippets are taken from a DocBook book based on the DocBook XML DTD. The book contains a number of chapters. To return all the chapter nodes of the book, enter //chapter in the XPath expression field and press Enter. This action returns all the chapter nodes of the DocBook book in the Results View. Click a record in the Results View to locate and highlight its corresponding chapter element and all its children nodes in the document you are editing.
To find all example nodes contained in the sect2 nodes of a DocBook XML document, use the following XPath expression: //chapter/sect1/sect2/example. Oxygen XML Editor adds a result in the Results View for each example node found in any sect2 node.

For example, if the result of the above XPath expression is:

```
/chapter[1]/sect1[3]/sect2[7]/example[1]
```

it means that in the edited file, the example node is located in the first chapter, third section level one, seventh section level 2.

**Figure 490. XPath Results Highlighted in Editor Panel with Character Precision**

---

**XPath and XML Catalogs**

The evaluation of the XPath expression tries to resolve the locations of documents referenced in the expression through XML Catalogs (on page 2972). These catalogs are configured in the XML Catalog preferences (on page 205) pages and the XML Parser preferences (on page 207).

**Example:**

As an example, consider the evaluation of the `collection(URIofCollection)` function (XPath 2.0). To resolve the references from the files returned by the `collection()` function with an XML catalog, specify the class name of the catalog-enabled parser for parsing these collection files. The class name is `ro.sync.xml.parser.CatalogEnabledXMLReader`. Specify it as it follows:
let $docs := collection(iri-to-uri{
  "file:///D:/temp/test/XQuery-catalog/mydocsdir?recurse=yes;select=*.xml;
  parser=ro.sync.xml.parser.CatalogEnabledXMLReader"})

XPath Prefix Mapping

To define default mappings between prefixes (that you can use in the XPath toolbar (on page 1852))
and namespace URIs go to the XPath preferences page (on page 229) and enter the mappings in the
Default prefix-namespace mappings table. The same preferences panel allows you to configure the default
namespace used in XPath 2.0 expressions.

⚠️ Important:
If you define a default namespace, Oxygen XML Editor binds this namespace to the first free prefix
from the list: default, default1, default2, and so on. For example, if you define the default namespace
xmlns="something" and the prefix default is not associated with another namespace, you can match
tags without prefix in an XPath expression typed in the XPath toolbar by using the prefix default.
To find all the <level> elements when you define a default namespace in the root element, use this
expression: //default:level in the XPath toolbar.
13. Working with Archives

Oxygen XML Editor includes a useful Archive Browser view (on page 1861) that offers the means to work with files directly from various types of archives (for example, opening and saving files directly in archives, or browsing and modifying archive structures). The archive support is available for all ZIP-type archives, including:

- ZIP archives
- EPUB books
- JAR archives (on page 2967)
- Office Open XML (OOXML) files
- Open Document Format (ODF) files
- IDML files (on page 2967)

You can transform, validate, and perform many other operations on files directly from an archive. For instance, you can transform, or validate files directly from OOXML or ODF packages, and the structure and content of the ZIP archives can be opened, edited, and saved, similar to any other ZIP archive browsing tool. Also, when browsing for a URL in various dialog boxes, you can use the Browse for archived file action to browse and select files from a particular archive.

For more information about working with an EPUB archive in Oxygen XML Editor, watch our video demonstration:

https://www.youtube.com/embed/OIGTNQwOCl8

Browsing Archives

Oxygen XML Editor includes a helper view called the Archive Browser that allows you to view the contents and structure of an archive, and it offers a variety of toolbar and contextual menu actions. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

To open an archive in the Archive Browser view, use one of the following methods:

- Open an archive from the Project view (on page 368).
- Select an archive in one of the file chooser dialog boxes in Oxygen XML Editor (such as the Open dialog box).
- Drag an archive from a system file explorer and drop it in the Archives Browser view.

When displaying an archive, the Archive Browser view locks the archive file. It is then automatically unlocked when the Archive Browser view is closed.
Tip:
If a file is not recognized by Oxygen XML Editor as a supported archive type, you can add it in the Archive preferences page (on page 260).

Figure 491. Archive Browser

Archive Browser Toolbar Actions

The following actions are available on the Archive Browser toolbar:

- **Open Archive menu**
  Provides access to the Open Archive action that opens a new archive in the browser. If the extension is not known as an archive extension, you will be directed to the Archive preferences page (on page 260) to add a new extension. The submenu keeps a list of recently open archive files and a Clear history action that allows you to delete the list.

- **Close**
  Closes the browsed archive and unlocks the archive file.

- **Validate (available for EPUB archives only)**
  Checks the EPUB archive to see if its content and structure is valid.

- **New folder**
  Creates a folder as child of the selected folder in the browsed archive.

- **New file**
  Creates a file as child of the selected folder in the browsed archive.

- **Add files**
Adds existing files as children of the selected folder in the browsed archive.

**Note:**
You can also add files in the archive by dragging them from the file browser or the Project view (on page 368) and dropping them in the Archive Browser view.

**Delete**
Deletes the selected resource in the browsed archive.

**Open in System Application**
Opens the selected resource in the default system application that is associated with that type of file.

**Archive Options**
Opens the Archive preferences page (on page 260).

**Archive Browser Contextual Menu Actions**
The following additional actions are available from the contextual menu for resources in the Archive Browser view:

- **Open**
  Opens a resource from the archive in the editor.

- **Extract**
  Extracts a resource from the archive in a specified folder.

- **New folder**
  Creates a folder as child of the selected folder in the browsed archive.

- **New file**
  Creates a file as child of the selected folder in the browsed archive.

- **Add files**
  Adds existing files as children of the selected folder in the browsed archive.

**Note:**
On OS X, the Add file action is also available and it allows you to add one file at a time.

- **Rename**
  Renames a resource in the archive.

- **Find/Replace in Files**
  Opens the Find/Replace in Files dialog box (on page 400) that allows you to search for and replace specific pieces of text inside the archive.
Cut
Cuts the selected archive resource.

Copy
Copies the selected archive resource.

Paste
Pastes a file or folder into the archive.

Delete
Removes a file or folder from archive.

Preview
Previews an image contained in the archive. See the Image Preview (on page 432) topic for more details.

Copy location
Copies the URL location of the selected resource.

Refresh
Refreshes the selected resource.

Properties
Shows the properties of the selected resource.

For more information, watch our video demonstration about working with an EPUB in the Archive Browser view:

https://www.youtube.com/embed/OIGTNQwOCl8

Working with Archive Files

Oxygen XML Editor includes support for working with various types of archives, including the following:

- **EPUB** - An e-book file format that can be used on many types of devices, such as smart phones, tablets, e-readers, or computers.
- **OOXML** - An XML-based file format for representing spreadsheets, charts, presentations, and word processing documents.
- **ODF** - An free and open-source XML-based file format for electronic office documents, such as spreadsheets, charts, presentations, and word processing documents.

When these types of files are opened in the Archive Browser view (on page 1861), their internal components are expanded:
• Document content (XHTML and image files).
• Packaging files.
• Container files.

**Figure 492. EPUB File Displayed in the Archive Browser View**

When an archive is expanded in the Archive Browser view, you can add or delete files that compose the archive structure. All changes made to the structure of an archive are saved immediately. You can open files from within the archive to edit them in the main editing pane and save changes back to the archive. You can also use the **Open in System Application** action to open the archive in the default system application that is associated with that type of file.

**EPUB-Specific Validation**

When working with EPUB archives, the Archive Browser includes a **Validate** action on the toolbar that checks the EPUB archive to make sure the structure and content are valid. Oxygen XML Editor uses the open-source EpubCheck validator to perform the validation. This validator detects many types of errors, including OCF container structure, OPF and OPS mark-up, as well as internal reference consistency.

For more information about working with an EPUB archive in Oxygen XML Editor, watch our video demonstration:

https://www.youtube.com/embed/OIGTNQwOCl8
Creating an Archive

To create an archive from scratch, follow these steps:

1. Go to File > New or click New on the main toolbar.
2. Choose your particular type of archive template. For example, select one of the ODF, OOXML, or EPUB templates.
3. Click Create and choose the name and location of the file.
4. Click Save.

A skeleton archive is saved on disk and open in the Archive Browser view (on page 1861).

Tip:
Use toolbar and contextual menu actions to edit, add, and remove resources from the archive.
For EPUB archives, you can use the Validate action to verify the integrity of the EPUB archive.

Editing and Saving Files Inside an Archive

You can open files directly from an archive in the Archive Browser view (on page 1861) and then edit them in the main editor pane. To open a file, simply double-click it or select Open from the contextual menu.

When saving the file back to the archive, you are prompted to choose if you want the application to make a backup copy of the archive before saving the new content. If you choose Never ask me again, you will not be asked again to make backup copies. You can re-enable the pop-up message from the Messages preferences page (on page 276).

Migrating Archives to DITA or TEI

Certain types of archives can be converted to DITA or TEI. For example, OOXML (Office Open XML) archive files with the DOCX file extension can be migrated to DITA or TEI.

To migrate DOCX files to DITA or TEI, follow these steps:

1. Open and expand the archive in the Archive Browser (on page 1861).
2. Open the document.xml file contained in the archive.
3. Run one of the following built-in transformation scenarios:
   a. DOCX DITA to migrate to DITA.
   b. DOCX TEI P5 to migrate to TEI.
4. You may need to do some manual reconfiguring to map DOCX styles to DITA or TEI content.

**Tip:**
Oxygen XML Editor also includes a built-in transformation scenario called **ODT TEI P5** for converting ODF archive files with the ODT file extension to TEI and a similar process can be used to migrate ODT files to TEI.
14.

Databases and SharePoint

Oxygen XML Editor provides support for connecting and integrating with various databases and Microsoft SharePoint. This section includes information about the database-related features in Oxygen XML Editor. It explains how to connect with the supported databases, presents the actions that are available for each type, and includes information about SharePoint integration.

Working with Databases

XML is a storage and interchange format for structured data and is supported by all major database systems. Oxygen XML Editor offers the means for managing the interaction with some of the most commonly used databases (both Relational and Native XML databases). Through this interaction, Oxygen XML Editor helps users with browsing, content editing, importing from databases, using XQuery with databases, SQL execution, and generating XML Schema from a database structure.

The types of connections that are supported in Oxygen XML Editor include:

- IBM DB2 (on page 1874)
- Microsoft SQL Server (on page 1878)
- Oracle Database (on page 1881)
- PostgreSQL (on page 1887)
- Berkeley DB XML (on page 1890)
- eXist (on page 1897)
- MarkLogic (on page 1902)
- MySQL (on page 1911)
- Generic JDBC (on page 1913)
- JDBC-ODBC (on page 1914)
- BaseX (on page 1915)
- WebDAV (on page 1920)
- Microsoft SharePoint (on page 1933)

Related Information:
Integration with Microsoft SharePoint (on page 1933)

Data Source Explorer View

The Data Source Explorer view displays your database connections. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.
You can connect to a database simply by expanding the connection node (click the connection). The database structure can be expanded to resource level, or even all the way to column level for tables inside relational databases. Oxygen XML Editor supports multiple simultaneous database connections and the connection tree in the **Data Source Explorer** view provides an easy method for browsing them.

**Figure 493. Data Source Explorer View**

The objects (nodes) that are displayed in the **Data Source Explorer** view depend on the connection type and structure of the database. Various contextual menu actions are available for each hierarchical level and for some connections you can add or move resources in a container by simply dragging them from the **Project view** (on page 368), a file browsing application, or another database.

**Toolbar Actions**

The following actions are available in the toolbar of this view:

- **Filters**
  
  Opens the **Data Sources / Table Filters preferences page** (on page 250), allowing you to decide which table types are displayed in the **Data Source Explorer** view.

- **Configure Database Sources**
  
  Opens the **Data Sources preferences page** (on page 246) where you can configure both data sources and connections.

**Database-Specific Contextual Menu Actions**

Each specific type of database will also include its own specific contextual menu actions in the **Data Source Explorer** view. The actions depend on the type of database, the type of node, or the hierarchical level of the node where the contextual menu is invoked.
For more information on the specific actions that are available, see the topics in this section for each specific type of database.

Related Information:
Data Sources Preferences (on page 246)

Table Explorer View

Relational databases tables in the Data Source Explorer view (on page 1868) can be displayed and edited in the Table Explorer view by selecting the Edit action from the contextual menu of a Table node or by double-clicking one of its fields. To modify the content of a cell, double-click it and start typing. When editing is complete, Oxygen XML Editor attempts to update the database with the new cell content.

You can sort the content of a table by one of its columns by clicking its column header.

Note the following:

- The first column is an index (not part of the table structure).
- Every column header contains the field name and its data type.
- The primary key columns are marked with this symbol: 🕔.
- Multiple tables are presented in a tabbed manner.

For performance issues, you can set the maximum number of cells that are displayed in the Table Explorer view (using the Limit the number of cells option in the Data Sources Preferences page (on page 250)). If a table that has more cells than the value set in the options is displayed in the Table Explorer view, a warning dialog box informs you that the table is only partially shown.

You are notified if the value you have entered in a cell is not valid (and thus cannot be updated).
If the content of the edited cell does not belong to the data type of the column, the cell is marked by a red square and remains in an editing state until a correct value is inserted. For example, in the following figure `propID` contains `LONG` values. If a character or string is inserted, the cell will look like this:

**Figure 495. Cell Containing an Invalid Value**

![Cell Containing an Invalid Value](image)

If the constraints of the database are not met (for instance, primary key constraints), an information dialog box will appear, notifying you of the reason the database has not been updated. For example, in the table below, trying to set the second record in the primary key `propID` column to 8, results in a duplicate entry error since that value has already been used in the first record:

**Figure 496. Duplicate Entry for Primary Key**

![Duplicate Entry for Primary Key](image)

**Table Explorer Contextual Menu Actions**

Common editing actions (`Cut`, `Copy`, `Paste`, `Select All`, `Undo`, `Redo`) are available in the contextual menu of an edited cell.

The contextual menu, available on every cell in the **Table Explorer** view, also includes the following actions:

- **Set NULL**
  
  Sets the content of the cell to **null**. This action is not available for columns that cannot have a value of **null**.

- **Insert row**
Inserts an empty row in the table.

Duplicate row

Makes a copy of the selected row and adds it in the Table Explorer view. Note that the new row will not be inserted in the database table until all conflicts are resolved.

Commit row

Commits the selected row.

Delete row

Deletes the selected row.

Copy

Copies the content of the cell.

Paste

Pastes copied content into the selected cell.

Table Explorer Toolbar Actions

The toolbar of the Table Explorer view also includes the following actions:

Export to XML

Opens the Export Criteria dialog box (a thorough description of this dialog box can be found in the Import from database (on page 1949) chapter).

Refresh

Performs a refresh for the sub-tree of the selected node.

Insert row

Inserts an empty row in the table.

Duplicate row

Makes a copy of the selected row and adds it in the Table Explorer view. Note that the new row will not be inserted in the database table until all conflicts are resolved.

Commit row

Commits the selected row.

Delete row

Deletes the selected row.

Data Source Explorer View (on page 1868)
Database Connection Support

Oxygen XML Editor offers support for a variety of Relational and Native XML database connections. The database drivers and connections for various types of database are configured in the Data Sources preferences page (on page 246) and once configured, the database connections can be viewed and managed in the Data Source Explorer view (on page 1868). Oxygen XML Editor also includes a Database perspective (on page 318) that helps you to manage databases.

The database support in Oxygen XML Editor offers a variety of capabilities, including:

- Browsing the structure of databases in the Data Source Explorer view (on page 1868).
- Viewing relational tables in the Table Explorer view (on page 1870).
- Executing SQL queries against databases.
- Calling stored procedures with input and output parameters.
- XQuery execution with databases.
- Exporting data from databases to XML.

Relational Database Support

Relational databases use a relational model and are based on tables linked by a common key. Oxygen XML Editor offers support for the most commonly used relational databases, including:

- IBM DB2
- Oracle 11g
- Microsoft SQL Server
- PostgreSQL
- MySQL

Oxygen XML Editor also offers generic support (table browsing and execution of SQL queries) for any JDBC-compliant database (for example, MariaDB).

Native XML Database Support

Native XML databases have an XML-based internal model and their fundamental unit of storage is XML. They use XML as an interface to specify documents as tree structured data that may contain unstructured text, but on disk the data is stored as optimized binary files. This makes query and retrieval processes faster. Oxygen XML Editor offers support for the most commonly used native XML databases, including:

- Berkeley DB XML
- eXist
- MarkLogic
- Oracle XML DB
- Base X
IBM DB2 Database Connections

Oxygen XML Editor includes support for IBM DB2 database connections. Oxygen XML Editor allows you to browse the structure of an IBM DB2 database in the Data Source Explorer view (on page 1868), open tables in the Table Explorer view (on page 1870), and perform various operations on the resources in the repository.

Configuring an IBM DB2 Database Connection

To configure the support for the IBM DB2 database, follow this procedure:

1. Go to the IBM website and in the DB2 Clients and Development Tools category select the DB2 Driver for JDBC and SQLJ download link. Fill out the download form and download the zip file. Unzip the zip file and use the db2jcc.jar and db2jcc_license_cu.jar files in Oxygen XML Editor for configuring a DB2 data source (on page 1875).
2. Configure IBM DB2 Data Source drivers (on page 1875).
3. Configure an IBM DB2 Server Connection (on page 1876).

4. To view your connection, go to the Data Source Explorer view (on page 1868) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 2969).

How to Configure IBM DB2 Data Source Drivers

**Note:**
Available in the Enterprise edition only.

To configure a data source for connecting to an IBM DB2 server, follow these steps:

1. Go to the IBM website and in the DB2 Clients and Development Tools category select the DB2 Driver for JDBC and SQLJ download link. Fill out the download form and download the zip file.
2. Unzip the downloaded archive.
3. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Data Sources.
4. Click the **New** button in the Data Sources panel.

The dialog box for configuring a data source is opened.

**Figure 498. Data Source Drivers Configuration Dialog Box**

5. Enter a unique name for the data source.
6. Select **DB2** in the driver **Type** drop-down menu.
7. Click the Add Files button and select the IBM DB2 driver files from the archive that you downloaded and unzipped.

The IBM DB2 driver files are:

- `db2jcc.jar`
- `db2jcc_license_cisuz.jar`
- `db2jcc_license_cu.jar`

8. Select the most appropriate Driver class.

9. Click the OK button to finish the data source configuration.

10. Continue on to configure your IBM DB2 connection (on page 1876).

### How to Configure an IBM DB2 Connection

**Note:**

The support to create an IBM DB2 connection is available in the Enterprise edition only.

To configure a connection to an IBM DB2 server, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Data Sources.
2. Click the + New button in the Connections panel.
   
   The dialog box for configuring a database connection is displayed.

#### Figure 499. Connection Configuration Dialog Box

3. Enter a unique name for the connection.

4. Select an IBM DB2 data source in the Data Source drop-down menu.
5. Enter the connection details.
   a. Enter the URL to the installed IBM DB2 engine.
   b. Enter the user name to access the IBM DB2 engine.
   c. Enter the password to access the IBM DB2 engine.
6. Click the OK button to finish the connection configuration.
7. To view your connection, go to the Data Source Explorer view (on page 1868) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 2969).

IBM DB2 Contextual Menu Actions

General Contextual Menu Actions

For relational databases, the following general actions are available in the contextual menu of the Data Source Explorer view (on page 1868), depending on the node where it is invoked:

- **Refresh**
  Performs a refresh on the selected node.

- **Disconnect (available on Connection nodes)**
  Closes the current database connection. If a table is already open, you are warned to close it before proceeding.

- **Configure Database Sources (available on Connection nodes)**
  Opens the Data Sources preferences page (on page 246) where you can configure both data sources and connections.

- **Edit (available on Table nodes)**
  Opens the selected table in the Table Explorer view (on page 1870).

- **Export to XML (available on Table nodes)**
  Opens the Export Criteria dialog box (a thorough description of this dialog box can be found in the Import from Database (on page 1949) chapter).

Database-Specific Contextual Menu Actions

In addition to the general contextual menu actions in the Data Source Explorer view (on page 1868), the various nodes in IBM DB2 connections include the following additional contextual menu actions:

- **XML Schema Repository Level Nodes**
  **Register**
  Opens a dialog box for adding a new schema file in the DB XML repository. In this dialog box, you enter a collection name and the necessary schema files. Schema dependencies management can be done by using the Add and Remove buttons.

- **Schema Level Nodes**
Microsoft SQL Server Database Connections

Oxygen XML Editor includes support for Microsoft SQL Server database connections. Oxygen XML Editor allows you to browse the structure of a SQL Server database in the Data Source Explorer view (on page 1868), open tables in the Table Explorer view (on page 1870), and perform various operations on the resources in the repository.

Configuring a Microsoft SQL Server Connection

To configure the support for a Microsoft SQL Server database, follow this procedure:

2. Configure MS SQL Server Data Source drivers (on page 1878).
3. Configure a MS SQL Server Connection (on page 1879).
4. To view your connection, go to the Data Source Explorer view (on page 1868) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 2969).

How to Configure Microsoft SQL Server Data Source Drivers

**Note:**
Available in the Enterprise edition only.

To configure a data source for connecting to a Microsoft SQL server, follow these steps:

2. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Data Sources.
3. Click the + New button in the Data Sources panel.
   
   The dialog box for configuring a data source is opened.
4. Enter a unique name for the data source.
5. Select SQLServer in the driver Type drop-down menu.
6. Click the Add Files button and select the Microsoft SQL Server driver file that you downloaded.
   The SQL Server driver file is called sqljdbc.jar.
7. Select the most appropriate Driver class.
8. Click the OK button to finish the data source configuration.
9. Continue on to configure your Microsoft SQL Server connection (on page 1879).

How to Configure a Microsoft SQL Server Connection

**Note:**
The support to configure a Microsoft SQL Server connection is available in the Enterprise edition only.

To configure a connection to a Microsoft SQL Server, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Data Sources.
2. Click the + New button in the Connections panel.
   The dialog box for configuring a database connection is displayed.
3. Enter a unique name for the connection.
4. Select the SQL Server data source in the Data Source drop-down menu.
5. Enter the connection details.
   a. Enter the URL of the SQL Server server.
      If you want to connect to the server using Windows integrated authentication, you must add ;integratedSecurity=true to the end of the URL. The URL will look like this:

```
jdbc:sqlserver://localhost;instanceName=SQLEXPRESS;integratedSecurity=true;
```

**Note:** For integrated authentication, leave the User and Password fields empty.

b. Enter the user name for the connection to the SQL Server.

c. Enter the password for the connection to the SQL Server.

6. Click the OK button to finish the connection configuration.

7. To view your connection, go to the Data Source Explorer view (on page 1868) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 2969).
Microsoft SQL Server Contextual Menu Actions

General Contextual Menu Actions

For relational databases, the following general actions are available in the contextual menu of the Data Source Explorer view (on page 1868), depending on the node where it is invoked:

- **Refresh**
  Performs a refresh on the selected node.

- **Disconnect (available on Connection nodes)**
  Closes the current database connection. If a table is already open, you are warned to close it before proceeding.

- **Configure Database Sources (available on Connection nodes)**
  Opens the Data Sources preferences page (on page 246) where you can configure both data sources and connections.

- **Edit (available on Table nodes)**
  Opens the selected table in the Table Explorer view (on page 1870).

- **Export to XML (available on Table nodes)**
  Opens the Export Criteria dialog box (a thorough description of this dialog box can be found in the Import from Database (on page 1949) chapter).

Database-Specific Contextual Menu Actions

In addition to the general contextual menu actions in the Data Source Explorer view (on page 1868), the resource level nodes in Microsoft SQL Server connections include the following additional contextual menu action:

- **XML Schema Repository Level Nodes**
  - **Register**
    Opens a dialog box for adding a new schema file in the DB XML repository. In this dialog box, you enter a collection name and the necessary schema files. Schema dependencies management can be done by using the Add and Remove buttons.

- **Schema Level Nodes**
  - **Add**
    Adds a new schema to the XML Schema files.
  - **Unregister**
    Removes the selected schema from the XML Schema Repository.
  - **View**
    Opens the selected schema in Oxygen XML Editor.
Oracle Database Connections

The Oracle database is a common relational type of database system. Oxygen XML Editor comes with built-in support for the 11g version of the database system. The Oracle database also includes an Oracle XML DB component that adds native XML support. Oxygen XML Editor allows you to browse Oracle repositories in the Data Source Explorer view (on page 1868), open tables in the Table Explorer view (on page 1870), and perform various operations on the resources in the repository.

![Figure 502. Oracle Database Connection](image)

Related Information:
Using XQuery with Oracle XML DB

Configuring an Oracle 11g Database Connection

To configure the support for a Oracle 11g database, follow this procedure:

2. Configure Oracle 11g Data Source drivers (on page 1882).
3. Configure an Oracle 11g Connection (on page 1883).
4. To view your connection, go to the Data Source Explorer view (on page 1868) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 2969).

How to Configure Oracle 11g Data Source Drivers

Note:
Available in the Enterprise edition only.
To configure a data source for connecting to an Oracle 11g server, follow these steps:

2. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Data Sources.
3. Click the **New** button in the Data Sources panel.

The dialog box for configuring a data source is opened.

4. Enter a unique name for the data source.
5. Select Oracle in the driver **Type** drop-down menu.
6. Click the **Add Files** button and select the Oracle driver file that you downloaded.
   The Oracle driver file is called `ojdbc5.jar`.
7. Select the most appropriate **Driver class**.
8. Click the **OK** button to finish the data source configuration.
9. Continue on to configure your Oracle connection (on page 1883).

**How to Configure an Oracle 11g Connection**

**Note:**
Available in the Enterprise edition only.
To configure a connection to an Oracle 11g server, follow these steps:

1. **Open the Preferences dialog box** *(Options > Preferences)* *(on page 98)* and go to Data Sources.
2. Click the **New** button in the Connections panel.

   The dialog box for configuring a database connection is displayed.

   **Figure 504. Connection Configuration Dialog Box**

3. Enter a unique name for the connection.
4. Select the *Oracle 11g* data source in the Data Source drop-down menu.
5. Enter the connection details.
   a. Enter the URL of the Oracle server.
   b. Enter the user name for the connection to the Oracle server.
   c. Enter the password for the connection to the Oracle server.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the Data Source Explorer view *(on page 1868)* (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective *(on page 2969)*.

**Oracle Database Contextual Menu Actions**

**General Contextual Menu Actions**

For relational databases, the following general actions are available in the contextual menu of the Data Source Explorer view *(on page 1868)*, depending on the node where it is invoked:

- **Refresh**
Performs a refresh on the selected node.

**Disconnect (available on Connection nodes)**

Closes the current database connection. If a table is already open, you are warned to close it before proceeding.

**Configure Database Sources (available on Connection nodes)**

Opens the Data Sources preferences page (on page 246) where you can configure both data sources and connections.

**Edit (available on Table nodes)**

Opens the selected table in the Table Explorer view (on page 1870).

**Export to XML (available on Table nodes)**

Opens the Export Criteria dialog box (a thorough description of this dialog box can be found in the Import from Database (on page 1949) chapter).

**Database-Specific Contextual Menu Actions**

In addition to the general contextual menu actions in the Data Source Explorer view (on page 1868), the various nodes in Oracle database connections include the following additional contextual menu actions:

**XML Schema Repository Level Nodes**

**Register**

Opens a dialog box for adding a new schema file in the XML repository. To add an XML Schema, enter the schema URI and location on your file system. *Local* scope means that the schema is visible only to the user who registers it. *Global* scope means that the schema is public.

**Note:**

Registering a schema may involve dropping/creating types. Hence you need type-related privileges such as DROP TYPE, CREATE TYPE, and ALTER TYPE. You need privileges to delete and register the XML schemas involved in the registering process. You need all privileges on XMLType tables that conform to the registered schemas. For XMLType columns, the ALTER TABLE privilege is needed on corresponding tables. If there are schema-based XMLType tables or columns in other database schemas, you need privileges such as the following:

- CREATE ANY TABLE
- CREATE ANY INDEX
- SELECT ANY TABLE
- UPDATE ANY TABLE
- INSERT ANY TABLE
- DELETE ANY TABLE
To avoid having to grant all these privileges to the schema owner, Oracle recommends that the registration be performed by a DBA if there are XML schema-based XMLType table or columns in other user database schemas.

XML Repository Level Nodes

Add container

Adds a new child container to the current one.

Add resource

Adds a new resource to the folder.

Container Level Nodes

Add container

Adds a new child container to the current one.

Add resource

Adds a new resource to the folder.

Delete

Deletes the current container.

Properties

Shows various properties of the current container.

Resource Level Nodes

Open

Opens the selected resource in the editor.

Open in System Application

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the Data Source Explorer view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

Rename

Renames the current resource

Move
Moves the current resource to a new container (also available through drag and drop).

**Delete**

Deletes the current container.

**Copy location**

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

**Properties**

Shows various properties of the current container.

**Compare**

Compares two selected resources using the Compare Files tool (on page 437).

### PostgreSQL Database Connections

Oxygen XML Editor includes support for PostgreSQL database connections. Oxygen XML Editor allows you to browse the structure of a PostgreSQL database in the Data Source Explorer view (on page 1868), open tables in the Table Explorer view (on page 1870), and perform various operations on the resources in the repository.

**Figure 505. PostgreSQL Database Connection**

![PostgreSQL Database Connection](image)
Configuring a PostgreSQL Database Connection

To configure the support for a PostgreSQL database, follow this procedure:

1. Go to http://jdbc.postgresql.org/download.html and download the PostgreSQL 8.3 JDBC3 driver.
2. Configure PostgreSQL Data Source drivers (on page 1888).
3. Configure a PostgreSQL Connection (on page 1888).
4. To view your connection, go to the Data Source Explorer view (on page 1868) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 2969).

How to Configure PostgreSQL 8.3 Data Source Drivers

To configure a data source for connecting to a PostgreSQL server, follow these steps:

1. Go to http://jdbc.postgresql.org/download.html and download the PostgreSQL 8.3 JDBC3 driver.
2. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Data Sources.
3. Click the New button in the Data Sources panel.

   The dialog box for configuring a data source is opened.
4. Enter a unique name for the data source.
5. Select PostgreSQL in the driver Type drop-down list.
6. Click the Add Files button and select the PostgreSQL driver file that you downloaded.

   The PostgreSQL driver file is called postgresql-8.3-603.jdbc3.jar.
7. Select the most appropriate Driver class.
8. Click the OK button to finish the data source configuration.
9. Continue on to configure your PostgreSQL connection (on page 1888).

How to Configure a PostgreSQL 8.3 Connection

To configure a connection to a PostgreSQL 8.3 server, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Data Sources.
2. Click the New button in the Connections panel.

   The dialog box for configuring a database connection is displayed.
3. Enter a unique name for the connection.
4. Select the *PostgreSQL 8.3* data source in the *Data Source* drop-down menu.
5. Enter the connection details.
   a. Enter the URL of the PostgreSQL 8.3 server.
   b. Enter the user name for the connection to the PostgreSQL 8.3 server.
   c. Enter the password for the connection to the PostgreSQL 8.3 server.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the *Data Source Explorer view* (on page 1868) (if the view is not displayed, it can be opened by selecting it from the *Window > Show View* menu) or switch to the *Database perspective* (on page 2969).

**PostgreSQL Contextual Menu Actions**

**General Contextual Menu Actions**

For relational databases, the following general actions are available in the contextual menu of the *Data Source Explorer view* (on page 1868), depending on the node where it is invoked:

**Refresh**

Performs a refresh on the selected node.

**Disconnect (available on Connection nodes)**

Closes the current database connection. If a table is already open, you are warned to close it before proceeding.
Configure Database Sources (available on Connection nodes)

Opens the Data Sources preferences page (on page 246) where you can configure both data sources and connections.

Edit (available on Table nodes)

Opens the selected table in the Table Explorer view (on page 1870).

Export to XML (available on Table nodes)

Opens the Export Criteria dialog box (a thorough description of this dialog box can be found in the Import from Database (on page 1949) chapter).

Database-Specific Contextual Menu Actions

In addition to the general contextual menu actions in the Data Source Explorer view (on page 1868), the resource level nodes in PostgreSQL connections include the following additional contextual menu action:

Resource Level Nodes

Compare

Compares two selected resources using the Compare Files tool (on page 437).

Berkeley DB XML Database Connections

Oxygen XML Editor includes support for Berkeley DB XML database connections. Oxygen XML Editor allows you to browse the structure of a Berkeley DB XML database in the Data Source Explorer view (on page 1868) and perform various operations on the resources in the repository.

Oracle Berkeley DB XML is an open source, embeddable XML database with XQuery-based access to documents stored in containers and indexed based on their content. It is built on top of the Oracle Berkeley DB and inherits its features and attributes, along with native XML support. A detailed description can be found at: http://www.oracle.com/us/products/database/berkeley-db/xml/overview/index.html.
Configuring a Berkeley DB XML Database Connection

Follow this procedure to configure the support for a Berkeley DB XML database:

2. Configure a Berkeley DB XML Connection (on page 1892).
3. To view your connection, go to the Data Source Explorer view (on page 1868) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 2969).

How to Configure Berkeley DB XML Data Source Drivers

**Prerequisite:**
For this procedure, you need to already have a Berkeley DB XML database installed on your system.

Oxygen XML Editor supports Berkeley DB XML versions 2.3.10, 2.4.13, 2.4.16 & 2.5.16. To configure a data source for a Berkeley DB XML database, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Data Sources.
2. Click the + New button in the Data Sources panel.
3. Enter a unique name for the data source.
4. Select Berkeley DBXML from the driver Type drop-down menu.
5. Click the Add Files button to add the Berkeley DB driver files.

The driver files for the Berkeley DB database (and their locations) are as follows:

- db.jar (check for it in [DBXML_DIR]/lib or [DBXML_DIR]/jar)
- dbxml.jar (check for it in [DBXML_DIR]/lib or [DBXML_DIR]/jar)
How to Configure a Berkeley DB XML Connection

Oxygen XML Editor supports Berkeley DB XML versions 2.3.10, 2.4.13, 2.4.16 & 2.5.16. To configure a connection to a Berkeley DB XML database, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Data Sources.
2. Click the New button in the Connections panel.
3. Enter a unique name for the connection.
4. Select a previously configured Berkeley data source from the Data Source drop-down menu.
5. Enter the connection details.
   a. Set the path to the Berkeley DB XML database directory in the Environment home directory field. Use a directory with write access. DO NOT use the installation directory where Berkeley DB XML is installed if you do not have write access to that directory.
   b. Select the Verbosity level: DEBUG, INFO, WARNING, or ERROR.
   c. Optionally, you can select the Join existing environment checkbox.
      If selected, an attempt is made to join an existing environment in the specified home directory and all the original environment settings are preserved. If that fails, try reconfiguring the connection with this option unchecked.
6. Click the OK button to finish the connection configuration.
7. To view your connection, go to the Data Source Explorer view (on page 1868) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 2969).

Berkeley DB XML Contextual Menu Actions

While browsing Berkeley DB XML connections in the Data Source Explorer view (on page 1868), the various nodes include the following contextual menu actions:

- **Connection Level Nodes**

  - **Configure Database Sources**
    
    Opens the Data Sources preferences page (on page 246) where you can configure both data sources and connections.

  - **Disconnect (when connected)**

    Stops the connection.

  - **New Collection**
Opens a **Container configuration** dialog box that allows you to add a new container in the repository.

**Figure 508. Container Configuration Dialog Box**

This dialog box allows you to configure the following:

- **Name** - The name of the new container.
- **Container type** - At creation time, every container must have a type defined for it. This container type identifies how XML documents are stored in the container. As such, the container type can only be determined at container creation time. You cannot change it when subsequent container opens. You can select one of the following types:
  - **Node container** - XML documents are stored as individual nodes in the container. Each record in the underlying database contains a single leaf node, its attributes and attribute values (if any), and its text nodes (if any). Berkeley DB XML also keeps the information it requires to reassemble the document from the individual nodes stored in the underlying databases. This is the default selection and is the preferred container type.
  - **Whole document container** - The container contains entire documents. The documents are stored without any manipulation of line breaks or whitespace.
- **Allow validation** - If selected, documents will be validated when they are loaded into the container. The default behavior is to not validate documents.
- **Index nodes** - If selected, indices for the container will return nodes rather than documents. The default is to index at the document level. This property has no meaning if the container type is **Whole document container**.

**Refresh**

Performs a refresh on the selected node.
Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the Find/Replace in Files dialog box (on page 400) that allows you to find and replace text in multiple files from the connection.

Container Level Nodes

Import Files

Allows you to add a new file on the connection, in the current folder.

Export

Allows you to export the folder on the remote connection to a local folder.

Cut

Removes the current selection and places it in the clipboard.

Paste

Pastes the copied selection.

Rename

Renames the current resource.

Delete

Deletes the current container.

Edit indices

Opens a Container Indices dialog box that allows you to configure indices properties for the selected Berkeley container.
This dialog box allows you to configure the following properties:

- **Granularity** - A measure of the level of details of your data in the database. You can select one of the following:
  - **Document level** - Good option for retrieving large documents.
  - **Node level** - Good option for retrieving nodes from within documents.
- **Node** - The name of the node.
- **Namespace** - The index namespace.
- **Index type**:
  - **Uniqueness** - Indicates whether or not the indexed value must be unique within the container.
  - **Path type** - Drop-down menu that allows you to select from the following:
    - **node** - Indicates that you want to index a single node in the path.
    - **edge** - Indicates that you want to index the portion of the path where two nodes meet.
  - **Node type** - Drop-down menu that allows you to select from the following:
    - **element** - An element node in the document content.
    - **attribute** - An attribute node in the document content.
    - **metadata** - A node found only in the metadata content of a document.
  - **Key type** - Drop-down menu that allows you to select from the following:
- **equality** - Improves the performances of tests that look for nodes with a specific value.
- **presence** - Improves the performances of tests that look for the existence of a node regardless of its value.
- **substring** - Improves the performance of tests that look for a node whose value contains a given sub-string.

- **Syntax** - The syntax describes the type of data the index contains and is mostly used to determine how indexed values are compared. The default value is `string`.

**Refresh**
Performs a refresh on the selected node.

**Properties**
Shows various properties of the current container.

**Find/Replace in Files**
Opens the Find/Replace in Files dialog box (on page 400) that allows you to find and replace text in multiple files from the connection.

**Resource Level Nodes**

**Open**
Opens the selected resource in the editor.

**Open in System Application**
When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the Data Source Explorer view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

**Cut**
Removes the current selection and places it in the clipboard.

**Copy location**
Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

**Rename**
Renames the current resource

**Delete**
Deletes the current container.
Refresh

Performs a refresh on the selected node.

Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the Find/Replace in Files dialog box (on page 400) that allows you to find and replace text in multiple files from the connection.

Compare

Compares two selected resources using the Compare Files tool (on page 437).

Debugging with Berkeley DB XML

The Berkeley DB XML database added a debugging interface starting with version 2.5. The current version is supported in the Oxygen XML Editor XQuery Debugger. The same restrictions and peculiarities (on page 1908) apply for the Berkeley debugger as for the MarkLogic debugger.

eXist Database Connections

Oxygen XML Editor includes support for eXist database connections. Oxygen XML Editor allows you to browse the structure of a eXist database in the Data Source Explorer view (on page 1868) and perform various operations on the resources in the repository.

Figure 510. eXist Database Connection
Configuring an eXist Database Connection

There are two ways to configure the support for an eXist database:

- Use the dedicated Create eXist-db XML connection wizard.
- Use the Data Sources preferences page to manually configure your connection.

How to Configure an eXist Connection Using the Built-in Wizard

To configure a connection for an eXist database using the dedicated Create eXist-db XML connection wizard, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98), go to Data Sources and click the Create eXist-db XML connection link.
2. Enter your connection details in the connection wizard and click OK.

Important:
To create an eXist connection using this wizard, Oxygen XML Editor expects the exist/webstart/exist.jnlp path to be accessible at the provided Host and Port.

3. To view your connection, go to the Data Source Explorer view (on page 1868) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 2969).

Important:
If you are using Oxygen XML Editor version 22.1 or newer and want to connect to an Exist 4.x or older database, the connection might fail. In this case, go to Data Sources preferences page, edit the Exist data source, and from the driver files list, remove the references to the log4j-api-*.jar and log4j-core-*.jar libraries.

How to Configure an eXist Connection Manually

Attention:
For this manual procedure, you need to already have an eXist database server installed.

Tip:
There is an easier way to configure an eXist database connection using a built-in wizard. For more information, see How to Configure an eXist Connection Using the Built-in Wizard (on page 1898).

Step 1: Configure eXist Data Source Drivers

Oxygen XML Editor supports eXist database server versions up to and including version 5.0. To configure a data source for an eXist database, follow these steps:
1. Open the **Preferences** dialog box (Options > Preferences) (on page 98) and go to **Data Sources**.

2. Click the + **New** button in the **Data Sources** panel.

3. Enter a unique name for the data source.

4. Select **eXist** from the driver **Type** drop-down menu.

5. Click the **Add Files** button to add the eXist driver files. The following driver files should be added and they are found in the installation directory of the eXist database server. Make sure you copy the files from the installation of the eXist server where you want to connect from Oxygen XML Editor.

   • The **exist.jar** file located in the base directory.
   • All JAR files in the **lib/core/** directory.

   **Important:**
   If you are using Oxygen XML Editor version 22.1 or newer and you want to connect to an Exist 4.x or older database, do not add references to the **log4j-api-*.*.jar** and **log4j-core-*.jar** libraries.

6. Click the **OK** button to finish the data source configuration.

**Step 2: Configure an eXist Connection**

To configure a connection to an eXist database, follow these steps:

1. Open the **Preferences** dialog box (Options > Preferences) (on page 98) and go to **Data Sources**.

2. Click the + **New** button in the **Connections** panel.

3. Enter a unique name for the connection.

4. Select a previously configured eXist data source from the **Data Source** drop-down menu.

5. Enter the connection details:
   a. Set the URI to the installed eXist engine in the **XML DB URI** field.
   b. Set the user name in the **User** field.
   c. Set the password in the **Password** field.
   d. Enter the start collection in the **Collection** field.

   eXist organizes all documents in hierarchical collections. Collections are like directories. They are used to group related documents together. This text field allows the user to set the default collection name.

6. Click the **OK** button to finish the connection configuration.

7. To view your connection, go to the **Data Source Explorer** view (on page 1868) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the **Database perspective** (on page 2969).

For more information about running XQuery against an eXist XML database, watch our video demonstration:

https://www.youtube.com/embed/Yoc5h1zSddA
eXist Contextual Menu Actions

While browsing eXist database connections in the Data Source Explorer view (on page 1868), the various nodes include the following contextual menu actions:

**Connection Level Nodes**

- **Configure Database Sources**
  
  Opens the Data Sources preferences page (on page 246) where you can configure both data sources and connections.

- **Disconnect (when connected)**
  
  Stops the connection.

- **Refresh**
  
  Performs a refresh on the selected node.

- **Find/Replace in Files**
  
  Opens the Find/Replace in Files dialog box (on page 400) that allows you to find and replace text in multiple files from the connection.

**Container Level Nodes**

- **New File or New Document**
  
  Creates a new file on the connection, in the current folder.

- **New Collection**
  
  Creates a new collection on the connection.

- **Import Folders**
  
  Imports folders on the server.

- **Import Files**
  
  Allows you to add a new file on the connection, in the current folder.

- **Export**
  
  Allows you to export the folder on the remote connection to a local folder.

- **Cut**
  
  Removes the current selection and places it in the clipboard.

- **Paste**
  
  Pastes the copied selection.

- **Refresh**
  
  Performs a refresh on the selected node.

- **Properties**
  
  Shows various properties of the current container.
**Find/Replace in Files**

Opens the Find/Replace in Files dialog box (on page 400) that allows you to find and replace text in multiple files from the connection.

**Resource Level Nodes**

**Open**

Opens the selected resource in the editor.

**Open in System Application**

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the Data Source Explorer view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

**Save As**

Allows you to save the selected resource as a file on disk.

**Cut**

Removes the current selection and places it in the clipboard.

**Copy**

Copies the current selection into the clipboard.

**Copy location**

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

**Rename**

Renames the current resource

**Delete**

Deletes the current container.

**Refresh**

Performs a refresh on the selected node.

**Properties**

Shows various properties of the current container.

**Find/Replace in Files**

Opens the Find/Replace in Files dialog box (on page 400) that allows you to find and replace text in multiple files from the connection.
MarkLogic Database Connections

Oxygen XML Editor Enterprise edition includes support for MarkLogic database connections. Once you configure a MarkLogic connection (on page 1903), you can use the Data Source Explorer view (on page 1868) to display all the application servers that are configured on the MarkLogic server. You can expand each application server and view all of its configured modules, and the Data Source Explorer view (on page 1868) allows you to open and edit these modules.

Note:
To browse modules located in a database, directory properties must be associated with them. These directory properties are generated automatically if the directory creation property of the database is set to automatic. If this property is set to manual or manual-enforced, add the directory properties of the modules manually, using the XQuery function `xdmp:directory-create()`. For example, for two documents with the `/code/modules/main.xqy` and `/code/modules/imports/import.xqy` IDs, run the following query:

```
(xdmp:directory-create('/code/modules/'), xdmp:directory-create('/code/modules/imports/'))
```

For more information about directory properties, go to: http://blakeley.com/blogofile/2012/03/19/directory-assistance/.

MarkLogic and XQuery

MarkLogic connections can be used in conjunction with XQuery scripts to debug and solve problems with XQuery transformations. XQuery modules can also be validated using a MarkLogic server to allow you to spot possible issues without the need of actually executing the XQuery script.

When debugging XQuery files with MarkLogic (on page 1906), you can use the Data Source Explorer view (on page 1868) to open the files from the application server that is involved in the debugging process. By using the Data Source Explorer view (on page 1868), any imported modules are better identified by the MarkLogic server. You can also use step actions and breakpoints (on page 1908) in the modules to help identify problems.

Modules Container

For each Application server (for example: Bill (HTTP port:8060)), you have access to the XQuery modules that are visible to that server. When editing, executing, or debugging XQuery it is recommended to open the XQuery files from this Modules container.
Note:
You can also manage resources for a MarkLogic database through a WebDAV connection, although it is not recommended if you work with XQuery files since imported modules may not be resolved correctly.

Requests Container

Each MarkLogic application server includes a Requests container. In this container, Oxygen XML Editor displays both queries that are stopped for debugging purposes and queries that are still running. To clean up the entire Requests container at the end of your session, right-click it and use the Cancel all requests action (on page 1910).

Figure 511. MarkLogic Connection in Data Source Explorer

Configuring a MarkLogic Database Connection

Note that this feature is available in Oxygen XML Editor Enterprise edition only.

Follow this procedure to configure the support for a MarkLogic database connection:

1. Download the MarkLogic driver from MarkLogic Community site.
2. Configure MarkLogic Data Source drivers (on page 1904).
3. Configure a MarkLogic Connection (on page 1904).
4. To view your connection, go to the Data Source Explorer view (on page 1868) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 2969).

Related Information:
MarkLogic Development in Oxygen XML Editor (on page 1905)
How to Configure MarkLogic Data Source Drivers

Notes:
- Available in the Enterprise edition only.
- Oxygen XML Editor supports MarkLogic version 4.0 or later.

To configure a data source for MarkLogic, follow this procedure:

2. Unzip the downloaded archive.
3. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Data Sources.
4. Click the + New button in the Data Sources panel.
5. Enter a unique name for the data source.
6. Select MarkLogic from the driver Type drop-down list.
7. Click the Add Files button and select the MarkLogic driver file from the lib folder of the archive that you downloaded and unzipped. The driver file name is `marklogic-xcc-{server_version}.jar`, where `{server_version}` is the MarkLogic server version.
8. Click the OK button to finish the data source configuration.
9. Continue on to [configure your MarkLogic Connection](on page 1904).

How to Configure a MarkLogic Connection

Notes:
- Available in the Enterprise edition only.
- Oxygen XML Editor supports MarkLogic version 4.0 or later.

To configure a connection to a MarkLogic database, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Data Sources.
2. Click the + New button in the Connections panel.
3. Enter a unique name for the connection.
4. Select a previously configured MarkLogic data source from the Data Source drop-down menu.
5. Enter the connection details.
   a. The host name or IP address of the installed MarkLogic engine in the XDBC Host field.
      Oxygen XML Editor uses XCC connector to interact with MarkLogic XDBC server and requires the basic authentication schema to be set. Starting with version MarkLogic 4.0 the default authentication method when you create an HTTP or WebDAV Server is digest, so make sure to change it to basic.
b. Set the port number of the MarkLogic engine in the **Port** field. A MarkLogic XDBC application server must be configured on the server on this port. This XDBC server will be used to process XQuery expressions against the server. Later, if you want to change the XDBC server, instead of editing the configuration just use the **Use it to execute queries** action (on page 1909) from Data Source Explorer.

c. Set the user name to access the MarkLogic engine in the **User** field.

d. Set the password to access the MarkLogic engine in the **Password** field.

e. Optionally, in the **WebDAV URL** field, set the URL used for browsing the MarkLogic database in the **Data Source Explorer** view (on page 1868). The **Database** field specifies the database that will have the XQuery expressions executed. If you set this option to default, the database associated to the application server of the configured port is used.

6. Click the **OK** button to finish the connection configuration.

7. To view your connection, go to the **Data Source Explorer** view (on page 1868) (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database perspective** (on page 2969).

**MarkLogic Development in Oxygen XML Editor**

The Oxygen XML Editor support for MarkLogic includes features designed for developers, such as debugging XQuery transformations, remote and collaborative debugging, XQuery editing and validation, and an **XQuery builder** (on page 974) that helps to improve productivity.

**Working with XQuery Files**

MarkLogic supports working with XQuery files to create queries over stored XML content. You can open an XQuery file, configure a transformation scenario to match your MarkLogic connection, write the XQuery, and then execute it.

When editing XQuery modules stored on the MarkLogic server, the **Outline view** (on page 972) collects and displays all the functions from all imported modules. The **Content Completion Assistant** (on page 2965) also presents all of these functions along with the latest built-in XQuery functions in accordance with the server version.

When developing queries for MarkLogic, it is best to open the resources from the **Data Source Explorer** view (on page 1868). When you execute or debug XQuery files opened from this view, imported modules can be resolved better by the MarkLogic server. Another advantage is that validation is automatically performed on the MarkLogic server, including any imported modules.

**XQuery Debugging**

Oxygen XML Editor allows you to use MarkLogic connections to debug real applications that use XQuery (for example, web applications that trigger XQuery executions). By setting the server in debug mode, you can
intercept all the XQuery scripts that run on that server. Oxygen XML Editor connects to the MarkLogic server, shows you the running XQuery scripts, and allows you to debug them. The remote debugging support also allows you to debug collaboratively. Multiple users can participate in the same debugging session. You can start a debugging session and another user can continue it, and vice versa.

**Working with Modules**

MarkLogic has a concept of two types of XQuery modules, *library* and *main* modules. A *library* module is used to define functions. Library modules cannot be evaluated directly. They are imported, either from other library modules or from main modules. A *main* module is used as an entry point that can be executed as an XQuery program. For more information on these types of modules, see XQuery Library Modules and Main Modules.

When working with *library* modules, you need to create a validation scenario and associate it with the module. In the validation scenario you need to specify a main module as the entry point for validation. The modules need to be deployed on a MarkLogic server because Oxygen XML Editor will request the server to validate the modules.

To validate *library* modules stored on a MarkLogic server, follow these steps:

1. **Configure a MarkLogic database connection** (on page 1903).
2. Expand the MarkLogic connection in the Data Source Explorer view (on page 1868) and open the *library* modules. The *main* module must also be opened from the Data Source Explorer view (on page 1868).
3. **Configure a validation scenario** (on page 741) for each *library* module. Specify the *main* module in the URL of the file to validate field.

   **Result:** Validation is done on the server that contains the *main* module. The *main* module and all other *library* modules involved in the validation must be saved. Otherwise, the server will validate what was saved on the server, without the uncommitted changes. Also, the Content Completion Assistant (on page 2965) and the Outline view (on page 972) should now present the functions from all the modules.

**Related Information:**

- Debugging with MarkLogic (on page 1906)
- Configuring a MarkLogic Database Connection (on page 1903)

**Debugging with MarkLogic**

Oxygen XML Editor includes support for debugging XQuery transformations that are executed against a MarkLogic database.

To use a debugging session against the MarkLogic engine, follow these steps:

1. **Configure a MarkLogic data source** (on page 1904) and a MarkLogic connection (on page 1904).
2. Make sure that the debugging support is enabled in the MarkLogic server that Oxygen XML Editor accesses. On the server side, debugging must be activated in the XDBC server and in the Task Server
section of the server control console (the switch `debug allow`). If the debugging is not activated, the MarkLogic server reports a **DBG-TASKDEBUGALLOW** error.

**Note:**
An XDBC application server must be running to connect to the MarkLogic server and this XDBC server will be used to process XQuery expressions against the server. You can change the XDBC application server that Oxygen XML Editor uses to process XQuery expressions by selecting the **Use it to execute queries** action (on page 1909) from the contextual menu in the **Data Source Explorer** view (on page 1868).

3. Open the XQuery file and start the debugging process.

   • If you want to debug an XQuery file stored on the MarkLogic server, it is recommended to use the **Data Source Explorer** view (on page 1868) and open the file from the application server that is involved in the debugging process. This improves the resolving of any imported modules.

   • The MarkLogic XQuery debugger integrates seamlessly into the **XQuery Debugger perspective** (on page 316). If you have a MarkLogic validation scenario configured for the XQuery file, you can choose to **debug the scenario** (on page 1975) directly.

   • Otherwise, switch to the **XQuery Debugger perspective** (on page 2969), open the XQuery file in the editor, and select the MarkLogic connection in the XQuery engine selector from the **debug control toolbar** (on page 1958).

   For general information about how a debugging session is started and controlled, see the **Working with the Debugger** (on page 1975) section.

In a MarkLogic debugging session, you can use step actions and **breakpoints** (on page 1979) to help identify problems. When you add a breakpoint (on page 1980) on a line where the debugger never stops, Oxygen XML Editor displays a warning message. These warnings are displayed for breakpoints you add either in the main XQuery (which you can open locally or from the server) or for breakpoints you add in any XQuery that is opened from the connection that participates in the debugging session. For more information, see Using Breakpoints for Debugging Queries that Import Modules with MarkLogic (on page 1908).

**Remote Debugging with MarkLogic**

Oxygen XML Editor allows you to debug remote applications that use XQuery (for example, web applications that trigger XQuery executions). Oxygen XML Editor connects to a MarkLogic server, shows you the running XQuery scripts and allows you to debug them. You can even pause the scripts so that you can start the debugging queries in the exact context of the application. You can also switch a server to debug mode to intercept all XQuery scripts.

Oxygen XML Editor also supports collaborative debugging. This feature allows multiple users to participate in the same debugging session. You can start a debugging session and at a certain point, another user can continue it.
**Important:**
When using the remote debugging feature, the HTTP and the XDBC servers involved in the debugging session must have the same module configuration.

For more information about the XQuery debugger for MarkLogic, watch our video demonstration:

https://www.youtube.com/embed/eQ4ThDZq1bk

Related Information:
- MarkLogic Development in Oxygen XML Editor (on page 1905)
- Configuring a MarkLogic Database Connection (on page 1903)

**Using Breakpoints for Debugging Queries that Import Modules with MarkLogic**

When debugging queries that imports modules stored in the database, it is recommended to place breakpoints (on page 1979) in the modules. When starting a new debugging session, make sure that the modules that you will debug are already opened in the editor. This is necessary so that the breakpoints in all the modules will be considered. Also, make sure that there are no other open modules that are not involved in the current debugging session.

To place breakpoints in the modules, use the following procedure:

1. In the Data Source Explorer view (on page 1868), open all the modules from the Modules container of the XDBC application server (on page 1904) that performs the debugging.
2. Set breakpoints (on page 1980) in the module as needed.
3. Continue debugging (on page 1975) the query.

If you get a warning that the breakpoints failed to initialize, try the following solutions:

- Check the Breakpoints view (on page 1962) and make sure there are no older breakpoints (set on resources that are not part of the current debugging context).
- Make sure you open the modules from the context of the application server that does the debugging and place breakpoints there.

Related Information:
- MarkLogic Database Connections (on page 1902)
- MarkLogic Development in Oxygen XML Editor (on page 1905)

**Peculiarities and Limitations of the MarkLogic Debugger**

MarkLogic debugger has the following peculiarities and limitations:
• Debugging support is only available for MarkLogic server versions 4.0 or newer.
• For MarkLogic server versions 4.0 or newer, there are three XQuery syntaxes that are supported: ‘0.9-ml’ (inherited from MarkLogic 3.2), ‘1.0-ml’, and ‘1.0’.
• All declared variables are presented as strings. The Value column of the Variables view contains the expression from the variable declaration. It can be evaluated by copying the expression with the Copy value action from the contextual menu of the Variables view (on page 1973) and pasting it in the XWatch view (on page 1965).
• There is no support for output to source mapping (on page 1976).
• There is no support for showing the trace (on page 1970).
• You can only set breakpoints (on page 1962) in imported modules in one of the following cases:
  ◦ When you open the module from the context of the application server involved in the debugging, using the Data Source Explorer view (on page 1868).
  ◦ When the debugger automatically opens the modules in the Editor.
• No breakpoints (on page 1979) are set in modules from the same server that are not involved in the current debugging session.
• No support for profiling (on page 1980) when an XQuery transformation is executed in the debugger.

MarkLogic Contextual Menu Actions

While browsing MarkLogic connections in the Data Source Explorer view (on page 1868), the various nodes include the following contextual menu actions:

Connection Level Nodes

Configure Database Sources

Opens the Data Sources preferences page (on page 246) where you can configure both data sources and connections.

Disconnect (when connected)

stops the connection.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the Find/Replace in Files dialog box (on page 400) that allows you to find and replace text in multiple files from the connection.

Container Level Nodes

Enable Debug Mode

Switches the server to a debugging mode. For more information, see MarkLogic debugging sessions (on page 1906).

Use it to Execute Queries

The server will be used to process XQuery expressions against it.
**Refresh**
Performs a refresh on the selected node.

**Module or Folder Level Nodes**

**Export**
Allows you to export the folder on the remote connection to a local folder.

**Refresh**
Performs a refresh on the selected node.

**Requests Level Nodes**

**Refresh**
Performs a refresh on the selected node.

**Cancel all requests**
Cancels all queries that are either running or stopped on the application server. You can use this action to clean up the entire Requests container at the end of your sessions.

**Resource Level Nodes**

**Open**
Opens the selected resource in the editor.

**Open in System Application**
When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the Data Source Explorer view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

**Copy location**
Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

**Refresh**
Performs a refresh on the selected node.

**Compare**
Compares two selected resources using the Compare Files tool (on page 437).
MySQL Database Connections

Oxygen XML Editor includes support for MySQL database connections. Oxygen XML Editor allows you to browse the structure of a SQL Server database in the Data Source Explorer view (on page 1868), open tables in the Table Explorer view (on page 1870), and perform various operations on the resources in the repository.

Configuring a MySQL Database Connection

To configure the support for a MySQL database, follow this procedure:

1. Configure MySQL Data Source drivers (on page 1911).
2. Configure a MySQL Connection. (on page 1912)
3. To view your connection, go to the Data Source Explorer view (on page 1868) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 2969).

How to Configure MySQL Data Source Drivers

To connect to a MySQL server, you need to create a generic JDBC type data source based on the MySQL JDBC driver available on the MySQL website.

To configure this data source, follow these steps:

1. Go to https://www.oxygenxml.com/database_drivers.html and download the appropriate MySQL driver.
2. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Data Sources.
3. Click the **New** button in the Data Sources panel.

   The dialog box for configuring a data source is opened.
4. Enter a unique name for the data source.
5. Select *Generic JDBC* in the driver **Type** drop-down list.
6. Click the **Add Files** button and select the MySQL driver file that you downloaded.
   The driver file for the MySQL server is called `mysql-com.jar`.
7. Select the most appropriate **Driver class**.
8. Click the **OK** button to finish the data source configuration.
9. Continue on to configure your MySQL connection *(on page 1912)*.

### How to Configure a MySQL Connection

To configure a connection to a MySQL server, follow these steps:

1. Open the **Preferences** dialog box *(Options > Preferences)* *(on page 98)* and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.
   The dialog box for configuring a database connection is displayed.
3. Enter a unique name for the connection.
4. Select the MySQL data source in the Data Source drop-down list.
5. Enter the connection details.
   a. Enter the URL of the MySQL server.
   b. Enter the user name for the connection to the MySQL server.
   c. Enter the password for the connection to the MySQL server.
6. Click the OK button to finish the connection configuration.
7. To view your connection, go to the Data Source Explorer view (on page 1868) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 2969).

**Generic JDBC Database Connections**

Oxygen XML Editor includes support for Generic JDBC database connections.

**Configuring a Generic JDBC Database Connection**

To configure the support for a generic JDBC database, follow this procedure:

1. Configure Generic JDBC Data Source drivers (on page 1914).
2. Configure a Generic JDBC Connection (on page 1914).
3. To view your connection, go to the Data Source Explorer view (on page 1868) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 2969).
How to Configure Generic JDBC Data Source Drivers

Starting with version 17, Oxygen XML Editor comes bundled with Java 8, which does not provide built-in access to JDBC-ODBC data sources. To access such sources, you need to find an alternative JDBC-ODBC bridge or use a platform-independent distribution of Oxygen XML Editor along with a Java VM version 7 or 6.

To configure a generic JDBC data source, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Data Sources.
2. Click the + New button in the Data Sources panel.
3. Enter a unique name for the data source.
4. Select Generic JDBC in the driver Type drop-down list.
5. Add the driver file(s) using the Add Files button.
6. Select the most appropriate Driver class.
7. Click the OK button to finish the data source configuration.
8. Continue on to configure a generic JDBC connection (on page 1914).

How to Configure a Generic JDBC Connection

To configure a connection to a generic JDBC database, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Data Sources.
2. Click the + New button in the Connections panel.
3. Enter a unique name for the connection.
4. Select the Generic JDBC data source in the Data Source drop-down menu.
5. Enter the connection details.
   a. Enter the URL of the generic JDBC database, with the following format: `jdbc: <subprotocol>:<dbname>`.
   b. Enter the user name for the connection to the generic JDBC database.
   c. Enter the password for the connection to the generic JDBC database.
6. Click the OK button to finish the connection configuration.
7. To view your connection, go to the Data Source Explorer view (on page 1868) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 2969).

JDBC-ODBC Database Connections

Oxygen XML Editor includes support for JDBC-ODBC database connections.

How to Configure a JDBC-ODBC Connection

Starting with version 17, Oxygen XML Editor comes bundled with Java 8, which does not provide built-in access to JDBC-ODBC data sources. To access such sources, you need to find an alternative JDBC-ODBC bridge or use a platform-independent distribution of Oxygen XML Editor along with a Java VM version 7 or 6.

To configure a connection to an ODBC data source, follow these steps:
1. Open the **Preferences** dialog box *(Options > Preferences)* *(on page 98)* and go to **Data Sources**.

2. Click the **New** button in the **Connections** panel.

   The dialog box for configuring a database connection is displayed.

   ![Connection Configuration Dialog Box](image)

   **Figure 514. Connection Configuration Dialog Box**

3. Enter a unique name for the connection.

4. Select **JDBC-ODBC Bridge** in the **Data Source** drop-down list.

5. Enter the connection details.
   a. Enter the URL of the ODBC source.
   b. Enter the user name of the ODBC source.
   c. Enter the password of the ODBC source.

6. Click the **OK** button to finish the connection configuration.

7. To view your connection, go to the **Data Source Explorer view** *(on page 1868)* (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database perspective** *(on page 2969)*.

---

**BaseX Database Connections**

Oxygen XML Editor includes support for BaseX database connections using a WebDAV connection. BaseX is a light-weight XML database engine and XQuery processor. Oxygen XML Editor allows you to browse the structure of a BaseX database in the **Data Source Explorer view** *(on page 1868)* and perform XQuery executions.
How to Configure a BaseX Connection

To configure a BaseX connection, follow these steps:

1. First of all, make sure the BaseX HTTP Server is started. For details about starting the BaseX HTTP server, go to http://docs.basex.org/wiki/Startup#BaseX_HTTP_Server. The configuration file for the HTTP server is named .basex and is located in the BaseX installation directory. This file helps you to find out which port the HTTP server using. The default port for BaseX WebDAV is 8984.

2. To ensure that everything is functioning, open a WebDAV URL inside a browser and check to see if it works. For example, the following URL retrieves a document from a database named TEST: http://localhost:8984/webdav/TEST/etc/factbook.xml.

3. Once you are sure that the BaseX WebDAV service is working, you can configure the WebDAV connection in Oxygen XML Editor as described in How to Configure a WebDAV Connection (on page 1920). The WebDAV URL should resemble this: http://{hostname}:{port}/webdav/. If the BaseX server is running on your own machine and it has the default configuration, the data required by the WebDAV connection is:

   - **WebDAV URL:** http://localhost:8984/webdav
   - **User:** admin
   - **Password:** admin

4. Once the WebDAV connection is created, to view your connection, go to the Data Source Explorer view (on page 1868) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 2969).

BaseX Contextual Menu Actions

While browsing BaseX connections in the Data Source Explorer view (on page 1868), the various nodes include the following contextual menu actions:

- **Connection Level Nodes**

  - **Configure Database Sources**
    
    Opens the Data Sources preferences page (on page 246) where you can configure both data sources and connections.

  - **Disconnect (when connected)**
    
    Stops the connection.

  - **New Folder**
    
    Creates a new folder on the connection.

  - **Import Files**
    
    Allows you to add a new file on the connection, in the current folder.

  - **Refresh**
    
    Performs a refresh on the selected node.
Find/Replace in Files

Opens the **Find/Replace in Files** dialog box *(on page 400)* that allows you to find and replace text in multiple files from the connection.

Folder Level Nodes

New File or New Document

Creates a new file on the connection, in the current folder.

New Folder

Creates a new folder on the connection.

Import Folders

Imports folders on the server.

Import Files

Allows you to add a new file on the connection, in the current folder.

Export

Allows you to export the folder on the remote connection to a local folder.

Cut

Removes the current selection and places it in the clipboard.

Copy

Copies the current selection into the clipboard.

Paste

Pastes the copied selection.

Rename

Renames the current resource.

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the **Find/Replace in Files** dialog box *(on page 400)* that allows you to find and replace text in multiple files from the connection.

Resource Level Nodes

Open

Opens the selected resource in the editor.
Open in System Application

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the Data Source Explorer view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

Cut

Removes the current selection and places it in the clipboard.

Copy

Copies the current selection into the clipboard.

Copy location

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Rename

Renames the current resource

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the Find/Replace in Files dialog box (on page 400) that allows you to find and replace text in multiple files from the connection.

Compare

Compares two selected resources using the Compare Files tool (on page 437).

Base X XQJ Connection

XQuery execution is possible in a BaseX connection through an XQJ connection.

Important:
The XQJ connector is only capable of running XQuery 1.0 scripts, therefore XQuery 3.0 and 3.1 scripts are not supported.
**BaseX XQJ Data Source**

First of all, create an XQJ data source as described in How to Configure an XQJ Data Source (on page 1919). The BaseX XQJ API-specific files that must be added in the configuration dialog box are `xqj-api-1.0.jar`, `xqj2-0.1.0.jar` and `basex-xqj-1.2.3.jar` (the version names of the JAR file may differ). These libraries can be downloaded from `xqj.net/basex/basex-xqj-1.2.3.zip`. As an alternative, you can also find the libraries in the BaseX installation directory, in the `lib` sub-directory.

**BaseX XQJ Connection**

The next step is to create an XQJ connection (on page 1920).

For a default BaseX configuration, the following connection details apply (you can modify them when necessary):

- **Port**: 1984
- **serverName**: localhost
- **user**: admin
- **password**: admin

**XQuery Execution**

Now that the XQJ connection is configured, open the XQuery file you want to execute in Oxygen XML Editor and create an XQuery Transformation (on page 1431). In the Transformer drop-down menu, select the name of the XQJ connection you created. Apply the transformation scenario and the XQuery will be executed.

**How to Configure an XQJ Data Source**

Any transformer that offers an XQJ API implementation can be used when validating XQuery or transforming XML documents. An example of an XQuery engine that implements the XQJ API is Zorba.

1. If your XQJ Implementation is native, make sure the directory containing the native libraries of the engine is added to your system environment variables: to **PATH** - on Windows, to **LD_LIBRARY_PATH** - on Linux, or to **DYLD_LIBRARY_PATH** - on OS X. Restart Oxygen XML Editor after configuring the environment variables.
2. **Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Data Sources.**
3. Click the **New** button in the Data Sources panel.
4. Enter a unique name for the data source.
5. Select **XQuery API for Java (XQJ)** in the Type combo box.
6. Click the **Add** button to add XQJ API-specific files.
   - You can manage the driver files using the **Add**, **Remove**, **Detect**, and **Stop** buttons.
   - Oxygen XML Editor detects any implementation of `javax.xml.xquery.XQDataSource` and presents it in Driver class field.
7. Select the most suited driver in the **Driver class** combo box.
8. Click the **OK** button to finish the data source configuration.
9. Continue on to configure the XQJ connection (on page 1920).
How to Configure an XQJ Connection

The steps for configuring an XQJ connection are the following:

1. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Data Sources.
2. Click the + New button in the Connections panel.
3. Enter a unique name for the connection.
4. Select one of the previously configured XQJ data sources (on page 1919) in the Data Source combo box.
5. Fill-in the connection details.
   The properties presented in the connection details table are automatically detected depending on the selected data source.
6. Click the OK button to finish the connection configuration.

WebDAV Connections

Oxygen XML Editor includes support for WebDAV server connections. Oxygen XML Editor allows you to browse the structure of a WebDAV connection in the Data Source Explorer view (on page 1868) and perform various operations on the resources in the repository.

How to Configure a WebDAV Connection

By default, Oxygen XML Editor contains built-in data source drivers for WebDAV connections. Based on this data source, you can create a WebDAV connection for browsing and editing data from a database that provides a WebDAV interface. The connection is available in the Data Source Explorer view (on page 1868).

To configure a WebDAV connection, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Data Sources.
2. Click the + New button in the Connections panel.
3. Enter a unique name for the connection.
4. Select one of the WebDAV data sources in the Data Source drop-down menu.
5. Enter the connection details:
   a. Set the URL to the WebDAV repository in the field WebDAV URL.
   b. Set the user name that is used to access the WebDAV repository in the User field.
   c. Set the password that is used to access the WebDAV repository in the Password field.
6. Click the OK button to finish the connection configuration.
7. To view your connection, go to the Data Source Explorer view (on page 1868) (if the view is not displayed, it can be opened by selecting it from the Window > Show View menu) or switch to the Database perspective (on page 2969).
   For more information about the WebDAV support in Oxygen XML Editor, watch our video demonstration:

   https://www.youtube.com/embed/vDXO36CqbvM
WebDAV Contextual Menu Actions

While browsing WebDAV connections in the Data Source Explorer view (on page 1868), the various nodes include the following contextual menu actions:

Connection Level Nodes

Configure Database Sources

Opens the Data Sources preferences page (on page 246) where you can configure both data sources and connections.

Disconnect (when connected)

Stops the connection.

New Folder

Creates a new folder on the connection.

Import Files

Allows you to add a new file on the connection, in the current folder.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the Find/Replace in Files dialog box (on page 400) that allows you to find and replace text in multiple files from the connection.

Folder Level Nodes

New File or New Document

Creates a new file on the connection, in the current folder.

New Folder

Creates a new folder on the connection.

Import Folders

Imports folders on the server.

Import Files

Allows you to add a new file on the connection, in the current folder.

Export

Allows you to export the folder on the remote connection to a local folder.

Cut

Removes the current selection and places it in the clipboard.

Copy

Copies the current selection into the clipboard.
Paste
Pastes the copied selection.

Rename
Renames the current resource

Delete
Deletes the current container.

Refresh
Performs a refresh on the selected node.

Find/Replace in Files
Opens the Find/Replace in Files dialog box (on page 400) that allows you to find and replace text in multiple files from the connection.

Resource Level Nodes
Open
Opens the selected resource in the editor.

Open in System Application
When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the Data Source Explorer view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

Cut
Removes the current selection and places it in the clipboard.

Copy
Copies the current selection into the clipboard.

Copy location
Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Rename
Renames the current resource

Delete
Deletes the current container.

Refresh
Performs a refresh on the selected node.

Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the Find/Replace in Files dialog box (on page 400) that allows you to find and replace text in multiple files from the connection.

Compare

Compares two selected resources using the Compare Files tool (on page 437).

SQL Execution Support

The database support in Oxygen XML Editor includes support for writing SQL statements, syntax highlighting, folding (on page 2966), and dragging and dropping from the Data Source Explorer view (on page 1868). It also includes transformation scenarios for executing the statements, and the results are displayed in the Table Explorer view (on page 1870).

Drag and Drop from Data Source Explorer View

Dragging operations from the Data Source Explorer view (on page 1868) and dropping them in the SQL Editor allows you to create SQL statements quickly by inserting the names of tables and columns in the SQL statements.

1. Configure a database connection (see the specific procedure for your database server in the Database Connection Support (on page 1872) section).
2. Browse to the table you will use in your statement.
3. Drag the table or a column of the table into the editor where a SQL file is open.

Drag and drop actions are available both on the table and on its fields. A pop-up menu is displayed in the SQL editor.
4. Select the type of statement from the pop-up menu.

Depending on your choice, dragging a table results in one of the following statements being inserted into the document:

- **SELECT `field1`, `field2`, ..., FROM `catalog`.`table`** (for example: `SELECT `DEPT`, `DEPTNAME`, `LOCATION` FROM `camera`.`cameraDesc`)
- **UPDATE `catalog`.`table` SET `field1` = `field2` = ...,** (for example: `UPDATE `camera`.`cameraDesc` SET `DEPT` = `DEPTNAME` = `LOCATION` = )
- **INSERT INTO `catalog`.`table` (`field1`, `field2`, ...) VALUES (, ,)** (for example: `INSERT INTO `camera`.`cameraDesc` (`DEPT`, `DEPTNAME`, `LOCATION`) VALUES (, , )`)
- **DELETE FROM `catalog`.`table`** (for example: `DELETE FROM `camera`.`cameraDesc`)

Depending on your choice, dragging a column results in one of the following statements being inserted into the document:

- **SELECT `field` FROM `catalog`.`table`** (for example: `SELECT `DEPT` FROM `camera`.`cameraDesc`)
- **UPDATE `catalog`.`table` SET `field` =** (for example: `UPDATE `camera`.`cameraDesc` SET `DEPT` = )
• INSERT INTO `catalog` . `table` ( `field1`) VALUES () (for example: 
`camera` . `cameraDesc` ( `DEPT`) VALUES ( )
• DELETE FROM `catalog` . `table` (for example: 
`camera` . `cameraDesc` WHERE 
`DEPT=`

SQL Validation

SQL validation support is offered for IBM DB2. Note that if you choose a connection that does not support SQL validation, you will receive a warning when trying to validate. The SQL document is validated using the connection from the associated transformation scenario.

Executing SQL Statements

The steps for executing an SQL statement on a relational database are as follows:

1. Configure a transformation scenario (on page 1330) using the Configure Transformation Scenario(s) action from the toolbar or the Document > Transformation menu.
   A SQL transformation scenario needs a database connection. You can configure a connection using the Preferences button from the SQL transformation dialog box.
   The dialog box contains the list of existing scenarios that apply to SQL documents.
2. Set parameter values for SQL placeholders using the Parameters button from the SQL transformation dialog box.
   For example, in SELECT * FROM `test` . `department` where DEPT = ? or DEPTNAME = ? the two parameters can be configured for the place holders (?) in the transformation scenario.
   When the SQL statement is executed, the first placeholder is replaced with the value set for the first parameter in the scenario, the second placeholder is replaced by the second parameter value, and so on.

   Restriction:
   When a stored procedure is called in an SQL statement executed on an SQL Server database, mixing inline parameter values with values specified using the Parameters button of the scenario dialog box is not recommended. This is due to a limitation of the SQL Server driver for Java applications. An example of stored procedure that is not recommended: call dbo.Test(22, ?).

3. Execute the SQL scenario by clicking the OK or Apply associated button.
   The result of a SQL transformation is displayed in a view (on page 508) at the bottom of the Oxygen XML Editor window.
4. View more complex return values of the SQL transformation in a separate editor panel.
   A more complex value returned by the SQL query (for example, an XMLTYPE or CLOB value) cannot be displayed entirely in the result table.
   a. Right-click the cell containing the complex value.
   b. Select the action Copy cell from the contextual menu.
The action copies the value in the clipboard.

c. Paste the value into an appropriate editor.
   For example, you can paste the value in an opened XQuery editor panel of Oxygen XML Editor.

XQuery and Databases

XQuery is a native XML query language that is useful for querying XML views of relational data to create XML results. It also provides the mechanism to efficiently and easily extract information from Native XML Databases (NXD) and relational data. The following database systems supported in Oxygen XML Editor offer XQuery support:

- **Native XML Databases:**
  - Berkeley DB XML
  - eXist
  - MarkLogic (validation support available starting with version 5)

- **Relational Databases:**
  - IBM DB2
  - Microsoft SQL Server (validation support not available)
  - Oracle (validation support not available)

Related Information:

[Editing XQuery Documents](on page 968)

Build Queries with Drag and Drop from the Data Source Explorer View

When a query is edited in the XQuery editor, the XPath expressions can be composed quickly by dragging them from the Data Source Explorer view ([on page 1868](on page 1868)) and dropping them into the editor panel.

1. Configure the data source drivers ([on page 1872](on page 1872)) for the particular relational database in the Data Sources preferences page ([on page 246](on page 246)).
2. Configure the connection ([on page 1872](on page 1872)) for the particular relational database in the Data Sources preferences page ([on page 246](on page 246)).
3. Browse the connection in the Data Source Explorer view ([on page 1868](on page 1868)), expanded to the table or column that you want to insert in the query.
4. Drag the table or column name to the XQuery editor panel.
5. Drop the table or column name where the XPath expression is needed.

An XPath expression that selects the dragged name is inserted in the XQuery document at the cursor position.
XQuery Validation When Connected to a Database

With Oxygen XML Editor, you can validate your XQuery documents when connected to a database. When you open an XQuery document from a connection that supports validation (for example, MarkLogic, or eXist), by default Oxygen XML Editor uses this connection for validation. If you open an XQuery file using a MarkLogic connection, the validation resolves imports better.

Related Information:
XQuery Validation (on page 969)

XQuery Transformation for Databases

XQuery is designed to retrieve and interpret XML data from any source, whether it is a database or document. Data is stored in relational databases but it is often required that the data be extracted and transformed as XML when interfacing to other components and services. Also, it is an XPath-based querying language supported by most NXD vendors. To perform a query, you need an XQuery transformation scenario.

1. Configure the data source drivers and the connection (on page 1872) for the particular database.
2. Configure an XQuery transformation scenario.
   a. Click the Configure Transformation Scenario toolbar button or go to menu Document > Transformation > Configure Transformation Scenario.
      The Configure Transformation Scenario dialog box (on page 1443) is opened.
   b. Click the New button toward the bottom of the dialog box.
   c. Select XML Transformation with XQUERY (on page 1377).
      The New Scenario dialog box for configuring an XQuery scenario is opened.
d. Insert the scenario name in the dialog box for editing the scenario.

e. Choose the database connection in the Transformer drop-down list.

f. Configure any other parameters as needed.

   For an XQuery transformation, the output tab has an option called Sequence that allows you to run an XQuery in lazy mode. The amount of data extracted from the database is controlled from the Size limit on Sequence view option (on page 224) in the XQuery preferences page. If you choose Perform FO Processing in the FO Processor tab, the Sequence option is ignored.

g. Click the OK button to finish editing the scenario.

Once the scenario is associated with the XQuery file, the query can include calls to specific XQuery functions that are implemented by that engine. The available functions depend on the target database engine selected in the scenario. For example, for eXist and Berkeley DB XML, the Content Completion Assistant (on page 2965) lists the functions supported by that database engine. This is useful for only inserting calls to the supported functions (standard XQuery functions or extension ones) into the query.
3. Run the transformation scenario.

To view a more complex value returned by the query that cannot be entirely displayed in the XQuery query result table at the bottom of the Oxygen XML Editor window (for example, an XMLTYPE or CLOB value), do the following:

- Right-click that table cell.
- Select the **Copy cell** action from the contextual menu to copy the value into the clipboard.
- Paste the value wherever you need it (for example, in an open XQuery editor panel of Oxygen XML Editor).

**Related Information:**

- XML Transformation with XQuery (on page 1377)
- XQuery XQJ Transformation (on page 1929)

---

**XQuery XQJ Transformation**

XQuery API for Java (XQJ) refers to the common Java API for the XQuery 1.0 specification. The XQJ API enables you to execute XQuery against an XML data source.

**Important:**

The XQJ connector is only capable of running XQuery 1.0 scrips, therefore XQuery 3.0 and 3.1 scripts are not supported.

Oxygen XML Editor supports any transformer that offers an XQJ API implementation and it be used for validating XQuery or transforming XML documents.

To configure the support for XQJ, do the following:

1. **Configure an XQJ Data Source (on page 1919).**
2. **Configure an XQJ Connection (on page 1920).**
3. To view your connection, go to the **Data Source Explorer view (on page 1868)** (if the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu) or switch to the **Database perspective (on page 2969).**

**How to Configure an XQJ Data Source**

Any transformer that offers an XQJ API implementation can be used when validating XQuery or transforming XML documents. An example of an XQuery engine that implements the XQJ API is **Zorba.**
1. If your XQJ Implementation is native, make sure the directory containing the native libraries of the engine is added to your system environment variables: to `PATH` - on Windows, to `LD_LIBRARY_PATH` - on Linux, or to `DYLD_LIBRARY_PATH` - on OS X. Restart Oxygen XML Editor after configuring the environment variables.

2. **Open the Preferences dialog box** (*Options > Preferences*) *(on page 98)* and go to Data Sources.

3. Click the **New** button in the Data Sources panel.

4. Enter a unique name for the data source.

5. Select **XQuery API for Java (XQJ)** in the Type combo box.

6. Click the **Add** button to add XQJ API-specific files.
   - You can manage the driver files using the Add, Remove, Detect, and Stop buttons.
   - Oxygen XML Editor detects any implementation of `javax.xml.xquery.XQDataSource` and presents it in Driver class field.

7. Select the most suited driver in the Driver class combo box.

8. Click the **OK** button to finish the data source configuration.

9. Continue on to **configure the XQJ connection** *(on page 1920)*.

### How to Configure an XQJ Connection

The steps for configuring an XQJ connection are the following:

1. **Open the Preferences dialog box** (*Options > Preferences*) *(on page 98)* and go to Data Sources.

2. Click the **New** button in the Connections panel.

3. Enter a unique name for the connection.

4. Select one of the previously configured **XQJ data sources** *(on page 1919)* in the Data Source combo box.

5. Fill-in the connection details.
   - The properties presented in the connection details table are automatically detected depending on the selected data source.

6. Click the **OK** button to finish the connection configuration.

### XQuery Database Debugging

Oxygen XML Editor includes a debugging interface that helps you to detect and solve problems with XQuery transformations that are executed against MarkLogic and Berkeley DB XML databases.

For more information about the debugging support in Oxygen XML Editor, see **Debugging XSLT Stylesheets and XQuery Documents** *(on page 1956)*.

### Debugging with MarkLogic

Oxygen XML Editor includes support for debugging XQuery transformations that are executed against a MarkLogic database.

To use a debugging session against the MarkLogic engine, follow these steps:
1. Configure a MarkLogic data source (on page 1904) and a MarkLogic connection (on page 1904).

2. Make sure that the debugging support is enabled in the MarkLogic server that Oxygen XML Editor accesses. On the server side, debugging must be activated in the XDBC server and in the Task Server section of the server control console (the switch `debug allow`). If the debugging is not activated, the MarkLogic server reports a DBG-TASKDEBUGALLOW error.

   **Note:**
   An XDBC application server must be running to connect to the MarkLogic server and this XDBC server will be used to process XQuery expressions against the server. You can change the XDBC application server that Oxygen XML Editor uses to process XQuery expressions by selecting the Use it to execute queries action (on page 1909) from the contextual menu in the Data Source Explorer view (on page 1868).

3. Open the XQuery file and start the debugging process.
   - If you want to debug an XQuery file stored on the MarkLogic server, it is recommended to use the Data Source Explorer view (on page 1868) and open the file from the application server that is involved in the debugging process. This improves the resolving of any imported modules.
   - The MarkLogic XQuery debugger integrates seamlessly into the XQuery Debugger perspective (on page 316). If you have a MarkLogic validation scenario configured for the XQuery file, you can choose to debug the scenario (on page 1975) directly.
   - Otherwise, switch to the XQuery Debugger perspective (on page 2969), open the XQuery file in the editor, and select the MarkLogic connection in the XQuery engine selector from the debug control toolbar (on page 1958).

   For general information about how a debugging session is started and controlled, see the Working with the Debugger (on page 1975) section.

In a MarkLogic debugging session, you can use step actions and breakpoints (on page 1979) to help identify problems. When you add a breakpoint (on page 1980) on a line where the debugger never stops, Oxygen XML Editor displays a warning message. These warnings are displayed for breakpoints you add either in the main XQuery (which you can open locally or from the server) or for breakpoints you add in any XQuery that is opened from the connection that participates in the debugging session. For more information, see Using Breakpoints for Debugging Queries that Import Modules with MarkLogic (on page 1908).

**Remote Debugging with MarkLogic**

Oxygen XML Editor allows you to debug remote applications that use XQuery (for example, web applications that trigger XQuery executions). Oxygen XML Editor connects to a MarkLogic server, shows you the running XQuery scripts and allows you to debug them. You can even pause the scripts so that you can start the debugging queries in the exact context of the application. You can also switch a server to debug mode to intercept all XQuery scripts.

Oxygen XML Editor also supports collaborative debugging. This feature allows multiple users to participate in the same debugging session. You can start a debugging session and at a certain point, another user can continue it.
Important:
When using the remote debugging feature, the HTTP and the XDBC servers involved in the debugging session must have the same module configuration.

For more information about the XQuery debugger for MarkLogic, watch our video demonstration:

https://www.youtube.com/embed/eQ4ThDZq1bk

MarkLogic Development in Oxygen XML Editor (on page 1905)
Configuring a MarkLogic Database Connection (on page 1903)

Using Breakpoints for Debugging Queries that Import Modules with MarkLogic

When debugging queries that imports modules stored in the database, it is recommended to place breakpoints (on page 1979) in the modules. When starting a new debugging session, make sure that the modules that you will debug are already opened in the editor. This is necessary so that the breakpoints in all the modules will be considered. Also, make sure that there are no other open modules that are not involved in the current debugging session.

To place breakpoints in the modules, use the following procedure:

1. In the Data Source Explorer view (on page 1868), open all the modules from the Modules container of the XDBC application server (on page 1904) that performs the debugging.
2. Set breakpoints (on page 1980) in the module as needed.
3. Continue debugging (on page 1975) the query.

If you get a warning that the breakpoints failed to initialize, try the following solutions:

- Check the Breakpoints view (on page 1962) and make sure there are no older breakpoints (set on resources that are not part of the current debugging context).
- Make sure you open the modules from the context of the application server that does the debugging and place breakpoints there.

Related Information:
MarkLogic Database Connections (on page 1902)
MarkLogic Development in Oxygen XML Editor (on page 1905)

Peculiarities and Limitations of the MarkLogic Debugger

MarkLogic debugger has the following peculiarities and limitations:
• Debugging support is only available for MarkLogic server versions 4.0 or newer.
• For MarkLogic server versions 4.0 or newer, there are three XQuery syntaxes that are supported: '0.9-ml' (inherited from MarkLogic 3.2), '1.0-ml', and '1.0'.
• All declared variables are presented as strings. The Value column of the Variables view contains the expression from the variable declaration. It can be evaluated by copying the expression with the Copy value action from the contextual menu of the Variables view (on page 1973) and pasting it in the XWatch view (on page 1965).
• There is no support for output to source mapping (on page 1976).
• There is no support for showing the trace (on page 1970).
• You can only set breakpoints (on page 1962) in imported modules in one of the following cases:
  ◦ When you open the module from the context of the application server involved in the debugging, using the Data Source Explorer view (on page 1868).
  ◦ When the debugger automatically opens the modules in the Editor.
• No breakpoints (on page 1979) are set in modules from the same server that are not involved in the current debugging session.
• No support for profiling (on page 1980) when an XQuery transformation is executed in the debugger.

Debugging with Berkeley DB XML

The Berkeley DB XML database added a debugging interface starting with version 2.5. The current version is supported in the Oxygen XML Editor XQuery Debugger. The same restrictions and peculiarities (on page 1908) apply for the Berkeley debugger as for the MarkLogic debugger.

Integration with Microsoft SharePoint

Restriction:
The SharePoint integration is only available in the Enterprise edition of Oxygen XML Editor.

Oxygen XML Editor provides support for browsing and managing SharePoint connections in the Data Source Explorer view (on page 1868) and there is also a specialized SharePoint Browser view (on page 1935). You can easily create new resources on the repository, copy and move them using contextual actions or the drag and drop support, or edit and transform the documents in the editor.

There are two types of integrations that are possible:

• SharePoint Online - A new implementation that uses the SharePoint REST API v.2 and it supports OAuth credentials (access tokens). If you need authentication, you must use this type of integration.
• SharePoint - The older implementation that was implemented using SharePoint Web Services (now deprecated) and it does NOT support OAuth credentials (access tokens).
Related Information:
Working with Databases (on page 1868)

How to Configure a SharePoint Connection

By default, Oxygen XML Editor contains built-in data source drivers for SharePoint. Use this data source to create a connection to a SharePoint server that will be available in the Data Source Explorer view or SharePoint Browser view (on page 1935).

There are two types of possible SharePoint connections:

- **SharePoint Online** - A new implementation that uses the SharePoint REST API v.2 and it supports OAuth credentials (access tokens). If you need authentication, you must use this type of integration.
- **SharePoint** - The older implementation that was implemented using SharePoint Web Services (now deprecated) and it does NOT support OAuth credentials (access tokens).

**SharePoint Online Connection**

To configure a SharePoint connection, follow these steps:

1. Open the **Connection** dialog box using one of these methods:
   - Select **New SharePoint Online Connection** from the **Settings** drop-down menu in the SharePoint Browser view (or using the quick action (on page 1935)).
   - Open the **Preferences** dialog box (**Options > Preferences**) (on page 98), go to **Data Sources**. Select **SharePoint Online** in the **Data Sources** pane and in the **Connections** pane, click the **New** button.
2. Enter a unique name for the connection.
3. Make sure **SharePoint Online** is selected in the **Data Source** combo box.
4. Enter the **Tenant URL** for your SharePoint repository and click **OK**.
In the **SharePoint Browser view** *(on page 1935)*, you can select your connection using the **Site** drop-down menu. Then select **Log in with Microsoft account** from the left pane (or user drop-down menu on the right side of the view) to open Microsoft’s log in page in your default browser. Once authenticated, your repository content should be displayed in the view.

**Note:**

If you are still logged in when you close Oxygen XML Editor, the authentication persists the next time the application is started. If, for some reason, the authentication fails to recover the access token, an error is displayed in the **Results** pane at the bottom of the application. If this happens, you need to re-authenticate Oxygen XML Editor by using the **Log in with Microsoft account** action.

**SharePoint Connection (Older Version)**

To configure a SharePoint connection, follow these steps:

1. Open the **Connection** dialog box using one of these methods:
   - Select **New SharePoint Connection** from the **Settings** drop-down menu in the **SharePoint Browser** view (or using the quick action *(on page 1935)*).
   - Open the **Preferences** dialog box (**Options > Preferences**) *(on page 98)*, go to **Data Sources**. Select **SharePoint** in the **Data Sources** pane and in the **Connections** pane, click the **New** button.

2. Enter a unique name for the connection.

3. Make sure **SharePoint** is selected in the **Data Source** combo box.

4. Fill-in the connection details:
   - a. Enter the **SharePoint URL** for your SharePoint repository.
   - b. Set the server domain in the **Domain** field. If you are using a SharePoint 365 account, leave this field empty.
   - c. Set the user name to access the SharePoint repository in the **User** field.
   - d. Set the password to access the SharePoint repository in the **Password** field.

5. Click **OK**.

**SharePoint Browser View**

The **SharePoint Browser** view allows you to connect to a SharePoint repository and perform SharePoint-specific actions on the available resources. To display this view, go to **Window > Show View > SharePoint Browser**.

**Getting Started**

When you first open the view, it includes some quick actions to help you **get connected to your SharePoint repository** *(on page 1934)* (these actions are also available in the **Settings** drop-down menu).
The SharePoint Browser View Interface

The header stripe of the SharePoint Browser view includes:

**Site drop-down menu**

Use this drop-down to select and connect to an already defined SharePoint connection (on page 1934).

**User drop-down menu**

This drop-down includes

- **Log in with Microsoft account** (if logged out) - Opens the Microsoft login page in your default browser and authenticates Oxygen XML Editor.
- **Log out** (if logged in) - Logs out of your Microsoft account and the authorization between Oxygen XML Editor and Microsoft is revoked.
- **Help** - Opens the online user guide to a topic relevant to the current context.

**Settings drop-down menu**

This drop-down includes

- **New SharePoint Online Connection** - Opens the Connection dialog box with the SharePoint Online data source automatically selected.
- **New SharePoint Connection** - Opens the Connection dialog box with the SharePoint (older version) data source automatically selected.
- **Configure Database Sources** - Opens the Database Sources preferences page where you can configure your SharePoint connection.
- **Layout** - Use this option to choose the layout for the view. You can choose between: Automatic, Vertical, and Horizontal.

Once you are connected, the view is separated into two panes. The left pane is a navigation area that presents the SharePoint site structure in a tree-like fashion with the following node types:
When a folder node is selected in the left pane, the right pane displays the contents of the folder (either folders or files).

You can filter and sort the displayed items. To display the available filters of a column, click the filter widget located on the column header. You can apply multiple filters at the same time.

**Figure 519. Column Filter**

### Checking Documents In and Out

To check out a document from the server, right-click the file and select **Check Out**. You can discard the previous checkout operation, making the file available for editing to other users, by selecting **Discard Check Out**.

To check in a document that has been checked out, right-click the file and select **Check In**. For SharePoint Online connections, you only have the option to enter a comment and click the **Check In** button to process it. For SharePoint (older version), you can also choose the check in type (**Minor Version**, **Major Version**, or **Overwrite**).

**Related Information:**

- How to Configure a SharePoint Connection *(on page 1934)*

### SharePoint Contextual Menu Actions

While browsing SharePoint connections in the **Data Source Explorer view** *(on page 1868)* or the **SharePoint Browser view** *(on page 1935)*, the following contextual menu actions are available, depending on the type of node:

- **Connection Nodes** *(Data Source Explorer view only)*
  - **Configure Database Sources**
    
    Opens the **Data Sources preferences page** *(on page 246)* where you can configure both data sources and connections.

- **Log in with Microsoft Account** *(when not connected)*
Opens the Microsoft login page in your default browser and authenticates Oxygen XML Editor.

**Disconnect (when connected)**

Stops the connection.

**Refresh**

Performs a refresh on the selected node.

**Find/Replace in Files**

Opens the Find/Replace in Files dialog box (on page 400) that allows you to find and replace text in multiple files from the connection.

**Site Nodes / Sub-site Nodes**

**Copy location**

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

**Refresh**

Performs a refresh on the selected node.

**Find/Replace in Files**

Opens the Find/Replace in Files dialog box (on page 400) that allows you to find and replace text in multiple files from the connection.

**Folder Level Nodes**

**New File or New Document**

Creates a new file on the connection, in the current folder.

**New Folder**

Creates a new folder on the connection.

**Import Folders**

Imports folders on the server.

**Import Files**

Allows you to add a new file on the connection, in the current folder.

**Rename**

Renames the current resource

**Delete**

Deletes the current container.

**Refresh**
Performs a refresh on the selected node.

Find/Replace in Files (Data Source Explorer view only)

Opens the Find/Replace in Files dialog box (on page 400) that allows you to find and replace text in multiple files from the connection.

Resource Level Nodes

Open

Opens the selected resource in the editor.

Open in System Application (Data Source Explorer view only)

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the Data Source Explorer view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

Copy location

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Check Out

Checks out the selected document on the server.

Check In

Checks in the selected document on the server. This action opens the Check In dialog box. For SharePoint Online connections, you only have the option to enter a comment and click the Check In button to process it.

For SharePoint (older version), the following options are available:

- **Minor Version** - Increments the minor version of the file on the server.
- **Major Version** - Increments the major version of the file on the server.
- **Overwrite** - Overwrites the latest version of the file on the server.
- **Comment** - Allows you to add a comment for a file that you check in.

Discard Check Out

Discards the previous checkout operation, making the file available to other users.

Rename

Renames the current resource

Delete

Deletes the current container.
**Refresh**

Performs a refresh on the selected node.

**Compare**

Compares two selected resources using the Compare Files tool (on page 437).

### Browsing for Remote Files with SharePoint Online

The Open URL dialog box (used for browsing remote files) includes support for connecting to a SharePoint Online server, with controls similar to the SharePoint Browser view (on page 1935). To open this dialog box, go to File > Open URL (or click the Open URL toolbar button), then choose the Browse for remote file option from the drop-down menu.

**Figure 520. Open URL Dialog Box for SharePoint Online**

The displayed dialog box is composed of the following:

**Server Type**

Specifies the type of server (SharePoint Online in this case).

**Note:**

If you select SharePoint On-Premises, the controls are similar to those for WebDav and other servers (on page 353).

**Server URL**

Specifies the protocol (HTTP, HTTPS or FTP) and the host name or IP of the server.
User drop-down menu

This drop-down includes:

- **Log in with Microsoft account** (if logged out) - Opens the Microsoft login page in your default browser and authenticates Oxygen XML Editor.
- **Log out** (if logged in) - Logs out of your Microsoft account and the authorization between Oxygen XML Editor and Microsoft is revoked.
- **Help** - Opens the online user guide to a topic relevant to the current context.

Browse

Use this button to retrieve the data from the server. Once the authentication completes, the files from the server will be available in the dialog box.

File URL

You can use this combo box to directly specify the URL to be opened or saved. This combo box also displays the current selection when the user changes selection by browsing the tree of folders and files on the server.

MS Azure Active Directory Authentication

It is possible to use your MS Azure Active Directory credentials for SharePoint authentication. To configure the application to use your *client ID* and *client secret*, set the following **Oxygen system properties** *(on page 301):*

- `com.oxygenxml.azure.active.directory.client.id` - Specifies a custom *client ID*.
- `com.oxygenxml.azure.active.directory.client.secret` - Specifies a custom *client secret*.

Your application should allow the following API permissions:

### Table 42. API Permissions - Microsoft Graph

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**Notice:**

The *Redirect URI* should be set to: http://localhost/oauth/redirect
15. Importing Data

Computer systems and databases contain data in incompatible formats and exchanging data between these systems can be very time consuming. Converting the data to XML can greatly reduce the complexity and create data that can be read by various types of applications.

Oxygen XML Editor offers support for importing text files, MS Excel files, Database Data, and HTML files into XML documents. The XML documents can be further converted into other formats using the Transform features (on page 1330).

Import from Text Files

Oxygen XML Editor includes the possibility of importing text files (txt or csv file extensions) as XML documents.

To import a text file into an XML file, follow these steps:

1. Go to File > Import/Convert > Text File to XML. A Select text file dialog box is displayed.
2. Select the URL of the text file (txt or csv file extensions).
3. Select the encoding of the text file.
4. Click the Next button. The Import Criteria dialog box is displayed.
5. Configure the settings for the conversion.
   a. Select the **Field delimiter** for the import settings. You can choose between the following: Comma, Semicolon, Tab, Space, or Pipe.
   b. The **Import settings** section presents the input data in a tabular form. By default, all data items are converted to element content (`<>` symbol), but this can be overridden by clicking the individual column headers. Clicking a column header once causes the data from this column to be converted to attribute values (`=` symbol). Clicking a second time causes the column data to be ignored (`×` symbol) when generating the XML file. You can cycle through these three options by continuing to click the column header.
   c. **First row contains field names** - If this option is selected, the default column headers are replaced (where such information is available) by the content of the first row. In other words, the first row is interpreted as containing the field names. The changes are also visible in the preview panel.
d. **Customize** - This button opens a **Presentation Names** dialog box that allows you to edit the name, XML name, and conversion criterion for the root and row elements. The XML names can be edited by double-clicking the desired item and entering the label. The conversion criteria can also be modified by selecting one of the following options in the drop-down menu: **ELEMENT**, **ATTRIBUTE**, or **SKIPPED**.

e. **Import Settings** - Clicking this button opens the **Import preferences page (on page 236)** that allows you to configure more import options.

f. The **XML Import Preview** panel contains an example of what the generated XML document looks like.

g. **Open in editor** - If selected, the new XML document created from the imported text file is opened in the editor.

h. **Save in file** - If selected, the new XML document is saved in the specified path.

6. Click **Import** to generate the XML document.

---

### Import from MS Excel Files

Oxygen XML Editor provides several methods for importing MS Excel files into an XML file. The first method is to use the Oxygen XML Editor **Smart Paste mechanism (on page 570)** by simply copying data from Excel and pasting it into a document in **Author** mode (note that this is only supported in DITA, DocBook, TEI, JATS, and XHTML documents). You can also copy data from Excel and paste it into inserted cells in **Grid** mode, but this is a more manual process. If you want to import an entire Excel file, Oxygen XML Editor also offers a configurable import wizard that works with any type of XML document.

#### Smart Paste Method in Author Mode

If you are importing data into DITA, DocBook, TEI, JATS, or XHTML documents, you can open the Excel spreadsheet in your office application, copy its content, and simply paste it into your document in **Author** mode.

The Oxygen XML Editor **Smart Paste mechanism (on page 570)** will convert the pasted content to the equivalent XML markup and considers various pasting solutions to keep the resulting document valid, while preserving the original text styling (such as bold, italics, underline) and formatting (such as lists, tables, paragraphs).

#### Grid Mode Method

The **Grid** mode in Oxygen XML Editor displays all content in an XML document as a structured grid of nested tables and you can work with the cells in those tables much like you would with any spreadsheet application. When importing Excel data into **Grid** mode, you first need to insert new cells in the particular nested table and then you can paste data from Excel the same as you would in any table or spreadsheet.

1. Copy the particular cells from your Excel spreadsheet that you want to import into an XML file.
2. Switch to **Grid** mode in Oxygen XML Editor.
3. Expand the particular nodes and locate the nested table where you want to insert the copied cells.
4. Right-click a particular row or column where you want to insert the data and select **Insert row** or **Insert column**, depending on the structure of the copied cells.
5. Paste the copied cells from the clipboard into the newly inserted cells in **Grid** mode.
6. You may need to make some manual adjustments. For example, if the selection of copied cells contained an empty cell, Oxygen XML Editor might ignore that cell.

**Import Wizard Method**

By default, this method supports importing Excel 97/2000/XP/2003 formats out-of-the-box. To import spreadsheet data from Excel 2007 or newer, additional libraries are needed before using this procedure. See *Import Data from MS Excel (2007 or Newer) (on page 1948)* for instructions on adding more libraries.

To use the **Import** wizard to import an Excel file into an XML file, follow these steps:

1. Go to **File > Import/Convert > MS Excel file to XML**.
2. Select the URL of the Excel file. The sheets of the document you are importing are presented in the **Available Sheets** section of this dialog box.
3. Click the **Next** button to proceed to the next stage of the wizard.
4. Configure the settings for the conversion. This stage of the wizard offers the following options:

**Import settings section**

Presents the input data in a tabular form. By default, all data items are converted to element content (\(<\) symbol), but this can be overridden by clicking the individual column headers. Clicking a column header once causes the data from this column to be converted to attribute values (\(=\) symbol). Clicking a second time causes the column data to be ignored (\(\times\) symbol) when generating the XML file. You can cycle through these three options by continuing to click the column header.

**First row contains field names**

If this option is selected, the default column headers are replaced (where such information is available) by the content of the first row. In other words, the first row is
interpreted as containing the field names. The changes are also visible in the preview panel.

**Customize**

This button opens a Presentation Names dialog box that allows you to edit the name, XML name, and conversion criterion for the root and row elements. The XML names can be edited by double-clicking the desired item and entering the label. The conversion criteria can also be modified by selecting one of the following option in the drop-down menu: ELEMENT, ATTRIBUTE, or SKIPPED.

**Import Settings**

Clicking this button opens the Import preferences page (on page 236) that allows you to configure more import options.

**Import formatted data (as displayed in Excel)**

If this option is selected, the imported data retains the Excel data formatting (such as the representation of numeric values or dates). If deselected, the data formatting is not imported.

**XML Import Preview panel**

Contains an example of what the generated XML document will look like.

**Open in editor**

If selected, the new XML document created from the imported file is opened in the editor.

**Save in file**

If selected, the new XML document is saved in the specified path.

5. Click Import to generate the XML document.

For more information about exchanging data between Oxygen XML Editor and spreadsheet applications, watch our video demonstration:

https://www.youtube.com/embed/8VwsF58zLkU

**Related Information:**

Exporting XML Content to Excel (on page 546)

**Import Data from MS Excel (2007 or Newer)**

To import spreadsheet data from Excel 2007 or newer (.xlsx), Oxygen XML Editor needs additional libraries from the release 3.17 of the Apache POI project.

To add this support, follow this procedure:

1. Go to Help > Install new add-ons to open an add-on selection dialog box.
2. Enter or paste https://www.oxygenxml.com/InstData/Addons/default/updateSite.xml in the Show add-ons from field or select it from the drop-down menu.
3. Select **Excel XLSX libraries v3.17** plugin and click **Next**.

4. Restart the application.

**Result:** You can now use the **Import wizard (on page 1946)** to import data from Excel 2007 or newer.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Older versions of the libraries should not be loaded in the application. Make sure the <strong>Excel XLSX libraries v3.10</strong> plugin is not installed.</td>
</tr>
</tbody>
</table>

### Alternate Method to Manually Add the Libraries

To manually add the libraries, follow these steps:

   The specific ZIP file that you need is: `poi-bin-3.17-20170915.zip`.

3. In the `{OXYGEN_INSTALL_DIR}/lib` directory, create a directory named `endorsed` (`{OXYGEN_INSTALL_DIR}/lib/endorsed`).

4. Copy the following `.jar` files into the new `endorsed` directory:
   - `curvesapi-1.04.jar`
   - `poi-ooxml-3.17.jar`
   - `poi-ooxml-schemas-3.17.jar`
   - `xmlbeans-2.6.0.jar`

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>The <code>.jar</code> files can be found in either the root folder where you unpacked the archive, or in the <code>ooxml-lib</code> subfolder.</td>
</tr>
</tbody>
</table>

**Result:** You can now use the **Import wizard (on page 1946)** to import data from Excel 2007 or newer.

### Related Information:

- [Exporting XML Content to Excel (on page 546)](#)

### Import Database Data as an XML Document

To import the data from a relational database table as an XML document, follow these steps:

1. Go to **File > Import/Convert > Database Data to XML** to start the **Import** wizard.

   This opens a **Select database table** dialog box that lists all the defined database connections:
2. Select the connection to the database that contains the appropriate data. Only connections configured in relational data sources can be used to import data.

3. If you want to edit, delete, or add a data source or connection, click the **Configure Database Sources** button. The **Preferences/Data Sources** option page is opened.

4. Click **Connect**.

5. In the list of sources, expand a schema and choose the required table.

6. Click the **Next** button. The **Import Criteria** dialog box is opened with a default query string in the **SQL Query** pane.
7. Configure the settings for the conversion.

a. **SQL Preview** - If this button is pressed, the **Settings** pane displays the labels that are used in the XML document and the first five lines from the database. By default, all data items are converted to element content (\(\text{<>}\) symbol), but this can be overridden by clicking the individual column headers. Clicking a column header once causes the data from this column to be converted to attribute values (\(\text{=}\) symbol). Clicking a second time causes the column data to be ignored (\(\text{X}\) symbol) when generating the XML file. You can cycle through these three options by continuing to click the column header.

b. **Customize** - This button opens a **Presentation Names** dialog box that allows you to edit the name, XML name, and conversion criterion for the root and row elements. The XML names can be edited by double-clicking the desired item and entering the label. The conversion criteria can also be modified by selecting one of the following option in the drop-down menu: **ELEMENT**, **ATTRIBUTE**, or **SKIPPED**.
c. **Import Settings** - Clicking this button opens the [Import preferences page](#page-236) that allows you to configure more import options.
d. The **XML Import Preview** panel contains an example of what the generated XML document looks like.
e. **Open in editor** - If selected, the new XML document created from the imported file is opened in the editor.
f. **Save in file** - If selected, the new XML document is saved in the specified path.
g. **Generate XML Schema** - Allows you to specify the path of the generated XML Schema file.

8. Click **Import** to generate the XML document.

---

### Import from HTML Files

Oxygen XML Editor offers two methods for importing HTML files into an XML document. The first method is to simply copy data from an HTML document and paste it into a document in **Author** mode, but this is only supported in DITA, DocBook, TEI, JATS, and XHTML documents. Oxygen XML Editor also offers a configurable import wizard that works with any type of XML document.

#### Smart Paste Method

If you are importing data into DITA, DocBook, TEI, JATS, or XHTML documents, you can open the HTML document in your web browser, copy its content, and paste it into your document in **Author** mode.

The Oxygen XML Editor **Smart Paste mechanism** *(on page 570)* will convert the pasted content to the equivalent XML markup and considers various pasting solutions to keep the resulting document valid, while preserving the original text styling (such as bold, italics, underline) and formatting (such as lists, tables, paragraphs).

#### Import Wizard Method

To use the **Import** wizard to import from HTML files, follow these steps:

1. Go to **File > Import/Convert > HTML File to XHTML**. The **Import HTML to XHTML** wizard is displayed.
2. Enter the URL of the HTML document.
3. Select the type of the resulting XHTML document:
   - XHTML5
   - XHTML 1.0 Transitional
   - XHTML 1.0 Strict
4. Click the **OK** button.

**Result:** The resulting document is an XHTML file containing a DOCTYPE declaration that references the XHTML DTD definition on the Web. The parsed content of the imported file is transformed to XHTML5, XHTML Transitional, or XHTML Strict depending on the option you chose.
**Import Content Dynamically**

Along with the built-in support for various useful URL protocols (such as HTTP or FTP), Oxygen XML Editor also provides special support for a *convert* protocol that can be used to chain predefined processors to dynamically import content from various sources.

A *dynamic conversion URL* chains various processors that can be applied, in sequence, on a target resource and has the following general syntax:

```
convert:/processor=xslt;ss=urn:processors: excel2d.xsl/processor=xslt!/urn:files:my.xls
```

The previous example first applies a processor (*excel*) on a target identified by the identifier (*urn:files:sample.xls*) and converts the Excel™ resource to XML. The second applied processor (*xslt*) applies an XSLT stylesheet identified using the identifier (*urn:processors:excel2d.xsl*) over the resulting content from the first applied processor. These identifiers are all mapped to real resources on disk via an *XML catalog* that is configured in the application, as in the following example:

```xml
<catalog xmlns="urn:oasis:names:tc:entity:xmlns:xml:catalog">
  <rewriteURI uriStartString="urn:files:" rewritePrefix="./resources/"/>
  <rewriteURI uriStartString="urn:processors:" rewritePrefix="./processors/"/>
</catalog>
```

The target resource part of the conversion URL must always follow the `!/` pattern. It can be any of the following:

- An absolute URL that points to a resource.
- An identifier that will be resolved to an actual resource via the *XML Catalog (on page 2972)* support in the application. In the example above, the *urn:files:sample.xls* target resource is resolved via the *XML catalog*.
- A relative location. This location can only be resolved to an actual resource URL when the application has enough information about the location where the URL is referenced.

For example, for a *DITA map (on page 2966)* with a `<topicref>` such as:

```
<topicref href="convert://.../processor=excel!/resources/sample.xls"/>
```

the *resources/sample.xls* path will be resolved relative to the *DITA map* location.

This type of URL can be opened in the application by using the *Open URL* action from the *File* menu. It can also be referenced from existing XML resources via *xi:include* or as a topic reference from a *DITA map*.

A GitHub project that contains various dynamic conversion samples for producing DITA content from various sources (and then publishing it) can be found here: [https://github.com/oxygenxml/dita-glass](https://github.com/oxygenxml/dita-glass).

**Conversion Processors**

A set of predefined conversion processors is provided in Oxygen XML Editor. Each processor has its own parameters that can be set to control the behavior of the conversion process. All parameters that are resolved to resources are passed through the *XML catalog* mapping.

The following predefined conversion processors are included:
• **xslt Processor** - Converts an XML input using the Saxon EE XSLT processor. The \( ss \) parameter indicates the stylesheet resource to be loaded. All other specified parameters will be set as parameters to the XSLT transformation.

convert:/processor=xslt;ss=urn:processors:convert.xsl;pl=v1!/urn:files:sample.xml

• **xquery Processor** - Converts an XML input using the Saxon EE XQuery processor. The \( ss \) parameter indicates the XQuery script to be loaded. All other specified parameters will be set as parameters to the XSLT transformation.

convert:/processor=xquery;ss=urn:processors:convert.xquery;pl=v1!/urn:files:sample.xml

• **excel Processor** - Converts an Excel™ input to an XML format that can later be converted by other piped processors. It has a single parameter \( sn \), which indicates the name of the sheet that needs to be converted. If this parameter is missing, the XML will contain the combined content of all sheets included in the Excel™ document.

convert:/processor=excel;sn=test!/urn:files:sample.xls

• **java Processor** - Converts an input to another format by applying a specific Java method. The \( jars \) parameter is a comma-separated list of JAR (on page 2967) libraries, or folders that libraries will be loaded from. The \( ccn \) parameter is the fully qualified name of the conversion class that will be instantiated. The conversion class needs to have a method with the following signature:

```java
public void convert(String systemID, String originalSourceSystemID,
    InputStream is, OutputStream os, LinkedHashMap<String, String> properties)
    throws IOException
```

convert:/processor=java;jars=libs;ccn=test.JavaToXML!/urn:files:java/WSEditorBase.java

• **js Processor** - Converts an input to another format by applying a JavaScript method. The \( js \) parameter indicates the script that will be used. The \( fn \) parameter is the name of the method that will be called from the script. The method must take a string as an argument and return a string. If any of the parameters are missing, an error is thrown and the conversion stops.

convert:/processor=js;js=urn:processors:md.js;fn=convertExternal!/urn:files:sample.md

• **json Processor** - Converts a JSON input to XML. It has no parameters.

convert:/processor=json!/urn:files:personal.json

• **xhtml Processor** - Converts HTML content to well-formed XHTML. It has no parameters.

convert:/processor=xhtml!/urn:files:test.html

• **wrap Processor** - Wraps content in a tag name making it well-formed XML. The \( rn \) parameter indicates the name of the root tag to use. By default, it is \( \text{wrapper} \). The \( encoding \) parameter specifies the encoding that should be used to read the content. By default, it is \( \text{UTF8} \). As an example, this processor can be used if you want to process a comma-separated values file with an XSLT stylesheet to produce XML content. The CSV file is first wrapped as well-formed XML, which is then processed with an xslt processor.

convert:/processor=wrap!/urn:files:test.csv
• **cache Processor** - Caches the converted content obtained from the original document to a temporary file. The cache will be used on subsequent uses of the same URL, thus increasing the speed for the application returning the converted content. If the original URL points to the local disk, the cache will be automatically invalidated when the original file content gets modified. Otherwise, if the original URL points to a remote resource, the cache will need to be invalidated by reloading (**Reload (F5)** from the toolbar) the URL content that is opened in the editor.

```xml
convert:/processor=cache/processor=xslt;...!/urn:files:test.csv
```

**Reverse Conversion Processors**

All processors defined above can also be used for saving content back to the target resource if they are defined in the URL as reverse processors. Reverse processors are evaluated right to left. These reverse processors allow round-tripping content to and from the target resource.

As an example, the following URL converts HTML to DITA when the URL is opened using the **h2d.xsl** stylesheet and converts DITA to HTML when the content is saved in the application using the **d2h.xsl** stylesheet.

```xml
convert:/processor=xslt;ss=h2d.xsl/rprocessor=xslt;ss=d2h.xsl!/urn:files:sample.html
```

⚠️ **Important:**

If you are publishing a **DITA map** that has such conversion URL references inside, you need to edit the transformation scenario and set the value of the parameter `fix.external.refs.com.oxygenxml` to **true**. This will instruct Oxygen XML Editor to resolve such references during a special pre-processing stage. Depending on the conversion, you may also require additional libraries to be added using the **Libaries** button in the **Advanced** tab of the transformation scenario.

**Related Information:**

16. Debugging XSLT Stylesheets and XQuery Documents

Oxygen XML Editor includes a powerful debugging interface that helps you to detect and solve problems with XSLT and XQuery transformations.

XSLT Debugger Perspective
The XSLT Debugger perspective (on page 2969) allows you to detect problems in an XSLT transformation by executing the process step by step. To switch the focus to this perspective, select the XSLT Debugger button in the top-right corner of the interface or Window > Open perspective > XSLT Debugger.

XQuery Debugger Perspective
The XQuery Debugger perspective (on page 2969) allows you to detect problems in an XQuery transformation process by executing the process step by step in a controlled environment and inspecting the information provided in the special views. To switch the focus to this perspective, select the XQuery Debugger button in the top-right corner of the interface or Window > Open perspective > XQuery Debugger.

XSLT/XQuery Debugging Overview
The XSLT Debugger and XQuery Debugger perspectives (on page 2969) allows you to test and debug XSLT 1.0 / 2.0 / 3.0 stylesheets and XQuery 1.0 / 3.0 documents including complex XPath 2.0 / 3.0 expressions. The interface presents simultaneous views of the source XML document, the XSLT/XQuery document and the result document. As you go step by step through the XSLT/XQuery document the corresponding output is generated step by step, and the corresponding position in the XML file is highlighted. At the same time, special views provide various types of debugging information and events useful to understand the transformation process.

The following set of features allow you to test and solve XSLT/XQuery problems:

- Support for XSLT 1.0 stylesheets (using Saxon 6.5.5 and Xalan XSLT engines), XSLT 2.0 / 3.0 stylesheets and XPath 2.0 / 3.0 expressions that are included in the stylesheets (using Saxon 9.9.1.5 XSLT engine) and XQuery 1.0 / 3.0 (using Saxon 9.9.1.5 XQuery engine).
- Stepping capabilities: step in, step over, step out, run, run to cursor, run to end, pause, stop.
- Output to source mapping between every line of output and the instruction element / source context that generated it.
- Breakpoints (on page 1979) on both source and XSLT/XQuery documents.
- Call stack on both source and XSLT/XQuery documents.
- Trace history on both source and XSLT/XQuery documents.
- Support for XPath expression evaluation during debugging.
- Step into imported/included stylesheets as well as included source entities.
- Available templates and hits count.
• Variables view.
• Dynamic output generation.

For even more information, watch our video demonstration:

https://www.youtube.com/embed/m9d8c4V-LJw

Debugger Layout

The XML and XSL files are displayed in Text mode (on page 476). The other modes (Author mode (on page 322), Grid mode (on page 321)) are available only in the Editor perspective (on page 312).

The XSLT/XQuery Debugger perspective (on page 2969) contains the following components:

• Source Document View (XML) - Displays and allows the editing of XML files (documents).
• XSLT/XQuery Document View (XSLT/XQuery) - Displays and allows the editing of XSL files (stylesheets) or XQuery documents.
• Output View - Displays the output that results from inputting a document (XML) and a stylesheet (XSL) or XQuery document in the transformer. The transformation result is written dynamically while the transformation is processed (using the Run button on the Control toolbar (on page 1961)). Several actions are available in the contextual menu for this view, including Find/Replace, Copy, and Format and Indent. There are two types of output views: a Text view (with XML syntax highlights) and XHTML view. For large outputs, the XHTML view can be disabled (see Debugger Settings (on page 227)).
• Control Toolbar (on page 1958) - Contains a variety of actions to help you configure and control the debugging process.
• Information Views (on page 1962) - The information views at the bottom of the editor display various types of information to help you understand the transformation process.

Tip:
The Output view and the various other information views are dockable (on page 2966) so that you can configure the workspace according to your preferences.
Figure 525. Debugger Interface

XML documents and XSL stylesheets or XQuery documents that were opened in the Editor perspective (on page 2969) are automatically sorted into the first two panes. When multiple files of each type are opened, the individual documents and stylesheets are separated using the familiar tab management system that you are used to in the Editor perspective. Selecting a tab brings the document or stylesheet into focus and enables editing without the need to go back to the Editor perspective.

In Debugger mode, the normal editor toolbar is not available. However, functions are still accessible from the Document menu and the contextual menus.

Bookmarks (on page 479) are replaced in the Debugger perspective by breakpoints (on page 1979).

During debugging, the current execution node is highlighted in both document (XML) and XSLT/XQuery views.

Related Information:
Steps in a Typical Debugging Process (on page 1975)
Identify the XSLT / XQuery Expression that Generated Particular Output (on page 1976)
Supported Processors for XSLT / XQuery Debugging (on page 1985)
Performance Profiling of XSLT Stylesheets and XQuery Documents (on page 1980)

Control Toolbar

The Control toolbar contains all the actions that you need to configure and control the debugging process. The following actions are described as they appear in the toolbar from left to right.
XML source selector

The current selection represents the source document used as input by the transformation engine. The selection list contains all open files (XML files being emphasized). This option allows you to use other file types also as source documents. In an XQuery debugging session this selection field can be set to the default value `NONE`, because usually XQuery documents do not require an input source.

XSL / XQuery selector

The current selection represents the stylesheet or XQuery document to be used by the transformation engine. The selection list contains all open files (XSLT / XQuery files being emphasized).

Link with editor

When selected, the XML and XSLT/XQuery selectors display the names of the files open in the central editor panels. This button is toggled off by default.

Output selector

The selection represents the output file specified in the associated transformation scenario. You can specify the path by using the text field, the `Insert Editor Variables (on page 292)` button, or the `Browse` button.

Configure parameters

Opens a dialog box that allows you to configure the XSLT / XQuery parameters to be used by the transformation.

Edit extensions

Allows you to add and remove the Java classes and `JARS (on page 2967)` used as XSLT extensions.

Turn on/off profiling

Enables / Disables current transformation profiling.

Enable XHTML output

Enables the rendering of the output in the `XHTML output view (on page 1957)` during the transformation process. For performance issues, disable XHTML output when working with very large files. Note that only XHTML conformant documents can be rendered by this view. To view the output result of other formats, such as HTML, save the `Text output` area to a file and use an external browser for viewing.
When starting a debug session from the Editor perspective (on page 2969) by using the Debug Scenario action, the state of this toolbar button reflects the state of the Show as XHTML output option from the scenario.

Turn on/off output to source mapping

Enables or disables the output to source mapping between every line of output and the instruction element / source context that generated it.

Debugger preferences

Quick link to Debugger preferences page (on page 227).

XSLT / XQuery engine selector

Lists the processors available for debugging XSLT and XQuery transformations (on page 1985).

XSLT / XQuery engine advanced options

If Saxon HE/PE/EE is selected, you can click this button to open the Advanced Saxon Transformation Options page (on page 1365).

Step into

Starts the debugging process and runs until the next instruction is encountered.

Step over

Run until the current instruction and its sub-instructions are over. Usually this will advance to the next sibling instruction.

Figure 527. Step over

Step out

Run until the parent of the current instruction is over. Usually this will advance to the next sibling of the parent instruction.
Run \textbf{Shift + F5}

Starts the debugging process. The execution of the process is paused when a \textit{breakpoint (on page 1962)} is encountered or the transformation ends.

\textbf{Run to cursor}

Starts the debugging process and runs until one of the following conditions occur: the line of cursor is reached, a valid \textit{breakpoint (on page 1979)} is reached or the execution ends.

\textbf{Run to end}

Runs the transformation until the end, without taking into account enabled \textit{breakpoints (on page 1979)}, if any.

\textbf{Pause}

Request to pause the current transformation as soon as possible.

\textbf{Stop}

Request to stop the current transformation without completing its execution.

\textbf{Show current execution nodes}

Reveals the current debugger context showing both the current instruction and the current node in the XML source. Possible displayed states:

- Entering (\text unconditional{\rightarrow}) or leaving (\text unconditional{\leftarrow}) an XML execution node.
- Entering (\text unconditional{\rightarrow}) or leaving (\text unconditional{\leftarrow}) an XSL execution node.
- Entering (\text unconditional{\rightarrow}) or leaving (\text unconditional{\leftarrow}) an XPath execution node.

\textbf{Note:}

When you set a MarkLogic server as a processor, the \textit{Show current execution nodes} button is named \textit{Refresh current session context from server}. Click this button to refresh the information in all the views.
Note:
For some of the XSLT processors (Saxon-HE/PE/EE) the debugger could be configured to step into the XPath expressions affecting the behavior of the following debugger actions: Step into, Step over or Step Out.

Related Information:
Advanced Saxon HE/PE/EE XQuery Transformation Options (on page 1380)

Debugging Information Views
The information views at the bottom of the editor is comprised of two panes that are used to display various types of information used to understand the transformation process. For each information type there is a corresponding tab. While running a transformation, relevant events are displayed in the various information views. This enables the developer to obtain a clear view of the transformation progress. By using the debug controls, developers can easily isolate parts of stylesheet. Therefore, they may be more easily understood and modified.

The information types include the following:

Left side information views

- **Breakpoints** view (on page 1962)
- **XWatch** view (on page 1965)
- **Context** view (on page 1964)
- **Messages** view (on page 1966) (XSLT only)
- **Variables** view (on page 1973)
- **Invocation Tree** view (on page 1982)

Right side information views

- **Stack** view (on page 1967)
- **Output Mapping Stack** view (on page 1968)
- **Trace** view (on page 1970)
- **Templates** view (on page 1971) (XSLT only)
- **Nodes/Values Set** view (on page 1972)
- **Hotspots** view (on page 1983)

Tip:
The information views are dockable (on page 2966) so that you can configure the workspace according to your preferences.
Breakpoints View

The Breakpoints view lists all breakpoints (on page 1979) that are set on open documents. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu. Breakpoints can be inserted (on page 1980) in the XML source document or the XSLT/XQuery document in debugging sessions.

Once you insert a breakpoint, it is automatically added to the list in the Breakpoints view and you can edit its associated condition. A breakpoint can have an associated break condition that represents an XPath expression evaluated in the current debugger context. For them to be processed, their evaluation result should be a boolean value. A breakpoint with an associated condition only stops the execution of the Debugger if the breakpoint condition is evaluated as true.

Figure 529. Breakpoints View

The Breakpoints view contains the following columns:

- **Enabled** - If selected, the current condition is evaluated and taken into account.
- **Resource** - Resource file and number of the line where the breakpoint is set. The Entire path of resource file is available as tooltip.
- **Condition** - XSLT/XQuery expression to be evaluated during debugging. The expression will be evaluated at every debug step.

Clicking a record highlights the breakpoint line in the document.

**Note:**

The breakpoints list is not deleted at the end of a transformation (it is preserved between debugging sessions).

The following actions are available in the contextual menu of the table:

- **Go to**
  Moves the cursor to the source of the breakpoint.

- **Run to Breakpoint**
Runs the debugger up to the point of this particular breakpoint and ignores the others (regardless of whether they were previously enabled or disabled).

**Enable**

Enables the breakpoint.

**Disable**

Disables the breakpoint. A disabled breakpoint will not be evaluated by the Debugger.

**Add**

Allows you to add a new breakpoint and breakpoint condition.

**Edit**

Allows you to edit an existing breakpoint.

**Remove**

Deletes the selected breakpoint.

**Enable all**

Enables all breakpoints.

**Disable all**

Disables all breakpoints.

**Remove all**

Removes all breakpoints.

**Related Information:**

Using Breakpoints (on page 1979)

**Context View**

The context node is valid only for XSLT debugging sessions and is a source node corresponding to the XSL expression that is evaluated. It is also called the context of execution. The context node implicitly changes as the processor hits various steps (at the point where XPath expressions are evaluated). This node has the same value as evaluating '.' (dot) XPath expression in XWatch view (on page 1965). The value of the context node is presented as a tree in the Context view. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.
The context nodes are presented in a tree-like fashion. Nodes from a defined namespace bound to a prefix are displayed using the qualified name. If the namespace is not bound to a prefix, the namespace URI is presented before the node name. The value of the selected attribute or node is displayed in the right side panel. The **Context** view also presents the current mode of the XSLT processor if this mode differs from the default one. The title bar displays the current element index and the number of elements that compose the current context (this information is not available if you choose Xalan or Saxon 6 as processing engine).

**XPath Watch (XWatch) View**

The **XWatch** view shows XPath expressions evaluated during the debugging process. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu. Expressions are evaluated dynamically as the processor changes its source context. When you type an XPath expression in the **Expression** column, Oxygen XML Editor supports you with syntax highlight and **content completion assistance** *(on page 832)*.
Table 44. XWatch columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Expression</td>
<td>XPath expression to be evaluated (XPath 1.0 or 2.0/3.0 compliant).</td>
</tr>
<tr>
<td>Value</td>
<td>Result of XPath expression evaluation. Value has a type (see the possible values (on page 1973) in the Variables View (on page 1973)) section. For Node Set results, the number of nodes in the set is shown in parenthesis.</td>
</tr>
</tbody>
</table>

Important:
Notes about working with the XWatch view:

- Expressions that reference variable names are not evaluated.
- The expression list is not deleted at the end of the transformation (it is preserved between debugging sessions).
- To insert a new expression, click the first empty line of the Expression column and start typing. As an alternative, right-click and select the Add action. Press Enter on the cell to add and evaluate.
- To delete an expression, click its Expression column and delete its content. As an alternative, right-click and select the Remove action. Press Enter on the cell to commit changes.
- If the expression result type is a Node Set, click it (Value column) and its value is displayed in the Nodes/Values Set view (on page 1972).
- The Copy, Add, Remove and Remove All actions are available in every row's contextual menu.

Messages View

Using an xsl:message instruction is one way to signal special situations encountered during transformation as well as a raw way of doing the debugging. The Messages view is available only for XSLT debugging sessions and shows all xsl:message calls executed by the XSLT processor during transformation. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Figure 532. Messages View
Table 45. Messages columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Message</td>
<td>Message content.</td>
</tr>
<tr>
<td>Terminate</td>
<td>Signals whether or not the processor terminates the transformation once it encounters the message (yes/no respectively).</td>
</tr>
<tr>
<td>Resource</td>
<td>Resource file where <em>xsl:message</em> instruction is defined and the message line number. The complete path of the resource is available as tooltip.</td>
</tr>
</tbody>
</table>

The following actions are available in the contextual menu:

**Go to**
- Highlight the XSL fragment that generated the message.

**Copy**
- Copies to clipboard message details (system ID, severity info, description, start location, terminate state).

**Clear all**
- Removes all messages from the view.

**Important:**
- Clicking a record from the table highlights the *xsl:message* declaration line.
- Message table values can be sorted by clicking the corresponding column header. Clicking the column header switches the sorting order between: ascending, descending, no sort.

**Stack View**

The **Stack** view shows the current execution stack of both source and XSLT/XQuery nodes. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

During the transformation, two stacks are managed. One for source nodes being processed and the other for XSLT/XQuery nodes being processed. Oxygen XML Editor shows both node types in one common stack. The source (XML) nodes are preceded by a red color icon while XSLT/XQuery nodes are preceded by a green color icon. The advantage of this approach is that you can always see the source scope on which an XSLT/XQuery instruction is executed (the last red color node on the stack). The stack is oriented upside down.
The contextual menu contains one action: **Go to**, which moves the selection in the editor panel to the line containing the XSLT element that is displayed on the selected line from the view.

### Table 46. Stack Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#</td>
<td>Order number, represents the depth of the node (0 is the stack base).</td>
</tr>
<tr>
<td>XML/XSLT/XQuery Node</td>
<td>Node from source or stylesheet document currently being processed. One particular stack node is the document root, noted as <strong>#document</strong>.</td>
</tr>
<tr>
<td>Attributes</td>
<td>Attributes of the node (a list of id=&quot;value&quot; pairs).</td>
</tr>
<tr>
<td>Resource</td>
<td>Resource file where the node is located. The entire path is available as tooltip.</td>
</tr>
</tbody>
</table>

**Important:**

Remarks:

- Clicking a record from the stack highlights that node’s location inside resource.
- Using Saxon, the stylesheet elements are qualified with XSL proxy, while using Xalan you only see their names. (example: `xsl:template` using Saxon and `template` using Xalan).
- Only the Saxon processor shows element attributes.
- The Xalan processor shows also the built-in rules.

### Output Mapping Stack View

The **Output Mapping Stack** view displays context data ([on page 1976](#)) and presents the XSLT templates/XQuery elements that generated specific areas of the output. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.
The Go to action of the contextual menu takes you to the line that contains the XSLT element displayed in the Output Mapping Stack view.

Table 47. Output Mapping Stack Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#</td>
<td>The order number in the stack of XSLT templates/XQuery elements. Number 0 corresponds to the bottom of the stack in the status of the XSLT/XQuery processor. The highest number corresponds to the top of the stack.</td>
</tr>
<tr>
<td>XSL/XQuery Node</td>
<td>The name of an XSLT template/XQuery element that participated in the generation of the selected output area.</td>
</tr>
<tr>
<td>Attributes</td>
<td>The attributes of the XSLT template/XQuery node.</td>
</tr>
<tr>
<td>Resource</td>
<td>The name of the file containing the XSLT template/XQuery element.</td>
</tr>
</tbody>
</table>

**Important:**

Remarks:

- Clicking a record highlights that XSLT template definition/XQuery element inside the resource (XSLT stylesheet file/XQuery file).
- Saxon only shows the applied XSLT templates having at least one hit from the processor. Xalan shows all defined XSLT templates, with or without hits.
- The table can be sorted by clicking the corresponding column header. When clicking a column header the sorting order switches between: ascending, descending, no sort.
- Xalan shows also the built-in XSLT rules.
Trace View

Usually, the XSLT/XQuery processors signal the following events during transformation:

- Entering a source (XML) node.
- Leaving a source (XML) node.
- Entering an XSLT/XQuery node.
- Leaving an XSLT/XQuery node.

The Trace view catches all of these events, so you can see how the process evolved. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

The red icon lines denote source nodes while the green icon lines denote XSLT/XQuery nodes. It is possible to save the element trace in a structured XML document (using the Export to XML action in the contextual menu). Thus, you have the possibility of comparing the trace results from multiple debug sessions.

**Figure 535. Trace History View**

<table>
<thead>
<tr>
<th>Depth</th>
<th>XML/XSL/XQuery Node</th>
<th>Attributes</th>
<th>Resource</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>#document</td>
<td></td>
<td>personal.xml</td>
</tr>
<tr>
<td>1</td>
<td>xs:template</td>
<td>(match=&quot;)&quot;</td>
<td>personal.xsl</td>
</tr>
<tr>
<td>2</td>
<td>html</td>
<td></td>
<td>personal.xsl</td>
</tr>
<tr>
<td>3</td>
<td>xs:element</td>
<td>(name=&quot;table&quot;)</td>
<td>personal.xsl</td>
</tr>
<tr>
<td>4</td>
<td>xs:message</td>
<td></td>
<td>personal.xsl</td>
</tr>
<tr>
<td>4</td>
<td>xs:message</td>
<td></td>
<td>personal.xsl</td>
</tr>
</tbody>
</table>

The contextual menu contains the following actions:

**Go to**

Moves the selection in the editor panel to the line containing the XSLT element or XML element that is displayed on the selected line from the view;

**Export to XML**

Saves the entire trace list in XML format.
Table 48. Trace History Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Depth</td>
<td>Shows you how deep the node is nested in the XML or stylesheet structure. The bigger the number, the more nested the node is. A depth 0 node is the document root.</td>
</tr>
<tr>
<td>XML/XSLT/XQuery Node</td>
<td>Represents the node from the processed source or stylesheet document. One particular node is the document root, noted as #document. Every node is preceded by an arrow that represents what action was performed on it (entering or leaving the node).</td>
</tr>
<tr>
<td>Attributes</td>
<td>Attributes of the node (a list of id=&quot;value&quot; pairs).</td>
</tr>
<tr>
<td>Resource</td>
<td>Resource file where the node is located. The complete path of the resource file is provided as tooltip.</td>
</tr>
</tbody>
</table>

**Important:**

Remarks:

- Clicking a record highlights that node's location inside the resource.
- Only the Saxon processor shows the element attributes.
- The Xalan processor shows also the built-in rules.

**Templates View**

The `<xsl:template>` is the basic element for stylesheets transformation. The Templates view is only available during XSLT debugging sessions and shows all `<xsl:template>` instructions used by the transformation. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Being able to see the number of hits for each of the templates allows you to get an idea of the stylesheet coverage by template rules with respect to the input source.

**Figure 536. Templates view**

The contextual menu contains one action: Go to, which moves the selection in the editor panel to the line that contains the XSLT template displayed on the selected line from the view.
### Table 49. Templates columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Match</td>
<td>The <code>match</code> attribute of the <code>xsl:template</code>.</td>
</tr>
<tr>
<td>Hits</td>
<td>The number of hits for the <code>xsl:template</code>. Shows how many times the XSLT processor used this particular template.</td>
</tr>
<tr>
<td>Priority</td>
<td>The template priority as established by XSLT processor.</td>
</tr>
<tr>
<td>Mode</td>
<td>The <code>mode</code> attribute of the <code>xsl:template</code>.</td>
</tr>
<tr>
<td>Name</td>
<td>The <code>name</code> attribute of the <code>xsl:template</code>.</td>
</tr>
<tr>
<td>Resource</td>
<td>The resource file where the template is located. The complete path of the resource file is available as tooltip.</td>
</tr>
</tbody>
</table>

**Important:**

Remarks:

- Clicking a record highlights that template definition inside the resource.
- Saxon only shows the applied templates having at least one hit from the processor. Xalan shows all defined templates, with or without hits.
- Template table values can be sorted by clicking the corresponding column header. When clicking a column header the sorting order switches between: ascending, descending, no sort.
- Xalan shows also the built-in rules.

### Nodes/Values Set View

The **Nodes/Values Set** view is always used in relation with the [Variables view](on page 1973) and [XWatch view](on page 1965). If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu. It shows an XSLT node set value in a tree form. This view is updated as a response to the following events:

- You click a variable that has a node set value in the [Variables](on page 1973) or [XWatch view](on page 1965).
- You click a tree fragment in the [Variables](on page 1973) or [XWatch view](on page 1965).
- You click an XPath expression evaluated to a node set in the [Variables](on page 1973) or [XWatch view](on page 1965).
Figure 537. Node Set view

The nodes / values set is presented in a tree-like fashion. The total number of items is presented in the title bar. Nodes from a defined namespace bound to a prefix are displayed using the qualified name. If the namespace is not bound to a prefix, the namespace URI is presented before the node name. The value of the selected attribute or node is displayed in the right side panel.

Important:
Remarks:

- For longer values in the right side panel, the interface displays it with an ellipsis (...) at the end. A more detailed value is available as a tooltip when hovering over it.
- Clicking a record highlights the location of that node in the source or stylesheet view.

Variables View

The Variables view displays variables and parameters (local and global), along with their values. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Variables and parameters play an important role during an XSLT/XQuery transformation. Oxygen XML Editor uses the following icons to differentiate variables and parameters:

- V - Global variable.
- {V} - Local variable.
- P - Global parameter.
- {P} - Local parameter.

The following value types are available:

- Boolean
- String
- Date - XSLT 2.0 / 3.0 only.
- Number
- **Set**
- **Object**
- **Fragment** - Tree fragment.
- **Any**
- **Undefined** - The value was not yet set, or it is not accessible.

**Note:**
When Saxon 6.5 is used, if the value is unavailable, then the following message is displayed in the **Value** field: "The variable value is unavailable".

When Saxon 9 is used:
- If the variable is not used, the **Value** field displays "The variable is declared but never used".
- If the variable value cannot be evaluated, the **Value** field displays "The variable value is unavailable".

- **Document**
- **Element**
- **Attribute**
- **ProcessingInstruction**
- **Comment**
- **Text**
- **Namespace**
- **Evaluating** - Value under evaluation.
- **Not Known** - Unknown types.

**Table 50. Variables Columns**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of variable / parameter.</td>
</tr>
<tr>
<td>Value Type</td>
<td>Type of variable/parameter.</td>
</tr>
</tbody>
</table>
### Table 50. Variables Columns (continued)

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Value</td>
<td>Current value of variable / parameter.</td>
</tr>
</tbody>
</table>

The value of a variable (the **Value** column) can be copied to the clipboard for pasting it to other editor areas with the **Copy value** action from the contextual menu. This is useful if you have long and complex values that cannot be easily remembered just by looking at them once.

---

**Important:**

**Remarks:**

- Local variables and parameters are the first entries presented in the table.
- Clicking a record highlights the variable definition line.
- Variable values could differ depending on the transformation engine used or stylesheet version set.
- If the value of the variable is a node set or a tree fragment, clicking it causes the **Node Set view** *(on page 1972)* to be shown with the corresponding set of values.
- Variable table values can be sorted by clicking the corresponding column header. Clicking the column header switches between the orders: ascending, descending, no sort.

---

### Multiple Output Documents in XSLT 2.0 and XSLT 3.0

For XSLT 2.0 and XSLT 3.0 stylesheets that store the output in multiple files by using the `xsl:result-document` instruction, the content of the file created in this way is displayed in an output view after the transformation is finished. There is one view for each `xsl:result-document` instruction so that the output is not mixed while still being presented in multiple views.

### Steps in a Typical Debugging Process

Depending on your situation and needs, the debugging process might be more complex, but the following procedure is an example of a typical debugging process:

1. **Open the source XML document** *(on page 348)* and **the XSLT/XQuery document** *(on page 348)*.
2. If you are in the **Editor perspective** *(on page 2969)*, switch to the **XSLT Debugger** or **XQuery Debugger perspective** *(on page 2969)* with one of the following actions:
   
   - Select **Window > Open perspective > XSLT Debugger/XQuery Debugger** or the **XSLT Debugger**/**XQuery Debugger** button in the top-right corner of the interface.
   - Select **Document > XML Document > Debug scenario** or use the **Debug scenario** action on the toolbar. This action initializes the Debugger **perspective** *(on page 2969)* with the
parameters of the transformation scenario. Any modification applied to the scenario parameters
(the transformer engine, XSLT parameters, transformer extensions, etc.) will be saved back in the
scenario when exiting from the Debugger perspective.

3. Select the source XML document in the XML source selector of the Control toolbar (on page 1959). In
the case of XQuery debugging, if your XQuery document has no implicit source, set the source selector
value to NONE.

5. Set XSLT/XQuery parameters using the Configure parameters button on the Control toolbar (on page
1959).

6. Set one or more breakpoints (on page 1979).

7. Step through the stylesheet using the following buttons available on the Control toolbar (on page
1960):
   - Step into
   - Step over
   - Step out
   - Run
   - Run to cursor
   - Run to end
   - Pause
   - Stop

8. Examine the data in the information views to find the bug in the transformation process.

For more information about fixing bugs in the transformation, see: Identify the XSLT / XQuery
Expression that Generated Particular Output (on page 1976).

Related Information:
Identify the XSLT / XQuery Expression that Generated Particular Output (on page 1976)

Identify the XSLT / XQuery Expression that Generated Particular Output

To quickly spot the XSLT templates or XQuery expressions with problems, it is important to know what XSLT
template in the XSLT stylesheet (or XQuery expression in the XQuery document) and what element in the
source XML document generated a specified area in the output.

Some of the debugging capabilities (for example, Step in) can be used for this purpose. Using Step in, you can
see how output is generated and link it with the XSLT/XQuery element being executed in the current source
context. However, this can become difficult on complex XSLT stylesheets or XQuery documents that generate
a large output.

You can click particular text in the Output view or XHTML output view and the editor will select the XML
source context and the XSLT template/XQuery element that generated that text. Also, inspecting the whole
stack of XSLT templates/XQuery elements that determined the state of the XSLT/XQuery processor at the
moment of generating the specified output area speeds up the debugging process.
This is an example of a typical procedure for identifying an expression that generated particular output:

1. Switch to the **XSLT Debugger** or **XQuery Debugger** perspective (on page 2969) with one of the following actions:
   
   - Select **Window > Open perspective > XSLT Debugger/XQuery Debugger** or the ![XSLT Debugger](XSLT Debugger.png) ![XQuery Debugger](XQuery Debugger.png) button in the top-right corner of the interface.
   
   - Select **Document > XML Document > Debug scenario** or use the ![Debug scenario](Debug scenario.png) action on the toolbar. This action initializes the Debugger perspective (on page 2969) with the parameters of the transformation scenario. Any modification applied to the scenario parameters (the transformer engine, XSLT parameters, transformer extensions, etc.) will be saved back in the scenario when exiting from the Debugger perspective.

2. Select the source XML document in the **XML source selector of the Control toolbar** (on page 1959). In the case of XQuery debugging, if your XQuery document has no implicit source, set the source selector value to **NONE**.

4. Select the appropriate engine in the **XSL/XQuery engine selector of the Control toolbar** (on page 1960).

5. Set XSLT/XQuery parameters using the **Configure parameters** button on the Control toolbar (on page 1959).

6. Apply the XSLT stylesheet or XQuery transformation using the ![Run to end](Run to end.png) button that is available on the Control toolbar (on page 1961).

7. Inspect the mapping by clicking a section of the output in either the **Text tab** or **XHTML tab** of the **Output view** (on page 316).
Figure 539. XHTML Output to Source Mapping
This action will highlight the XSLT / XQuery element and the XML source context. This XSLT template/XQuery element that is highlighted in the XSLT/XQuery editor represents only the top of the stack of XSLT templates/XQuery elements that determined the state of the XSLT/XQuery processor at the moment of generating the clicked output section. In the case of complex transformations, inspecting the whole stack of XSLT templates/XQuery elements speeds up the debugging process. This stack is available in the **Output Mapping Stack view** (on page 1968).

**Related Information:**
- Output Mapping Stack View (on page 1968)
- Trace View (on page 1970)
- Templates View (on page 1971)

**Using Breakpoints**

The Oxygen XML Editor XSLT/XQuery Debugger allows you to interrupt XSLT/XQuery processing to gather information about variables and processor execution at particular points. To ensure **breakpoints** are persistent between work sessions, they are saved at project level. You can set a maximum of 100 **breakpoints** per project.
**Inserting Breakpoints**

To insert a *breakpoint*, follow these steps:

1. Click the line where you want to insert the *breakpoint* in the XML source document or the XSLT/XQuery document. Breakpoints are automatically created on the ending line of a start tag, even if you click a different line.

2. Click the vertical stripe on the left side of the editor panel or use **Shift+F7**.

**Result:**

Once you insert a *breakpoint*, it is automatically added to the list in the Breakpoints view and you can edit its associated *condition*. A *breakpoint* can have an associated break condition that represents an XPath expression evaluated in the current debugger context. For them to be processed, their evaluation result should be a boolean value. A *breakpoint* with an associated condition only stops the execution of the Debugger if the *breakpoint condition* is evaluated as **true**.

**Figure 541. Example: Breakpoints**

<table>
<thead>
<tr>
<th></th>
<th>&lt;title&gt;&lt;/title&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>&lt;body&gt;</td>
</tr>
<tr>
<td>6</td>
<td>&lt;p&gt;&lt;/p&gt;</td>
</tr>
<tr>
<td>7</td>
<td>&lt;table frame=&quot;all&quot; rowsep=&quot;1&quot;</td>
</tr>
<tr>
<td>8</td>
<td>&lt;title&gt;text&lt;/title&gt;</td>
</tr>
<tr>
<td>9</td>
<td>&lt;tgroup cols=&quot;2&quot;&gt;</td>
</tr>
</tbody>
</table>

**Removing Breakpoints**

To remove a *breakpoint*, click its icon (●) in the vertical stripe on the left side of the editor panel or right-click the *breakpoint* and select **Remove** or **Remove all**.

**Related Information:**

Breakpoints View *(on page 1962)*

**Performance Profiling of XSLT Stylesheets and XQuery Documents**

Whether you are trying to identify a performance issue that is causing your production XSLT/XQuery transformation to not meet customer expectations or you are trying to proactively identify issues prior to deploying your XSLT/XQuery transformation, using the XSLT/XQuery profiler feature is essential to helping you save time and ultimately ensure a better performing, more scalable XSLT/XQuery transformation.

The XSLT/XQuery profiling feature can use any available XSLT/XQuery processor that can be used for debugging and it is available from the debugging *perspective* *(on page 2969)*.

**Enabling the Profiler**

Enabling and disabling the profiler is controlled by the 🔄 ⏸️ Profiler button from the debugger Control toolbar *(on page 1959)*. The XSLT/XQuery profiler is off by default. This option is not available during a
debugger session so you need to set it before starting the transformation. For information about a common debugging procedure, see Steps in a Typical Debugging Process (on page 1975).

Profiling Information Views

Immediately after enabling the profiler, two new information views are added to the current debugger information views (on page 1962):

- **Invocation tree view (on page 1982)** on left side
- **Hotspots view (on page 1983)** on right side

Profiling data is available only after the transformation ends successfully.

On the left side (Invocation tree view (on page 1982)), you can examine how style instructions are processed. This result view is also named call-tree, as it represents the order of style processing. The profiling result shows the duration time for each of the style-instruction including the time needed for its called children.

On the right side (Hotspots view (on page 1983)), you can immediately spot the time the processor spent in each instruction. As an instruction usually calls other instructions, the used time of the called instruction is extracted from the duration time of the caller (the hotspot only presents the inherent time of the instruction).

Source Backmapping

In either the Invocation tree (on page 1982) or Hotspots view (on page 1983), you can use the backmapping feature to find the XSLT stylesheet or XQuery expression definition. Clicking the selected item causes Oxygen XML Editor to highlight the XSLT stylesheet or XQuery expression source line where the instruction is defined.

Figure 542. Source Backmapping

Saving and Customizing Profiling Data

The profiling data can be saved (exported) into XML and HTML format. In either the Invocation tree (on page 1982) or Hotspots view (on page 1983), right-click anywhere in the view and select Export to XML or Export to HTML. The HTML report can be customized based upon the profiling raw data. When you select Export to HTML, Oxygen XML Editor will save it as XML and apply an XSLT stylesheet to render the
report as XML. You can customize these stylesheets to suit your needs. By default, they are located in:

\[\text{OXYGEN_INSTALL_DIR}/frameworks/profiler/\].

Other Profiling Notes

- If you want to change the XSLT/XQuery profiler settings (on page 228), use the contextual menu and choose the corresponding View settings entry.
- Profiling exhaustive transformations may run into an OutOfMemory error due to the large amount of information being collected. If this is the case, you can close unused projects when running the profiling or use high values for Java VM options \(-Xms\) and \(-Xmx\). If this does not help you can shorten your source XML file and try again.
- For more information about the XSLT/XQuery Profiler, watch our video demonstration:

  https://www.youtube.com/embed/4ftHschjLqA

Invocation Tree View

The Invocation Tree view shows a top-down call tree that represents how XSLT instructions or XQuery expressions are processed. If the view is not displayed, it can be opened by selecting it from the Window > Show View menu.

Figure 543. Invocation Tree View

The entries in the invocation tree include a few possible icons that indicate the following:

- ◯ - Points to a call whose inherent time is insignificant compared to its total time.
- ☰ - Points to a call whose inherent time is significant compared to its total time (greater than 1/3rd of its total time).

Every entry in the invocation tree includes textual information that depends on the XSLT/XQuery profiler settings (on page 228):
A percentage number of the total time that is calculated with respect to either the root of the tree or the calling instruction.

A total time measurement in milliseconds or microseconds. This is the total execution time that includes calls into other instructions.

A percentage number of the inherent time that is calculated with respect to either the root of the tree or the calling instruction.

An inherent time measurement in milliseconds or microseconds. This is the inherent execution time of the instruction.

An invocation count that shows how often the instruction has been invoked on this call-path.

An instruction name that contains also the attributes description.

The **Invocation Tree** view also includes the following contextual menu actions:

### Export to HTML

Selecting this option will save the profiling data as XML and then apply an XSLT stylesheet to render the report as HTML. These stylesheets are included in the subfolder: `\[OXYGEN_INSTALL_DIR\]/frameworks/profiler/`. You can use them to customize your own report based on the profiling raw data.

### Export to XML

Use this option to save the profiling data as an XML file in a specified location.

### View settings

Opens the **XSLT/XQuery Profiler preferences page (on page 228)** that allows you to configure various profiling settings.

### Hotspots View

The **Hotspots** view displays a list of all instruction calls that lie above the threshold defined in the **XSLT/XQuery profiler settings (on page 228)**. If the view is not displayed, it can be opened by selecting it from the **Window > Show View** menu.

![Figure 544. Hotspots View](image)
By opening a hotspot instruction entry, the tree of back-traces leading to that instruction call are calculated and shown.

Every hotspot is described by the values from the following columns:

- **Instruction** - The name of the instruction.
- **Time** - The inherent time in milliseconds or microseconds of how much time has been spent in the hotspot, along with a bar whose length is proportional to this value. All calls into this instruction are summed up regardless of the particular call sequence.
- **Hits** - The invocation count of the hotspot entry.

If you click the handle on the left side of a hotspot, a tree of back-traces will be shown.

Every entry in the backtrace tree has textual information attached to it that depends on the XSLT/XQuery profiler settings (on page 228):

- A percentage number that is calculated with respect to either the total time or the called instruction.
- A time measured in milliseconds or microseconds of how much time has been contributed to the parent hotspot on this call-path.
- An invocation count that shows how often the hotspot has been invoked on this call-path.

Note:
This is not the number of invocations of this instruction.

An instruction name that also contains its attributes.

The Hotspots view also includes the following contextual menu actions:

**Export to HTML**
Selecting this option will save the profiling data as XML and then apply an XSLT stylesheet to render the report as HTML. These stylesheets are included in the subfolder: [OXYGEN_INSTALL_DIR]/frameworks/profiler/. You can use them to customize your own report based on the profiling raw data.

**Export to XML**
Use this option to save the profiling data as an XML file in a specified location.

**View settings**
Opens the XSLT/XQuery Profiler preferences page (on page 228) that allows you to configure various profiling settings.

**Debugging XSLT that Call Java Extensions**

It is possible to debug an XSLT that calls Java extensions. This is achieved through a transformation scenario where the Java extensions are specified, and the debugging can be done based upon the same scenario.

To debug XSLT with Java extensions, follow this procedure:
1. Create an XSLT transformation scenario (on page 1406) for your XSLT document (select Configure Transformation Scenario(s) action from the toolbar, then click New, and select XSLT transformation).

2. In the New scenario dialog box, click the Extensions button (in the XSLT tab), specify the Java extensions (JAR libraries) that are needed, and click OK.

3. Once you are finished configuring the transformation scenario, click OK, then select Save and close.

4. Use the Debug scenario action on the toolbar and the debugging will be based upon the same transformation scenario you just configured and saved.

Tip:
You could achieve this during a typical debugging process (on page 1975) by specifying the Java extensions using the Edit extensions button on the debugger control toolbar (on page 1959).

Related Information:
Validating XSLT Stylesheets that Call Java Extensions (on page 827)

Debugging Java Extensions
The XSLT/XQuery debugger does not step into Java classes that are configured as XSLT/XQuery extensions of the transformation. To step into Java classes, inspect variable values, and set breakpoints (on page 1979) in Java methods, you can set up a Java debug configuration in an IDE (such as the Eclipse SDK) as described in the following steps:

1. Create a debug configuration.
   a. Set at least 256 MB as heap memory for the Java virtual machine (recommended 1024 MB) by setting the -Xmx parameter in the debug configuration (for example, `-Xmx1024m`).
   b. Make sure the [OXYGEN_INSTALL_DIR]/lib/oxygen.jar file and your Java extension classes are on the Java classpath.
      The Java extension classes should be the same classes that were set as an extension (on page 1959) of the XSLT/XQuery transformation in the debugging perspective (on page 2969).
   c. Set the class ro.sync.exml.Oxygen as the main Java class of the configuration.
      The main Java class ro.sync.exml.Oxygen is located in the oxygen.jar file.
2. Start the debug configuration.
   Now you can set breakpoints and inspect Java variables as in any Java debugging process executed in the selected IDE (Eclipse SDK, and so on.).

Supported Processors for XSLT / XQuery Debugging
The following built-in XSLT processors are integrated in the debugger and can be selected in the Control Toolbar (on page 1958):
• **Saxon 9.9.1.5 HE (Home Edition)** - a limited version of the Saxon 9 processor, capable of running XSLT 1.0, XSLT 2.0 / 3.0 basic and XQuery 1.0 transformations, available in both the XSLT debugger and the XQuery one,

• **Saxon 9.9.1.5 PE (Professional Edition)** - capable of running XSLT 1.0 transformations, XSLT 2.0 basic ones and XQuery 1.0 ones, available in both the XSLT debugger and the XQuery one,

• **Saxon 9.9.1.5 EE (Enterprise Edition)** - a schema-aware processor, capable of running XSLT 1.0 transformations, XSLT 2.0 / 3.0 basic ones, XSLT 2.0 / 3.0 schema-aware ones and XQuery 1.0 / 3.0 ones, available in both the XSLT debugger and the XQuery debugger,

• **Saxon 6.5.5** - capable of running only XSLT 1.0 transformations, available only in the XSLT debugger,

• **Xalan 2.7.2** - capable of running only XSLT 1.0 transformations, available only in the XSLT debugger.
17. Framework and Author Mode Customization

This section contains information and tutorials about customizing the authoring experience through custom frameworks and customizing the Author editing mode through CSS styling or API extensions.

Creating and Configuring Custom Frameworks

Oxygen XML Editor includes built-in, configured frameworks (on page 2967) for DocBook, DITA, TEI, XHTML, and JATS, but you can also create your own customization to handle other types of documents. A common use-case is wanting to customize the interface to accommodate the needs of your authoring team.

Fully configuring a framework usually involves customizing CSS stylesheets, XML schemas, GUI components (menu actions, toolbars, inline components, content completion proposals, and more), configuring other more general settings, then bundling the framework to share with your team. The CSS and GUI components are used to customize the interface, while other general settings can be configured to accommodate custom document templates, XML catalogs, transformation scenarios, and more.

Advanced users who are familiar with API development can also create custom Author mode operations (on page 2030) for a particular framework.

This section includes information about numerous possibilities for creating and customizing a framework, and how to share your customization with others.

Tip:
A sample framework customization package is available that you can dabble with and use to help you get started. It can be downloaded from: https://www.oxygenxml.com/php/get_oxygen_sample_framework.php. The package includes a sample CSS file, XSL file, schema files, document templates, an XML catalog file, custom icons, and other resources.

Creating a Framework through the Configuration Dialog

The easiest way to create a custom framework (on page 2967) (document type) is by extending an existing built-in framework, such as DITA or DocBook, and then making modifications to it. You can then easily share the custom framework (on page 2131) with your team.

To create a custom framework by extending an existing one, follow these steps:
1. In a location where you have full write access, create a folder structure similar to this:
   
   `custom_frameworks/dita-extension`

2. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Document Type Association > Locations (on page 113). Add the path to your `custom_frameworks` folder in the Additional frameworks directories list and click OK or Apply to save your changes.

3. Go to the Document Type Association preferences page (on page 111) and select an existing framework configuration (for example, DITA) and use the Extend button to create an extension for it.

   **Step Result:** This opens the Document Type Configuration dialog box (on page 113) where you can define the set of rules and settings for your custom framework.

4. Give the extension an appropriate name, select External for the Storage option, click the browsing button ( ), to specify the location of the custom directory you created in step 1.

5. Continue to configure the extension using the tabs on the bottom half of the dialog box. For details about each of those tabs, see the child topics in the Document Type Configuration dialog box (on page 113) section. For even more information about customizing the extended framework, see the various topics and tutorials in the Creating and Configuring Custom Frameworks (on page 1987) section.

   Make sure that you save any resources you reference in your framework configuration (CSS files, new document templates, schemas used for validation, catalogs, etc.) in your custom framework directory you created in step 1.

6. Click OK to close the configuration dialog box and then OK or Apply to save your changes.

   **Results:** You now have a fully functional framework that can be shared with others (on page 2131).

---

**Related Information:**

Sharing a Framework (on page 2131)

---

### Creating a Framework Using an Extension Script

A custom framework (on page 2967) (document type) can be created using a special XML descriptor file, either from scratch or by extending an existing built-in framework (such as DITA or DocBook) and then making modifications to it. You can then easily share the custom framework (on page 2131) with your team.

The easiest way to create such a descriptor is to use the New document wizard (on page 335) and choose the Extend Framework Script or Create Framework Script template.

### Creating a Custom Framework Starting from an Existing Framework

To create a custom framework by extending an existing one, follow these steps:

1. In a location where you have full write access, create a folder structure similar to this:

   `custom_frameworks/dita-extension`

2. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Document Type Association > Locations (on page 113). Add the path to your `custom_frameworks` folder in the Additional frameworks directories list and click OK or Apply to save your changes and close the dialog box.
3. Click the [New] button on the toolbar and select the **Extend Framework Script** template. Save it inside the previously configured framework path (e.g. `custom_frameworks/dita-extension`).

4. Set the `@base` attribute on the script element to the value of the name of the extended framework (e.g. DITA).

   **Note:**
   Removing the `@base` attribute will create a framework from scratch.

5. Edit the script as described in **Framework Extension Script File (on page 1990)**.

To test your customization, open a document that matches the newly created framework and inspect how your settings apply or go to **Options > Preferences > Document Type Association** and inspect the resulting framework structure.

   **Note:**
   If you want to use the framework in an older Oxygen XML Editor version that does not have support for these scripts, you can compile the script to obtain the *.framework file by using the **Compile Framework Extension script** action from the contextual menu or by running the scripts/compileFrameworkScript.bat external tool.

### Creating a Custom Framework Without a Base Framework

To create a custom framework without starting from an existing one, follow these steps

1. In a location where you have full write access, create a folder structure similar to this:
   
   `custom_frameworks/dita-extension`

2. Open the **Preferences** dialog box (**Options > Preferences**) (on page 98) and go to **Document Type Association > Locations** (on page 113). Add the path to your `custom_frameworks` folder in the **Additional frameworks directories** list and click **OK** or **Apply** to save your changes and close the dialog box.

3. Click [New] button on the toolbar and select the **Create Framework Script** template. Save it inside the previously configured framework path, `custom_frameworks/dita-extension`.

4. Edit the script as described in **Framework Extension Script File (on page 1990)**.

To test your customization, open a document that matches the newly created framework and inspect how your settings apply or go to **Options > Preferences > Document Type Association** and inspect the newly generated framework structure.

   **Note:**
   If you want to use the framework in an older Oxygen XML Editor version that does not have support for these scripts, you can compile the script to obtain the *.framework file by using the **Compile Framework Extension script** action from the contextual menu or by running the scripts/compileFrameworkScript.bat external tool.
Framework Extension Script File

The framework extension file is used to describe a new framework configuration. Optionally, you can extend an existing built-in framework configuration (such as DITA or DocBook) and then make additions and changes to it.

The easiest way to create such a file is to use the New document wizard (on page 335) and choose the Extend Framework Script or Create Framework Script template.

The following examples assume that the newly created framework extends a built-in one.

Basic Information

Once you have created a new script file, you need to:

- Specify the name of the framework using the <name> element. Optionally, you can also add a description using the <description> element.
- If you want to extend an existing framework (such as DITA or DocBook), specify the name of the extended framework using the @base attribute on the <script> element.
- The <priority> element might be needed to instruct Oxygen XML Editor to use this new framework instead of the one being extended or another framework that matches the same document.

Example: Extending the Built-in DITA Framework

```xml
<script xmlns="http://www.oxygenxml.com/ns/framework/extend"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://www.oxygenxml.com/ns/framework/extend
    base="DITA">
    <name>My custom DITA framework</name>
    <description>A custom framework based on the built-in DITA framework</description>
    <priority>High</priority>
</script>
```

Changing the Association Rules

Oxygen XML Editor identifies the type of a document when the document matches at least one of the association rules.

Example: Instructing the Built-in Associations to Inherit None to Add Your Own

```xml
<associationRules inherit="none">
    <addRule rootElementLocalName="concept"/>
    <addRule fileName="test.xml"/>
</associationRules>
```
Changing the Classpath

The **Classpath** tab displays a list of folders and *JAR (on page 2967)* libraries that hold implementations for API extensions, implementations for custom **Author** mode operations, various resources (such as stylesheets), and **framework (on page 2967)** translation files. Oxygen XML Editor loads the resources looking in the folders in the order they appear in the list.

**Example: Customizing and Extending the Classpath Inherited From the Base Framework**

```xml
<classpath inherit="all"/>

<!-- Contribute this resource before the ones inherited from the base framework
because Oxygen loads the resources looking in the folders in the order they
appear in the list. -->

<addEntry path="${framework}/resources_2x" position="before"/>

<removeEntry path="${baseFramework}/refactoring"/>
</classpath>
```

**Note:**

When removing entries with framework editor variables, take into consideration how they were added in the base framework.

- An entry present in the base framework with the path `/${framework}/file` can be removed using an identical path or by using the `/${baseFramework}/file` variable.
- An entry present in the base framework with the path `/${frameworkDir}/file` can be removed using an identical path or by using the `/${baseFrameworkDir}/file` variable.

Changing XML Catalogs

For cases where you need to reference the location of a schema file from a remote web location and an internet connection may not be available, an **XML Catalog (on page 2972)** may be used to map the web location to a local file system entry.

**Example: Customizing and Extending the XML Catalogs Inherited From the Base Framework**

```xml
<xmlCatalogs inherit="all"/>

<!-- Contribute this resource before the ones inherited from the base framework
because Oxygen loads the resources looking in the folders in the order they
appear in the list. -->

<addEntry path="${framework}/catalog.xml" position="before"/>
```
<removeEntry path="${baseFramework}/oldCatalog.xml"/>
</xmlCatalogs>

Changing the Document Templates

You can create your own custom document templates or remove templates inherited from the base framework.

Example: Customizing and Extending the XML Catalogs Inherited From the Base Framework

```xml
<documentTemplates inherit="all">
  <!-- Contribute this resource before the ones inherited from the base framework to make them appear first in the list. -->
  <addEntry path="${framework}/newTemplates" position="before"/>
</documentTemplates>
```

Adding New Transformation Scenarios and Removing Existing Ones

You can import newly created transformation scenarios and export them in one of the following locations:

- The Transformation Scenarios View (on page 1450).
- The Configure Transformation Scenario(s) Dialog Box (on page 1443).
- The Transformation Tab (on page 137).

Example: Importing New Transformation Scenarios

The `@href` attribute from the `<addScenarios>` element is used to point to the location of the scenarios export file. You can also remove any scenario inherited from the base framework as well as setting the default scenarios (the one used when another specific scenario is not specified).

```xml
<transformationScenarios>
  <addScenarios href="scenarioExport.scenarios"/>
  <removeScenario name="DITA HTML5"/>
  <defaultScenarios>
    <name>DITA</name>
    <name>XML</name>
  </defaultScenarios>
</transformationScenarios>
```

Adding New Validation Scenarios and Removing Existing Ones

You can import newly created validation scenarios and export them in one of the following locations:

- The Configure Validation Scenario Dialog Box (on page 741).
- The Validation Tab (on page 138).
Example: Importing New Validation Scenarios

The [@href](#) attribute from the `<addScenarios>` element is used to point to the location of the scenarios export file. You can also remove any scenario inherited from the base framework as well as setting the default scenarios (the one used when another specific scenario is not specified).

```xml
<validationScenarios>
  <addScenarios href="validationScenarioExport.scenarios"/>
  <removeScenario name="DITA"/>
  <defaultScenarios>
    <name>DITA Validation</name>
    <name>XML Validation</name>
  </defaultScenarios>
</validationScenarios>
```

Customizing the Author Mode Through New CSS Files

The Author mode layout is driven by CSS rules. To customize it, you need to create new CSS files and add them in the new framework.

Example: Using Larger Fonts in Titles

```xml
<author>
  <css>
    <addCss path="${framework}/titles.css" position="after"/>
    <!--
    Adding CSS after the ones in the base gives the opportunity to
    override rules from previous CSSs.
    -->
    <removeCss path="${framework}/base.css"/>
  </css>
</author>
```

The `${framework}/titles.css` file contains a rule like this:

```css
*[class~='topic/title'] {
  font-size:larger;
}
```

Example: Creating an Alternate CSS That Activates When the User Selects it in the Styles Menu

```xml
<author>
  <css>
    <addCss path="${framework}/pink.css" title="Pink titles" alternate="true"/>
  </css>
</author>
```

The `${framework}/pink.css` file contains a rule like this:
Defining Author Actions for the New Framework

Create external author actions (on page 2003), save them in a specific subdirectory of your particular framework directory (on page 2006), and they will be loaded automatically.

Removing Author Actions from the Base Framework

Suppose that the base framework configuration defines some author actions (on page 2003) that are added in the main menu (on page 129), contextual menu (on page 130), toolbar (on page 132), or content completion window (on page 133). If you do not want to inherit one of these actions in the new framework and you also want to remove it from all the GUI elements, you can use the <removeAction> element:

```xml
<author>
  <authorActions>
    <removeAction id="action.to.remove"/>
  </authorActions>
</author>
```

Note:

If the new framework has an external author action (on page 2003) with the same ID as one of the actions specified in a <removeAction> element, the action will not be removed from the GUI elements (menus, toolbars, content completion window).

Author Toolbar Configuration

The Author mode-specific toolbars for the new framework can be customized by:

- Adding or removing actions from toolbars.
- Changing toolbar groups by adding or removing actions.
- Creating new toolbars and action groups.

Example: Customizing the Toolbar

```xml
<author>
  <toolbars>
    <toolbar>
      <!-- Remove an action inherited from the base framework. -->
      <removeAction id="bold"/>
      
      <!-- Insert an action into an existing group -->
      <group name="${i18n(link)}">
        <addAction id="insert.note"/>
      </group>
    </toolbar>
  </toolbars>
</author>
```
Note:

If you create a toolbar or group configuration and a toolbar/group with the same name already exists in the base framework, you will change the one inherited instead of creating a new one. You can inspect the names of the existing toolbars/groups inherited from the base framework in the Toolbar Subtab (on page 132).

Example: Creating a New Toolbar

A new toolbar is created if the @name attribute does not match a toolbar inherited from the base.

```
<author>
  <toolbars>
    <toolbar name="Extra Toolbar">
      <!-- Add actions, separators and new groups-->
      <separator/>
      <addAction id="insert.note"/>

      <group name="New group">
        <addAction id="insert.note"/>
        <addAction id="insert.table"/>
      </group>
    </toolbar>
  </toolbars>
</author>
```

Example: Adding an Action in the Toolbar at a Specific Location

You can insert items (actions or groups) relative to other items already present in the toolbar because they were inherited from the base framework configuration. The @anchor attribute specifies either the ID of an action or the name of a group already present in the toolbar and the @position attribute specifies whether the new item should be added before or after it.
Note:
If the `@anchor` attribute is missing, the entries will be added either first or last, according to `@position` value.

```xml
<toolbar>
  <addAction id="insert.note" anchor="bold" position="before"/>
  <group name="Table menu" anchor="${i18n(link)}" position="after">
    <addAction id="insert.table"/>
  </group>
</toolbar>
```

Author Menu and Contextual Menu Configuration

The **Author** mode-specific menus for the new framework can be customized by:

- Adding or removing actions and submenus.
- Changing existing submenus by adding or removing actions.

**Example: Customizing the Contextual Menu**

```xml
<contextualMenu>
  <!-- Add new actions and submenu -->
  <separator/>
  <addAction id="insert.table"/>
  <submenu name="Other actions">
    <addAction id="insert.note"/>
  </submenu>
  <!-- Contribute to an existing submenu -->
  <submenu name="${i18n(section)}">
    <addAction id="paragraph"/>
  </submenu>
  <!-- Remove a submenu inherited from the base framework. -->
  <removeSubmenu name="${i18n(link)}"/>
</contextualMenu>
```

Note:
The framework main menu is configured similarly, inside a `<menu>` container.
Tip:
You can inspect the names of the submenus inherited from the base framework in the Contextual Menu Subtab (on page 130) and Menu Subtab (on page 129).

Example: Adding an Action in the Contextual Menu at a Specific Location
You can insert new actions and submenus relative to other actions and submenus already present in the menu because they were inherited from the base framework configuration. The @anchor attribute specifies the ID of an Author mode action or a name of a submenu already present in the menu and the @position attribute specifies whether the new action should be added before or after it.

Note:
If the @anchor attribute is missing, the entries will be added either first or last, according to @position value.

```xml
<contextualMenu>
  <addAction id="insert.note" anchor="edit.image.map" position="before"/>

  <submenu name="Table menu" anchor="${i18n(insert)}" position="after">
    <addAction id="insert.table"/>
  </submenu>
</contextualMenu>
```

Configuring the Content Completion in Author Mode
You can replace content completion entries obtained from the associated schema with Author mode actions (on page 2003).

In the <authorActions> container, you can specify the Author mode actions to be contributed. Optionally, you can mark them as a replacement for an existing schema proposal with the @replacedElement attribute.

The <schemaProposals> element allows you to remove proposals detected from the associated schema through the <removeProposal> element. If some proposals were removed in the base framework configuration and you want them re-added, you can do so through the <addProposal> element.

Example: Customizing the Content Completion Assistant

```xml
<contentCompletion>
  <authorActions>
    <addAction id="insert.note" replacedElement="note" inCCWindow="true"/>
  </authorActions>

  <schemaProposals>
    <removeProposal renderName="table"/>
  </schemaProposals>

  <!-- The base framework removed the "list" element proposal. We want it back... -->
</contentCompletion>
```
Using Framework Extension Points

The Extensions tab specifies implementations of Java interfaces used to provide advanced functionality to the document type. Libraries that contain the implementations must be present in the classpath of your framework (on page 1991). The Javadoc available at https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ contains details about how each API implementation functions.

Example: Setting a Custom Extensions Bundle

```xml
<extensionPoints>
  <extension
    name="extensionsBundleClassName"
    value="ro.sync.ecss.extensions.dita.map.DITAMapExtensionsBundle"/>
</extensionPoints>
```

Reusing Parts of the Script Using XInclude

Elements in the script can be specified in dedicated files that can then be referenced using XInclude in the script.

Example: Using XInclude to Reference Elements in the Script

```xml
<script xmlns="http://www.oxygenxml.com/ns/framework/extend">
  <name>New framework</name>
  <xi:include href="classpath.xml" xmlns:xi="http://www.w3.org/2001/XInclude"/>
</script>
```

Where the referenced `classpath.xml` has this content:

```xml
<classpath xmlns="http://www.oxygenxml.com/ns/framework/extend">
  <addEntry path="test.jar"/>
</classpath>
```

Customizing the Author Editing Experience for a Framework

You can customize the editing experience in Author mode for you and any other user who shares the same framework. This includes the ability to configure actions, menus, toolbars, icons, structure insertion shortcuts, and content completion proposals specifically for a particular framework (on page 2967) (document type). Advanced users who are familiar with API development can also create custom Author mode operations (on page 2030) for a particular framework.
Configuring and Managing Multiple CSS Styles for a Framework

Oxygen XML Editor provides a **Styles** drop-down menu on the toolbar that allows you to select one *main (non-alternate) CSS style* (on page 2968) and multiple *alternate CSS styles* (on page 2964). This makes it easy to change the look of the document as it appears in **Author** mode.

An example of a common use case is when content authors want to use custom styling within a document. You can select a *main CSS stylesheet* that styles the whole document and then apply *alternate styles*, as layers, to specific parts of the document.

**Note:**

When altering a CSS file configured as a stylesheet for the current document framework, you can quickly check its effects in the **Author** mode by using the **Reload** document action that is available on the toolbar.

Managing the CSS Styles

The *main* (on page 2968) and *alternate* (on page 2964) styles that are listed in the **Styles** drop-down menu can be controlled in the **Document Type** configuration dialog box (on page 113). To access it, follow these steps:

1. Open the **Preferences** dialog box (on page 98).
2. Go to **Document Type Association**.
3. Select the appropriate document type and click the **Edit** button.

**Important:**

If you do not have access rights to the folder where the *framework* (on page 2967) files are stored, you can either elevate read/write permissions on that *framework* folder or you can extend the *framework* and customize the CSS stylesheets in the extension. If you want to share the customized extension with the rest of your team, see **Sharing the Extended Framework** (on page 2131).

The CSS styles (CSS files) associated with the particular document type are listed in the **CSS subtab** (on page 119) of the **Author** tab.
You can Add, Edit, or Delete styles from this dialog box to manage the main (on page 2968) and alternate (on page 2964) styles associated to the particular document type. You can also change the order of the styles by using the Move Up and Move Down buttons. This also changes the order that they appear in the Styles drop-down menu. The alternate styles are combined with the main CSS sequentially, in the order that they appear in this list. Therefore, if the same style rules are included in multiple CSS files, the alternate style that is listed last in this list takes precedence, since it is the last one to be combined (applied as a layer).

The URI column shows the path of each CSS file. The names listed in the Styles drop-down menu match the values in the Title column. The value in the Alternate column determines whether it is a main or alternate CSS. If the value is no, it is a main CSS. If the value is yes, it is an alternate CSS and the style can be combined with a main CSS or other alternate styles when using the Styles drop-down menu.

**Note:**
To group alternate styles into categories (submenus), use a vertical bar character (|) in the Title column. You can use multiple vertical bars for multiple submenus. The text before each vertical bar will be rendered as the name of a submenu entry in the Styles drop-down menu, while the text after the final vertical bar is rendered as the name of the style inside the submenu.

**Example:** Suppose that you want to add two alternate style sheets in separate submenus, with the Title column set to My Styles|User Assistance|Hints and My Styles|User Actions|Inline Actions, respectively.
Oxygen XML Editor will add a **My Styles** submenu with two submenus (**User Assistance** that contains the **Hints** style, and **User Actions** that contains the **Inline Actions** style) in the **Styles** drop-down menu.

The **Enable multiple selection of alternate CSSs** checkbox (on page 120) at the bottom of the pane must be selected for the **alternate CSS styles** (on page 2964) to be combined. They are applied like layers and you can activate any number of them. If this option is not selected, the **alternate** styles are treated like **main CSS styles** (on page 2968) and you can only select one at a time. By default, this option is selected. There are also a few options that allow you to specify how to handle the CSS if there are CSS styles specified in the document. You can choose to **ignore** or **merge** them.

The following rules apply for merging CSS styles:

- CSS files with the same title will be merged.
- CSS files without a title will contribute to all others.
- They are merged sequentially, in the order that they appear in the list.

**Using the Styles Drop-down Menu**

You can use the **Styles** drop-down menu to select a **main css style** (on page 2968) that applies to the whole document and then select one or more **alternate css styles** (on page 2964) that behave like layers and are merged sequentially with the **main style**. Each of the styles that are listed in this drop-down menu have a corresponding CSS file that defines how your documents are rendered in **Author** mode and in the output. Also, the selections from this drop-down menu are persistent, meaning that Oxygen XML Editor remembers them when subsequent documents are opened.

**Main CSS Style**

The **main styles** are listed in the top section and each of their corresponding CSS files are primarily used to render basic things such as the font and background of the document. You can only select one main style at a time.

**Alternate CSS Styles**

The **alternate styles** are listed in the bottom section and their corresponding CSS files are used to render numerous different types of things in the document as they are merged with the selected **main styles**. You can select as many alternate styles as you wish. If you are unsure about how each of the styles with change
the look of your documents based solely upon their name, there is no harm in selecting them to see the
difference. You can simply deselect them to revert to the previous look.

**Note:**
If you deselect the **Enable multiple selection of alternate CSSs** option *(on page 120)* in the **CSS**
subtab of the **Document Type** configuration dialog box *(on page 113)*, the alternate styles are treated
like **main CSS styles** and you can only select one at a time.

**EXAMPLE: CSS Styles in DITA**
Oxygen XML Editor comes with a set of built-in CSS layer stylesheets for DITA documents (as well as
some that are specifically for **DITA maps (on page 2966)**). In the subsequent figure, a DITA document has
the **Century** style selected for the **main CSS style** and the alternate styles **Full width, Show table column
specification, Hints, and Inline actions** are combined for additive styling to specific parts of the document.

**Tip:**
The **Hints** style displays tooltips throughout DITA documents that offer additional information to help
you with the DITA structure. The **Inline actions** style displays possible elements that are allowed to be
inserted at various locations throughout DITA documents.

**Figure 546. Styles Drop-down Menu in a DITA Document**

**Related Information:**
CSS Subtab *(on page 119)*
Creating and Customizing Author Mode Actions for a Framework

There are several possibilities for creating new Author mode actions:

- You can create new actions for a framework or edit existing ones using the Actions subtab of the Document Type configuration dialog box (on page 113). In this case, the actions are stored internally in the *framework file.
- You can export existing actions from the Document Type configuration dialog box (on page 113) into individual XML files or use a built-in template to create a new XML file that defines a single action. In this case, the actions are stored externally as separate XML files. The benefits of using this approach are explained in the Creating or Editing Actions Using an Individual XML File for Each Action (on page 2003) section below.

Creating or Editing Actions Using the Document Type Configuration Dialog Box

To add or configure Author mode actions for a framework (on page 2967) (document type) using the Document Type configuration dialog box (on page 113), follow this procedure:

1. Open the Preferences dialog box (Options > Preferences) (on page 98), go to Document Types Association, and select the framework.
2. Select your framework and click the Edit button (or you can use the Duplicate or Extend button to create an extension of the framework (on page 1987)).
3. In the resulting Document Type configuration dialog box (on page 113), go to the Author tab, then the Actions subtab.
4. To create a new action, click the New button. To edit an existing action, select the action and click the Edit button.

   **Step Result:** In either case, this opens the Action configuration dialog box (on page 121) where you can configure numerous aspects of the action.
5. Once you are finished, click OK several times to exit the configuration dialog box.

**Result:** Your changes are stored in the *framework file for your particular framework.

Creating or Editing Actions Using an Individual XML File for Each Action

It is possible to work with Author mode actions outside the Document Type configuration dialog box (on page 113) and store them externally from the *framework file. You can either export existing actions or use a template to create a new action from scratch. The benefits of using this approach are:

- You can share, copy, or reuse each individual action across multiple projects or frameworks.
- It is easier to develop and test action configurations. After configuring the XML file that defines an action, you can test its functionality by opening a document from your particular framework and invoking the action to see if it works as expected. If you did not get the desired result, you can simply repeat the process until you are happy with the result without having to navigate through the framework configuration dialog box.

**Exporting Actions**
To export existing Author mode actions into individual XML files, follow this procedure:

1. Open the Preferences dialog box (Options > Preferences) (on page 98), go to Document Types Association, and select the framework.
2. Select your framework and click the Edit button (or you can use the Duplicate or Extend button to create an extension of the framework (on page 1987)).
3. In the resulting Document Type configuration dialog box (on page 113), go to the Author tab, then the Actions subtab.
4. [Important] Make sure the Storage option (on page 114) in the top part of the dialog box is set to External and the external location must be a subdirectory of your current framework directory (see the Notes About the Storage Path section (on page 2006)).
5. Select the action (or multiple actions) you want to export, right-click, and use the Export action (this action is also located at the bottom of the table of actions).

   **Step Result:** If you choose to export a single action, a resulting dialog box will allow you to select the destination path for the new XML file that contains the configuration details of the action. If you export multiple actions, they will automatically be saved as individual XML files inside a newly created folder (it will have _externalAuthorActions at the end of the folder name) inside your current framework directory.
6. [Important] Click OK several times to confirm your changes and exit the Preferences dialog box. The files will not be created until you exit this dialog box.

   **Step Result:** Each exported action is extracted from the framework configuration file and exported as an individual XML file.
7. To configure and test a particular action, you can open its corresponding XML file in Oxygen XML Editor, make changes, save the file, then open a document from your framework, test the action and repeat until you get the desired result.

   **Note:**
   You can add or edit the action files outside of Oxygen XML Editor, but you will need to restart the application each time to reload the changes.

**Creating New Actions**

To create a new Author mode action outside the framework configuration dialog box, follow these steps:

1. Open the New document wizard (on page 335), search for a template called Author Action, and choose a storage path and file name. Remember that ultimately, it must be saved in a subdirectory of your particular framework directory (see the Notes About the Storage Path section (on page 2006)). Complete the creation process.

   **Step Result:** The resulting XML file contains some hints and it is an example of an action configuration that will insert a new paragraph.
2. Configure the action as needed and save your changes.
**Note:**

You can use XInclude to reuse different fragments (such as XPath expressions or configured operations between actions).

**Example: Reusing and XPath Expression**

```xml
<a:operations>
  <a:operation id="InsertFragmentOperation">
    <a:xpathCondition>
      <xi:include href="expression.txt" xmlns:xi="http://www.w3.org/2001/XInclude" parse="text"/>
    </a:xpathCondition>
    <a:arguments>
      <a:argument name="insertLocation">
        <xi:include href="expression.txt" xmlns:xi="http://www.w3.org/2001/XInclude" parse="text"/>
      </a:argument>
    </a:arguments>
  </a:operation>
</a:operations>
```

Where the content of the `expression.txt` file is `self::para`.

**Example: Reusing an Entire Operation**

```xml
<a:operations xmlns:a="http://www.oxygenxml.com/ns/author/external-action">
  <xi:include href="operation.xml" xpointer="element(/1/1)" xmlns:xi="http://www.w3.org/2001/XInclude"/>
</a:operations>
```

Where the content of `operation.xml` is:

```xml
<a:operations xmlns:a="http://www.oxygenxml.com/ns/author/external-action">
  <a:operation id="ToggleSurroundWithElementOperation">
    <a:xpathCondition>ancestor-or-self::p</a:xpathCondition>
    <a:arguments>
      <a:argument name="element"><i/></a:argument>
    </a:arguments>
  </a:operation>
</a:operations>
```

**Step Result:** At this point, the action has been created but it needs to be added to the UI (in a toolbar or menu).

3. Add the new action to a UI component. For example, to add it in a toolbar, open the **Document Type configuration dialog box** *(on page 113)*, go to the **Author** tab, then the **Toolbar** subtab *(on page 132)*, and add the action.
4. To test the action, you can open a document from your framework and test the action. If you don't get the desired result, open the action file, make changes, then test them again. Repeat until you get the desired result.

**Note:**
You can add or edit the action files outside of Oxygen XML Editor, but you will need to restart the application each time to reload the changes.

**Notes About the Storage Path**
As mentioned above, it is imperative that the action configuration files be stored in a specific subdirectory of your particular framework directory.

There are two possible naming conventions for this subdirectory:

- `{framework_directory}/externalAuthorActions` - If there are multiple framework subdirectories inside `{framework_directory}`, using this path structure will make the actions available to all of them.
- `{framework_directory}/{framework_file_name}.externalAuthorActions` - Using this path structure will make the actions only available in the framework stored inside the `{framework_file_name}.framework` file.

**Note:**
When exporting actions from the UI (on page 2003), this is the directory structure that is used.

**Action Configuration Tips**

- If an action is configured to insert a fragment that contains entities, you need to wrap it in `CDATA` markup.
- For a list of default operation, see Built-in Author Mode Operations (on page 2006).

**Related Information:**
Framework Configuration Dialog Box: Actions Subtab (on page 120)

**Built-in Author Mode Operations**
This topic lists the default operations for the Author mode.

**ChangeAttributeOperation**
This operation allows you to add/modify/remove an attribute. You can use this operation in your own custom Author mode action to modify the value for a certain attribute on a specific XML element. The arguments of the operation are:

- **name**
  The attribute local name.
namespace
   The attribute namespace.

elementLocation
   The XPath location that identifies the element.

value
   The new value for the attribute. If empty or null the attribute will be removed.

ediTAttribute
   If an in-place editor exists for this attribute, it will automatically activate the in-place editor and start editing.

removeIfEmpty
   The possible values are true and false. True means that the attribute should be removed if an empty value is provided. The default behavior is to remove it.

ChangeAttributesOperation
   This operation allows you to add/modify/remove multiple attributes. You can use this operation in your own custom Author mode action to modify the value for one or more attributes for one or more XML elements. The arguments of the operation are:

   elementLocations
      The XPath location that identifies the elements whose attributes will be affected. If not defined, the element at the cursor location will be used.

   attributeNameS
      The names of the attributes to add, modify, or remove, separated by the new-line character (\n). The values can be local names or Clark notations.

   values
      The new attributes values, each on a new line, separated by the new-line character (\n). An empty value will remove the attribute if removeIfEmpty is set to true.

   removeIfEmpty
      The possible values are true (default) and false. True means that the attribute will be removed if an empty value is provided.

ChangePseudoClassesOperation
   Operation that sets a list of pseudo-class values to nodes identified by an XPath expression. It can also remove a list of values from nodes identified by an XPath expression. The operation accepts the following parameters:

   setLocations
      An XPath expression indicating a list of nodes that will have the specified list of pseudo-classes set. If it is not defined, then the element at the cursor position will be used.
setPseudoClassNames

A space-separated list of pseudo-class names that will be set on the matched nodes.

removeLocations

An XPath expression indicating a list of nodes that will have the specified list of pseudo-classes removed. If it is not defined, then the element at the cursor position will be used.

removePseudoClassNames

A space-separated list of pseudo-class names that will be removed from the matched nodes.

includeAllNodes

The possible values are yes and no. If set to yes, comments, CDATA, and text nodes are included when evaluating XPath expressions. If set to no, they are ignored.

DeleteElementOperation

Deletes the node indicated by the elementLocation parameter XPath expression. If missing, the operation will delete the node at the cursor location.

DeleteElementsOperation

Deletes the nodes indicated by the elementLocations parameter XPath expression. If missing, the operation will delete the node at the cursor location.

ExecuteCommandLineOperation

This operation allows you to start a process executing a given command line. It has the following arguments:

name

The name of the operation (or name of the console panel that corresponds to the process run by an action built over this operation).

workingDirectory

The path to the directory where the command line is executed. The default value is . (current directory).

cmdLine

The command line to be executed (accepts editor variables (on page 2021)).

showConsole

If set to true, the console panel will be displayed in Oxygen XML Editor. The default value is false.

ExecuteMultipleActionsOperation

This operation allows the execution of a sequence of actions, defined as a list of action IDs. The actions must be defined by the corresponding framework, or one of the common actions for all frameworks supplied by Oxygen XML Editor.

actionIDs
The action IDs list that will be executed in sequence, the list must be a string sequence containing the IDs separated by commas or new lines.

**ExecuteMultipleWebappCompatibleActionsOperation**

An implementation of an operation that runs a sequence of Oxygen XML Web Author-compatible actions, defined as a list of IDs.

**ExecuteTransformationScenariosOperation**

This operation allows running one or more transformation scenarios defined in the current document type association (on page 2966), in the project options, or in the global options. A use case would be to add a toolbar button that triggers publishing to various output formats. The argument of the operation is:

scenarioNames

The list of scenario names that will be executed, separated by new lines.

**ExecuteValidationScenariosOperation**

This operation allows running one or more validation scenarios defined in the current document type association (on page 2966), in the project options, or in the global options. The single argument for the operation is:

scenarioNames

The list of scenario names that will be executed, separated by new lines.

**InsertEquationOperation**

Inserts a fragment containing a MathML equation at the cursor offset. The argument of this operation is:

fragment

The XML fragment containing the MathML content that should be inserted.

**InsertFragmentOperation**

Inserts an XML fragment at the current cursor position. The selection, if there is one, remains unchanged. The fragment will be inserted in the current context of the cursor position meaning that if the current XML document uses some namespace declarations then the inserted fragment must use the same declarations. The namespace declarations of the inserted fragment will be adapted to the existing namespace declarations of the XML document. For more details about its list of parameters, see Arguments of InsertFragmentOperation Operation (on page 2027).

**InsertOrReplaceFragmentOperation**

Similar to InsertFragmentOperation (on page 2009), except it removes the selected content before inserting the fragment. Also, the insertPosition parameter has another possible value: Replace. If this value is used, the operation deletes the node selected by the XPath expression denoted by the insertLocation parameter. For more details about its list of parameters, see Arguments of InsertFragmentOperation Operation (on page 2027).
**InsertOrReplaceTextOperation**

Inserts a text at current position removing the selected content, if any. The argument of this operation is:

- **text**
  
  The text section to insert.

**InsertXIncludeOperation**

Insert an XInclude element at the cursor offset. Opens a dialog box that allows you to browse and select content to be included in your document and automatically generates the corresponding XInclude instruction.

**JSOperation**

Allows you to call the Java API from custom JavaScript content. For some sample JSOperation implementations, see [https://github.com/oxygenxml/javascript-sample-operations](https://github.com/oxygenxml/javascript-sample-operations).

**Notice:**

For the Oxygen XML Web Author, this operation cannot be invoked using the JavaScript API.

This operation accepts the following parameter:

- **script**

  The JavaScript content to execute. It must have a function called `doOperation()`, which can use the predefined `authorAccess` variable. The `authorAccess` variable has access to the entire `ro.sync.ecss.extensions.api.AuthorAccess` Java API.

The following example is a script that retrieves the current value of the `type` attribute on the current element, allows the end-user to edit its new value and sets the new value in the document:

```javascript
function doOperation(){
    //The current node is either entirely selected...
    currentNode = authorAccess.getEditorAccess().getFullySelectedNode();
    if(currentNode != null){
        //or the cursor is placed in it
        caretOffset = authorAccess.getEditorAccess().getCaretOffset();
        currentNode = authorAccess.getDocumentController().getNodeAtOffset(caretOffset);
    }
    //Get current value of the @type attribute
    currentTypeValue = "";
    currentTypeValueAttr = currentNode.getAttribute("type");
    if(currentTypeValueAttr != null){
        currentTypeValue = currentTypeValueAttr.getValue();
    }
    //Ask user for new value for attribute.
}
```
newTypeValue = javax.swing.JOptionPane.showInputDialog
    ("Input @type value", currentTypeValue);
if(newTypeValue != null){
    //Create and set the new attribute value for the @type attribute.
    attrValue = new Packages.ro.sync.ecss.extensions.api.node.AttrValue
        (newTypeValue);
    authorAccess.getDocumentController().setAttribute
        ("type", attrValue, currentNode);
}
}

---

**Tip:**

You can call functions defined inside a script called `commons.js` from your custom script content so that you can use that external script file as a library of functions. Note that this `commons.js` file must be placed in the root of the `framework` directory (for example, `\OXYGEN_INSTALL_DIR\frameworks\dita\commons.js`) because that is the only location where Oxygen XML Editor will look for it.

---

**MoveCaretOperation**

Flexible operation for moving the cursor within a document and it is also capable of performing a selection. The operation accepts the following arguments:

- **xpathLocation**
  
  An XPath expression that identifies the node relative to where the cursor will be moved. If the expression identifies more than one node, only the first one will be taken into account.

- **position**
  
  The position relative to the node obtained from the XPath expression where the cursor will be moved. When also choosing to perform a selection, you can use the following possible values:

  - **Before** - Places the cursor at the beginning of the selection.
  - **Inside, at the beginning** - Places the cursor at the beginning of the selection.
  - **After** - Places the cursor at the end of the selection.
  - **Inside, at the end** - Places the cursor at the end of the selection.

- **selection**
  
  Specifies if the operation should select the element obtained from the XPath expression, its content, or nothing at all. The possible values of the argument are: `None`, `Element`, and `Content`.

**MoveElementOperation**

Flexible operation for moving an XML element to another location from the same document. XPath expressions are used to identify the source element and the target location. The operation takes the following parameters:
sourceLocation

XPath expression that identifies the content to be moved.

deleteLocation

XPath expression that identifies the node to be removed. This parameter is optional. If missing, the sourceLocation parameter will also identify the node to be deleted.

surroundFragment

A string representation of an XML fragment. The moved node will be wrapped in this string before moving it in the destination.

targetLocation

XPath expression that identifies the location where the node must be moved to.

insertPosition

Argument that indicates the insert position.

moveOnlySourceContentNodes

When true, only the content of the source element is moved.

processTrackedChangesForXpathLocations

When nodes are located via an XPath expression and the nodes are deleted with Change Tracking (on page 2971) enabled, they are considered as being present by default (thus, the change tracking is ignored). If you set this argument to true and change tracking is enabled, deleted nodes will be ignored when the XPath locations are computed (thus, the change tracking is NOT ignored).

OpenInSystemAppOperation

Opens a resource in the system application that is associated with the resource in the operating system. The arguments of this operation are:

resourcePath

An XPath expression that, when executed, returns the path of the resource to be opened. Editor variables (on page 292) are expanded in the value of this parameter, before the expression is executed.

isUnparsedEntity

Possible values are true or false. If the value is true, the value of the resourcePath argument is treated as the name of an unparsed entity.

ReloadContentOperation

Reloads the content of the editor by re-reading the information from the URL used to open it. It accepts the following argument:

markAsNotModified
The possible values are `true` and `false`. After reloading the editor, the content may appear as modified and in some cases where the content is already present on the file server, you would not want the user to save it again. You can set this flag to `true` to prevent the editor from showing the content as modified.

**RemovePseudoClassOperation**

An operation that removes a pseudo-class from an element. Accepts the following parameters:

- **name**
  
  Name of the pseudo-class to be removed.

- **includeAllNodes**
  
  The possible values are `yes` and `no`. If set to `yes`, comments, CDATA, and text nodes are included when evaluating XPath expressions. If set to `no`, they are ignored.

- **elementLocation**
  
  The XPath location that identifies the element. If it is not defined, then the element at the cursor position is used. It can also identify multiple elements, in which case the pseudo class will be removed from all of them.

**Example:**

Suppose that there is a pseudo-class called `myClass` on the element `paragraph` and there are CSS styles matching the pseudo-class.

```xml
paragraph:myClass{
    font-size:2em;
    color:red;
}
paragraph{
    color:blue;
}
```

In the previous example, by removing the pseudo-class, the layout of the `paragraph` is rebuilt by matching the other rules (in this case, the foreground color of the `paragraph` element will become blue.

**RenameElementOperation**

This operation allows you to rename all occurrences of the elements identified by an XPath expression. The operation requires two parameters:

- **elementName**
  
  The new element name.

- **elementLocation**
  
  The XPath expression that identifies the element occurrences to be renamed. If this parameter is missing, the operation renames the element at current cursor position.
**ReplaceElementContentOperation**

An operation that replaces the content of the element at the cursor location (or fully selected element). The operation accepts the following parameters:

- **fragment**
  Specifies the fragment that will be inserted as the element content.

- **elementLocation**
  An XPath expression that identifies the element. If it is not defined, then the element at the cursor position is used.

**SetPseudoClassOperation**

An operation that sets a pseudo-class to an element. The operation accepts the following parameters:

- **elementLocation**
  An XPath expression that identifies the element that will have the pseudo-class set. If it is not defined, then the element at the cursor position is used.

- **name**
  The pseudo-class local name.

- **includeAllNodes**
  The possible values are **yes** and **no**. If set to **yes**, comments, CDATA, and text nodes are included when evaluating XPath expressions. If set to **no**, they are ignored.

**ShowElementDocumentationOperation**

Opens the associated specification HTML page for the current element. The operation accepts as parameter a URL pattern that points to the HTML page containing the documentation.

**SurroundWithFragmentOperation**

Surrounds the selected content with a text fragment. Since the fragment can have multiple nodes, the surrounded content will be always placed in the first leaf element. If there is no selection, the operation will simply insert the fragment at the cursor position. For more details about the list of parameters go to: [Arguments of SurroundWithFragmentOperation (on page 2029)](#).

**SurroundWithTextOperation**

This operation has two arguments (two text values) that will be inserted before and after the selected content. If there is no selected content, the two sections will be inserted at the cursor position. The arguments of the operation are:

- **header**
  The text that is placed before the selection.

- **footer**
  The text that is placed after the selection.
TogglePseudoClassOperation

An implementation of an operation to toggle on/off the pseudo-class of an element. Accepts the following parameters:

name

- Name of the pseudo-class to be toggled on/off.

includeAllNodes

- The possible values are yes and no. If set to yes, comments, CDATA, and text nodes are included when evaluating XPath expressions. If set to no, they are ignored.

elementLocation

- The XPath location that identifies one or more elements that will have the pseudo class toggled. If it is not defined, then the element at the cursor position is used.

Example:

```xml
paragraph:myClass{
  color:red;
}
paragraph{
  color:blue;
}
```

By default, the paragraph content is rendered in blue. Suppose that you have a TogglePseudoClassOperation configured for the myClass pseudo-class. Invoking it the first time will set the myClass pseudo-class and the paragraph will be rendered in red. Invoking the operation again, will remove the pseudo-class and the visible result will be a blue rendered paragraph element.

ToggleSurroundWithElementOperation

This operation allows wrapping and unwrapping content in a specific wrapper element that can have certain attributes specified on it. It is useful to implement toggle actions such as highlighting text as bold, italic, or underline. The operation supports processing multiple selection intervals, such as multiple cells within a table column selection. The arguments of the operation are:

element

- The element to wrap or unwrap content.

schemaAware

- This argument applies only on the surround with element operation and controls whether or not the insertion is valid, based upon the schema. If the insertion is not valid, then wrapping action will be broken up into smaller intervals until the wrapping action is valid. For example, if you try to wrap a paragraph element with a bold element, it would not be valid, so the operation will wrap the text inside the paragraph instead, since it would be valid at that position.
**ToggleCommentOperation**

This operation allows for commenting or un-commenting the selected content. It does not have any arguments. If the selection is text, the operation wraps the selection in a comment. If the selection is a comment, the operation removes the comment.

**UnwrapTagsOperation**

This operation allows removing the element tags either from the current element or for an element identified with an XPath location. The argument of the operation is:

```plaintext
unwrapElementLocation
```

An XPath expression that identifies the element to unwrap. If it is not defined, the element at the cursor position is unwrapped.

**XQueryUpdateOperation**

Allows you to execute an XQuery Update script directly over content in **Author** mode.

---

**Notice:**

This operation is not applicable to the Oxygen XML Author Component or the Oxygen XML Web Author.

It supports the following arguments:

- **script**
  
  The XQuery Update script to be executed. The value can either be an XQuery script or a URL that points to the XQuery Update script. You can use the `${framework}` (on page 299) or `${frameworkDir}` (on page 299) editor variables to refer the scripts from the framework directory.
  
  The script will be executed in the context of the node at the cursor position. If the script declares the following variable, it will also receive the selected nodes (assuming that entire nodes are selected):

  ```xml
  declare variable $oxyxq:selection external;
  ```

  In the example below (on page 2017), you can see how this argument is used.

- **externalParams**
  
  A string that can assign multiple key-value pairs separated by a comma or a new line character.
  
  For example, if an XQuery script declares two external parameters like this:

  ```xml
  declare variable $param1 external;
  declare variable $param2 external;
  ```

  You can pass custom values for each parameter by setting the `externalParams` to `param1=value1,param2=value2`.

- **expandXincludeReferences**

---
Makes all Xinclude elements transparent to the XQuery transformer. When the Xinclude references are transparent, the XQueryUpdateOperation can use the referenced elements for further processing in the current document, but it cannot change their values in the original document. The default value is false, which means the Xinclude elements are not transparent.

An example of an XQuery Update Script that converts paragraphs to list items:

```xml
declare namespace oxyxq = "http://www.oxygenxml.com/ns/xqu";
(: This variable will be linked to the selected nodes assuming that there are actually fully selected nodes. For example this selection will return null:
<p>{SEL_START}text{SEL_END} in para</p>
but this will give two "p" elements:
{SEL_END}<p>text</p><p>text2</p>{SEL_END}
If a multiple selection exists it will also be processed and forwarded.
Again, only fully selected nodes will be passed.
:)
declare variable $oxyxq:selection external;
(: We will process either the selection or the context node :) let $toProcess := if (empty($oxyxq:selection)) then 
  .
else
  ($oxyxq:selection)
return if (not(empty($toProcess))) then
  {
    (: Create the list :) let $ul :=
    <ul>
      { for $sel in $toProcess
        return
        <li>{$sel}</li>
      }
    </ul>
return
  (: Delete the processed nodes :) for $sel in $toProcess
    return
    delete node $sel,
  (: Inserts the constructed list :)
```
XSLTOperation and XQueryOperation

Applies an XSLT or XQuery script on a source element and then replaces or inserts the result in a specified target element.

Notice:
For Oxygen XML Web Author, these operations cannot be invoked using the JavaScript API.

These operations accept the following parameters:

sourceLocation

An XPath expression indicating the element that the script will be applied on. If it is not defined, then the element at the cursor position will be used.

There may be situations where you want to look at an ancestor of the current element and take decisions in the script based on this. To do this, you can set the sourceLocation to point to an ancestor node then use the oxy:current-element() function to access the current element, as in the following example:

```xml
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="2.0"
    xpath-default-namespace="http://docbook.org/ns/docbook"
    xmlns:oxygen="http://www.oxygenxml.com/ns/author/xpath-extension-functions"
    exclude-result-prefixes="oxy">
  <xsl:template match="/"
    select="oxy:current-element()" />
</xsl:template>

<xsl:template match="para">
  <!-- And the context is again inside the current element, but we can use information from the entire XML -->
  <xsl:variable name="keyImage" select="/imagedata[@fileref='images/lake.jpeg']/ancestor::inlinemediaobject/@xml:id/string()"/>
  <xref linkend="{$keyImage}" role="key_include"
    xmlns="http://docbook.org/ns/docbook">
    <xsl:value-of
      select="{$currentElementLocation"/>
  </xref>
</xsl:template>
```
targetLocation

An XPath expression indicating the insert location for the result of the transformation. If it is not defined then the insert location will be at the cursor location.

script

The script content (XSLT or XQuery). The base system ID for this will be the framework file, so any include/import reference will be resolved relative to the .framework file that contains this action definition.

For example, for the following script, the imported xslt_operation.xsl needs to be located in the current framework directory.

```xml
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    version="1.0">
  <xsl:import href="xslt_operation.xsl"/>
</xsl:stylesheet>
```

You can also use a path for an included or imported reference. When using a path, the following apply:

- A relative path is resolved to the framework directory.
- The `${framework}` editor variable (on page 299) can also be used to reference resources from the framework directory.
- The path is passed through the catalog mappings. It helps to use an absolute URL (for instance, http://www.oxygenxml.com/fr/testy.xsl) and map it in the catalog.xml file from the framework directory to a resource from the framework.

action

The insert action relative to the node determined by the target XPath expression. It can be: Replace, At cursor position, Before, After, Inside as first child or Inside as last child.

caretPosition

The position of the cursor after the action is executed. It can be: Preserve, Before, Start, First editable position, End, or After. If this parameter is not set, you can still indicate the position of the cursor by using the `${caret}` editor variable (on page 297) in the inserted content.

expandEditorVariables

Parameter controlling the expansion of editor variables (on page 292) returned by the script processing. Expansion is enabled by default.

suspendTrackChanges

It has 2 possible values (true and false). The default value is false. When set to true, the Track Changes (on page 2971) feature is deactivated. When using this argument, after the action is finished, the state of the Track Changes feature is restored to its initial value.
**externalParams**

A string that can assign multiple key-value pairs separated by a comma or a new line character.

For example, if an XQuery script declares two external parameters like this:

```xml
declare variable $param1 external;
declare variable $param2 external;
```

You can pass custom values for each parameter by setting the `externalParams` to `param1=value1,param2=value2`.

**XSLTOperation Example: Sort a list with respect to the language declared on the root element:**

Suppose you want an action that will sort a list with respect to the language declared on the root element and you have an XML file like this:

```xml
<article xml:lang="en">
  <ul>
    <li>B</li>
    <li>C</li>
    <li>A</li>
  </ul>
</article>
```

The **XSLTOperation** needs to be configured as follows:

- **sourceLocation** is set to `/*` so that the script has access to the root element and its children.
- **targetLocation** is left untouched (assuming that the action is active only when the cursor is inside the list).

The XSLT script would look like this:

```xml
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
 xmlns:oxy="http://www.oxygenxml.com/ns/author/xpath-extension-functions"
 xmlns:xm="http://www.w3.org/2001/XMLSchema"
 exclude-result-prefixes="xs oxy" version="2.0">

  <xsl:template match="/">
    <!--
    sourceLocation parameter was set to /* to have a larger context.
    We can pinpoint the element that contained the caret
    using the oxy:current-element() function.
    -->
    <xsl:apply-templates select="oxy:current-element()"/>
  </xsl:template>

  <xsl:template match="ul">

  </xsl:template>

</xsl:stylesheet>
```
Because the sourceLocation parameter was set to /* we now have access to the root element and its attributes. -->

```xml
<xsl:variable name="lang" select="/*/@xml:lang"/>
<xsl:variable name="collationURI">
  <xsl:value-of select="concat("http://www.w3.org/2013/collation/UCA?lang=', $lang')"/>
</xsl:variable>

<xsl:copy>
  <xsl:copy-of select="@*"/>
</xsl:copy>

<!-- Copy the list items, but sorted. -->
<xsl:apply-templates select="li">
  <xsl:sort collation="{$collationURI} select="text()"/>
</xsl:apply-templates>
</xsl:copy>
</xsl:template>

<!-- This copy template will handle the contents of the list items. -->
<xsl:template match="@* | node()">
  <xsl:copy>
    <xsl:copy-of select="@* | node()"/>
  </xsl:copy>
</xsl:template>
</xsl:stylesheet>

Using Entities and Xincludes with the XSLTOperation

- **Entities** will be resolved in the result.
- **Xincludes** are also resolved in the result, and you can alter the XML obtained after the resolving using the XSLT/XQuery script of the operation, but you cannot alter the included document itself.

Editor Variables in Author Mode Operations

**Author** mode operations can include parameters that contain the following editor variables *(on page 292)*:

- `$caret` - The position where the cursor is located. This variable can be used in a code template, in **Author** mode operations, or in a **selection** plugin.

**Note:**
The `$caret` editor variable is available only for parameters that take XML content as values. It is replaced with the `$UNIQUE_CARET_MARKER` macro. The default Author operations process this macro and position the cursor at the designated offset.
Note:
The ${caret} editor variable can be used for setting a fixed cursor position inside an XML fragment. To set the cursor position depending on the fragment inserted in the document, you can use AuthorDocumentFilter and inside the insertFragment(AuthorDocumentFilterBypass, int, AuthorDocumentFragment) method, use the AuthorDocumentFragment.setSuggestedRelativeCaretOffset(int) API on the given fragment.

- **${selection}** - The currently selected text content in the currently edited document. This variable can be used in a code template, in Author mode operations, or in a selection plugin.
- **${ask('message', type, ('real_value1':'rendered_value1'; 'real_value2':'rendered_value2'; ...), 'default-value', @id)}** - To prompt for values at runtime, use the ask('message', type, ('real_value1':'rendered_value1'; 'real_value2':'rendered_value2'; ...), 'default-value') editor variable. You can set the following parameters:
  - **message** - The displayed message. Note the quotes that enclose the message.
  - **default-value** - Optional parameter. Provides a default value.
  - **@id** - Optional parameter. Used for identifying the variable to reuse the answer using the ${answer(@id)} editor variable.
  - **type** - Optional parameter (defaults to generic), with one of the following values:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Format</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
</table>
  | generic (default) | ${ask('message', generic, 'default')}) | The input is considered to be generic text that requires no special handling. | - ${ask('Hello world!')} - The dialog box has a Hello world! message displayed.  
<p>|              |                            |                                                  | - ${ask('Hello world!', generic, 'Hello again!')} - The dialog box has a Hello world! message displayed and the value displayed in the input box is 'Hello again!'. |
| url         | ${ask('message', url, 'default_value')}) |                                                  |                                                                         |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description: Input is considered a URL. Oxygen XML Editor checks that the provided URL is valid.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>\n</td>
</tr>
<tr>
<td></td>
<td>- <code>${ask('Input URL', url, 'http://www.example.com')}</code> - The displayed dialog box has the name Input URL. The expected input type is URL. The input field displays the default value <a href="http://www.example.com">http://www.example.com</a>.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>relative_url</th>
<th>Format: <code>${ask('message', relative_url, 'default')}</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Description:</td>
<td>Input is considered a URL. Oxygen XML Editor tries to make the URL relative to that of the document you are editing.</td>
</tr>
<tr>
<td>Note:</td>
<td>If the <code>$ask</code> editor variable is expanded in content that is not yet saved (such as an <code>untitled</code> file, whose path cannot be determined), then Oxygen XML Editor will transform it into an absolute URL.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>${ask('File location', relative_url, 'C:/example.txt')}</code> - The dialog box has the name 'File location'. The URL inserted in the input box is made relative to the currently edited document location.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>password</th>
<th>Format: <code>${ask('message', password, 'default')}</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Description:</td>
<td>The input is hidden with bullet characters.</td>
</tr>
<tr>
<td>Example:</td>
<td>- <code>${ask('Input password', password)}</code> - The displayed dialog box has the name 'Input password' and the input is hidden with bullet symbols.</td>
</tr>
<tr>
<td></td>
<td>- <code>${ask('Input password', password, 'abcd')}</code> - The displayed dialog box has the name 'Input password' and the input hidden with bullet symbols. The input field already contains the default abcd value.</td>
</tr>
</tbody>
</table>

<p>| combobox     | Format: <code>${ask('message', combobox, ('real_value1':'rendered_value1';...;'real_valueN':'rendered_valueN'), 'default')}</code> |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>combobox</td>
<td>Displays a dialog box that offers a drop-down menu. The drop-down menu is populated with the given rendered_value values. Choosing such a value will return its associated value (real_value).</td>
<td>• ${ask('Operating System', combobox, ('win':'Microsoft Windows';'macos':'macOS';'lnx':'Linux/UNIX'), 'macos')} - The dialog box has the name 'Operating System'. The drop-down menu displays the three given operating systems. The associated value will be returned based upon your selection.</td>
</tr>
<tr>
<td>editable_combobox</td>
<td>Displays a dialog box that offers a drop-down menu with editable elements. The drop-down menu is populated with the given rendered_value values. Choosing such a value will return its associated real value (real_value) or the value inserted when you edit a list entry.</td>
<td></td>
</tr>
</tbody>
</table>
Parameter

| Note: | The list of 'real_value':'rendered_value' pairs can be computed using ${xpath_eval()}. |
| Note: | The 'default' parameter specifies the default-selected value and can match either a key or a value. |

Example:

- `${ask('Operating System', editable_combobox, ('win': 'Microsoft Windows'; 'macos': 'macOS'; 'lnx': 'Linux/UNIX'), 'macos')}` - The dialog box has the name 'Operating System'. The drop-down menu displays the three given operating systems and also allows you to edit the entry. The associated value will be returned based upon your selection or the text you input.
- `${ask('Operating System', editable_combobox, ({$xpath_eval(for $item in //items return ''||$item||''::''||$item||'')); 'macos'})}`

Radio

Format: `${ask('message', radio, ('real_value1':'rendered_value1';...;'real_valueN':'rendered_valueN'), 'default')}`

Description: Displays a dialog box that offers a series of radio buttons. Each radio button displays a 'rendered_value' and will return an associated real_value.

| Note: | The list of 'real_value':'rendered_value' pairs can be computed using ${xpath_eval()}. |
| Note: | The 'default' parameter specifies the default-selected value and can match either a key or a value. |

Example:

- `${ask('Operating System', radio, ('win': 'Microsoft Windows'; 'macos': 'macOS'; 'lnx': 'Linux/UNIX'), 'macos')}` - The dialog box has the name 'Operating System'. The radio button group allows you to choose between the three operating systems.
<table>
<thead>
<tr>
<th>Parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong></td>
</tr>
<tr>
<td>In this example, macOS is the default-selected value and if selected, it would return macos for the output.</td>
</tr>
</tbody>
</table>

- **${ask('Operating System', radio, ($xpath_eval(for $item in //items return ""||$item||":""||$item||""||""||$item||""||""||$item||""||""))} 'macos')**

- **${timeStamp}** - The timestamp, which is the current time in Unix format. For example, it can be used to save transformation results in multiple output files on each transformation.

- **${uuid}** - Universally unique identifier, a unique sequence of 32 hexadecimal digits generated by the Java UUID class.

- **${id}** - Application-level unique identifier. It is a short sequence of 10-12 letters and digits that is not guaranteed to be universally unique.

- **${cfn}** - Current file name without the extension and parent folder. The current file is the one currently open and selected.

- **${cfne}** - Current file name with extension. The current file is the one currently open and selected.

- **${cf}** - Current file as file path, that is the absolute file path of the currently edited document.

- **${cfd}** - Current file folder as file path, that is the path of the currently edited document up to the name of the parent folder.

- **${frameworksDir}** - The path (as file path) of the frameworks directory. When used to define references inside a framework configuration, it expands to the parent folder of that specific framework folder. Otherwise, it expands to the main frameworks folder defined in the Document Type Association > Locations preferences page.

- **${pd}** - The file path to the folder that contains the current project file (.xpr).

- **${oxygenInstallDir}** - Oxygen XML Editor installation folder as file path.

- **${homeDir}** - The path (as file path) of the user home folder.

- **${pn}** - Current project name.

- **${env(VAR_NAME)}** - Value of the VAR_NAME environment variable. The environment variables are managed by the operating system. If you are looking for Java System Properties, use the **${system(var.name)}** editor variable.

- **${system(var.name)}** - Value of the var.name Java System Property. The Java system properties can be specified in the command-line arguments of the Java runtime as -Dvar.name=var.value. If you are looking for operating system environment variables, use the **${env(VAR_NAME)}** editor variable instead.

- **${date(pattern)}** - Current date. The allowed patterns are equivalent to the ones in the Java SimpleDateFormat class. Example: yyyy-MM-dd.

**Note:**
This editor variable supports both the xs:date and xs:dateTime parameters. For details about xs:date, go to: [http://www.w3.org/TR/xmlschema-2/#date](http://www.w3.org/TR/xmlschema-2/#date). For details about xs:dateTime, go to: [http://www.w3.org/TR/xmlschema-2/#dateTime](http://www.w3.org/TR/xmlschema-2/#dateTime).
How to Find More Information About the Arguments of an Operation

If you need to find more information about the arguments of an operation, there are several places where this information is available:

- In the API documentation for the particular operation.
- By invoking the `getArguments()` method on the operation.
- In the source code of the operation.
- In Oxygen XML Editor:
  1. Go to Options > Preferences > Document Type Association, select a document type and click the New, Edit, Duplicate, or Extend button (on page 111).
  2. Go to the Author tab and then the Actions subtab. At the bottom of this subtab, click + New to open the Action dialog box (on page 121).
  3. Locate the Operation field and click the Choose button on the right side. This will open a dialog box that displays the default operations.
  4. Double-click the operation (or select it and click OK).

The arguments for the operation will now be displayed in the Action dialog box (on page 121).

Arguments of InsertFragmentOperation Operation

**fragment**

This argument has a textual value. This value is parsed by Oxygen XML Editor as it was already in the document at the cursor position. You can use entity references declared in the document and it is namespace aware. The fragment may have multiple roots.

You can even use namespace prefixes that are not declared in the inserted fragment, if they are declared in the document where the insertion is done. For the sake of clarity, you should always prefix and declare namespaces in the inserted fragment!

If the fragment contains namespace declarations that are identical to those found in the document, the namespace declaration attributes will be removed from elements contained by the inserted fragment.

There are two possible scenarios:

- **Prefixes that are not bound explicitly**
  
  For instance, the fragment:

  ```xml
  <x:item id="dty2"/>
  &ent;
  <x:item id="dty3"/>
  ```

  Can be correctly inserted in the document: ('|' marks the insertion point):

  ```xml
  <?xml version="1.0" encoding="UTF-8"?>
  <!DOCTYPE x:root []
  <!ENTITY ent "entity"> ```
<x:root xmlns:x="nsp">
  |
</x:root>

Result:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE x:root [<!ENTITY ent "entity">]>
<x:root xmlns:x="nsp">
  <x:item id="dty2"/>
  &ent;
  <x:item id="dty3"/>
</x:root>
```

- **Default namespaces**

  If there is a default namespace declared in the document and the document fragment (on page 2966) does not declare a namespace, the elements from the fragment are considered to be in no namespace.

  For instance, the fragment:

  ```xml
  <item id="dty2"/>
  <item id="dty3"/>
  ```

  Inserted in the document:

  ```xml
  <?xml version="1.0" encoding="UTF-8"?>
  <root xmlns="nsp">
    |
  </root>
  ```

  Gives the result document:

  ```xml
  <?xml version="1.0" encoding="UTF-8"?>
  <root xmlns="nsp">
    <item xmlns="" id="dty2"/>
    <item xmlns="" id="dty3"/>
  </root>
  ```

**insertLocation**

An XPath expression that is relative to the current node. It selects the reference node for the fragment insertion. When missing, the fragment will be inserted at the cursor position.

**insertPosition**
Specifies where the insertion is made relative to the reference node selected by the
`insertLocation`. It can be one of the following constants:

- **Inside as first child** (default value) - The fragment is inserted as first child of the reference node.
- **Inside as last child** - The fragment is inserted as the last child of the reference node.
- **After** - The fragment is inserted after the reference node.
- **Before** - The fragment is inserted before the reference node.

`goToNextEditablePosition`

After inserting the fragment, the first editable position is detected and the cursor is placed at that location. It handles any in-place editors used to edit attributes. It will be ignored if the fragment specifies a cursor position using the `$({caret})` editor variable (on page 297). The possible values of this action are `true` and `false`.

`schemaAware`

This argument applies only on the surround with element operation and controls whether or not the insertion is valid, based upon the schema. If the insertion is not valid, then wrapping action will be broken up into smaller intervals until the wrapping action is valid. For example, if you try to wrap a `paragraph` element with a `bold` element, it would not be valid, so the operation will wrap the text inside the paragraph instead, since it would be valid at that position.

`insertEvenIfInvalid`

The possible values of this argument are `true` and `false`. If `true`, the content that would make the document invalid is accepted. If `false` and the insertion is not valid, the operation will not be executed and an error message will be displayed.

**Arguments of SurroundWithFragmentOperation**

`fragment`

The XML fragment that will surround the selection. For example, consider the fragment:

```xml
<F>
    <A/>
    <B>
        <C/>
    </B>
</F>
```

and the document:

```xml
<doc>
    <X/>
    <Y/>
    <Z/>
</doc>
```
Considering the selected content to be surrounded is the sequence of elements $X$ and $Y$, then the result is:

```xml
<doc>
  <F>
    <A>
      <X/></X>
      <Y/></Y>
    </A>
    <B>
      <C/></C>
    </B>
  </F>
  <Z/></Z>
</doc>
```

Since the element $A$ was the first leaf in the fragment, it received the selected content. The fragment was then inserted in the place of the selection.

**Note:**
If the first leaf is not the desired location for the surrounded fragment, you can use `ro.sync.ecss.extensions.commons.operations.InsertOrReplaceFragmentOperation` and set the following arguments:

- **fragment**
  The XML fragment that will surround the selection. Use the `${selection}` editor variable in the location you want to place the surrounded fragment.

- **schemaAware**
  Set it to `false` to avoid moving the fragment if it is not valid at the given location.

**schemaAware**
This argument applies only on the surround with element operation and controls whether or not the insertion is valid, based upon the schema. If the insertion is not valid, then wrapping action will be broken up into smaller intervals until the wrapping action is valid. For example, if you try to wrap a `paragraph` element with a `bold` element, it would not be valid, so the operation will wrap the text inside the paragraph instead, since it would be valid at that position.

**Adding a Custom Operation to an Existing Framework**
This task explains how to add a custom **Author** mode operation to an existing **framework (on page 2967)** (document type).
1. Set up a sample project by following the instructions for installing the SDK.

   **Tip:**
   The SDK contains a sample framework project called `oxygen-sample-framework`.

2. A variety of classes in the `simple.documentation.framework.operations` package implement the `ro.sync.ecss.extensions.api.AuthorOperation` interface. Depending on your use-case, modify one of these classes.

3. Copy the operation class inside a Java JAR library.

4. Pack the operation class inside a Java JAR library.

5. Open the Preferences dialog box (Options > Preferences) (on page 98), go to Document Type Association, and edit the document type (you need write access to the `OXYGEN_INSTALL_DIR`) to open the Document Type configuration dialog box (on page 113).
   a. In the Classpath tab, add a reference to your JAR library (for example, `customAction.jar`).
   b. Go to the Author tab, then go to the Actions subtab.
   c. Click the `New` button and use the Action dialog box (on page 121) to create a new action that uses your custom operation.
   d. Mount the action to the toolbars or menus. You can also define a shortcut key.

6. Share the modifications (on page 2131) with your colleagues. The files that should be shared are your `customAction.jar` library and the `.framework` configuration file from the `OXYGEN_INSTALL_DIR/frameworks/[FRAMEWORK_DIR]` directory.

**Related Information:**

AuthorOperation API

**Example: Configuring the Insert Section Action for a Framework**

This topic describes the procedure for defining the **Insert Section** action for a custom framework (on page 2967). It is assumed that the icon files, `Section16.gif` for the menu item and `Section20.gif` for the toolbar, are already available. Although you could use the same icon size for both the menu and toolbar, usually the icons from the toolbars are larger than the ones found in the menus. These files should be placed in your custom `framework` directory (`OXYGEN_INSTALL_DIR/frameworks/[CUSTOM_FRAMEWORK_DIR]`).
1. Set the **ID** field to `insert_section`. This is a unique action identifier.

2. Set the **Name** field to `Insert Section`. This will be the action's name, displayed as a tooltip when the action is placed in the toolbar, or as the menu item name.

3. Set the **Menu access key** to `i`. On Windows, the menu items can be accessed using **Alt+letter** keys combination, when the menu is visible. The **letter** is visually represented by underlining the first letter from the menu item name having the same value.

4. Add a **Description**.

5. Set the **Large icon (20x20)** field to `${framework}/Section20.gif`. A good practice is to store the image files inside the `framework` directory and use **editor variable (on page 292)** `${framework}` to make the image relative to the `framework` location.

   If the images are bundled in a **JAR (on page 2967)** archive together with some Java operations implementation, for instance, it might be convenient for you to reference the images not by the file name, but by their relative path location in the class-path.

   If the image file `Section20.gif` is located in the `images` directory inside the `JAR` archive, you can reference it by using `/images/Section20.gif`. The `JAR` file must be added into the **Classpath** list.

6. Set the **Small icon (16x16)** field to `${framework}/Section16.gif`.

7. Click the text field next to **Shortcut key** and set it to `Ctrl+Shift+S (Meta+Shift+S on macOS)`. This will be the key combination to trigger the action using the keyboard only.

   The shortcut is enabled only by adding the action to the main menu of **Author mode (on page 2034)**, which contains all the actions that the author will have in a menu for the current document type.
At this time the action has no functionality added to it. Next you must define how this action operates.

An action can have multiple operation modes. The first action mode enabled by the evaluation of its associated XPath expression will be executed when the action is triggered by the user. The XPath expression needs to be version 2.0 and its scope must be only element and attribute nodes of the edited document. Otherwise, the expression will not return a match and will not trigger the action. If the expression is left empty, the action will be enabled anywhere in the scope of the root element. For this example, suppose you want the action to add a section only if the current element is either a `<book>`, `<article>`, or another `<section>`.

a. Set the XPath expression field to:

```
local-name()='section' or local-name()='book' or local-name()='article'
```

b. Set the invoke operation field to `InsertFragmentOperation` built-in operation, designed to insert an XML fragment at the cursor position. This belongs to a set of built-in operations, a complete list of which can be found in the `Author Default Operations (on page 2006)` section. This set can be expanded with your own Java operation implementations.

c. Configure the arguments section as follows:

```
<section xmlns="http://www.oxygenxml.com/sample/documentation">
  <title/>
</section>
```

- `insertLocation` - leave it empty. This means the location will be at the cursor position.
- `insertPosition` - select "Inside".

**Example: Configuring the Insert Table Action for a Framework**

This topic describes the procedure for defining the `Insert Table` action for a custom framework (on page 2967). Suppose that you want to create an action that inserts a table with three rows and three columns into a document and the first row is the table header. As with the `insert section` action (on page 2031), you will use the `InsertFragmentOperation` built-in operation.

Place the icon files for the menu item, and for the toolbar, in your custom framework directory (`{OXYGEN_INSTALL_DIR}\frameworks\{CUSTOM_FRAMEWORK_DIR}\`).

1. Set ID field to `insert_table`.
2. Set Name field to `Insert table`.
3. Set Menu access key field to `t`.
4. Set Description field to `Adds a table element`.
5. Set Toolbar icon to `$(framework) / toolbaricon.png`.
6. Set Menu icon to `$(framework) / menuicon.png`.
7. Set Shortcut key to `Ctrl + Shift + T (Command + Shift + T on OS X)`.
8. Set up the action's functionality:
a. Set **XPath expression** field to `true()`.  
`true()` is equivalent with leaving this field empty.

b. Set **Invoke operation** to use `InsertFragmentOperation` built-in operation that inserts an XML fragment to the cursor position.

c. Configure operation's arguments as follows:

<table>
<thead>
<tr>
<th><strong>fragment</strong></th>
<th>set it to:</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;table xmlns=&quot;http://www.oxygenxml.com/sample/documentation&quot;&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;header&gt;&lt;td/&gt;&amp;lt;td/&amp;gt;&amp;lt;td/&gt;&amp;lt;/header&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;tr&gt;&lt;td/&gt;&amp;lt;td/&amp;gt;&amp;lt;td/&amp;gt;&amp;lt;/tr&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;tr&gt;&lt;td/&gt;&amp;lt;td/&amp;gt;&amp;lt;td/&amp;gt;&amp;lt;/tr&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;/table&gt;</code></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>insertLocation</strong></th>
<th>to add tables at the end of the section use the following code:</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ancestor::*[last()]</code></td>
<td></td>
</tr>
</tbody>
</table>

### Using Retina/HiDPI Icons for the Actions from a Framework

Higher resolution icons can also be included in customized frameworks (on page 2967) for rendering them in a Retina or HiDPI display. The icons can be referenced directly from the Document Type Configuration dialog box (on page 113) (from the Action dialog box (on page 121)) or from an API (ro.sync.exml.workspace.api.node.customizer.XMLNodeRendererCustomizer (on page 2113)).

As with any image, the higher resolution icons are stored in the same images folder as the normal resolution images and they are identified by a scaling factor that is included in the name of the image files. For instance, icons with a Retina scaling factor of 2 will include `@2x` in the name (for example, `myIcon@2x.png`).

Developers should not specify the path of the alternate icons (`@2x` or `@3x`) in the Action dialog box (on page 121) or the XMLNodeRendererCustomizer API (on page 2113). When using a Retina or HiDPI display, Oxygen XML Editor automatically searches the folder of the normal icon for a corresponding image file with a Retina scaling factor in the name. If the higher resolution icon file does not exist, the normal icon is scaled and used instead.

**Related Information:**

- Retina/HiDPI Images in Author Mode (on page 678)

### Customizing the Menu for a Framework

Defined actions can be grouped into customized menus in the Oxygen XML Editor menu bar.
1. Open the **Document Type** configuration dialog box *(on page 113)*, select your custom **framework** *(on page 2967)*, and go to the **Author** tab.

2. Go to the **Menu** subtab. In the left side you have the list of actions and some special entries:
   - **Submenu** - Creates a submenu. You can nest an unlimited number of menus.
   - **Separator** - Creates a separator into a menu. This way you can logically separate the menu entries.

3. The right side of the panel displays the current actions for that menu tree. To change its name, click this label to select it, then click the **Edit** button.

4. Select the **Submenu** label in the left panel section and the appropriate label in the right panel section, then click the ➜ **Add as child** button. Change the submenu name to **Table**, using the **Edit** button.

5. Select the **Insert section** action in the left panel section and the **Table** label in the right panel section, then click the ➜ **Add as sibling** button.

6. Now select the **Insert table** action in the left panel section and the **Table** in the right panel section. Click the ➜ **Add as child** button.

**Figure 548. Configuring the Menu**

When opening a test document for a custom **framework** in **Author** mode, the menu you created is displayed in between the **Tools** and the **Document** menus. The upper part of the menu contains generic **Author** mode actions (common to all document types) and the two actions created previously (with **Insert table** under the **Table** submenu).
Customizing the Contextual Menu for a Framework

The contextual menu is displayed when you right-click in the Author editing area. You can only configure the bottom part of the menu, since the top part is reserved for a list of generic actions (such as Copy, Paste, Undo, etc.)

1. Open the Document Type configuration dialog box (on page 113) for the particular framework (on page 2967) and go to the Author tab. Next, go to the Contextual Menu subtab.
2. Follow the same steps as explained in the Configuring the Main Menu (on page 2034), except changing the menu name because the contextual menu does not have a name.

Note:

You can choose to reuse a submenu that contains general authoring actions. In this case, all actions (both general and framework-specific ones) are grouped together under the same submenu.
To test it, open the test file, and open the contextual menu. In the lower part there is shown the Table sub-menu and the Insert section action.

### Customizing the Content Completion Assistant for Author Mode Only

You can customize the content of the following Author controls, adding items (which, when invoked, perform custom actions) or filtering the default contributed ones:

- **Content Completion Assistant (on page 2965)** window
- **Elements view (on page 589)**
- **Insert Element** menus (from the Outline view (on page 498) or breadcrumb (on page 560) contextual menus)

You can use the content completion customization support in a custom framework (on page 2967) by following this procedure:

1. Open the Document type configuration dialog box (on page 113) for your custom framework and select the Author tab. Next, go to the Content Completion tab (on page 133).

![Figure 551. Customize Content Completion](image)

The top side of the Content Completion section contains the list with all the actions defined within the custom framework and the list of actions that you decided to include in the Content Completion Assistant list of proposals. The bottom side contains the list with all the items that you decided to remove from the Content Completion Assistant list of proposals.

2. If you want to add a custom action to the list of current Content Completion proposals, select the action item from the Available actions list and click the Add as child or Add as sibling button to include it in the Current actions list. A Content Completion Item dialog box appears, giving you the possibility to select where to provide the selected action.
3. If you want to exclude a certain item from the Content Completion proposals, you can use the + Add button from the Filter - Remove content completion items list. The Remove item dialog box is displayed, allowing you to input the item name and to choose the controls that filter it. The Item name combo box accepts wildcards.

Customizing the Toolbars for a Framework

This procedure describes how to add defined actions to a toolbar for a custom framework. You can also create additional custom toolbars with existing or custom actions.
1. Open the **Document Type** configuration dialog box *(on page 113)* for your custom framework and select the **Author** tab.
2. Go to the **Toolbar** subtab.

**Figure 554. Configuring the Toolbar**

The panel is divided in two sections. The left side contains a list of actions, while the right side contains an action tree, displaying the list of actions added in the toolbar. The special entry called **Separator** allows you to visually separate the actions in the toolbar.

3. To add an action, select it in the left panel and select the particular toolbar label where you want it added in the right panel section, then click the **Add as child** or **Add as sibling** button.

**Result:** When opening a document for the particular framework in **Author** mode, the toolbar with the new buttons will be displayed in the toolbar area.

**Tip:**
If you have many custom toolbar actions, or want to group actions according to their category, add more toolbars with custom names and split the actions to better suit your purpose. If your toolbar is not displayed when switching to the **Author** mode, right-click the main toolbar, select **Configure Toolbars**, and make sure the appropriate toolbar (such as the **Author Custom Actions** toolbar) is selected.

**Note:**
A maximum of 16 toolbars can be added. If you add more, all extra toolbars will be automatically converted to sub-toolbars for the last added toolbar.

**Customizing Text-to-Markup Shortcut Patterns**

Some built-in frameworks include a configuration file that defines shortcut patterns that can be used in **Author** mode to automatically insert a certain XML structure. More specifically, the XML structure (fragment)
automatically replaces a specific prefix pattern. For example, if you are editing a DITA document using the built-in DITA framework, entering a hyphen (-) followed by a space at the beginning of a paragraph would automatically replace them with an unordered list element (<ul>) with a child list item element (<li>). This is made possible by the AutoCorrect mechanism in Oxygen XML Editor.

It is possible to customize the particular configuration file (structureAutocorrect.xml) to define your own markup insertion shortcut patterns by following these steps:

1. Create a new resources folder (if it does not already exist) in the frameworks directory for the particular document type (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources`).
2. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Document Type Association. Select the particular document type, click the Edit button, and in the Classpath tab (on page 118) add a link to that resources folder (if it does not already exist).
3. Create a new structureAutocorrect.xml file or edit an existing one (this file already exists in the resources folder of particular document types and you can use an existing file as a starting point for your customization).
4. Make the appropriate changes to your structureAutocorrect.xml file. The file should look like this:

```xml
<structure-autocorrect>
  <!-- Unordered lists -->
  <prefix-replacement prefix="-">
    <ul><li/></ul>
  </prefix-replacement>

  <!-- Ordered lists -->
  <prefix-replacement prefix="1.">
    <ol><li/></ol>
  </prefix-replacement>

  <!-- Code block -->
  <prefix-replacement prefix="```">
    <codeblock/>
  </prefix-replacement>
</structure-autocorrect>
```

Using this example, when a user enters one of the defined prefixes at the start of an element that allows the corresponding fragment, Oxygen XML Editor will automatically replace the prefix with its corresponding fragment. For example, entering a hyphen (-) at the beginning of a paragraph followed by a space would automatically replace them with an unordered list element (<ul>) with a child list item element (<li>). Any subsequently added content would be placed inside the first node/element that does not have a child node/element (in this example, the cursor would be placed in the first <li> element).

5. Save the file in the resources folder for the particular document type, using the fixed name: structureAutocorrect.xml (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources/structureAutocorrect.xml`).
6. Restart the application and open a document for your particular framework to test your customization.

**Note:**
Once the file is created, changes that you make to it are processed by Oxygen XML Editor when you press the 🔁 Reload toolbar button.

---

**Customizing Smart Paste Support**

The *Smart Paste feature* preserves certain style and structure information when copying content from some of the most common applications and pasting into *frameworks* (document types) that support *Smart Paste* in Oxygen XML Editor. For other document types, the default behavior of the paste operation is to keep only the text content without the styling.

The style of the pasted content can be customized by editing an XSLT stylesheet for a particular document type (*framework*). The XSLT stylesheet must accept an XHTML flavor of the copied content as input, and transform it to the equivalent XML markup that is appropriate for the target document type of the paste operation.

**How to Customize the Smart Paste Mapping**

To customize the mapping between the markup of the copied content and the markup of the pasted content for a particular document type, follow these steps:

1. Make sure the particular framework contains a folder named resources in the following path structure:
   
   /frameworks/[Document Type]/resources

2. Create an XSLT file named xhtml2content.xsl and save it in the resources folder for the particular framework.
   
   For example: /frameworks/[Document Type]/resources/xhtml2content.xsl

3. Add your customized styling in the XSLT file. A list of supported parameters can be found in the \[Supported Parameters for the Custom Smart Paste XSLT (on page 2042)\] section below.

**Tip:**

The built-in DITA framework includes an xhtml2ditaDriver.xsl file (in \[OXYGEN_INSTALL_DIR]/frameworks/dita/resources) that imports various other stylesheets that apply cleanup and handle the conversion from the pasted HTML content to DITA. If you are using a custom extension of the DITA framework, you can copy the entire contents of the built-in dita/resources folder and customize the stylesheets according to your needs.

4. You can test modifications done in the stylesheet by pasting content without having to restart Oxygen XML Editor.
**Result:** When you paste content from external applications (such as a web browser or and Office document) to a document that is open in **Author** mode, and that matches the particular framework, the styling from the `xhtml2content.xsl` stylesheet will be applied on the clipboard contents.

**Customized Smart Paste Stylesheet Sample:**

```xml
<xsl:stylesheet version="1.0"
 xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
 xmlns:xhtml="http://www.w3.org/1999/xhtml"
 xmlns:urn:hl7-org:v3"
 exclude-result-prefixes="xsl xhtml">

<xsl:output method="xml" indent="no" omit-xml-declaration="yes"/>

<xsl:template match="xhtml:b | xhtml:strong">
  <content styleCode="bold">
    <xsl:apply-templates select="@* | node()"/>
  </content>
</xsl:template>

<xsl:template match="*">
  <xsl:apply-templates select="@* | node()"/>
</xsl:template>

<xsl:template match="@* | node()">
  <xsl:copy>
    <xsl:apply-templates select="@* | node()"/>
  </xsl:copy>
</xsl:template>

</xsl:stylesheet>
```

**Supported Parameters for the Custom Smart Paste XSLT**

The following parameters can be used in your XSLT stylesheet for customizing the Smart Paste mechanism:

- **inTableContext**
  
  The custom XSLT stylesheet receives this parameter with a value of `true` if the end-user is pasting content inside a table.

- **folderOfPasteTargetXml**
  
  A URL pointing to the folder where the currently edited XML document is located. This is used to save images relative to the current XML document.

- **context.path.names**
A sequence of element names showing the current context in the XML document where the paste occurred.

context.path.uris

A sequence of namespaces, one for each context path name.

context.path.separator

The separator between the path names. Its value can be used to split the context path names to a sequence.

By default, there is an extra check in place to ensure that the applied XSLT does not remove the original text from the pasted content. If there is a file called externalPasteOptions.xml in the resources folder, you can use it to specify the default behavior for checking if the XSLT stylesheet loses content during conversion:

```xml
<!-- Options that control external paste
(automatic conversions when pasting HTML and URL flavors from the clipboard). -->
<pasteOptions>
  <!--True to check if the entire sequence of words which get pasted are converted to the target vocabulary. If the check fails, the content will be inserted as a simple sequence of words without any formatting.--> 
  <check EntireContentIsFullyPreserved>true</checkEntireContentIsFullyPreserved>
</pasteOptions>
```

**Customize the Content Completion Assistant**

Oxygen XML Editor gathers information from the associated schemas (DTDs, XML Schema, RelaxNG) to determine the proposals that appear in the Content Completion Assistant (on page 2965). Oxygen XML Editor also includes support that allows you to customize the Content Completion Assistant to suit your specific needs.

There are two ways to customize the Content Completion Assistant in Oxygen XML Editor:

- You can add, modify, or remove actions that are proposed for each particular document type (framework (on page 2967)) by using the Content Completion subtab in the Document Type Association configuration dialog box (on page 133). To access this subtab, open the Preferences dialog box (Options > Preferences) (on page 98), go to Document Type Association, use the New, Edit, Duplicate, or Extend button (on page 111), click on the Author tab, and then the Content Completion subtab.
Note:
This works only for Author visual mode.

• You can use a `cc_config.xml` configuration file that is specific to each document type (framework) to configure the values that are proposed in certain contexts, to customize the attributes or elements that are proposed, or to customize how certain aspects of the proposals are rendered in the interface. The rest of the topics in this section explain how you can use this configuration file to customize the content completion.

Related Information:
Customizing the Content Completion Assistant for Author Mode Only (on page 2037)

Customizing the Content Completion Assistant Using a Configuration File

Oxygen XML Editor gathers information from the associated schemas (DTDs, XML Schema, RelaxNG) to determine the proposals that appear in the Content Completion Assistant (on page 2965). Oxygen XML Editor also includes support that allows you to customize the Content Completion Assistant to suit your specific needs.

There are two ways to customize the Content Completion Assistant in Oxygen XML Editor:

• You can add, modify, or remove actions that are proposed for each particular document type (framework (on page 2967)) by using the Content Completion subtab in the Document Type Association configuration dialog box (on page 133). To access this subtab, open the Preferences dialog box (Options > Preferences) (on page 98), go to Document Type Association, use the New, Edit, Duplicate, or Extend button (on page 111), click on the Author tab, and then the Content Completion subtab.

• You can use a `cc_config.xml` configuration file that is specific to each document type (framework) to configure the values that are proposed in certain contexts, to customize the attributes or elements that are proposed, or to customize how certain aspects of the proposals are rendered in the interface. The rest of the topics in this section explain how you can use this configuration file to customize the content completion.

Customizing the Content Completion Assistant for Author Mode Only (on page 2037)

Configuring the Proposals for Elements and Attributes

There are many cases where elements have a relaxed content model and can accept a large number of child elements. For example, the DITA list item element (`<li>`) accepts more than 60 child elements. Oxygen XML Editor includes support to allow the content architect to put some constraints on the possible elements or attributes, or to impose some best practices in the way content is edited.
For an example of a specific use-case, suppose that you want to restrict DITA list item elements (<li>) to only accept paragraph elements (<p>). In this case, the Content Completion Assistant (on page 2965) should not offer any element other than a paragraph (<p>) when a list item (<li>) is inserted into a document. It would also be helpful if the required child element (<p>) was automatically inserted whenever a list item (<li>) is inserted.

One method of changing the content model is to alter the element definition in the associated schema (XML Schema, DTD, RelaxNG), but this may be quite complicated in some cases. Fortunately, Oxygen XML Editor offers a simple, alternative method of using a configuration file to customize the content completion proposals for each element.

Setting up the Content Completion Configuration File
To customize the configuration file for the Content Completion Assistant (on page 2965), follow these steps:

1. Create a new resources folder (if it does not already exist) in the frameworks directory for the particular document type (for example, OXYGEN_INSTALL_DIR/frameworks/dita/resources).
2. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Document Type Association. Select the particular document type, click the Edit button, and in the Classpath tab (on page 118) add a link to that resources folder (if it does not already exist).
3. Create a new configuration file or edit an existing one.
   a. To easily create a new configuration file, you can use the Content Completion Configuration document template that is included in Oxygen XML Editor (File > New > Framework templates > Oxygen Extensions > Content Completion Configuration). The document template includes details about how each element and attribute is used in the configuration file.
   b. If a configuration file (cc_config.xml) already exists for the particular document type (in the resources folder), you can modify this existing file.
   c. If you extend a framework, you need to copy the content of the cc_config.xml file from the base framework and modify it. You also need to make sure that the file in your extension is listed in the Classpath tab (on page 118) before the one from the base framework. If you only want to make small changes or add extra rules in your content completion configuration file, you need to rename it to cc_config_ext.xml and it will be merged with the base cc_config.xml.
4. Make the appropriate changes to your custom configuration file.
5. Save the file in the resources folder for the particular document type, using the fixed name: cc_config.xml (for example, OXYGEN_INSTALL_DIR/frameworks/dita/resources/cc_config.xml).
6. Restart the application and open an XML document. In the Content Completion Assistant you should see your customizations.
Tip:
In some cases, you can simply use the Refresh (F5) action to test your customizations, without having to restart the application.

Attention:
In the Classpath tab (on page 118), if you have references to multiple resources folders, each with its own cc_config.xml file, the first reference listed in the Classpath tab takes precedence and the multiple configuration files are not combined.

Configuring Elements or Attributes that are Proposed for Each Element
For the purposes of customizing the elements or attributes that are proposed for each individual element, the configuration file (cc_config.xml) uses <elementProposals> elements. This element allows you to customize or filter the child elements and attributes for an element.

Warning:
Note that you can only choose elements or attributes that are already allowed by the schema in a particular context. For example, you cannot specify an element that is not allowed by the schema as a child of a particular node.

Elements:
To control the elements that are proposed for an element, you can use the following attributes for the <elementProposals> element:

- **path** - A path within the document that matches the element that will have its content completion proposals changed. For example, "title" matches all the <title> elements in the document, while "chapter/title" matches only the <title> elements that are direct children of the <chapter> element.
You can use simplified forms of XPath in this attribute.

The XPath expressions can accept multiple attribute conditions and inside each condition you can use AND/OR boolean operators and parentheses to override the priority.

You can use one or more of the following attribute conditions (default attribute values are not taken into account):

- **element[@attr]** - Matches all instances of the specified element that include the specified attribute.
- **element[not(@attr)]** - Matches all instances of the specified element that do not include the specified attribute.
- **element[@attr = "value"]** - Matches all instances of the specified element that include the specified attribute with the given value.
- **element[@attr != "value"]** - Matches all instances of the specified element that include the specified attribute and its value is different than the one given.
**Example:** The following are examples of how you could use multiple boolean operators and parentheses inside an attribute condition:

```xml
*[a and b or c and d]
*[a and (b or c) and d]
```

The following are just examples of how simplified XPath expressions might look like:

- `elementName`
- `//elementName`
- `/elementName1/elementName2/elementName3`
- `//xs:localName`

**Note:**
Using a namespace prefix requires that you declare it on the `<elementProposals>` element. For example:
```xml
<elementProposals xmlns:db5="http://docbook.org/ns/docbook" path="db5:listitem" insertElements="db5:para" />
```

- `//xs:documentation[@lang="en"]`

**Note:**
If the `@path` attribute is missing, the customization will apply to the proposals for all elements. You can intentionally omit this attribute and use `possibleElements (on page 2047)` or `rejectElements (on page 2048)` to specify or restrict particular elements for a framework (on page 2967).

For example, suppose that in your DITA documents, you want to restrict your users from using `<image>` and `<fig>` elements because you do not want images to be included in your output. The configuration file should look like this:
```xml
<elementProposals rejectElements="image fig" />
```

Since the `@path` attribute is missing, the specified element will be filtered out from the proposals for the entire framework.

- **insertElements** - A space-separated sequence of child element names. Each time the element specified in the `@path` attribute is inserted into the document, these child elements will also be inserted in the order that they are listed. For example, `insertElements="b i"` will insert exactly one `<b>` element, followed by an `<i>` element. An empty value ("") means that no child elements should be inserted.

**Note:**
If this attribute is missing, the default required child elements will be inserted, as specified in the associated schema for the document.

- **possibleElements** - A space-separated list of element names that will be shown in the content completion list when invoked inside an element that is specified in the `@path` attribute. For example, `"b i codeph ph"` means that the **Content Completion Assistant** will contain these four elements when
invoked on the element specified in the @path attribute. The following other possible values are also supported:

- **NONE**: There will be no proposals in the content completion list.
- **ALL**: All the possible elements specified in the associated schema will be presented in the content completion list. This is also the default behavior if this attribute is missing.
- **INSERTED**: The proposals will be the same list of elements that are defined in the @insertElements attribute.

When using this attribute to specify multiple elements, only use one entry with the element names separated by a space:

```xml
<elementProposals possibleElements="b i codeph ph" />
```

- **rejectElements**: A space-separated list of element names that will be filtered out from the list of proposals that are presented in the content completion list. Each time the element specified in the @path attribute is inserted into the document, the list of proposals in the Content Completion Assistant will include the entries that are defined in the associated schema, minus the elements specified in this attribute.

When using this attribute to specify multiple elements, only use one entry with the element names separated by a space:

```xml
<elementProposals rejectElements="image fig imagemap foreign" />
```

**Attributes:**

To control the attributes that are proposed for an element, you can use the following attributes for the <elementProposals> element:

- **path**: A path within the document that matches the element that will have its attribute proposals changed. For example, "title" matches all the <title> elements in the document, while "chapter/title" matches only the <title> elements that are direct children of the <chapter> element. You can use
simplified forms of XPath in this attribute. For examples of such forms of XPath expressions, see the note in XML Preferences (on page 178).

**Note:**

If this attribute is missing, the customization will apply to the proposals for all elements. You can intentionally omit this attribute and use `possibleAttributes` (on page 2049) or `rejectAttributes` (on page 2049) to specify or restrict attributes for an entire `framework`.

For example, suppose that you only want to allow a limited set of attributes in a customized `framework`. The configuration file should look like this:

```xml
<elementProposals possibleAttributes="id domains href scope format type conref props keyref class"/>
```

Since the `@path` attribute is missing, this applies to the entire `framework` and only the specified attributes will be proposed.

- **insertAttributes** - A space-separated sequence of attribute names that will be inserted along with the element.

```xml
<elementProposals path="ol/li" insertAttributes="product platform"/>
```

- **insertAttribute** - This is similar to the preceding attribute, but this one also allows you to specify a value for the attribute that will be inserted. This attribute should be used like this:

```xml
<elementProposals path="ol/li">
  <insertAttribute name="platform" value="test"/>
</elementProposals>
```

- **possibleAttributes** - A space-separated list of attribute names that will be shown in the content completion list when invoked inside an element that is specified in the `@path` attribute.

When using this attribute to specify multiple attributes, only use one entry with the attribute names separated by a space:

```xml
<elementProposals possibleAttributes="scope format type"/>
```

- **rejectAttributes** - A space-separated list of attribute names that will be filtered out from the list of proposals that are presented in the content completion list. Each time the element specified in the `@path` attribute is inserted into the document, the list of proposals in the `Content Completion Assistant` will include the entries that are defined in the associated schema, minus the attributes specified in this attribute.

When using this attribute to specify multiple attributes, only use one entry with the attribute names separated by a space:

```xml
<elementProposals rejectAttributes="importance platform product"/>
```
Other Important Notes About the Configuration File

Important:

• By default, the element names that do not have a namespace prefix are considered from no-namespace. Consider declaring the namespace mapping on the root of the configuration file and prefixing the element names from the @elementPath and @model attributes.
• This configuration file only affects the content completion assistance. It has no effect on validation or operations invoked from other areas in the interface (such as the toolbar or menus).
• To test the effects of your changes, you should restart the application, although in some cases, you can simply use the Reload (F5) action to test your customizations.
• When an XML element from the document is matched against a list of configured elementProposals, the first one in sequence takes precedence. Therefore, make sure you place the more specific elementProposals (those with a longer path) first in your configuration file.
• Regular expression patterns can be used in the following attributes: @possibleElements, @rejectElements, @possibleAttributes, and @rejectAttributes. For example, code*, *block, con*ref, _*.
• Only simple recursion cases are detected and avoided by the editor, and logged to the console. Therefore, if complex elementProposals patterns are defined, you should avoid infinite recursions.

Examples: Configuring the Element Proposals

• Example 1: Automatically Insert Elements

Suppose that you want to automatically insert a paragraph element (p) whenever a DITA ordered list item element (ol/li) is inserted, and also to not allow any other element besides a paragraph inside the ordered list items.

To achieve this, the configuration file should include the following:

```xml
<elementProposals path="ol/li" insertElements="p"
  possibleElements="_INSERTED_">

```

Tip:
This particular example modifies an action that inserts a list in a DITA document. There are several ways to invoke this action in the interface. For example, there is a toolbar button and an action in the DITA menu that inserts a list. However, since the configuration file only affects the Content Completion Assistant, this modification will have no effect on the behavior of the toolbar or menu action. Those actions would need to be configured separately if you want the result to be the same as the content completion proposal. For more information, see Customizing the Author Editing Experience for a Framework (on page 1998).
• Example 2: Insert Complex Element Structure

For a more complex example, suppose that you want to insert a complex structure whenever a DITA `<prolog>` element is inserted.

For instance, if you need to insert the following structure inside `<prolog>` elements:

```xml
<prolog>
  <author></author>
  <metadata>
    <keywords>
      <keyword></keyword>
      <keyword></keyword>
    </keywords>
  </metadata>
</prolog>
```

The configuration file should include the following:

```xml
<elementProposals path="prolog" insertElements="author metadata"/>
<elementProposals path="prolog/metadata" insertElements="keywords"/>
<elementProposals path="prolog/metadata/keywords" insertElements="keyword, keyword"/>
```

• Example 3: Limit Possible Elements

Suppose that you also want to limit the proposals for the `<keywords>` element to only allow the user to insert `<audience>` or `<keyword>` elements. The configuration file should include the following:

```xml
<elementProposals path="prolog/metadata" insertElements="keywords" possibleElements="audience keywords"/>
```

Suppose that you want to simply restrict your users from inserting `<image>` elements inside DITA list item elements (`<li>`), but still propose all the other elements that are defined in the associated schema. The configuration file should look like this:

```xml
<elementProposals path="li" rejectElements="image"/>
```

Examples: Configuring the Attributes Proposals

• Example 1: Automatically Insert Attributes

Suppose that you want to insert an `@id` attribute (with an empty value) whenever a DITA list item element (`<li>`) is inserted. The configuration file should include the following:

```xml
<elementProposals path="li" insertAttributes="id"/>
```

• Example 2: Limit Possible Attributes

Suppose that you also want to limit the number of choices for attributes that are presented to the user whenever a DITA list item element (`<li>`) is inserted. The configuration file should look like this:
Suppose that you want to simply restrict your users from inserting @conref attributes inside DITA topics (<topic> element), but still propose all the other attributes that are defined in the associated schema. The configuration file should look like this:

```
<elementProposals path="topic" rejectAttributes="conref"/>
```

Related Information:
- Configuring the Proposals for Attribute and Element Values (on page 2052)
- Customizing the Rendering of Elements (on page 2056)

**Configuring the Proposals for Attribute and Element Values**

Oxygen XML Editor includes support for configuring the proposed values that appear in the Content Completion Assistant (on page 2965). To do so, a configuration file is used, along with the associated schema, to add or replace possible values for attributes or elements that are proposed in the Content Completion Assistant.

For an example of a specific use-case, suppose that you want the Content Completion Assistant to propose several possible values for the language code when you use an @xml:lang attribute.

**Setting up the Content Completion Configuration File**

To customize the configuration file for the Content Completion Assistant (on page 2965), follow these steps:

1. Create a new resources folder (if it does not already exist) in the frameworks directory for the particular document type (for example, OXYGEN_INSTALL_DIR/frameworks/dita/resources).
2. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Document Type Association. Select the particular document type, click the Edit button, and in the Classpath tab (on page 118) add a link to that resources folder (if it does not already exist).
3. Create a new configuration file or edit an existing one.
   a. To easily create a new configuration file, you can use the Content Completion Configuration document template that is included in Oxygen XML Editor (File > New > Framework templates > Oxygen Extensions > Content Completion Configuration). The document template includes details about how each element and attribute is used in the configuration file.
   b. If a configuration file (cc_config.xml) already exists for the particular document type (in the resources folder), you can modify this existing file.
   c. If you extend a framework, you need to copy the content of the cc_config.xml file from the base framework and modify it. You also need to make sure that the file in your extension is listed in the Classpath tab (on page 118) before the one from the base framework. If you only want to make small changes or add extra rules in your content completion configuration file, you need to rename it to cc_config_ext.xml and it will be merged with the base cc_config.xml.
4. Make the appropriate changes to your custom configuration file.
5. Save the file in the `resources` folder for the particular document type, using the fixed name: `cc_config.xml` (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources/cc_config.xml`).

6. Restart the application and open an XML document. In the Content Completion Assistant you should see your customizations.

**Tip:**
In some cases, you can simply use the `Refresh (F5)` action to test your customizations, without having to restart the application.

**Attention:**
In the Classpath tab (on page 118), if you have references to multiple resources folders, each with its own `cc_config.xml` file, the first reference listed in the Classpath tab takes precedence and the multiple configuration files are not combined.

### Configuring Proposed Values

For the purposes of adding or replacing the values that are proposed, the configuration file (`cc_config.xml`) includes a series of `match` instructions that will match an element or attribute name. You also have the possibility of using an `@editable` attribute on the `<match>` element to specify the editable state of the attribute values, as reflected in the Attributes view (on page 584) and the In-place Attributes Editor (on page 586). The possible values for the `@editable` attribute are:

- **true** - The attribute values can be edited by choosing from a combo box or manually providing a value.
- **false** - The attribute values cannot be edited.
- **onlyAllowedItems** - The attribute values can be edited, but only by choosing from a list of proposed values, in a non-editable combo box.

A new value is specified inside one or more `<item>` elements, which are grouped inside an `<items>` element. The behavior of the `<items>` element is specified with the help of the `@action` attribute, which can have any of the following values:

- **append** - Adds new values to appear in the proposals list (default value).
- **addIfEmpty** - Adds new values to the proposals list only if no other values are contributed by the schema.
- **replace** - Replaces the values contributed by the schema with new values to appear in the proposals list.

The values in the configuration file can be specified either directly or by calling an external XSLT file that will extract data from an external source.
Other Important Notes About the Configuration File

Important:

• This configuration file only affects the content completion assistance, not validation.
• To test the effects of your changes, you should restart the application.

Example: Specifying Values Directly

If you want to specify the values directly, the configuration file should look like this:

```xml
<!-- Replaces the values for an element with the local name "lg", from the given namespace -->
<match elementName="lg" elementNS="http://www.oxygenxml.com/ns/samples">
   <items action="replace">
      <item value="stanza"/>
      <item value="refrain"/>
   </items>
</match>

<!-- Adds two values for an attribute with the local name "type", from any namespace -->
<match attributeName="type" editable="onlyAllowedItems">
   <items>
      <item value="stanza"/>
      <item value="refrain"/>
   </items>
</match>
```

Example: Calling an External XSLT Script

If you want to collect values from an external XSLT script, the configuration file should include something like this:

```xml
<xslt href="../xsl/get_values_from_db.xsl" useCache="false" action="replace"/>
```

In this example, the `get_values_from_db.xsl` is executed to extract values from a database.

Tip:

You can use `xsl:message` as a debugging mechanism. These messages are presented in the results area at the bottom of the application whenever the Content Completion Assistant is invoked.
Configuring Proposed Values in the Context Where the Content Completion was Invoked

Web Author Customization Note:
This particular scenario is not supported for an Oxygen XML Web Author customization.

A more complex scenario is if you want to choose the possible values to propose, depending on the context of the element where the content completion was invoked.

Suppose that you want to propose certain possible values for one property (for example, \texttt{color}) and other values for another property (for example, \texttt{shape}). If the property represents a color, then the values should represent applicable colors, while if the property represents a shape, then the values should represent applicable shapes. See the following code snippets:

Your main document:

\begin{verbatim}
<sampleArticle>
  <!-- The possible values for @value should be "red" and "blue" -->
  <property name="color" value=""/>
  <!-- The possible values for @value should be "square" and "rectangle" -->
  <property name="shape" value=""/>
</sampleArticle>
\end{verbatim}

The content completion configuration file:

\begin{verbatim}
<config xmlns="http://www.oxygenxml.com/ns/ccfilter/config">
  <match elementName="property" attributeName="value">
    <xslt href="get_values.xsl" useCache="false" action="replace"/>
  </match>
</config>
\end{verbatim}

The stylesheet that defines the possible values based on the context of the property on which the content completion was invoked:

\begin{verbatim}
<xsl:stylesheet
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:saxon="http://saxon.sf.net/"
  exclude-result-prefixes="xs"
  version="2.0">

  <xsl:param name="documentSystemID" as="xs:string"/>
</xsl:stylesheet>
\end{verbatim}
The `contextElementXPathExpression` parameter will be bound to an XPath expression that identifies the element in the context where the content completion was invoked.

**Related Information:**
- Configuring the Proposals for Elements and Attributes (on page 2044)
- Customizing the Rendering of Elements (on page 2056)

**Customizing the Rendering of Elements**

In addition to the support for configuring the proposals that appear in the Content Completion Assistant (on page 2965), Oxygen XML Editor also includes support for customizing how the elements are rendered. You can do this by using the `XMLNodeRendererCustomizer` API extension (on page 2113), but you can also use the same configuration file that is used to configure the content completion proposals.

For an example of a specific use-case, suppose that in DITA you want the names of paragraph elements (`<p>`) to be rendered as "Paragraph" instead of "p" in the various components in Author mode (such as in the Outline view (on page 498), Elements view (on page 589), Attributes view (on page 584), and the breadcrumb navigation bar). To achieve this, you can use the `<elementRenderings>` element in the configuration file.

**Setting up the Content Completion Configuration File**

To customize the configuration file for the Content Completion Assistant (on page 2965), follow these steps:
1. Create a new `resources` folder (if it does not already exist) in the `frameworks` directory for the particular document type (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources`).

2. Open the Preferences dialog box (Options > Preferences) and go to Document Type Association. Select the particular document type, click the Edit button, and in the Classpath tab (on page 118) add a link to that `resources` folder (if it does not already exist).

3. Create a new configuration file or edit an existing one.
   a. To easily create a new configuration file, you can use the Content Completion Configuration document template that is included in Oxygen XML Editor (File > New > Framework templates > Oxygen Extensions > Content Completion Configuration). The document template includes details about how each element and attribute is used in the configuration file.
   b. If a configuration file (`cc_config.xml`) already exists for the particular document type (in the `resources` folder), you can modify this existing file.
   c. If you extend a framework, you need to copy the content of the `cc_config.xml` file from the base framework and modify it. You also need to make sure that the file in your extension is listed in the Classpath tab (on page 118) before the one from the base framework. If you only want to make small changes or add extra rules in your content completion configuration file, you need to rename it to `cc_config_ext.xml` and it will be merged with the base `cc_config.xml`.

4. Make the appropriate changes to your custom configuration file.

5. Save the file in the `resources` folder for the particular document type, using the fixed name: `cc_config.xml` (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources/cc_config.xml`).

6. Restart the application and open an XML document. In the Content Completion Assistant you should see your customizations.

**Tip:**
In some cases, you can simply use the Refresh (F5) action to test your customizations, without having to restart the application.

**Attention:**
In the Classpath tab (on page 118), if you have references to multiple `resources` folders, each with its own `cc_config.xml` file, the first reference listed in the Classpath tab takes precedence and the multiple configuration files are not combined.

---

**Changing the Rendering of Elements (Their Names, Annotations, and Icons)**

For the purposes of customizing how the content completion elements are rendered, you can use the `<render>` element inside a `<elementRenderings>` element to specify how element names, their annotations, and their icons are rendered.

The `<elementRenderings>` element supports the `@platform` attribute, which can have one of the following values:

- `webapp`

The element renderings are only applied to Oxygen XML Web Author.
standalone

The element renderings are only applied to standalone distributions of Oxygen.

eclipse

The element renderings are only applied to Eclipse plugin distributions of Oxygen.

Note:

If the @platform attribute is missing, the element renderings are applied to all types of distributions.

You can use the following attributes for the `<render>` element:

**element**

Identifies the element to be customized, in the form of a qualified name. If it does not have a prefix, it is considered to be from noNamespace.

**as**

Provides the name (label) that will be displayed for the element in various components in Author mode (the Content Completion Assistant, the breadcrumb navigation bar, the Full Tags display mode (on page 552), and the Outline (on page 498), Elements (on page 589), and Attributes (on page 584) views). This attribute is optional. If it is missing, the name of the element is used.

If you want to translate this label into another language, use the ${i18n(key_name)} editor variable (on page 299). The following code snippet shows how the DITA paragraph elements `<p>` can be translated:

```xml
<elementRenderings>
  <render element="p" as="${i18n(cc_p)}"/>
</elementRenderings>
```

Note:

The cc_p id is a key that identifies the translations available for the paragraph element.

**iconPath**

Optional attribute that specifies the icon for the element. This is shown in the Content Completion Assistant and the Outline view (on page 498) in Author mode. If it is a relative path, the full path of the icon image file will be computed starting from the directory of the configuration file (for example, a value of "myImg.png" will cause Oxygen XML Editor to load "frameworks/$(framework)/resources/myImg.png"). If you want to access a built-in resource, the value can begin with a forward slash "/", and the image file will be searched for in the Oxygen XML Editor classpath resources (for example,"/images/OrderedList16.png" will load an icon from the built-in Oxygen XML Editor JAR file resources.

**xml:lang (Deprecated)**
It is recommended to use the `$i18n(key_name)` editor variable (on page 299) instead. Optional attribute that could be used to render the same element differently, depending on the language. If there are multiple `<render>` elements for the same `@element` attribute (element name) and the `@xml:lang` attribute is missing on one of them, that one will be considered the default fallback value to be used if none of the others match the language specified in the interface.

**Note:**

The default entry should be listed first, since the application tries to match them in sequence and the last match found is the one that is used.

For example, suppose that you want the name of DITA paragraph elements (`<p>`) to be rendered as "Paragraphe" if the language is French, "Absatz" if the language is German, and "Paragraph" if the language is English (or any other language). Your configuration file should look something like this:

```xml
<elementRenderings>
  <render element="p" as="Paragraph"/>
  <render element="p" as="Paragraphe" xml:lang="fr"/>
  <render element="p" as="Absatz" xml:lang="de"/>
</elementRenderings>
```

You can also use the configuration file to customize the annotations for elements. For this purpose, the `<render>` element also accepts the following element to change the tooltip annotations for an element (in both Author mode and Text mode):

```
annotation
```

This element can be used within the `<render>` element to customize the tooltip annotations that are displayed for the element in various components in Author mode (such as tooltips shown in the Content Completion Assistant documentation window, the breadcrumb navigation bar, the Full Tags display mode (on page 552), and the Outline (on page 498), Elements (on page 589), Attributes (on page 584) views), as well as the tooltips that are displayed when you hover over elements in Text mode. You can use HTML content to style the annotations (see the example below (on page 2060)).

**Note:**

If this element is missing, the styling for the annotations for that element is collected from the associated schema (on page 576).

**Tip:**

The annotations can also be translated in the configuration file. For example:

```xml
<elementRenderings>
  <render element="p" as="${i18n(cc_p)}">$i18n(cc_p)</annotation>
</elementRenderings>
```
Other Important Notes About the Configuration File for Rendering Elements

Important:

- This configuration file only affects the content completion assistance, not validation.
- To test the effects of your changes, you should restart the application, although in some cases, you can simply use the Reload (F5) action to test your customizations.
- If the framework (on page 2967) has an associated style guide, then the annotations defined in the configuration file will take precedence over those defined in the style guide. To check to see if your framework uses a style guide, look for the following folder:  
  ${oXygenInstallDir}frameworks/${framework}/styleguide/. If that folder exists, it is recommended that you make your annotation changes directly in the style guide, rather than in the configuration file.
- If an XMLNodeRendererCustomizer API extension (on page 2113) has been implemented for the framework and a configuration file is also used, the rendering customization for an element will be the result of merging the two. For example, if the XMLNodeRendererCustomizer implementation customizes the element name, while the configuration file specifies an icon for the element, the properties of both customizations will be rendered. However, if both implementations define the same property (for example, both specify the rendering of an element name), the customizations defined in the configuration file take precedence.
- The rendering customizations defined in the configuration file also apply to aspects of the Oxygen XML Web Author interface.

Example: Changing the Rendering of an Element
Suppose that you want to render the name of the DITA `<title>` element to begin with a capital letter, use a custom icon for it, and provide specific documentation for that element in the various components in Author mode. The configuration file should look like this:

```xml
<elementRenderings>
  <render element="title" as="Title" iconPath="cimg/AcceptAll16.png">
    <annotation>
      <html xmlns="http://www.w3.org/1999/xhtml">
        <head>
          <title>Documentation for the Title Element</title>
        </head>
        <body>
          <p>A <i>heading</i> or <b>label</b> for the main parts of a topic</p>
        </body>
      </html>
    </annotation>
  </render>
</elementRenderings>
```
Customizing Annotations in the Content Completion Assistant

Oxygen XML Editor gathers documentation from the associated schemas (DTD, XML Schema, RelaxNG) and presents it for each element or attribute. For example, if you open the Content Completion Assistant (on page 2965) for a recognized XML vocabulary, documentation is displayed for each element provided by the associated schema. Similar information is displayed when you hover over tag names presented in the Elements view (on page 589). If you hover over attributes in the Attributes view (on page 584) you also see information about each attribute, gathered from the same schema.

If you have a framework configuration (on page 113) set up for your XML vocabulary, there is a special XML configuration file that can be added to provide additional documentation information or links to additional information for certain elements and attributes.

To provide this additional information in the Content Completion Assistant, follow these steps:

1. Create a new folder in the configuration directory for the document type.
   
   **Example:** OXYGEN_INSTALL_DIR/frameworks/dita/styleguide

2. Use the New document wizard to create a file using the Content Completion Styleguide document template (in the Framework Templates > Oxygen Extensions section).

3. Save the file in the folder created in step 1, using the fixed name: contentCompletionElementsMap.xml.

4. Open the Preferences dialog box (Options > Preferences) (on page 98), go to Document Type Association, and edit the document type configuration for your XML vocabulary. Now you need to indicate where Oxygen XML Editor will locate your mapping file by doing one of the following:
   - In the Classpath tab add a link to the newly created folder.
   - In the Catalogs tab add a new catalog file (on page 769). The selected file needs to contain the following:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE catalog PUBLIC "-//OASIS//DTD XML Catalogs V1.1//EN"
   "http://www.oasis-open.org/committees/entity/release/1.1/catalog.dtd">
<catalog xmlns="urn:oasis:names:tc:entity:xmlns:xml:catalog">
```
where \( \text{processed Dt Name} \) is the name of the document type in lower case and with spaces replaced by underscores.

**Note:**
If Oxygen XML Editor finds a mapping file in both locations, the one in the Catalogs tab takes precedence.

5. Make the appropriate changes to your custom mapping file.

   **Example:** You can look at how the DITA mapping file is configured: OXYGEN_INSTALL_DIR/frameworks/dita/styleguide/contentCompletionElementsMap.xml

   The associated XML Schema contains additional details about how each element and attribute is used in the mapping file.

6. Re-open the application and open an XML document.

   In the Content Completion Assistant (on page 2965), you should see the additional annotations for each element.

**Translating Annotations**

Annotations in the Content Completion Assistant can be displayed in various languages. Based on the language set for the interface, Oxygen XML Editor looks for several filename formats to determine the information to load for the content completion annotations. These files that begin with the name `contentCompletionElementsMap`, are located in the `styleguide` folder for each built-in framework (for example, OXYGEN_INSTALL_DIR/frameworks/dita/styleguide).

For example, for English, the files are loaded in the following order (from specific to more general):

- `contentCompletionElementsMap_en_US.xml` or `contentCompletionElementsMap_en_UK.xml`, and so on
- `contentCompletionElementsMap_en.xml`
- `contentCompletionElementsMap.xml`

If you want the annotations to be displayed in another language, you need to create similar files for the particular language. For example, to show annotations in German, create a file with one of the following names (and store it in the `styleguide` folder for your framework):

- `contentCompletionElementsMap_de_DE.xml`
- `contentCompletionElementsMap_de.xml`

**Related Information:**
Customizing the Rendering of Elements (on page 2056)
Customizing the Content Completion Assistant for Author Mode Only

You can customize the content of the following Author controls, adding items (which, when invoked, perform custom actions) or filtering the default contributed ones:

- **Content Completion Assistant (on page 2965) window**
- **Elements** view (on page 589)
- **Insert Element** menus (from the Outline view (on page 498) or breadcrumb (on page 560) contextual menus)

You can use the content completion customization support in a custom framework (on page 2967) by following this procedure:

1. Open the Document type configuration dialog box (on page 113) for your custom framework and select the Author tab. Next, go to the **Content Completion** tab (on page 133).

   ![Figure 555. Customize Content Completion](image)

   The top side of the Content Completion section contains the list with all the actions defined within the custom framework and the list of actions that you decided to include in the Content Completion Assistant list of proposals. The bottom side contains the list with all the items that you decided to remove from the Content Completion Assistant list of proposals.

2. If you want to add a custom action to the list of current Content Completion proposals, select the action item from the Available actions list and click the Add as child or Add as sibling button to include it in the Current actions list. A Content Completion Item dialog box appears, giving you the possibility to select where to provide the selected action.
3. If you want to exclude a certain item from the **Content Completion** proposals, you can use the **Add** button from the **Filter - Remove content completion items** list. The **Remove item** dialog box is displayed, allowing you to input the item name and to choose the controls that filter it. The **Item name** combo box accepts wildcards.

**Related Information:**
Customizing the Content Completion Assistant Using a Configuration File *(on page 2044)*

**Configuring Transformation Scenarios for a Framework**

When distributing a **framework** *(on page 2967)* to users, it is a good idea to have the transformation scenarios already configured. This helps the content authors publish their work in various formats. By being contained in the **framework** configuration, the scenarios can be distributed along with the actions, menus, toolbars, and catalogs.
These are the steps that allow you to create a transformation scenario for your framework.

1. Create an `xsl` folder inside your custom `framework` directory

   (`/OXYGEN_INSTALL_DIR\frameworks\[CUSTOM_FRAMEWORK_DIR\]`).

   The folder structure for the documentation `framework` should be:

   ```
   oxygen
   frameworks
   [CUSTOM_FRAMEWORK_DIR]
   schema
   css
   templates
   xsl
   ```

2. Create an `xsl` file and save it in the `xsl` folder. To help you get started, you can use the sample `sdf.xsl` file found in the sample framework customization package.

3. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Document Type Associations. Select the particular `framework`, click the Edit button to open Document Type Configuration dialog box (on page 113), and choose the Transformation tab. Click the Add New button and choose the appropriate type of transformation (for example, XML transformation with XSLT).

   In the New scenario dialog box, fill in the following fields:

   - Fill in the Name field with the name of your transformation scenario.
   - Set the XSL URL field to path of your custom stylesheet (for example, `{framework}/xsl/mycustom.xsl`).
4. Change to the **Output** tab. Configure the fields as follows:

- Set the **Save as** field to `$(cfd)/$(cfn).html`. This means the transformation output file will have the name of the XML file and the *html* extension and will be stored in the same folder.
- Select the **Open in Browser/System Application** option.

**Note:**

To set the browser or system application that will be used, open the **Preferences** dialog box (**Options** > **Preferences**) *(on page 98)*, go to **Global**, and set it in the **Default Internet browser** field. This will take precedence over the default system application settings.

- Select the **Saved file** option.

5. Click the **OK** button to save the new scenario.

Now the scenario is listed in the **Transformation** tab:

**Figure 559. Transformation Tab**
To test the transformation scenario that you just created, you can use the sample sdf.xml file found in the sample framework customization package. Click the Apply Transformation Scenario(s) button to display the Transform with dialog box. The scenario list contains the scenario you defined earlier. Select the SDF to HTML scenario that you just defined and click the Apply associated button. The HTML file is saved in the same folder as the XML file and displayed in the browser.

Configuring Validation Scenarios for a Framework

You can distribute a framework with a series of already configured validation scenarios. Also, this provides enhanced validation support that allows you to use multiple grammars to check the document. For example, you can use Schematron rules to impose guidelines that are otherwise impossible to enforce using conventional validation.

Note:

If a main file is associated with the current file, the validation scenarios defined in the main file, along with any Schematron schema defined in the default scenarios for that particular framework, are used for the validation. These take precedence over other types of validation units defined in the default scenarios for the particular framework. For more information on main files, see Main Files Support or Working with Modular XML Files in the Main Files Context.

To associate a validation scenario with a specific framework, follow these steps:

1. Open the Preferences dialog box (Options > Preferences) and go to Document Type Association.
2. Select the document type and click the Edit button to open the Document Type Configuration dialog box, then choose the Validation tab. This tab displays a list of document types. To set one or more of the validation scenarios listed in this tab to be used as the default validation scenario (when another one is not specified in the validation process) for a specific document type, check the Default box for that specific document type.
3. To edit an existing scenario, select the scenario and click the Edit button. To add a new scenario, click the New button.

In either case, a scenario configuration dialog box is displayed. It lists all the validation units for the scenario.
This scenario configuration dialog box allows you to configure the following information and options:

**Name**

The name of the validation scenario.

**URL of the file to validate**

The URL of the main module that includes the current module. It is also the entry module of the validation process when the current one is validated. To edit the URL, double-click its cell and specify the URL of the main module by doing one of the following:

- Enter the URL in the text field or select it from the drop-down list.
- Use the Browse drop-down button to browse for a local, remote, or archived file.
- Use the Insert Editor Variable button to insert an editor variable (on page 292) or a custom editor variable (on page 301).
Figure 561. Insert an Editor Variable

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>${Desktop}</td>
<td>My Desktop</td>
</tr>
<tr>
<td>${start-dir}</td>
<td>Start directory of custom validator</td>
</tr>
<tr>
<td>${standard-params}</td>
<td>List of standard params for command line</td>
</tr>
<tr>
<td>${fn}</td>
<td>The current file name without extension</td>
</tr>
<tr>
<td>{currentFileURL}</td>
<td>The path of the currently edited file (URL)</td>
</tr>
<tr>
<td>{fou}</td>
<td>The path of current file directory (URL)</td>
</tr>
<tr>
<td>{frameworks}</td>
<td>Oxygen frameworks directory (URL)</td>
</tr>
<tr>
<td>{pdu}</td>
<td>Project directory (URL)</td>
</tr>
<tr>
<td>{oxygencurrent}</td>
<td>Oxygen installation directory (URL)</td>
</tr>
<tr>
<td>{home}</td>
<td>The path to user home directory (URL)</td>
</tr>
<tr>
<td>{proj}</td>
<td>Project name</td>
</tr>
<tr>
<td>{java.env(VAR_NAME)}</td>
<td>Value of environment variable VAR_NAME</td>
</tr>
<tr>
<td>{system(var.name)}</td>
<td>Value of system variable var.name</td>
</tr>
</tbody>
</table>

**File type**

The type of the document that is validated in the current validation unit. Oxygen XML Editor automatically selects the file type depending on the value of the **URL of the file to validate** field.

**Validation engine**

You can select one of the engines available in Oxygen XML Editor for validation of the particular document type.

**Default engine** means that the default engine is used to run the validation for the current document type, as specified in the preferences page for that type of document (for example, XSLT preferences page (on page 216), XQuery preferences page (on page 224), XML Schema preferences page (on page 208)).

The **DITA Validation** engine performs DITA-specific checks in the context of the specifications (it is similar to the checks done with the DITA Maps Manager Validate and Check for Completeness action (on page 2706), but for a local file rather than an entire DITA map (on page 2966)).

The **Table Layout Validation** engine looks for table layout problems (for more information, see Report table layout problems (on page 2710)).

**Automatic validation**

If this option is selected, the validation operation defined by this row is also applied by the automatic validation feature (on page 728). If the Automatic validation feature is disabled in the Document Checking preferences page (on page 196), then this option is ignored, as the preference setting has a higher priority.

**Schema**
This option becomes active when you set the **File type** to **XML Document** and allows you to specify the schema used for the validation unit.

**Specify Schema**

Opens the **Specify Schema** dialog box that allows you to set a schema to be used for validating XML documents.

**Figure 562. Specify Schema Dialog Box**

The **Specify Schema** dialog box contains the following options:

**Use detected schema**

Uses the schema detected for the particular document (*on page 760*).

**Use custom schema**

Allows you to specify the schema using the following options:

- **URL** - Allows you to specify or select a URL for the schema. It also keeps a history of the last used schemas. The URL must point to the schema file that can be loaded from the local disk or from a remote server through HTTP(S), FTP(S) or a custom protocol (*on page 2281*). You can specify the URL by using the text field, the history drop-down, the **Insert Editor Variables** (*on page 292*) button, or the browsing actions in the **Browse** drop-down list.

- **Schema type** - Select a possible schema type from this combo box that is populated based on the extension of the schema file that was entered in the **URL** field. The possible schema types are: XML Schema, DTD, Relax NG, Relax NG Compact, Schematron, or NVDL.

- **Embedded Schematron rules** - If you have selected XML Schema or Relax NG schemas with embedded Schematron rules and you want to use those embedded rules, select this option.

- **Extensions** - Opens a dialog box that allows you to specify **Java extension JARs** (*on page 2967*) to be used during the validation.
• **Public ID** - Allows you to specify a public ID if you have selected a DTD.

• **Schematron phase** - If you select a Schematron schema, this drop-down list allows you to select a Schematron phase that you want to use for validation. The listed phases are defined in the Schematron document.

**Move Up**

Moves the selected validation unit up one spot in the list.

**Move Down**

Moves the selected validation unit down one spot in the list.

**Add**

Adds a new validation unit to the list.

**Remove**

Removes an existing validation unit from the list.

4. Configure any of the existing validation units according to the information above, and you can use the buttons at the bottom of the table to add, remove, or move validation units. Note that if you add a Schematron validation unit, you can also select the validation phase.

5. Click **Ok**.

The newly created validation scenario is now included in the list of scenarios in the Validation tab (on page 138). You can use the **Default** checkbox to specify that the new scenario be used as the default validation scenario when another specific scenario is not specified in the validation process.

### Customizing New Document Templates for a Framework

You can create your own custom document templates and attach them to a custom framework (on page 2967). You can then share the custom framework (on page 2131) so that all users will have access to the templates in the New document wizard (on page 335).

To create your own custom document template and have it appear in the new document wizard, follow these steps:

1. Create a new file and customize it to become a starting point for creating new files of this type.

   **Tip:**
   
   You can use editor variables (on page 292) in the template file content and they will be expanded when the files are opened. Also, see Customizing Document Templates (on page 344) for other template customization tips (for example, you could add placeholders or hints (on page 346) to assist authors).

2. Save the new template in a directory (for example, called templates) within your custom framework directory.
Attention:
The name that you use to save the template will be the name that appears in the new document wizard, including capitalization, space, and characters (for example, `My Custom Template1.xml` will appear in the new file wizard as `My Custom Template1`). You can also configure the displayed name in a properties file by following the procedure found in the Configure the Displayed Names for Document Templates (on page 346) section.

3. Open the Document Type configuration dialog box (on page 113) for that specific framework, go to the Templates tab (on page 135), and click the button in the bottom-right corner to add your new directory to the list. It is recommended that the reference be made relative to the framework directory (for example, `_${frameworkDir}/templates`). Binding to an absolute file (e.g., `C:\some_dir\templates`) makes the association difficult to share between users.

4. Click OK for all of the dialog boxes to save your changes.

5. To test the template, open the new document wizard (New toolbar button or File > New) and you should see your custom template in the folder for your custom framework (in the Framework templates section).

Related Information:
Customizing Document Templates (on page 344)

Configuring XML Catalogs

For cases where you need to reference the location of a schema file from a remote web location and an Internet connection may not be available, an XML Catalog (on page 2972) may be used to map the web location to a local file system entry. The following procedure presents an example of using an XML catalog in a custom framework (on page 2967) by modifying an XML Schema file.

1. Create a catalog file that will help the parser locate the schema for validating the XML document. The file must map the location of the schema to a local version of the schema.

  Example:
  Create a new XML file called `catalog.xml` and save it in your custom framework directory (`[OXYGEN_INSTALL_DIR]\frameworks\[CUSTOM_FRAMEWORK_DIR]\`). The content of the file should look like this:

```xml
<?xml version="1.0"?>
<catalog xmlns="urn:oasis:names:tc:entity:xmlns:xml:catalog">
  <uri name="http://www.oxygenxml.com/SDF/abs.xsd" url="schema/abs.xsd"/>
  <uri name="http://www.oxygenxml.com/SDF/abs.xsd"/>
</catalog>
```
2. Add catalog files to your custom framework using the Catalogs tab (on page 136) from the Document Type configuration dialog box (on page 113).

To test the catalog settings, restart Oxygen XML Editor and try to validate a new sample document for your custom framework. There should be no errors.

Example:
The schema that validates the document refers the other file abs.xsd through an import element:

```xml
```

The @schemaLocation attribute references the abs.xsd file:

```xml
xsi:schemaLocation="http://www.oxygenxml.com/sample/documentation/abstracts"
  http://www.oxygenxml.com/SDF/abs.xsd"/>
```

The catalog mapping is:

```xml
http://www.oxygenxml.com/SDF/abs.xsd -> schema/abs.xsd
```

This means that all the references to http://www.oxygenxml.com/SDF/abs.xsd must be resolved to the abs.xsd file located in the schema directory (note that the schema directory needs to be in the same folder as the XML Catalog). The URI element is used by URI resolvers (for example, to resolve a URI reference used in an XSLT stylesheet).

Localizing Frameworks

Oxygen XML Editor supports framework (on page 2967) localization (translating framework actions, buttons, and menu entries to various languages). This lets you develop and distribute a framework to users that speak other languages without changing the distributed framework. Changing the language used in Oxygen XML Editor in the Global preferences page is enough to set the right language for each framework.

To localize the content of a framework, follow this procedure:

1. Create a translation.xml file that contains all the translation (key, value) mappings. The translation.xml has the following format:

   ```xml
   <translation>
   <languageList>
     <language description="English" lang="en_US"/>
     <language description="German" lang="de_DE"/>
     <language description="French" lang="fr_FR"/>
   </languageList>
   <key value="list">
     <comment>List menu item name.</comment>
   </key>
   ```
Oxygen XML Editor matches the GUI language with the language set in the translation.xml file. If this language is not found, the first available language declared in the <languagelist> tag for the corresponding framework is used.

2. The translation.xml file must be stored in a directory named i18n located in the framework folder. You also need to add a reference to the i18n directory in the Classpath list corresponding to the edited document type (on page 118).

3. After you create this file, you can use the keys defined in it to customize the name and description of the following:
   - Actions
   - Menu entries
   - Contextual menus
   - Toolbars
   - Static CSS content

For example, if you want to localize the bold action, open the Preferences dialog box (Options > Preferences) (on page 98) and go to Document Type Association. Use the New or Edit button to open the Document type configuration dialog box (on page 113), go to Author > Actions, and rename the bold action to ${i18n(translation_key)}. Actions with a name format other than ${i18n(translation_key)} are not localized. Translation_key corresponds to the key from the translation.xml file.

4. Next, open the translation.xml file and edit the translation entry if it exists or create one if it does not exist. This is an example of an entry in the translation.xml file:

```
<key value="translation_key">
    <comment>Bold action name.</comment>
    <val lang="en_US">Bold</val>
    <val lang="de_DE">Bold</val>
    <val lang="fr_FR">Bold</val>
</key>
```

To use a description from the translation.xml file in the Java code used by your custom framework, use the new ro.sync.ecss.extensions.api.AuthorAccess.getAuthorResourceBundle() API method to request the associated value for a certain key. This allows all the dialog boxes that you present from your custom operations to have labels translated in multiple languages.

You can also reference a key directly in the CSS content:
Note:
You can enter any language you want in the `<languagelist>` tag and any number of keys.

DocBook Example:
The `translation.xml` file for the DocBook framework is located here: `[OXYGEN_INSTALL_DIR]/frameworks/docbook/i18n/translation.xml`. In the Classpath list corresponding to the DocBook document type, the following entry was added: `${framework}/i18n/`.

To see how the DocBook actions are defined to use these keys for their name and description, open the Preferences dialog box (Options > Preferences) (on page 98) and go to Document Type Association > Author > Actions. If you look in the Java class `ro.sync.ecss.extensions.docbook.table.SADocbookTableCustomizerDialog` available in the oxygen-sample-framework module of the Oxygen SDK Maven archetype, you can see how the new `ro.sync.ecss.extensions.api.AuthorResourceBundle` API is used to retrieve localized descriptions for various keys.

Framework Java Extensibility Guide
Advanced users can extend the functionality of custom frameworks and Author mode. The Oxygen SDK is also available to provide developers the ability to extend the functionality of Oxygen XML Editor.

You can add extensions (on page 2969) to your custom framework (on page 2967) (document type) by using the Extensions tab from the Document Type configuration dialog box (on page 113).

Note:
It is possible for a plugin to share the same classes with a framework. For further details, go to How to Share the Classloader Between a Framework and a Plugin (on page 2282).

Related Information:
Extending Oxygen With the SDK (on page 2251)
SDK Common Use Cases (on page 2311)

Configuring an Extensions Bundle
All extensions (on page 2969) that are provided by Oxygen XML Editor are includes in a single bundle.
Note:
The individual extensions can still be set (open the Preferences dialog box (Options > Preferences) (on page 98), go to Document Type Association, double-click a document type, and go to the extension tab), and if present, they take precedence over the single provider. However, this practice is discouraged and the single provider should be used instead.

The extensions bundle is represented by the `ro.sync.ecss.extensions.api.ExtensionsBundle` class. The provided implementation of the `ExtensionsBundle` is instantiated when the Document Type Association (on page 2966) rules defined for the custom framework (on page 2967) matches a document opened in the editor. Therefore, references to objects that need to be persistent throughout the application running session must not be kept in the bundle because the next detection event can result in creating another `ExtensionsBundle` instance.

To configure an extensions bundle, follow this procedure:

1. Create a new Java project in your IDE. Create a `lib` folder in the Java project folder and copy in it the `oxygen.jar` file from the `{OXYGEN_INSTALL_DIR}/lib` folder.
2. Create the class (for example, `simple.documentation.framework.SDFExtensionsBundle`) to extend the abstract class `ro.sync.ecss.extensions.api.ExtensionsBundle`.
   
   For example:
   ```java
   public class SDFExtensionsBundle extends ExtensionsBundle {
   }
   ```
3. A Document Type ID and a short description should be defined first by implementing the methods `getDocumentTypeID` and `getDescription`. The Document Type ID is used to uniquely identify the current framework. Such an ID must be provided especially if options related to the framework need to be persistently stored and retrieved between sessions.
   
   For example:
   ```java
   public String getDocumentTypeID() {
   }
   
   public String getDescription() {
       return "A custom extensions bundle used for the Simple Document" + 
               "Framework document type";
   }
   ```
4. To be notified about the activation of the custom Author Extension in relation with an open document, `ro.sync.ecss.extensions.api.AuthorExtensionStateListener` should be implemented.
   
   The activation and deactivation events received by this listener should be used to perform custom initializations and to register or remove listeners such as `ro.sync.ecss.extensions.api.AuthorListener`, `ro.sync.ecss.extensions.api.AuthorMouseListener`, or `ro.sync.ecss.extensions.api.AuthorCaretListener`.
   
   The custom Author Extension state listener should be provided by implementing the `createAuthorExtensionStateListener` method.
   
   For example:
public AuthorExtensionStateListener createAuthorExtensionStateListener() {
    return new SDFAuthorExtensionStateListener();
}

The AuthorExtensionStateListener is instantiated and notified about the activation of the framework when the rules of the Document Type Association match a document opened in the Author editing mode. The listener is notified about the deactivation when another framework is activated for the same document, the user switches to another mode or the editor is closed. A complete description and implementation of ro.sync.ecss.extensions.api.AuthorExtensionStateListener can be found in Implementing an Author Extension State Listener (on page 2089).

If Schema-Aware mode (on page 152) is active in Oxygen XML Editor, all actions that can generate invalid content will be redirected toward the ro.sync.ecss.extensions.api.AuthorSchemaAwareEditingHandler. The handler can resolve a specific case, let the default implementation take place, or reject the edit entirely by throwing an ro.sync.ecss.extensions.api.InvalidEditException. The actions that are forwarded to this handler include typing, delete, or paste.

See Handling Schema-Aware Editing Events (on page 2126) for more details about this handler.

5. Customizations of the content completion proposals are permitted by creating a schema manager filter extension. The interface that declares the methods used for content completion proposals filtering is ro.sync.contentcompletion.xml.SchemaManagerFilter. The filter can be applied on elements, attributes, or on their values. The createSchemaManagerFilter method is responsible for creating the content completion filter. A new SchemaManagerFilter will be created each time a document matches the rules defined by the Document Type Association that contains the filter declaration.

For example:

```java
public SchemaManagerFilter createSchemaManagerFilter() {
    return new SDFSchemaManagerFilter();
}
```

A detailed presentation of the schema manager filter can be found in the Configuring a Content Completion Handler (on page 2082) section.

6. The Author mode supports link-based navigation between documents and document sections. Therefore, if the document contains elements defined as links to other elements (for example, links based on the @id attributes), the extension should provide the means to find the referenced content. To do this, an implementation of the ro.sync.ecss.extensions.api.link.ElementLocatorProvider interface should be returned by the createElementLocatorProvider method. Each time an element pointed by a link needs to be located, the method is invoked.

For example:

```java
public ElementLocatorProvider createElementLocatorProvider() {
    return new DefaultElementLocatorProvider();
}
```

For more information on how to implement an element locator provider, see the Configuring a Link Target Element Finder (on page 2107) section.
The drag and drop functionality can be extended by implementing the 
`ro.sync.exml.editor.xmleditor.pageauthor.AuthorDnDListener` interface. Relevant methods from the listener are invoked when the mouse is dragged, moved over, or exits the Author editing mode, when the drop action changes, and when the drop occurs. Each method receives the `DropTargetEvent` containing information about the drag and drop operation. The drag and drop extensions are available in Author mode for both Oxygen XML Editor Eclipse plugin and standalone application. The Text mode corresponding listener is available only for Oxygen XML Editor Eclipse plugin. The methods corresponding to each implementation are: `createAuthorAWTDndListener`, `createTextSWTDndListener`, and `createAuthorSWTDndListener`.

```java
public AuthorDnDListener createAuthorAWTDndListener() {
    return new SDFAuthorDndListener();
}
```

For more details about the Author mode drag and drop listeners, see the Configuring a custom Drag and Drop Listener (on page 2084) section.

Another extension that can be included in the bundle is the reference resolver. For example, the references represented by the ref element and the attribute indicating the referenced resource is location. To be able to obtain the content of the referenced resources you will have to implement a Java extension class that implements `ro.sync.ecss.extensions.api.AuthorReferenceResolver`. The method responsible for creating the custom references resolver is `createAuthorReferenceResolver`.

The method is called each time a document opened in an Author editing mode matches the Document Type Association where the extensions bundle is defined. The instantiated references resolver object is kept and used until another extensions bundle corresponding to another document type is activated as result of the detection process.

```java
public AuthorReferenceResolver createAuthorReferenceResolver() {
    return new ReferencesResolver();
}
```

A more detailed description of the references resolver can be found in the Configuring a References Resolver (on page 2085) section.

To be able to dynamically customize the default CSS styles for a certain `ro.sync.ecss.extensions.api.node.AuthorNode`, an implementation of `ro.sync.ecss.extensions.api.StylesFilter` can be provided. The extensions bundle method responsible for creating the StylesFilter is `createAuthorStylesFilter`. The method is called each time a document opened in an Author editing mode matches the Document Type Association where the extensions bundle is defined. The instantiated filter object is kept and used until another extensions bundle corresponding to another document type is activated as a result of the detection process.

```java
public StylesFilter createAuthorStylesFilter() {
    return new SDFStylesFilter();
}
```
See the Configuring CSS Styles Filter (on page 2106) section for more details about the styles filter extension.

10. To edit data in custom tabular format, implementations of the 
    ro.sync.ecss.extensions.api.AuthorTableCellSpanProvider and the 
    ro.sync.ecss.extensions.api.AuthorTableColumnWidthProvider interfaces should be provided. 
    The two methods from the ExtensionsBundle specifying these two extension points are 
    createAuthorTableCellSpanProvider and createAuthorTableColumnWidthProvider. 
    For example:

    ```java
    public AuthorTableCellSpanProvider createAuthorTableCellSpanProvider() {
        return new TableCellSpanProvider();
    }
    
    public AuthorTableColumnWidthProvider createAuthorTableColumnWidthProvider() {
        return new TableColumnWidthProvider();
    }
    ```

    The two table information providers are not reused for different tables. The methods are called for each 
    table in the document so new instances should be provided every time. Read more about the cell span 
    and column width information providers in Configuring a Table Cell Span Provider (on page 2098) and 
    Configuring a Table Column Width Provider (on page 2092) sections.

    If the functionality related to one of the previous extension points does not need to be modified, then 
    the developed ro.sync.ecss.extensions.api.ExtensionsBundle should not override the corresponding 
    method and leave the default base implementation to return null.

11. An XML vocabulary can contain links to various areas of a document. If the document contains 
    elements defined as links, you can choose to present a more relevant text description for each link. To 
    do this, an implementation of the ro.sync.ecss.extensions.api.link.LinkTextResolver interface should be 
    returned by the createLinkTextResolver method. This implementation is used each time the oxy_link-
    text() function (on page 2206) is encountered in the CSS styles associated with an element. 
    For example:

    ```java
    public LinkTextResolver createLinkTextResolver() {
        return new DitaLinkTextResolver();
    }
    ```

    Oxygen XML Editor offers built-in implementations for DITA and 
    DocBook: ro.sync.ecss.extensions.dita.link.DitaLinkTextResolver and 
    ro.sync.ecss.extensions.docbook.link.DocbookLinkTextResolver respectively.

12. Pack the compiled class into a JAR (on page 2967) file.

13. Copy the JAR file into your custom framework directory (for example, frameworks/sdf).

14. Add the JAR file to the class path. To do this, open the Preferences dialog box (Options > Preferences) 
    (on page 98), go to Document Type Association, select the document type (for example, SDF), click the
Edit button, select the **Classpath** tab, and click the **+ Add** button. In the displayed dialog box, enter the location of the **JAR** file relative to the Oxygen XML Editor **frameworks** folder.

15. Register the Java class by going to the **Extensions** tab. Click the **Choose** button and select the name of the class (for example, **SDFExtensionsBundle**).

**Note:**
The complete source code for framework customization examples can be found in the oxygen-sample-framework module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

---

**Adding a Custom Image Decorator for Author Mode**

The **AuthorImageDecorator** extension point allows you to add a custom decorator over images in **Author** mode. For example, you could use it to add a message over an image informing the user that they can double-click the image to edit it.

**How to Implement an **AuthorImageDecorator****

To implement your own **AuthorImageDecorator**, follow this procedure:

1. Implement the **ro.sync.ecss.extensions.api.AuthorImageDecorator** interface.
2. To instruct Oxygen XML Editor to use this newly created implementation, use either of the following methods:
   a. If you have configured an extensions bundle (on page 2075), you can return the **AuthorImageDecorator** implementation using the **ro.sync.ecss.extensions.api.ExtensionsBundle.getAuthorImageDecorator()** method.
   b. Specify the **AuthorImageDecorator** in the **Author image decorator** individual extension in the **Extensions** tab (on page 139) of the **Document Type** configuration dialog box (on page 113) for your particular document type.

**Example**

The following example illustrates an implementation for presenting a simple message over an image that informs the user that they can double-click the image to edit it:

```java
/**
 * Custom Author image decorator for drawing string over images.
 */

public class CustomAuthorImageDecorator extends AuthorImageDecorator { ...
```
Example result: In the top-left corner of the image, the following message will be displayed: [Double-click to edit image].

Adding Custom Persistent Highlights

The Author API includes a class that allows you to create or remove custom persistent highlights, set new properties for the highlights, and customize their appearance. An example of a possible use case would be if you want to implement your own way of editing review comments. The custom persistent highlights get serialized in the XML document as processing instructions, with the following format:

```xml
<?oxy_custom_start prop1="val1"....?> xml content <?oxy_custom_end?>
```

This functionality is available through the AuthorPersistentHighlighter class that is accessible through the AuthorEditorAccess#getPersistentHighlighter() method.

For more information, see the JavaDoc details for this class at https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/ecss/extensions/api/highlights/AuthorPersistentHighlighter.html.

Configuring the Automatic ID Generation and Unique Attributes Recognizer

The ro.sync.ecss.extensions.api.UniqueAttributesRecognizer interface can be implemented if you want to provide for your framework (on page 2967) the following features:

- **Automatic ID generation** - You can automatically generate unique IDs for newly inserted elements. Implementations are already available for the DITA and DocBook frameworks (on page 2967). The following methods can be implemented to accomplish this: assignUniqueIDs(int startOffset, int endOffset), isAutoIDGenerationActive()
• Avoiding copying unique attributes when "Split" is called inside an element - You can split the current block element (on page 2964) by pressing the "Enter" key and then choosing "Split". This is a very useful way to create new paragraphs, for example. All attributes are by default copied on the new element but if those attributes are IDs you sometimes want to avoid creating validation errors in the editor. Implementing the following method, you can decide whether or not an attribute should be copied during the split: boolean copyAttributeOnSplit(String attrQName, AuthorElement element)

Tip:
The ro.sync.ecss.extensions.commons.id.DefaultUniqueAttributesRecognizer class is an implementation of the interface that can be extended by your customization to provide easy assignation of IDs in your framework (on page 2967). You can also check out the DITA and DocBook implementations of ro.sync.ecss.extensions.api.UniqueAttributesRecognizer to see how they were implemented and connected to the extensions bundle.

Note:
The complete source code for framework customization examples can be found in the oxygen-sample-framework module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

Configuring Content Completion Proposals
You can filter or contribute to proposals offered for content completion by implementing the ro.sync.contentcompletion.xml.SchemaManagerFilter interface.

```java
import java.util.List;
import ro.sync.contentcompletion.xml.CIAttribute;
import ro.sync.contentcompletion.xml.CIElement;
import ro.sync.contentcompletion.xml.CIValue;
import ro.sync.contentcompletion.xml.Context;
import ro.sync.contentcompletion.xml.SchemaManagerFilter;
import ro.sync.contentcompletion.xml.WhatAttributesCanGoHereContext;
import ro.sync.contentcompletion.xml.WhatElementsCanGoHereContext;
import ro.sync.contentcompletion.xml.WhatPossibleValuesHasAttributeContext;

public class SDFSQueryManagerFilter implements SchemaManagerFilter {

You can implement the various callbacks of the interface either by returning the default values given by Oxygen XML Editor or by contributing to the list of proposals. The filter can be applied on elements, attributes or on their values. Attributes filtering can be implemented using the filterAttributes method and changing the default content completion list of ro.sync.contentcompletion.xml.CIAttribute for the element provided by the current ro.sync.contentcompletion.xml.WhatAttributesCanGoHereContext context. For example, the
SDFSchemaManagerFilter checks if the element from the current context is the `table` element and adds the `frame` attribute to the `table` list of attributes.

```java
/**
 * Filter attributes of the "table" element.
 */
public List<CIAttribute> filterAttributes(List<CIAttribute> attributes, WhatAttributesCanGoHereContext context) {
    // If the element from the current context is the 'table' element add the
    // attribute named 'frame' to the list of default content completion proposals
    if (context != null) {
        ContextElement contextElement = context.getParentElement();
        if (contextElement.getQName().equals("table")) {
            CIAttribute frameAttribute = new CIAttribute();
            frameAttribute.setName("frame");
            frameAttribute.setRequired(false);
            frameAttribute.setFixed(false);
            frameAttribute.setDefaultValue("void");
            if (attributes == null) {
                attributes = new ArrayList<CIAttribute>();
            }
            attributes.add(frameAttribute);
        }
    }
    return attributes;
}
```

The elements that can be inserted in a specific context can be filtered using the `filterElements` method. The SDFSchemaManagerFilter uses this method to replace the `td` child element with the `th` element when `header` is the current context element.

```java
public List<CIElement> filterElements(List<CIElement> elements, WhatElementsCanGoHereContext context) {
    // If the element from the current context is the 'header' element remove the
    // 'td' element from the list of content completion proposals and add the
    // 'th' element.
    if (context != null) {
        Stack<ContextElement> elementStack = context.getElementStack();
        if (elementStack != null) {
            ContextElement contextElement = context.getElementStack().peek();
            if (contextElement.getQName().equals("header")) {
                if (elements != null) {
                    for (Iterator<CIElement> iterator = elements.iterator(); iterator.hasNext();)
```
CIElement element = iterator.next();

// Remove the 'td' element
if ("td".equals(element.getQName())) {
    elements.remove(element);
    break;
}

} else {
    elements = new ArrayList<CIElement>();
}

// Insert the 'th' element in the list of content completion proposals
CIElement thElement = new SDDElement();
    thElement.setName("th");
    elements.add(thElement);
}

} else {

// If the given context is null then the given list of content completion
// elements contains global elements.
}

return elements;

The elements or attributes values can be filtered using the filterElementValues or filterAttributeValues methods.

Note:
The complete source code for framework customization examples can be found in the oxygen-sample-framework module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

Configuring a Custom Drag and Drop Listener

Sometimes it is useful to perform various operations when certain objects are dropped from outside sources in the editing area. You can choose from three interfaces to implement depending on whether you are using the Eclipse plugin or the standalone version of the application, or if you want to add the handler for the Text or Author modes.

Interfaces for the Drag and Drop Listener

ro.sync.exml.editor.xmleditor.pageauthor.AuthorDnDListener

    Receives callbacks from the standalone application for Drag And Drop in Author mode.

com.oxygenxml.editor.editors.author.AuthorDnDListener
Receives callbacks from the Eclipse plugin for Drag And Drop in **Author** mode.

*com.oxygenxml.editor.editors.TextDnDListener*

Receives callbacks from the Eclipse plugin for Drag And Drop in **Text** mode.

**Configuring a Reference Resolver**

This information is helpful if you need to provide a handler for resolving references and obtain the content they reference. For example, suppose the element that has references is `ref` and the attribute indicating the referenced resource is `location`. You need to implement a Java extension class for obtaining the referenced resources.

1. Create the class `simple.documentation.framework.ReferencesResolver`. This class must implement the `ro.sync.ecss.extensions.api.AuthorReferenceResolver` interface.

```java
import ro.sync.ecss.extensions.api.AuthorReferenceResolver;
import ro.sync.ecss.extensions.api.AuthorAccess;
import ro.sync.ecss.extensions.api.node.AttrValue;
import ro.sync.ecss.extensions.api.node.AuthorElement;
import ro.sync.ecss.extensions.api.node.AuthorNode;

public class ReferencesResolver implements AuthorReferenceResolver {

    public boolean hasReferences(AuthorNode node) {
        boolean hasReferences = false;
        if (node.getType() == AuthorNode.NODE_TYPE_ELEMENT) {
            AuthorElement element = (AuthorElement) node;
            if ("ref".equals(element.getLocalName())) {

```
3. The method `getDisplayName` returns the display name of the node that contains the expanded referenced content. It takes `AuthorNode` as an argument that represents the node that needs the display name. The referenced content engine will ask this `AuthorReferenceResolver` implementation for the display name for each node that is considered a reference. In the following example, the display name is the value of the `location` attribute from the `ref` element.

```java
public String getDisplayName(AuthorNode node) {
    String displayName = "ref-fragment";
    if (node.getType() == AuthorNode.NODE_TYPE_ELEMENT) {
        AuthorElement element = (AuthorElement) node;
        if ("ref".equals(element.getLocalName())) {
            AttrValue attrValue = element.getAttribute("location");
            if (attrValue != null) {
                displayName = attrValue.getValue();
            }
        }
    }
    return displayName;
}
```

4. The method `resolveReference` resolves the reference of the node and returns a `SAXSource` with the parser and its input source. It takes `AuthorNode` as an argument that represents the node that needs the reference resolved, the `systemID` of the node, the `AuthorAccess` with access methods to the `Author` mode data model and a SAX `EntityResolver` that resolves resources that are already opened in another editor or resolve resources through the `XML Catalog (on page 2972)`. In the implementation, you need to resolve the reference relative to the `systemID`, and create a parser and an input source over the resolved reference.

```java
public SAXSource resolveReference(AuthorNode node, String systemID, AuthorAccess authorAccess, EntityResolver entityResolver) {
    SAXSource saxSource = null;
    if (node.getType() == AuthorNode.NODE_TYPE_ELEMENT) {
        AuthorElement element = (AuthorElement) node;
        if ("ref".equals(element.getLocalName())) {
            AttrValue attrValue = element.getAttribute("location");
        }
    }
    return saxSource;
}
```
if (attrValue != null) {
    String attrStringVal = attrValue.getValue();
    try {
        URL absoluteUrl = new URL(new URL(systemID),
            authorAccess.getUtilAccess().correctURL(attrStringVal));

        InputSource inputSource = entityResolver.resolveEntity(null, 
            absoluteUrl.toString());
        if (inputSource == null) { 
            inputSource = new InputSource(absoluteUrl.toString());
        }

        XMLReader xmlReader = authorAccess.newNonValidatingXMLReader();
        xmlReader.setEntityResolver(entityResolver);

        saxSource = new SAXSource(xmlReader, inputSource);
    } catch (MalformedURLException e) {
        logger.error(e, e);
    } catch (SAXException e) {
        logger.error(e, e);
    } catch (IOException e) {
        logger.error(e, e);
    }
}

return saxSource;
}

5. The method `getReferenceUniqueID` should return a unique identifier for the node reference. The unique identifier is used to avoid resolving the references recursively. The method takes `AuthorNode` as an argument that represents the node with the reference. In the following example, the unique identifier is the value of the `location` attribute from the `ref` element.

```java
public String getReferenceUniqueID(AuthorNode node) {
    String id = null;
    if (node.getType() == AuthorNode.NODE_TYPE_ELEMENT) {
        AuthorElement element = (AuthorElement) node;
        if ("ref".equals(element.getLocalName())) { 
            AttrValue attrValue = element.getAttribute("location");
            if (attrValue != null) { 
                id = attrValue.getValue();
            }
        }
    }
    return id;
}
```
6. The method `getReferenceSystemID` should return the `systemID` of the referenced content. It takes `AuthorNode` as an argument that represents the node with the reference and the `AuthorAccess` with access methods to the Author mode data model. For example, the value of the `location` attribute is used from the `ref` element and resolved relatively to the XML base URL of the node.

```java
public String getReferenceSystemID(AuthorNode node,
                                   AuthorAccess authorAccess) {
    String systemID = null;
    if (node.getType() == AuthorNode.NODE_TYPE_ELEMENT) {
        AuthorElement element = (AuthorElement) node;
        if ("ref".equals(element.getLocalName())) {
            AttrValue attrValue = element.getAttribute("location");
            if (attrValue != null) {
                String attrStringVal = attrValue.getValue();
                try {
                    URL absoluteUrl = new URL(node.getXMLBaseURL(),
                                               authorAccess.getUtilAccess().correctURL(attrStringVal));
                    systemID = absoluteUrl.toString();
                } catch (MalformedURLException e) {
                    logger.error(e, e);
                }
            }
        }
    }
    return systemID;
}
```

In the listing below, the XML document contains the `ref` element:

```xml
<ref location="referenced.xml">Reference</ref>
```

When no reference resolver is specified, the reference has the following layout:

**Figure 563. Reference with no specified reference resolver**

Reference without a reference resolver

When the above implementation is configured, the reference has the expected layout:
Configuring a State Listener for Author Mode

The ro.sync.ecss.extensions.api.AuthorExtensionStateListener implementation is notified when the Author mode extension (where the listener is defined) is activated or deactivated in the document type detection process.

```java
import ro.sync.ecss.extensions.api.AuthorAccess;
import ro.sync.ecss.extensions.api.AuthorExtensionStateListener;

public class SDFAuthorExtensionStateListener implements AuthorExtensionStateListener {
    private AuthorListener sdfAuthorDocumentListener;
    private AuthorMouseListener sdfMouseListener;
    private AuthorCaretListener sdfCaretListener;
    private OptionListener sdfOptionListener;

    public void activated(AuthorAccess authorAccess) {
        // Get the value of the option.
        String option = authorAccess.getOptionsStorage().getOption("sdf.custom.option.key", ");
        // Use the option for some initializations...

        // Add an OptionListener.
        authorAccess.getOptionsStorage().addOptionListener(sdfOptionListener);

        // Add author DocumentListeners.
        sdfAuthorDocumentListener = new SDFAuthorListener();
    }
}
```

When the association rules of the framework (on page 2967) (document type) configuration match that of a document open in the Author editing mode, the activation event received by this listener should be used to perform custom initializations and to register listeners such as ro.sync.ecss.extensions.api.AuthorListener, ro.sync.ecss.extensions.api.AuthorMouseListener, or ro.sync.ecss.extensions.api.AuthorCaretListener.
authorAccess.getDocumentController().addAuthorListener(sdfAuthorDocumentListener);

// Add MouseListener.
sdfMouseListener = new SDFAuthorMouseListener();
authorAccess.getEditorAccess().addAuthorMouseListener(sdfMouseListener);

// Add CaretListener.
sdfCaretListener = new SDFAuthorCaretListener();
authorAccess.getEditorAccess().addAuthorCaretListener(sdfCaretListener);

// Other custom initializations...

The **authorAccess** parameter received by the *activated* method can be used to gain access to specific **Author** mode actions and informations related to components such as the editor, document, workspace, tables, or the **change tracking** manager.

If options specific to the custom developed **Author Extension** need to be stored or retrieved, a reference to the **ro.sync.ecss.extensions.api.OptionsStorage** can be obtained by calling the **getOptionsStorage** method from the **authorAccess**. The same object can be used to register **ro.sync.ecss.extensions.api.OptionListener** listeners. An option listener is registered in relation with an option **key** and will be notified about the value changes of that option.

An **AuthorListener** can be used if events related to the **Author** mode document modifications are of interest. The listener can be added to the **ro.sync.ecss.extensions.api.AuthorDocumentController**. A reference to the document controller is returned by the **getDocumentController** method from the **authorAccess**. The document controller can also be used to perform operations involving document modifications.

To provide access to the **Author** mode component-related functionality and information, the **authorAccess** has a reference to the **ro.sync.ecss.extensions.api.access.AuthorEditorAccess** that can be obtained when calling the **getEditorAccess** method. At this level, **AuthorMouseListener** and **AuthorCaretListener** can be added to provide notification of mouse and cursor events that occur in the **Author** editor mode.

The **deactivation** event is received when another **framework** is activated for the same document, the user switches to another editor mode or the editor is closed. The **deactivate** method is typically used to unregister the listeners previously added on the **activate** method and to perform other actions. For example, options related to the deactivated **Author Extension** can be saved at this point.

```java
public void deactivated(AuthorAccess authorAccess) {
    // Store the option.
    authorAccess.getOptionsStorage().setOption("sdf.custom.option.key", optionValue);

    // Remove the OptionListener.
```

```java```
authorAccess.getOptionsStorage().removeOptionListener(sdfOptionListener);

// Remove DocumentListeners.
authorAccess.getDocumentController().removeAuthorListener(
    sdfAuthorDocumentListener);

// Remove MouseListener.
authorAccess.getEditorAccess().removeAuthorMouseListener(sdfMouseListener);

// Remove CaretListener.
authorAccess.getEditorAccess().removeAuthorCaretListener(sdfCaretListener);

// Other actions...
}

**Note:**
The complete source code for framework customization examples can be found in the oxygen-sample-framework module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

### Configuring Tables

There are standard CSS properties used to indicate what elements are tables, table rows and table cells. What CSS is missing is the possibility to indicate the cell spanning, row separators or the column widths. Oxygen XML Editor offers support for adding extensions to solve these problems.

The table in this example is a simple one. The header must be formatted in a different way than the ordinary rows, so it will have a background color.

```css
table{
    display:table;
    border:1px solid navy;
    margin:1em;
    max-width:1000px;
    min-width:150px;
}

table[width]|
    width:attr(width, length);
}

tr, header{
    display:table-row;
}
Suppose that in the schema, the `<td>` tag has the attributes `@row_span` and `@column_span` that are not automatically recognized by Oxygen XML Editor, a Java extension will be implemented that will provide information about the cell spanning. See the section Configuring a Table Cell Span Provider (on page 2098).

Suppose the column widths are specified by the `@width` attribute of the `<customcol>` elements that are not automatically recognized by Oxygen XML Editor. It is necessary to implement a Java extension that will provide information about the column widths. For more information, see Configuring a Table Column Width Provider (on page 2092).

The table from the example does not make use of the attributes `@colsep` and `@rowsep` (which are automatically recognized) but if you want the rows to be separated by horizontal lines, it is necessary to implement a Java extension that will provide information about the row and column separators. For more information, see Configuring a Table Cell Row and Column Separator Provider (on page 2102).

### Configuring a Table Column Width Provider

In a custom framework (on page 2967), the `<table>` element as well as the table columns can have specified widths. For these widths to be considered by Author mode, you need to provide the means for determining them. As explained in Configuring Tables (on page 2091), if you use the table element attribute `width` Oxygen XML Editor can determine the table width automatically. In this example the table has `<col>` elements with `@width` attributes that are not recognized by default. You will need to implement a Java extension class to determine the column widths.

1. Create the class `simple.documentation.framework.TableColumnWidthProvider`. This class must implement the `ro.sync.ecss.extensions.api.AuthorTableColumnWidthProvider` interface.

```java
import ro.sync.ecss.extensions.api.AuthorAccess;
import ro.sync.ecss.extensions.api.AuthorOperationException;
import ro.sync.ecss.extensions.api.AuthorTableColumnWidthProvider;
import ro.sync.ecss.extensions.api.WidthRepresentation;
import ro.sync.ecss.extensions.api.node.AuthorElement;
```
public class TableColumnWidthProvider
    implements AuthorTableColumnWidthProvider {

2. Method init is taking as argument an ro.sync.ecss.extensions.api.node.AuthorElement that represents the XML <table> element. In our case the column widths are specified in <col> elements from the <table> element. In such cases you must collect the span information by analyzing the <table> element.

    public void init(AuthorElement tableElement) {
        this.tableElement = tableElement;
        AuthorElement[] colChildren = tableElement.getElementsByLocalName("customcol");
        if (colChildren != null && colChildren.length > 0) {
            for (int i = 0; i < colChildren.length; i++) {
                AuthorElement colChild = colChildren[i];
                if (i == 0) {
                    colsStartOffset = colChild.getStartOffset();
                } else if (i == colChildren.length - 1) {
                    colsEndOffset = colChild.getEndOffset();
                }
                // Determine the 'width' for this col.
                AttrValue colWidthAttribute = colChild.getAttribute("width");
                String colWidth = null;
                if (colWidthAttribute != null) {
                    colWidth = colWidthAttribute.getValue();
                    // Add WidthRepresentation objects for the columns this 'customcol'
                    // specification spans over.
                    colWidthSpecs.add(new WidthRepresentation(colWidth, true));
                }
            }
        }
    }

3. The method isTableAcceptingWidth should check if the table cells are a <td> element.

    public boolean isTableAcceptingWidth(String tableCellsTagName) {
        return "td".equals(tableCellsTagName);
    }

4. The method isTableAndColumnsResizable should check if the table cells are a <td> element. This method determines if the table and its columns can be resized by dragging the edge of a column.

    public boolean isTableAndColumnsResizable(String tableCellsTagName) {
        return "td".equals(tableCellsTagName);
    }

5. Methods getTableWidth and getCellWidth are used to determine the table and column width. The table layout engine will ask this ro.sync.ecss.extensions.api.AuthorTableColumnWidthProvider implementation what is the table width for each table element and the cell width for each cell element.
from the table that was marked as cell in the CSS using the property \texttt{display:table-cell}. The implementation is simple and just parses the value of the \texttt{width} attribute. The methods must return \texttt{null} for the tables / cells that do not have a specified width.

```java
public WidthRepresentation getTableWidth(String tableCellsTagName) {
    WidthRepresentation toReturn = null;
    if (tableElement != null && "td".equals(tableCellsTagName)) {
        AttrValue widthAttr = tableElement.getAttribute("width");
        if (widthAttr != null) {
            String width = widthAttr.getValue();
            if (width != null) {
                toReturn = new WidthRepresentation(width, true);
            }
        }
    }
    return toReturn;
}
```

```java
public List<WidthRepresentation> getCellWidth(AuthorElement cellElement, int colNumberStart, int colSpan) {
    List<WidthRepresentation> toReturn = null;
    int size = colWidthSpecs.size();
    if (size >= colNumberStart && size >= colNumberStart + colSpan) {
        toReturn = new ArrayList<WidthRepresentation>(colSpan);
        for (int i = colNumberStart; i < colNumberStart + colSpan; i++) {
            // Add the column widths
            toReturn.add(colWidthSpecs.get(i));
        }
    }
    return toReturn;
}
```

6. Methods \texttt{commitTableWidthModification} and \texttt{commitColumnWidthModifications} are used to commit changes made to the width of the table or its columns when using the mouse drag gestures.

```java
public void commitTableWidthModification(AuthorDocumentController authorDocumentController, int newTableWidth, String tableCellsTagName) throws AuthorOperationException {
    if ("td".equals(tableCellsTagName)) {
        if (newTableWidth > 0) {
            if (tableElement != null) {
                String newWidth = String.valueOf(newTableWidth);
                authorDocumentController.setAttribute(}
```
"width",
    new AttrValue(newWidth),
    tableElement);
} else {
    throw new AuthorOperationException("Cannot find the table element.");
}

public void commitColumnWidthModifications
(AuthorDocumentController authorDocumentController,
    WidthRepresentation[] colWidths, String tableCellsTagName)
throws AuthorOperationException {
    if ("td".equals(tableCellsTagName)) {
        if (colWidths != null && tableElement != null) {
            if (colsStartOffset >= 0 && colsEndOffset >= 0
                && colsStartOffset < colsEndOffset) {
                authorDocumentController.delete(colsStartOffset,
                    colsEndOffset);
            } else {
                String xmlFragment = createXMLFragment(colWidths);
                int offset = -1;
                AuthorElement[] header = tableElement.getElementsByLocalName("header");
                if (header != null && header.length > 0) {
                    // Insert the cols elements before the 'header' element
                    offset = header[0].getStartOffset();
                } else if (offset == -1) {
                    throw new AuthorOperationException("No valid offset to insert column width");
                }
                authorDocumentController.insertXMLFragment(xmlFragment, offset);
            }
        } else {
            throw new AuthorOperationException("Cannot find the table element.");
        }
    }

    private String createXMLFragment(WidthRepresentation[] widthRepresentations) {
        StringBuffer fragment = new StringBuffer();
        String ns = tableElement.getNamespace();
        for (int i = 0; i < widthRepresentations.length; i++) {
            WidthRepresentation width = widthRepresentations[i];
            fragment.append("<customcol");
            String strRepresentation = width.getWidthRepresentation();
            fragment.append(strRepresentation);
            fragment.append("/>");
        }
        return fragment.toString();
    }
}
if (strRepresentation != null) {
    fragment.append(" width=" + width.getWidthRepresentation() + "\"\";
}
if (ns != null && ns.length() > 0) {
    fragment.append(" xmlns=" + ns + "\"\";
    fragment.append("/>\");
    return fragment.toString();
}

7. The following three methods are used to determine what type of column width specifications the table column width provider support. In our case all types of specifications are allowed:

    public boolean isAcceptingFixedColumnWidths(String tableCellsTagName) {
        return true;
    }

    public boolean isAcceptingPercentageColumnWidths(String tableCellsTagName) {
        return true;
    }

    public boolean isAcceptingProportionalColumnWidths(String tableCellsTagName) {
        return true;
    }

Note:
The complete source code for framework customization examples can be found in the oxygen-sample-framework module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

In the listing below, the XML document contains the table element:

<table width="300">
    <customcol width="50.0px"/>
    <customcol width="1*"/>
    <customcol width="2*"/>
    <customcol width="20%"/>
    <header>
        <td>C1</td>
        <td>C2</td>
        <td>C3</td>
        <td>C4</td>
    </header>
When no table column width provider is specified, the table has the following layout:

![Figure 565. Table layout when no column width provider is specified](image)

When the above implementation is configured, the table has the correct layout:
Configuring a Table Cell Span Provider

In a custom framework (on page 2967), the `<table>` element can have cells that span over multiple columns and rows. As explained in Configuring Tables (on page 2091), you need to indicate Oxygen XML Editor a method to determine the cell spanning. If you use the `@rowspan` and `@colspan` attributes, Oxygen XML Editor can determine the cell spanning automatically. In the following example, the `<td>` element uses the `@row_span` and `@column_span` attributes that are not recognized by default. You will need to implement a Java extension class for defining the cell spanning.

1. Create the class `simple.documentation.framework.TableCellSpanProvider`. This class must implement the `ro.sync.ecss.extensions.api.AuthorTableCellSpanProvider` interface.

```java
import ro.sync.ecss.extensions.api.AuthorTableCellSpanProvider;
import ro.sync.ecss.extensions.api.node.AttrValue;
import ro.sync.ecss.extensions.api.node.AuthorElement;

public class TableCellSpanProvider
    implements AuthorTableCellSpanProvider {
```

2. The `init` method takes `ro.sync.ecss.extensions.api.node.AuthorElement` that represents the XML `<table>` element as its argument. In this example, the cell span is specified for each of the cells so you leave this method empty. However, there are cases (such as the CALS table model) when the cell spanning is specified in the `<table>` element. In such cases, you must collect the span information by analyzing the `<table>` element.
3. The `getColSpan` method is taking as argument the table cell. The table layout engine will ask this `AuthorTableSpanSupport` implementation what is the column span and the row span for each XML element from the table that was marked as cell in the CSS using the property `display:table-cell`. The implementation is simple and just parses the value of `column_span` attribute. The method must return `null` for all the cells that do not change the span specification.

```java
public Integer getColSpan(AuthorElement cell) {
    Integer colSpan = null;

    AttrValue attrValue = cell.getAttribute("column_span");
    if(attrValue != null) {
        // The attribute was found.
        String cs = attrValue.getValue();
        if(cs != null) {
            try {
                colSpan = new Integer(cs);
            } catch (NumberFormatException ex) {
                // The attribute value was not a number.
            }
        }
    }
    return colSpan;
}
```

4. The row span is determined in a similar manner:

```java
public Integer getRowSpan(AuthorElement cell) {
    Integer rowSpan = null;

    AttrValue attrValue = cell.getAttribute("row_span");
    if(attrValue != null) {
        // The attribute was found.
        String rs = attrValue.getValue();
        if(rs != null) {
            try {
                rowSpan = new Integer(rs);
            } catch (NumberFormatException ex) {
                // The attribute value was not a number.
            }
        }
    }
    return rowSpan;
}
```
5. The method `hasColumnSpecifications` always returns `true` considering column specifications always available.

```java
public boolean hasColumnSpecifications(AuthorElement tableElement) {
    return true;
}
```

**Note:**
The complete source code for framework customization examples can be found in the `oxygen-sample-framework` module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

6. In the listing below, the XML document contains the table element:

```xml
<table>
    <header>
        <td>C1</td>
        <td>C2</td>
        <td>C3</td>
        <td>C4</td>
    </header>
    <tr>
        <td>cs=1, rs=1</td>
        <td>column_span="2" row_span="2">cs=2, rs=2</td>
        <td row_span="3">cs=1, rs=3</td>
    </tr>
    <tr>
        <td>cs=1, rs=1</td>
    </tr>
    <tr>
        <td column_span="3">cs=3, rs=1</td>
    </tr>
</table>
```

When no table cell span provider is specified, the table has the following layout:
When the above implementation is configured, the table has the correct layout:

**Figure 567. Table layout when no cell span provider is specified**

<table>
<thead>
<tr>
<th>C1</th>
<th>C2</th>
<th>C3</th>
<th>C4</th>
</tr>
</thead>
<tbody>
<tr>
<td>cs=1, rs=1</td>
<td>cs=2, rs=2</td>
<td>cs=1, rs=3</td>
<td></td>
</tr>
<tr>
<td>cs=1, rs=1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>cs=3, rs=1</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Figure 568. Cells spanning multiple rows and columns.**

<table>
<thead>
<tr>
<th>C1</th>
<th>C2</th>
<th>C3</th>
<th>C4</th>
</tr>
</thead>
<tbody>
<tr>
<td>cs=1, rs=1</td>
<td>cs=2, rs=2</td>
<td>cs=1, rs=3</td>
<td></td>
</tr>
<tr>
<td>cs=1, rs=1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>cs=3, rs=1</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Note:
The complete source code for framework customization examples can be found in the oxygen-sample-framework module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

Configuring a Table Cell Row and Column Separator Provider

In a custom framework (on page 2967), the <table> element has separators between rows. As explained in Configuring Tables (on page 2091), you need to indicate a method to determine the way rows and columns are separated. If you use the @rowsep and @colsep cell element attributes, or your table is conforming to the CALS table model, Oxygen XML Editor can determine the cell separators. Even if there are no attributes that define the separators, you can still force a separator between rows by implementing a Java extension.

1. Create the class simple.documentation.framework.TableCellSepProvider. This class must implement the ro.sync.ecss.extensions.api.AuthorTableCellSepProvider interface.

   ```java
   import ro.sync.ecss.extensions.api.AuthorTableCellSepProvider;
   import ro.sync.ecss.extensions.api.node.AuthorElement;

   public class TableCellSepProvider implements AuthorTableCellSepProvider{
   }
   ```

2. The init method takes the ro.sync.ecss.extensions.api.node.AuthorElement interface that represents the XML <table> element as its argument. If the separator information is implicit, it does not depend on the current table, so you leave this method empty. However, there are cases (such as the CALS table model) when the cell separators are specified in the <table> element. In such cases, you should initialize your provider based on the given argument.

   ```java
   public void init(AuthorElement table) {
   }
   ```

3. The getColSep method takes the table cell as its argument. The table layout engine will ask this AuthorTableCellSepProvider implementation if there is a column separator for each XML element from the table that was marked as cell in the CSS using the property display:table-cell. The following example returns false, meaning there will not be column separators.

   ```java
   /**
    * @return false - No column separator at the right of the cell.
    */
   @Override
   public boolean getColSep(AuthorElement cellElement, int columnIndex) {
       return false;
   }
   ```

4. The row separators are determined in a similar manner. This time the example returns true, forcing a separator between the rows.
```java
/**
 * @return true - A row separator below each cell.
 */
@Override
public boolean getRowSep(AuthorElement cellElement, int columnIndex) {
    return true;
}
```

**Note:**
The complete source code for framework customization examples can be found in the oxygen-sample-framework module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

5. In the example below, the XML document contains the table element:

```xml
<table>
    <header>
        <td>H1</td>
        <td>H2</td>
        <td>H3</td>
        <td>H4</td>
    </header>
    <tr>
        <td>C11</td>
        <td>C12</td>
        <td>C13</td>
        <td>C14</td>
    </tr>
    <tr>
        <td>C21</td>
        <td>C22</td>
        <td>C23</td>
        <td>C24</td>
    </tr>
    <tr>
        <td>C31</td>
        <td>C32</td>
        <td>C33</td>
        <td>C34</td>
    </tr>
</table>
```

When the borders for the `<td>` element are removed from the CSS, the row separators become visible:
Customizing Attribute Value Editors

The `CustomAttributeValueEditor` extension point allows you customize the attribute value editing mechanisms in Oxygen XML Editor. It changes the `Browse` button found in the attribute editors to an `Edit` button. When a user clicks that `Edit` button, your custom attribute value editor will be presented.

The `Edit` button can be accessed in the following attribute editors:

- The `Attributes` view in **Author mode** (on page 584) (when the `Expand` button is used to reveal an expanded panel).
- The `Attributes` view in **Text mode** (on page 502) (when the `Expand` button is used to reveal an expanded panel).
- The **In-place Attributes Editor** (on page 586) when invoked in **Author** mode.
- The **In-place Attributes Editor** invoked in the **Outline view** (on page 498).

How to Implement a `CustomAttributeValueEditor`

To implement your own `CustomAttributeValueEditor`, follow this procedure:

1. Extend the `ro.sync.ecss.extensions.api.CustomAttributeValueEditor` abstract class.
2. To instruct Oxygen XML Editor to use this newly created implementation, use either of the following methods:
a. If you have configured an extensions bundle (on page 2075), you can return the CustomAttributeValueEditor implementation using the ro.sync.ecss.extensions.api.ExtensionsBundle.createCustomAttributeValueEditor() method.
b. Specify the CustomAttributeValueEditor in the Author custom attribute value editor individual extension in the Extensions tab (on page 139) of the Document Type configuration dialog box (on page 113) for your particular document type.

Example

The following example creates a very simple custom attribute value editor:

```java
/**
 * A custom attribute value editor.
 */
public class MyCustomAttributeValueEditor extends CustomAttributeValueEditor {

/**
 * @see ro.sync.ecss.extensions.api.Extension#getDescription()
 */
@Override
public String getDescription() {
    return "My custom attribute value editor";
}

/**
 * @see ro.sync.ecss.extensions.api.CustomerAttributeValueEditor#getAttributeValue
 (ro.sync.ecss.extensions.api.EditedAttribute, java.lang.Object)
 */
@Override
public String getAttributeValue(EditedAttribute attribute, Object parentComponent)
    throws CancelledByUserException {
    // Show an input dialog for collecting the new value
    return JOptionPane.showInputDialog("Set a new value for " + attribute.getAttributeQName() + ":");
}

/**
 * @see ro.sync.ecss.extensions.api.CustomerAttributeValueEditor#shouldHandleAttribute
 (ro.sync.ecss.extensions.api.EditedAttribute)
 */
@Override
public boolean shouldHandleAttribute(EditedAttribute attribute) {
    // Handle all attributes
    return true;
}
```
Example result: If a user were to click the Edit button in any of the attribute editors, the following dialog box would be displayed that allows the user to insert a value for the particular attribute:

![Input dialog box](image)

Customizing the CSS Styles Filter

You can modify the CSS styles for each `ro.sync.ecss.extensions.api.node.AuthorNode` rendered in the Author mode using an implementation of `ro.sync.ecss.extensions.api.StylesFilter`. You can implement the various callbacks of the interface either by returning the default value given by Oxygen XML Editor or by contributing to the value. The received styles `ro.sync.ecss.css.Styles` can be processed and values can be overwritten with your own. For example, you can override the `KEY_BACKGROUND_COLOR` style to return your own implementation of `ro.sync.exml.view.graphics.Color` or override the `KEY_FONT` style to return your own implementation of `ro.sync.exml.view.graphics.Font`.

For instance, in this simple document example, the filter can change the value of the `KEY_FONT` property for the `</table>` element:

```java
package simple.documentation.framework;

import ro.sync.ecss.css.Styles;
import ro.sync.ecss.extensions.api.StylesFilter;
import ro.sync.ecss.extensions.api.node.AuthorNode;
import ro.sync.exml.view.graphics.Font;

public class SDFStylesFilter implements StylesFilter {

    public Styles filter(Styles styles, AuthorNode authorNode) {
        if (AuthorNode.NODE_TYPE_ELEMENT == authorNode.getType() && "table".equals(authorNode.getName())) {
            styles.setProperty(Styles.KEY_FONT, new Font(null, Font.BOLD, 12));
        }
        return styles;
    }

}
Customizing Elements that Wrap Profiled Content

For each framework (on page 2967) (document type), you can configure the phrase-type elements that wrap the profiled content by setting a custom ro.sync.ecss.extensions.api.ProfilingConditionalTextProvider. This configuration is set by default for DITA and DocBook frameworks.

Creating a Custom Link Target Reference Finder

If you need to create a custom link target reference finder you can do so by creating the class that will implement the ro.sync.ecss.extensions.api.link.ElementLocatorProvider interface. As an alternative, your class could extend ro.sync.ecss.extensions.commons.DefaultElementLocatorProvider, the default implementation.

Note:
The complete source code of the ro.sync.ecss.extensions.commons.DefaultElementLocatorProvider, ro.sync.ecss.extensions.commons.IDElementLocator or ro.sync.ecss.extensions.commons.XPointerElementLocator can be found in the oxygen-sample-framework project.
Default Link Target Reference Finder

The DefaultElementLocatorProvider implementation is used by default to find link target references. It offers support for the most common types of links:

- Links based on ID attribute values (on page 2108).
- XPointer element() scheme (on page 2109).

The method `getElementLocator` determines what `ElementLocator` should be used. In the default implementation, it checks if the link is an XPointer element() scheme. Otherwise, it assumes it is an ID. A non-null `IDTypeVerifier` will always be provided if a schema is associated with the document type.

The `link` string argument is the anchor (on page 2964) part of the URL that is composed from the value of the link property specified for the link element in the CSS.

```java
public ElementLocator getElementLocator(IDTypeVerifier idVerifier,
                                       String link) {
    ElementLocator elementLocator = null;
    try {
        if (link.startsWith("element(")) {
            // xpointer element() scheme
            elementLocator = new XPointerElementLocator(idVerifier, link);
        } else {
            // Locate link element by ID
            elementLocator = new IDElementLocator(idVerifier, link);
        }
    } catch (ElementLocatorException e) {
        logger.warn("Exception when create element locator for link: "
                    + link + ". Cause: " + e, e);
    }
    return elementLocator;
}
```

ID Element Locator

The `IDEElementLocator` is an implementation of the abstract class `ro.sync.ecss.extensions.api.link.ElementLocator` for links that use an ID.

The constructor only assigns field values and the method `endElement` is empty for this implementation.

The method `startElement` checks each of the element's attribute values and when one matches the link, it considers the element found if one of the following conditions is satisfied:

- The qualified name of the attribute is `xml:id`.
- The attribute type is ID.

The attribute type is checked with the help of the method `IDTypeVerifier.hasIDType`. 
public boolean startElement(String uri, String localName, String name, Attr[] atts) {
    boolean elementFound = false;
    for (int i = 0; i < atts.length; i++) {
        if (link.equals(atts[i].getValue())) {
            if("xml:id".equals(atts[i].getQName())) {
                // xml:id attribute
                elementFound = true;
            } else {
                // check if attribute has ID type
                String attrLocalName = ExtensionUtil.getLocalName(atts[i].getQName());
                String attrUri = atts[i].getNamespace();
                if (idVerifier.hasIDType(localName, uri, attrLocalName, attrUri)) {
                    elementFound = true;
                }
            }
        }
    }
    return elementFound;
}

XPointer Element Locator

XPointerElementLocator is an implementation of the abstract class ro.sync.ecss.extensions.api.link.ElementLocator for links that have one of the following XPointer element() scheme patterns:

- **element (elementID)**
  Locate the element with the specified ID.

- **element (/1/2/3)**
  A child sequence appearing alone identifies an element by means of stepwise navigation, which is directed by a sequence of integers separated by slashes (/). Each integer n locates the nth child element of the previously located element.

- **element (elementID/3/4)**
  A child sequence appearing after a NCName identifies an element by means of stepwise navigation, starting from the element located by the given name.

The constructor separates the ID/integers, which are delimited by slashes(/) into a sequence of identifiers (an XPointer path). It will also check that the link has one of the supported patterns of the XPointer element() scheme.
public XPointerElementLocator(IDTypeVerifier idVerifier, String link) {
    super(link);
    this.idVerifier = idVerifier;

    link = link.substring("element ".length(), link.length() - 1);

    StringTokenizer stringTokenizer = new StringTokenizer(link, "/", false);
    xpointerPath = new String[stringTokenizer.countTokens()];
    int i = 0;
    while (stringTokenizer.hasMoreTokens()) {
        xpointerPath[i] = stringTokenizer.nextToken();
        boolean invalidFormat = false;

        // Empty xpointer component is not supported
        if (xpointerPath[i].length() == 0){
            invalidFormat = true;
        }

        if (i > 0){
            try {
                Integer.parseInt(xpointerPath[i]);
            } catch (NumberFormatException e) {
                invalidFormat = true;
            }
        }

        if (invalidFormat){
            throw new ElementLocatorException("Only the element() scheme is supported when locating XPointer links." + "Supported formats: element(elementID), element(/1/2/3), element(elemID/2/3/4).");
        }
        i++;
    }

    if (Character.isDigit(xpointerPath[0].charAt(0))){
        // This is the case when xpointer have the following pattern /1/5/7
        xpointerPathDepth = xpointerPath.length;
    } else {
        // This is the case when xpointer starts with an element ID
        xpointerPathDepth = -1;
    }
The method `startElement` will be invoked at the beginning of every element in the XML document (even when the element is empty). The arguments it takes are

- `uri`  
  The namespace URI, or the empty string if the element has no namespace URI or if namespace processing is disabled.

- `localName`  
  Local name of the element.

- `qName`  
  Qualified name of the element.

- `atts`  
  Attributes attached to the element. If there are no attributes, this argument will be empty.

The method returns `true` if the processed element is found to be the one indicated by the link.

The `XPointerElementLocator` implementation of the `startElement` will update the depth of the current element and keep the index of the element in its parent. If the `xpointerPath` starts with an element ID then the current element ID is verified to match the specified ID. If this is the case the depth of the XPointer is updated taking into account the depth of the current element.

If the XPointer path depth is the same as the current element depth then the kept indices of the current element path are compared to the indices in the XPointer path. If all of them match then the element has been found.

```java
public boolean startElement(String uri, String localName,  
        String name, Attr[] atts) {  
    boolean linkLocated = false;  
    // Increase current element document depth  
    startElementDepth ++;

    if (endElementDepth != startElementDepth) {  
        // The current element is the first child of the parent  
        currentElementIndexStack.push(new Integer(1));
    } else {  
        // Another element in the parent element  
        currentElementIndexStack.push(new Integer(lastIndexInParent + 1));
    }

    if (startWithElementID) {  
        // This the case when xpointer path starts with an element ID.
```
String xpointerElement = xpointerPath[0];
for (int i = 0; i < atts.length; i++) {
    if (xpointerElement.equals(atts[i].getValue())){
        if (idVerifier.hasIDType(
            localName, uri, atts[i].getQName(), atts[i].getNamespace())){
            xpointerPathDepth = startElementDepth + xpointerPath.length - 1;
            break;
        }
    }
}

if (xpointerPathDepth == startElementDepth){
    // check if xpointer path matches with the current element path
    linkLocated = true;
    try {
        int xpointerIdx = xpointerPath.length - 1;
        int stackIdx = currentElementIndexStack.size() - 1;
        int stopIdx = startWithElementID ? 1 : 0;
        while (xpointerIdx >= stopIdx && stackIdx >= 0) {
            int xpointerIndex = Integer.parseInt(xpointerPath[xpointerIdx]);
            int currentElementIndex = ((Integer)currentElementIndexStack.get(stackIdx)).intValue();
            if (xpointerIndex != currentElementIndex) {
                linkLocated = false;
                break;
            }
            xpointerIdx--;
            stackIdx--;
        }
    } catch (NumberFormatException e) {
        logger.warn(e,e);
    }
    return linkLocated;
}
public void endElement(String uri, String localName, String name) {
    endElementDepth = startElementDepth;
    startElementDepth --;
    lastIndexInParent = ((Integer)currentElementIndexStack.pop()).intValue();
}

Customizing XML Node Rendering

You can use this API extension to customize the way an XML node is rendered in the Outline view (on page 498) in Author mode, breadcrumb navigation bar (on page 560) in Author mode, Outline view (on page 498) in Text mode, Content Completion Assistant (on page 2965) window, or DITA Maps Manager view (on page 2662).

Note:

There are two methods to provide an implementation of ro.sync.exml.workspace.api.node.customizer.XMLNodeRendererCustomizer:

• As a part of a bundle, returning it from the createXMLNodeCustomizer() method of the ExtensionsBundle associated with your document type in the Document type configuration dialog box (on page 113) (Extensions bundle field in the Extensions tab).
• As an individual extension, associated with your document type in the Document type configuration dialog box (on page 113) (XML node renderer customizer field in the Individual extensions section of the Extensions tab).

Support for Retina/HiDPI Displays

To support Retina or HiDPI displays, the icons provided by the XMLNodeRendererCustomizer should be backed up by a copy of larger size using the proper Retina/HiDPI naming convention (on page 678).

For example, for the <title> element, if the XMLNodeRendererCustomizer returns the path ${framework}/images/myImg.png, then to support Retina images with a scaling factor of 2, an extra file (myImg@2x.png) should be added to the same images directory (${framework}/images/myImg@2x.png). If the higher resolution icon (the @2x file) does not exist, the normal icon is scaled and used instead.

For more information about using Retina/HiDPI images, refer to the Using Retina/HiDPI Images in Author Mode (on page 678) section.
Customizing Author Operations

Oxygen XML Editor Author mode has a built-in set of operations covering the insertion of text and XML fragments (see the Author Default Operations (on page 2006)) and the execution of XPath expressions on the current document edited in Author mode. However, there are situations where you need to extend this set. The following examples are just a few of the possible situations:

- You need to enter an element whose attributes will be edited by the user through a graphical user interface.
- The user must send selected element content (or the whole document) to a+ server for some kind of processing.
- Content authors need to extract pieces of information from a server and insert it directly into the edited XML document.
- You need to apply an XPath expression on the current document and process the nodes of the resulting node set.

To extend the Oxygen XML Editor Author mode functionality through Java, you will need the Oxygen SDK available on the Oxygen XML Editor website. It includes the source code of the Author mode operations in the built-in document types and the full documentation (in Javadoc format) of the public API available for Author mode custom actions.

The subsequent Java examples make use of AWT classes. If you are developing extensions for the Oxygen XML Editor XML Editor plugin for Eclipse, you will have to use their SWT counterparts.

Attention:
Make sure the Java classes of your custom Author mode operations are compiled with the same Java version used by Oxygen XML Editor. Otherwise, the classes may not be loaded by the Java virtual machine. For example, if you run Oxygen XML Editor with a Java 1.8 virtual machine but the Java classes of your custom Author mode operations are compiled with a Java 9 or later virtual machine then the custom operations cannot be loaded and used by the Java 1.8 virtual machine.
Important:
From a legal standpoint, you can freely develop and share extensions using the Oxygen SDK ONLY if you have a legal, active license to use Oxygen XML Editor and ONLY if such extensions are used from inside Oxygen XML Editor. To use such extensions outside of Oxygen XML Editor (for example, a 3rd-party application that has Oxygen XML Editor built in to it), an additional license must be purchased to use the SDK according the Oxygen XML SDK Licensing Policy.

Related Information:
https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/ecss/extensions/api/AuthorOperation.html
Extending Oxygen With the SDK (on page 2251)

Example 1 - Simple Use of a Dialog Box from an Author Mode Operation

In this example, functionality is added for inserting images in a custom framework. The images are represented by the `<image>` element. The location of the image file is represented by the value of the `@href` attribute. In the Java implementation, a dialog box will be displayed with a text field where the user can enter a full URL or browse for a local file.

1. Set up a sample project following this set of instructions. The framework project is oxygen-sample-framework.
2. Modify the `simple.documentation.framework.InsertImageOperation` class that implements the `ro.sync.ecss.extensions.api.AuthorOperation` interface. This interface defines three methods: `doOperation`, `getArguments` and `getDescription`

A short description of these methods follows:

- The `doOperation` method is invoked when the action is performed either by pressing the toolbar button, by selecting the menu item or by pressing the shortcut key. The arguments taken by this method can be one of the following combinations:
  - An object of type `ro.sync.ecss.extensions.api.AuthorAccess` and a map.
  - Argument names and values.
- The `getArguments` method is used by Oxygen XML Editor when the action is configured. It returns the list of arguments (name and type) that are accepted by the operation.
- The `getDescription` method is used by Oxygen XML Editor when the operation is configured. It returns a description of the operation.

Example:

Here is the implementation of these three methods:

```java
/**
 * Performs the operation.
 */
public void doOperation()
```
AuthorAccess authorAccess,
ArgumentsMap arguments)
throws IllegalArgumentException,
AuthorOperationException {

JFrame oxygenFrame = (JFrame) authorAccess.getWorkspaceAccess().getParentFrame();

String href = displayURLDialog(oxygenFrame);
if (href.length() != 0) {
    // Creates the image XML fragment.
    String imageFragment =
        "<image xmlns='http://www.oxygenxml.com/sample/documentation' href="
        + href + "]"><'/>";

    // Inserts this fragment at the cursor position.
    int caretPosition = authorAccess.getEditorAccess().getCaretOffset();
    authorAccess.getDocumentController().insertXMLFragment(imageFragment, caretPosition);
}
}

/**
 * Has no arguments.
 * @return null.
 */
public ArgumentDescriptor[] getArguments() {
    return null;
}

/**
 * @return A description of the operation.
 */
public String getDescription() {
    return "Inserts an image element. Asks the user for a URL reference.";
}

Note:
The complete source code for framework customization examples can be found in the Oxygen-
sample-framework module of the Oxygen SDK, available as a Maven archetype on the Oxygen
XML Editor website.
Important:

Make sure you always specify the namespace of the inserted fragments.

3. Package the compiled class into a **JAR** (**on page 2967**) file. An example of an Ant script that packages the classes folder content into a JAR archive named sdf.jar is listed below:

```xml
<?xml version='1.0' encoding='UTF-8'?>
<project name='project' default='dist'>
  <target name='dist'>
    <jar destfile='sdf.jar' basedir='classes'>
      <fileset dir='classes'>
        <include name='**/*'/>
      </fileset>
    </jar>
  </target>
</project>
```

4. Copy the sdf.jar file into your custom **framework** directory
   (`{OXYGEN_INSTALL_DIR}\frameworks\{CUSTOM_FRAMEWORK_DIR}`).

5. Add the sdf.jar to the class path. To do this, open the **Preferences** dialog box (**Options > Preferences**) (**on page 98**), go to **Document Type Association**, select **SDF**, and click the **Edit** button.

6. Select the **Classpath** tab in the lower part of the **Document Type** configuration dialog box (**on page 113**) and click the ➕ Add button. In the displayed dialog box, enter the location of the JAR file, relative to the Oxygen XML Editor frameworks folder.

7. Next, create the action that will use the defined operation. Go to the **Actions** subtab. Copy the icon files for the menu item and for the toolbar in your custom **framework** directory (`{OXYGEN_INSTALL_DIR}\frameworks\{CUSTOM_FRAMEWORK_DIR}`).

8. Define the action's properties:
   - Set **ID** to insert_image.
   - Set **Name** to Insert image.
   - Set **Menu access key** to letter i.
   - Set **Toolbar action** to `${framework}/toolbarImage.png`.
   - Set **Menu icon** to `${framework}/menuImage.png`.
   - Set **Shortcut key** to Ctrl (Meta on macOS)+Shift+i.

9. Next, set up the operation. You want to add images only if the current element is a `<section>`, `<book>` or `<article>.
   - Set the value of **XPath expression** to
     ```
     local-name()='section' or local-name()='book'
     or local-name()='article'
     ```
   - Set the **Invoke operation** field to `simple.documentation.framework.InsertImageOperation`.
To test the action, open or create an XML file and place the cursor at a valid location. Then click the button associated with the action from the toolbar. In the dialog box, select an image URL and click **OK**. The image is inserted into the document.

### Example 2 - Operations with Arguments - Report from Database Operation

In this example, an operation is created that connects to a relational database and executes an SQL statement. The result should be inserted in the edited XML document as a table. To make the operation fully configurable, it will have arguments for the database connection string, the user name, the password and the SQL expression.

1. Set up a sample project following this set of instructions. The framework project is **oxygen-sample-framework**.
2. Create the class `simple.documentation.framework.QueryDatabaseOperation`. This class must implement the `ro.sync.ecss.extensions.api.AuthorOperation` interface.

```java
import ro.sync.ecss.extensions.api.ArgumentDescriptor;
```
import ro.sync.ecss.extensions.api.ArgumentsMap;
import ro.sync.ecss.extensions.api.AuthorAccess;
import ro.sync.ecss.extensions.api.AuthorOperation;
import ro.sync.ecss.extensions.api.AuthorOperationException;

public class QueryDatabaseOperation implements AuthorOperation{

3. Now define the operation's arguments. For each of them, you will use a String constant representing the argument name:

private static final String ARG_JDBC_DRIVER = "jdbc_driver";
private static final String ARG_USER = "user";
private static final String ARG_PASSWORD = "password";
private static final String ARG_SQL = "sql";
private static final String ARG_CONNECTION = "connection";

4. You must describe the argument name and type. To do this, implement the getArguments method that will return an array of argument descriptors:

public ArgumentDescriptor[] getArguments() {
    ArgumentDescriptor args[] = new ArgumentDescriptor[] {
        new ArgumentDescriptor{
            ARG_JDBC_DRIVER,
            ArgumentDescriptor.TYPE_STRING,
            "The name of the Java class that is the JDBC driver."),
        new ArgumentDescriptor{
            ARG_CONNECTION,
            ArgumentDescriptor.TYPE_STRING,
            "The database URL connection string."),
        new ArgumentDescriptor{
            ARG_USER,
            ArgumentDescriptor.TYPE_STRING,
            "The name of the database user."),
        new ArgumentDescriptor{
            ARG_PASSWORD,
            ArgumentDescriptor.TYPE_STRING,
            "The database password."),
        new ArgumentDescriptor{
            ARG_SQL,
            ArgumentDescriptor.TYPE_STRING,
            "The SQL statement to be executed.")
    };
    return args;
}
These names, types and descriptions will be listed in the **Arguments** table when the operation is configured.

5. When the operation is invoked, the implementation of the *doOperation* method extracts the arguments, forwards them to the method that connects to the database and generates the XML fragment. The XML fragment is then inserted at the cursor position.

```java
public void doOperation(AuthorAccess authorAccess, ArgumentsMap map)
    throws IllegalArgumentException, AuthorOperationException {

    // Collects the arguments.
    String jdbcDriver =
        (String)map.getArgumentValue(ARG_JDBC_DRIVER);
    String connection =
        (String)map.getArgumentValue(ARG_CONNECTION);
    String user =
        (String)map.getArgumentValue(ARG_USER);
    String password =
        (String)map.getArgumentValue(ARG_PASSWORD);
    String sql =
        (String)map.getArgumentValue(ARG_SQL);

    int caretPosition = authorAccess.getCaretOffset();
    try {
        authorAccess.getDocumentController().insertXMLFragment(
            getFragment(jdbcDriver, connection, user, password, sql),
            caretPosition);
    } catch (SQLException e) {
        throw new AuthorOperationException(
            "The operation failed due to the following database error: " +
            e.getMessage(), e);
    } catch (ClassNotFoundException e) {
        throw new AuthorOperationException(
            "The JDBC database driver was not found. Tried to load ' " +
            jdbcDriver + "', e);
    }
}
```

6. The *getFragment* method loads the JDBC driver, connects to the database and extracts the data. The result is a `<table>` element from the [http://www.oxygenxml.com/sample/documentation](http://www.oxygenxml.com/sample/documentation) namespace. The `<header>` element contains the names of the SQL columns. All the text from the XML fragment is escaped. This means that the `<` and `&` characters are replaced with the `&lt;` and `&amp;` character entities to ensure that the fragment is well-formed.
```java
private String getFragment(
    String jdbcDriver,
    String connectionURL,
    String user,
    String password,
    String sql) throws SQLException,
    ClassNotFoundException {

    Properties pr = new Properties();
    pr.put("characterEncoding", "UTF8");
    pr.put("useUnicode", "TRUE");
    pr.put("user", user);
    pr.put("password", password);

    // Loads the database driver.
    Class.forName(jdbcDriver);
    // Opens the connection
    Connection connection =
        DriverManager.getConnection(connectionURL, pr);
    java.sql.Statement statement =
        connection.createStatement();
    ResultSet resultSet =
        statement.executeQuery(sql);

    StringBuffer fragmentBuffer = new StringBuffer();
    fragmentBuffer.append(
        "<table xmlns=",
        "'http://www.oxygenxml.com/sample/documentation'>")

    //
    // Creates the table header.
    //
    fragmentBuffer.append("<header>");
    ResultSetMetaData metaData = resultSet.getMetaData();
    int columnCount = metaData.getColumnCount();
    for (int i = 1; i <= columnCount; i++) {
        fragmentBuffer.append("<td>");
        fragmentBuffer.append(xmlEscape(metaData.getColumnName(i)));
        fragmentBuffer.append("</td>");
    }
```
fragmentBuffer.append("</header>");

//
// Creates the table content.
//
while (resultSet.next()) {
    fragmentBuffer.append("<tr>");
    for (int i = 1; i <= columnCount; i++) {
        fragmentBuffer.append("<td>");
        fragmentBuffer.append(xmlEscape(resultSet.getObject(i)));
        fragmentBuffer.append("</td>");
    }
    fragmentBuffer.append("</tr>");
}
fragmentBuffer.append("</table>");

// Cleanup
resultSet.close();
statement.close();
connection.close();
return fragmentBuffer.toString();

Note:
The complete source code for framework customization examples can be found in the oxygen-sample-framework module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

7. Package the compiled class into a JAR (on page 2967) file.
8. Copy the JAR file and the JDBC driver files into your custom framework directory
   ([OXYGEN_INSTALL_DIR]/frameworks/[CUSTOM_FRAMEWORK_DIR]).
9. Add the JARS to the class path. To do this, open the Document Type Association preferences page
    (on page 111), select SDF and click the Edit button. Select the Classpath tab in the lower part of the
    Document Type configuration dialog box (on page 113) and click the Add button. In the displayed
    dialog box, enter the location of the JAR file, relative to the Oxygen XML Editor frameworks folder.
10. Go to the Actions subtab. The action properties are:
    • Set ID to clients_report.
    • Set Name to Clients Report.
    • Set Menu access key to letter r.
    • Set Description to Connects to the database and collects the list of clients.
• Set Toolbar icon to \${framework}/TableDB20.png (the TableDB20.png icon is stored in the frameworks/sdf folder).
• Leave empty the Menu icon.
• Set shortcut key to Ctrl + Shift + C (Command + Shift + C on OS X).

11. The action will work only if the current element is a section. Set up the operation as follows:
   • Set XPath expression to:

   ```xml
   local-name()=‘section’
   ```

   • Use the Java operation defined earlier to set the Invoke operation field. Click the Choose button, then select `simple.documentation.framework.QueryDatabaseOperation`. Once selected, the list of arguments is displayed. In the figure below the first argument, `jdbc_driver`, represents the class name of the MySQL JDBC driver. The connection string has the URL syntax: `jdbc://<database_host>:<database_port>/<database_name>`.

   The SQL expression used in the example follows, but it can be any valid SELECT expression that can be applied to the database:

   ```sql
   SELECT userID, email FROM users
   ```

12. Add the action to the toolbar, using the Toolbar panel.

**Figure 571. Java Operation Arguments Setup**

To test the action, open or create an XML file and place the cursor at a valid location. Then click the Create Report button from the toolbar. You can see below the toolbar with the action button and sample table inserted by the Clients Report action.
Handling Author Mode Action Events

The *AuthorActionEventHandler* extension point allows you to handle certain *Author* mode actions in a special way. For example, a specific use-case would be if you want to insert new lines when you press *Enter* instead of it opening the *Content Completion Assistant* (on page 2965).

How to Implement an *AuthorActionEventHandler*

To implement your own *AuthorActionEventHandler*, follow this procedure:

1. Implement the *ro.sync.ecss.extensions.api.AuthorActionEventHandler* interface.
2. To instruct Oxygen XML Editor to use this newly created implementation, use either of the following methods:
   a. If you have configured an extensions bundle (on page 2075), you can return the *AuthorActionEventHandler* implementation using the *ro.sync.ecss.extensions.api.ExtensionsBundle.getAuthorActionEventHandler()* method.
   b. Specify the *AuthorActionEventHandler* in the *Author action event handler* individual extension in the *Extensions* tab (on page 139) of the *Document Type* configuration dialog box (on page 113) for your particular document type.

Example

The following example illustrates the use-case mentioned in the introduction, that is an implementation for inserting a new line when the user presses *Enter* in *Author* mode. It uses the *canHandleEvent* method to make sure the insertion will be performed in an element that will preserve the *new-line* character. Then the *handleEvent* method inserts the new line at the current cursor position.
public class CustomAuthorActionEventEventHandler implements AuthorActionEventHandler {

    /**
     * @see ro.sync.ecss.extensions.api.AuthorActionEventHandler#canHandleEvent(AuthorAccess, AuthorActionEventType)
     */
    @Override
    public boolean canHandleEvent(AuthorAccess authorAccess, AuthorActionEventType type) {
        boolean canHandle = false;

        if (type == AuthorActionEventType.ENTER) {
            AuthorDocumentController documentController = authorAccess.getDocumentController();
            int caretOffset = authorAccess.getEditorAccess().getCaretOffset();
            try {
                AuthorNode nodeAtOffset = documentController.getNodeAtOffset(caretOffset);
                if (nodeAtOffset instanceof AuthorElement) {
                    AuthorElement elementAtOffset = (AuthorElement) nodeAtOffset;
                    AttrValue xmlSpace = elementAtOffset.getAttribute("xml:space");
                    if (xmlSpace != null && xmlSpace.getValue().equals("preserve")) {
                        canHandle = true;
                    }
                }
                return canHandle;
            } catch (BadLocationException ex) {
                if (logger.isDebugEnabled()) {
                    logger.error(ex.getMessage(), ex);
                }
            }
        }
        return canHandle;
    }

    /**
     * @see ro.sync.ecss.extensions.api.AuthorActionEventHandler#handleEvent(AuthorAccess, ro.sync.ecss.extensions.api.AuthorActionEventType)
     */
    @Override
    public boolean handleEvent(AuthorAccess authorAccess,
AuthorActionEventType eventType) {
    int caretOffset = authorAccess.getEditorAccess().getCaretOffset();
    // Insert a new line
    authorAccess.getDocumentController().insertText(caretOffset, "\n");
    return true;
}
/**
 * @see ro.sync.ecss.extensions.api.Extension#getDescription()
 */
@Override
public String getDescription() {
    return "Insert a new line";
}
}

Handling Schema-Aware Editing Events

The AuthorSchemaAwareEditingHandlerAdapter extension point allows you to handle certain Author mode actions in various ways. For example, implementing the AuthorSchemaAwareEditingHandlerAdapter makes it possible to handle events such as typing, the keyboard delete event at a given offset (using Delete or Backspace keys), delete element tags, delete selection, join elements, or paste fragment. It also makes it possible to improve solutions that are proposed by the paste mechanism in Oxygen XML Editor when pasting content (through the use of some specific methods (on page 2127)).

How to Implement an AuthorSchemaAwareEditingHandlerAdapter

For this handler to be called, the Schema-Aware Editing option (on page 152) must be set to On or Custom in the Schema-Aware preferences page (on page 152). The handler can either resolve a specific case, let the default implementation take place, or reject the edit entirely by throwing an InvalidEditException.

To implement your own AuthorSchemaAwareEditingHandlerAdapter, follow this procedure:

1. Implement the ro.sync.ecss.extensions.api.AuthorSchemaAwareEditingHandlerAdapter extension.
2. To instruct Oxygen XML Editor to use this newly created implementation, configure an extensions bundle (on page 2075) and return the AuthorSchemaAwareEditingHandlerAdapter implementation using the ro.sync.ecss.extensions.api.ExtensionsBundle.getAuthorSchemaAwareEditingHandlerAdapter() method.

Example

Typing events can be handled using the handleTyping method. For example, the AuthorSchemaAwareEditingHandler checks if the schema is not a learned one, was loaded successfully, and if
the **Smart paste and drag and drop** option *(on page 153)* is selected. If these conditions are met, the event will be handled.

```java
public class AuthorSchemaAwareEditingHandlerAdapter
    extends AuthorSchemaAwareEditingHandler {

    /**
     * @see AuthorSchemaAwareEditingHandler#handleTyping
     * (int, char, ro.sync.ecss.extensions.api.AuthorAccess)
     */
    public boolean handleTyping(int offset, char ch, AuthorAccess authorAccess)
        throws InvalidEditException {
        boolean handleTyping = false;
        AuthorSchemaManager authorSchemaManager =
            authorAccess.getDocumentController().getAuthorSchemaManager();
        if (!authorSchemaManager.isLearnSchema() &&
            !authorSchemaManager.hasLoadingErrors() &&
            authorSchemaManager.getAuthorSchemaAwareOptions().isEnableSmartTyping()) {
            try {
                AuthorDocumentFragment characterFragment =
                    authorAccess.getDocumentController().createNewDocumentTextFragment
                    (String.valueOf(ch));
                handleTyping = handleInsertionEvent
                    (offset, new AuthorDocumentFragment[] {characterFragment}, authorAccess);
            } catch (AuthorOperationException e) {
                throw new InvalidEditException
                    (e.getMessage(), "Invalid typing event: " + e.getMessage(), e, false);
            }
        }
        return handleTyping;
    }
```

**Note:**

The complete source code for framework customization examples can be found in the `oxygen-sample-framework` module of the Oxygen SDK, available as a Maven archetype on the Oxygen XML Editor website.

### Methods for Improving the Paste Mechanism

**getAncestorDetectionOptions**

When pasting content in Author mode, if the result causes the document to become invalid, Oxygen XML Editor will propose solutions to make it valid. As a possible solution, Oxygen XML Editor might surround the pasted content in a sequence of ancestor elements. This
**getAncestorDetectionOptions** method allows you to choose which parent elements might be a possible solution.

**canBeReplaced**

Allows you to improve solutions that might be proposed by the paste mechanism when pasting content in Oxygen XML Editor. For example, when pasting an element inside an empty element with the same name, this **canBeReplaced** method allows Oxygen XML Editor to replace the empty node rather than pasting it after or before the empty node. The callback could also reject this behavior if, for instance, the replacement node contains attributes.

- **AuthorDocumentFragment Class**

---

**Handling When URLs or XHTML Fragments are Dropped or Pasted in Author Mode**

The **AuthorExternalObjectInsertionHandler** extension can be used to configure how URLs or XHTML fragments from external applications are handled when they are dropped or pasted in **Author** mode.

**How to Implement an **AuthorExternalObjectInsertionHandler**

To implement your own **AuthorExternalObjectInsertionHandler**, follow this procedure:

1. Implement the **ro.sync.ecss.extensions.api.AuthorExternalObjectInsertionHandler** interface.
2. To instruct Oxygen XML Editor to use this newly created implementation, use either of the following methods:
   a. If your framework is an extension of DITA, DocBook, TEI, or XHTML, you can specify the **AuthorExternalObjectInsertionHandler** in the **Author extern object Insertion handler** individual extension in the **Extensions** tab (on page 139) of the **Document Type** configuration dialog box (on page 113) for your particular document type.
   b. Otherwise, you can configure an extensions bundle (on page 2075), then return the **AuthorExternalObjectInsertionHandler** implementation using the **ro.sync.ecss.extensions.api.ExtensionsBundle.createAuthorExternalObjectInsertionHandler()** method.
3. You can use a stylesheet to convert the pasted XHTML to your own XML vocabulary by overwriting the following method:

   **ro.sync.ecss.extensions.api.AuthorExternalObjectInsertionHandler.getImporterStylesheetFileName(AuthorAccess)**

   and return the file name of the stylesheet that will be applied. The path to the importer stylesheet must also be added in the **Classpath** tab (on page 118) in the **Document Type** configuration dialog box (on page 113) for your particular document type.

**Example**

The following example illustrates an implementation for the DITA framework:
/**
 * @see ro.sync.ecss.extensions.api.ExtensionsBundle#
 * createExternalObjectInsertionHandler()
 */

@Override
public AuthorExternalObjectInsertionHandler createExternalObjectInsertionHandler() {
    return new DITAExternalObjectInsertionHandler();
}

/**
 * @see ro.sync.ecss.extensions.api.AuthorExternalObjectInsertionHandler#
 * getImporterStylesheetFileName(ro.sync.ecss.extensions.api.AuthorAccess)
 */

@Override
protected String getImporterStylesheetFileName(AuthorAccess authorAccess) {
    return "xhtml2ditaDriver.xsl";
}

Tip:
For XHTML fragments, there is another method that you could use to configure how they are handled when they are pasted in Author mode. For more information, see Customizing Smart Paste Support (on page 2041).

Presenting an Edit Properties Dialog Box for Actions in Author Mode

The EditPropertiesHandler extension point allows you to present a specialized dialog box when the action of double-clicking an element tag is intercepted in Author mode. For example, you could use it to present a dialog box that allows the user to editing the properties of an image.

How to Implement an EditPropertiesHandler
To implement your own EditPropertiesHandler, follow this procedure:

1. Implement the ro.sync.ecss.extensions.api.EditPropertiesHandler interface.
2. To instruct Oxygen XML Editor to use this newly created implementation, use either of the following methods:
   a. If you have configured an extensions bundle (on page 2075), you can return the EditPropertiesHandler implementation using the ro.sync.ecss.extensions.api.ExtensionsBundle.createEditPropertiesHandler() method.
   b. Specify the EditPropertiesHandler in the Author edit properties handler individual extension in the Extensions tab (on page 139) of the Document Type configuration dialog box (on page 113) for your particular document type.
Example

The following example illustrates an implementation for presenting a simple properties editing dialog box when a user double-clicks an `<image>` tag in Author mode (with tags displayed from the Tags display mode drop-down menu):

```java
public class CustomEditPropertiesHandler implements EditPropertiesHandler {

    /**
     * @see ro.sync.eCSS.extensions.api.Extension#getDescription()
     */
    @Override
    public String getDescription() {
        return "Sample implementation that handles properties for a table element."
    }

    /**
     * @see ro.sync.eCSS.extensions.api.EditPropertiesHandler#canEditProperties
     */
    @Override
    public boolean canEditProperties(AuthorNode authorNode) {
        // If this node is an image element we can edit its properties.
        return "image".equals(authorNode.getDisplayName());
    }

    /**
     * @see ro.sync.eCSS.extensions.api.EditPropertiesHandler#editProperties
     */
    @Override
    public void editProperties(AuthorNode authorNode, AuthorAccess authorAccess) {
        // If we receive this call then it surely an image.
        AuthorElement imageElement = (AuthorElement) authorNode;
        String currentValue = ""
        AttrValue altValue = imageElement.getAttribute("alt");
        if (altValue != null) {
            currentValue = altValue.getValue();
        }
        String newValue = JOptionPane.showInputDialog(
            (Component) authorAccess.getWorkspaceAccess().getParentFrame(),
            "Alternate text",
            currentValue);
    }
}
```
```java
if (newValue != null) {
    authorAccess.getDocumentController().setAttribute("alt", new AttrValue(newValue), imageElement);
}
}
```

**Example result:** If a user were to double-click an `<image>` tag icon in **Author** mode, the following dialog box would be displayed that allows the user to edit the *alternate text* property for the image:

![Example dialog box](image)

**Sharing a Framework**

You can create a custom framework by extending a built-in document type (on page 1987) (such as DITA or DocBook) using the **Document Type Association** preferences page (on page 111), make modifications to it, and then share the extension with your team.

**Sharing the Extended Framework**

There are several ways that you can share the extended custom framework (on page 1987) with others:

- Distribute the extended framework along with a project by following these steps:
  1. In a location where you have full write access, create a folder for your project.
  2. Go to the **Project view** (on page 368) and create a project. Save it in the folder you created in step 1.
  3. Create a custom framework by extending an existing one (on page 1987), if you have not already done so, and copy the custom framework directory to the folder you created in step 1. Make sure your custom framework directory includes any resources that are referenced in your framework (CSS files, new document templates, schemas used for validation, catalogs, etc.).
  4. Go to **Options > Preferences > Document Type Association > Locations** (on page 113) and select **Project Options** (on page 2970) at the bottom of the page.
  5. In the **Additional frameworks directories** list, add an entry using the `$pd` editor variable (on page 300) like this: `$pd/custom_frameworks`. 
6. You can then share the new project directory with other users. For example, you can commit it to your version control system and have them update their working copy. When they open the customized project file in their Project view (on page 368), the new framework becomes available in the list of document types.

- Pack and deploy the extended framework as an add-on (on page 2132).
- Distribute the directory of the extended framework (on page 1987) to the other members of your team. They will simply copy that directory to their /frameworks directory. The new framework will be available in their list of document types when Oxygen XML Editor starts.

To test the extended framework, the other members of your team can check the list of document types in the Document Type Association preferences page (on page 111) to see if the framework is present and if it appears before the built-in frameworks (meaning that it has higher priority).

Packing and Deploying Frameworks as Add-ons

In Oxygen XML Editor, custom framework (on page 2967) can be packed and deployed as an add-on.

Packing a Framework as an Add-on

This procedure is suitable for developers who want a better control over the add-on (on page 2969) package or those who want to automate some of the steps:

1. Pack the full custom framework (on page 1987) (or an extension of a framework) as a ZIP file or a Java Archive (on page 2967). Note that you should pack the entire root directory not just its contents.
2. [Optional] If you created a Java Archive at the previous step, digitally sign the package. You will need a certificate signed by a trusted authority. To sign the JAR, you can either use the jarsigner command-line tool inside Oracle's Java Development Kit ([JDK_DIR]/bin/jarsigner.exe) or if you are working with Apache Ant (on page 2964), you can use the signjar task (a front for the jarsigner command-line tool). The benefit of having a signed add-on is that you can verify the integrity of the add-on issuer. If you do not have such a certificate, you can generate one yourself using the keytool command-line utility.

   Note:
   This approach is recommended for tests since anyone can create a self-signed certificate.

3. Create a descriptor file. You can use a template that Oxygen XML Editor provides by going to File > New and selecting the Oxygen add-ons update site template. The products the add-on is compatible with can be specified in the template. Once deployed, this descriptor file is referenced as update site.

Alternate Packing Method: Add-ons Packager

Alternatively, you can use the Add-ons Packager plugin by following this procedure:

1. Go to Help > Install new add-ons to open an add-on selection dialog box.
2. Enter or paste https://www.oxygenxml.com/InstData/Addons/optional/updateSite.xml in the Show add-ons from field.
3. Select the Add-ons Packager add-on and click Next.
4. Select the I accept all terms of the end user license agreement option and click Finish.
5. Restart the application.

**Result:** If the add-on is correctly installed, the Add-ons packager toolbar action is available.
6. Invoke the Add-ons packager toolbar action and input the required information in the displayed dialog box.
7. Click OK to complete the packaging process.

**Deploying an Add-on**

To deploy an add-on, copy the ZIP or Java Archive (on page 2967) file and the descriptor file to an HTTP server. The URL to this location serves as the Update Site URL.

**Basic Customization Tutorial**

This section contains topics meant to provide a general tutorial for customizing a framework (on page 2967). It includes information about creating a basic document type association, some basic customizations, testing the configuration, packaging and deploying the custom framework, and more.

**Tip:**
A sample framework customization package is available that you can dabble with and use to help you get started. It can be downloaded from: [https://www.oxygenxml.com/php/get_oxygen_sample_framework.php](https://www.oxygenxml.com/php/get_oxygen_sample_framework.php). The package includes a sample CSS file, XSL file, schema files, document templates, an XML catalog file, custom icons, and other resources.

**Framework Customization Overview**

The most important elements of a document type customization are represented by an XML Schema to define the XML structure, the CSS to render the information and the XML instance template that links the first two together.

**XML Grammar**

To provide as-you-type validation and to compute valid insertion proposals, Oxygen XML Editor needs an XML grammar (XML Schema, DTD, or Relax NG) associated to the XML. The grammar specifies how the internal structure of the XML is defined. For information about associating a schema and how Oxygen XML Editor detects the schema, see [Associating a Schema to XML Documents (on page 759)](page_759).

Consider a use-case where several users are testing a system and must send report results to a content management system. The customization should provide a visual editor for this type of document. The following XML Schema, test_report.xsd defines a report with results of a testing session. The report
consists of a title, few lines describing the test suite that was run, and a list of test results (each with a name and a boolean value indicating if the test passed or failed).

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema">
    <xs:element name="report">
        <xs:complexType>
            <xs:sequence>
                <xs:element ref="title"/>
                <xs:element ref="description"/>
                <xs:element ref="results"/>
            </xs:sequence>
        </xs:complexType>
    </xs:element>
    <xs:element name="title" type="xs:string"/>
    <xs:element name="description">
        <xs:complexType>
            <xs:sequence maxOccurs="unbounded">
                <xs:element name="line">
                    <xs:complexType mixed="true">
                        <xs:sequence minOccurs="0" maxOccurs="unbounded">
                            <xs:element name="important" type="xs:string"/>
                        </xs:sequence>
                    </xs:complexType>
                </xs:element>
            </xs:sequence>
        </xs:complexType>
    </xs:element>
    <xs:element name="results">
        <xs:complexType>
            <xs:sequence maxOccurs="unbounded">
                <xs:element name="entry">
                    <xs:complexType>
                        <xs:sequence>
                            <xs:element name="test_name" type="xs:string"/>
                            <xs:element name="passed" type="xs:boolean"/>
                        </xs:sequence>
                    </xs:complexType>
                </xs:element>
            </xs:sequence>
        </xs:complexType>
    </xs:element>
</xs:schema>
```
CSS Stylesheet

A set of rules must be defined for describing how the XML document is to be rendered in Author mode. This is done using Cascading Style Sheets (CSS). CSS is a language used to describe how an HTML or XML document should be formatted by a browser. CSS is widely used in the majority of websites.

The elements from an XML document are displayed in the layout as a series of boxes. Some of the boxes contain text and may flow one after the other, from left to right. These are called inline boxes. There are also other types of boxes that flow one below the other (such as paragraphs). These are called block boxes.

For example, consider the way a traditional text editor arranges the text. A paragraph is a block, because it contains a vertical list of lines. The lines are also blocks. However, blocks that contain inline boxes arrange its children in a horizontal flow. That is why the paragraph lines are also blocks, while the traditional "bold" and "italic" sections are represented as inline boxes.

The CSS allows us to specify that some elements are displayed as tables. In CSS, a table is a complex structure and consists of rows and cells. The `table` element must have children that have a `table-row` style. Similarly, the `row` elements must contain elements with a `table-cell` style.

To make it easy to understand, the following section describes how each element from a schema is formatted using a CSS file. Note that this is just one of infinite possibilities for formatting the content.

**report**

The root of a report document. It should be rendered as a box that contains all other elements. To achieve this, the display type is set to `block`. Additionally, some margins are set for it. The CSS rule that matches this element is:

```css
report {
    display: block;
    margin: 1em;
}
```

**title**

The title of the report. Usually titles have a large font. The `block` display is used so that the subsequent elements will be placed below it, and its font is changed to double the size of the normal text.

```css
title {
    display: block;
    font-size: 2em;
}
```
description

Contains several lines of text describing the report. The lines of text are displayed one below the other, so the description has the block display. Also, the background color is changed to make it standout.

description {
    display:block;
    background-color:#EEEEFF;
    color:black;
}

line

A line of text in the description. A specific aspect is not defined and it just indicates that the display should be block style.

line {
    display:block;
}

important

Defines important text from the description. Since it can be mixed with text, its display property must be set to inline. Also, the text is emphasized with bold to make it easier to spot.

important {
    display:inline;
    font-weight:bold;
}

results

Displays the list of test_names and the results for each one. To make it easier to read, it is displayed as a table, with a green border and margins.

results{
    display:table;
    margin:2em;
    border:1px solid green;
}

entry

The results are displayed as a table so the entry is a row in the table. Thus, the display is table-row.

entry {
    display:table-row;
}

test_name, passed
The name of the individual test, and its result. They are cells in the results table with the display set to `table-cell`. Padding and a border are added to emphasize the table grid.

```css
test_name, passed{
    display:table-cell;
    border:1px solid green;
    padding:20px;
}
passed{
    font-weight:bold;
}
```

The full content of the CSS file `test_report.css` is:

```css
report {
    display:block;
    margin:1em;
}
description {
    display:block;
    background-color:#EEEEFF;
    color:black;
}
line {
    display:block;
}
important {
    display:inline;
    font-weight:bold;
}
title {
    display:block;
    font-size:2em;
}
results{
    display:table;
```
Note:
You can edit attributes in-place in the **Author** mode using form-based controls *(on page 567).*
XML Instance Template

Based on the XML Schema and CSS file Oxygen XML Editor can help the content author in loading, editing, and validating the test reports. An XML document template must be created as a kind of skeleton that the users can use as a starting point for creating new test reports. The template must be generic enough and reference the XML Schema file and the CSS stylesheets.

This is an example:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<?xml-stylesheet type="text/css" href="test_report.css"?>
<report xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:noNamespaceSchemaLocation="test_report.xsd">
  <title>Automated test report</title>
  <description>
    <line>This is the report of the test automatically ran.
    Each test suite is ran at 20:00h each day.
    Please <important>check</important> the failed ones!</line>
  </description>
  <results>
    <entry>
      <test_name>Database connection test</test_name>
      <passed>true</passed>
    </entry>
    <entry>
      <test_name>XSLT Transformation test</test_name>
      <passed>true</passed>
    </entry>
    <entry>
      <test_name>DTD validation test</test_name>
      <passed>false</passed>
    </entry>
  </results>
</report>
```

The processing instruction `xml-stylesheet` associates the CSS stylesheet to the XML file. The `href` pseudo attribute contains the URI reference to the stylesheet file. In the example, the CSS is in the same directory as the XML file.

The next step is to place the XSD file and the CSS file on a web server and modify the template to use the HTTP URLs, like this:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<report xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
```
If you want to share the files with other team members, you could create an archive containing the `test_report.xml`, `test_report.css`, and `test_report.xsd` and send it to the other users.

**Creating and Configuring a Custom Framework**

This basic tutorial is meant to provide an example of creating and configuring a custom document type (*framework (on page 2967)*). This basic tutorial offers examples for creating a custom schema, adjusting the authoring experience through custom CSS styling, and creating a custom action.

**Step 1: Organize Framework Files**

First, create a new folder for your customized *framework (on page 2967)*. This folder will be used to store all files related to the documentation *framework*. The folder structure will look something like this:

```
   oxygen
   frameworks
     sdf
       schema
       css
```

The `frameworks` directory is the container where all the Oxygen XML Editor *framework* customizations are located. Each subdirectory contains files related to a specific type of XML documents (schemas, catalogs, stylesheets, CSS stylesheets, etc.) Distributing a *framework* means delivering a *framework* directory.

It is assumed that you have the right to create files and folders inside the Oxygen XML Editor installation directory. If you do not have this right, you will have to install another copy of the program in a folder you have access to, the home directory for instance, or your desktop.

To test your *framework* distribution, copy it in the `frameworks` directory of the newly installed application and start Oxygen XML Editor by running the provided start-up script files.

You should copy the created schema files `abs.xsd` and `sdf.xsd`, `sdf.xsd` being the main schema, to the `schema` directory and the CSS file `sdf.css` to the `css` directory.

**Step 2: Extend an Existing Framework**

The easiest way to create a custom *framework (on page 2967)* (document type) is by extending an existing built-in framework, such as DITA or DocBook, and then making modifications to it.
1. Open the Preferences dialog box (Options > Preferences) (on page 98) and go to Document Type Association > Locations (on page 113). Add the path to your custom framework directory in the Additional frameworks directories list and click OK or Apply to save your changes.

2. Go to the Document Type Association preferences page (on page 111) and select an existing framework configuration (for example, DocBook) and use the Extend button to create an extension for it.

   **Step Result:** This opens the Document Type Configuration dialog box (on page 113) where you can define the set of rules and settings for your custom framework.

3. Give the extension an appropriate name, select External for the Storage option, click the browsing button (_folder_ ) to specify the location of your custom framework directory.

4. Click OK to close the configuration dialog box and then OK or Apply to save your changes.

**Results:** You now have a fully functional framework that you can continue to customize.

### Step 3: Create a Custom XML Schema

To illustrate an example of creating an XML Schema for a custom DocBook framework (on page 2967), suppose the documents are either articles or books, and composed of sections. The sections may contain `<title>`, `<para>`, `<figure>`, `<table>`, and other `<section>` elements. To complete the picture, each section includes a `<def>` element from another namespace.

The first schema file:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema"

targetNamespace="http://www.oxygenxml.com/sample/documentation"

xmlns:doc="http://www.oxygenxml.com/sample/documentation"

xmlns:abs="http://www.oxygenxml.com/sample/documentation/abstracts"

elementFormDefault="qualified">

<xs:import namespace="http://www.oxygenxml.com/sample/documentation/abstracts"

schemaLocation="abs.xsd"/>
```

Next, the structure of the sections is defined. They all start with a `<title>`, then have the optional `<def>` element then either a sequence of other sections, or a mixture of paragraphs, images, and tables.

```xml
<xs:element name="book" type="doc:sectionType"/>
<xs:element name="article" type="doc:sectionType"/>
<xs:element name="section" type="doc:sectionType"/>
```
<xs:complexType name="sectionType">
  <xs:sequence>
    <xs:element name="title" type="xs:string"/>
    <xs:element ref="abs:def" minOccurs="0"/>
    <xs:choice>
      <xs:sequence>
        <xs:element ref="doc:section" maxOccurs="unbounded"/>
      </xs:sequence>
      <xs:choice maxOccurs="unbounded">
        <xs:element ref="doc:para"/>
        <xs:element ref="doc:image"/>
        <xs:element ref="doc:table"/>
      </xs:choice>
    </xs:choice>
  </xs:sequence>
</xs:complexType>

The paragraph contains text and other custom styling markup, such as bold (\textbf{}) and italic (\textit{}) elements.

<xs:element name="para" type="doc:paragraphType"/>

<xs:complexType name="paragraphType" mixed="true">
  <xs:choice minOccurs="0" maxOccurs="unbounded">
    <xs:element name="emphasis"/>
    <xs:element name="i"/>
  </xs:choice>
</xs:complexType>

The \texttt{image} element has an attribute with a reference to the file containing image data.

<xs:element name="image">
  <xs:complexType>
    <xs:attribute name="href" type="xs:anyURI" use="required"/>
  </xs:complexType>
</xs:element>

The \texttt{table} element contains a header row and then a sequence of rows (\texttt{tr}) elements each of them containing the cells. Each cell has the same content as the paragraphs.

<xs:element name="table">
  <xs:complexType>
    <xs:sequence>
      <xs:element name="header">
        <xs:complexType>
          <xs:sequence>
            <xs:element name="td" maxOccurs="unbounded"/>
The `<def>` element is defined as a text only element in the imported schema `abs.xsd`:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema"

targetNamespace="http://www.oxygenxml.com/sample/documentation/abstracts"
>
<xs:element name="def" type="xs:string" />
</xs:schema>
```

Now the XML data structure will be styled.

**Step 4: Associate the Schema to the Framework**

In the bottom section of the **Document Type** configuration dialog box (on page 113), there are a series of tabs. The **Schema** tab refers to the schema that is used for validation of the documents that match the defined association rules.
Important: If the document references a schema directly (for example, using a `DOCTYPE` declaration, `xsi:schemaLocation` attribute, or a Relax NG `xml-model` processing instruction), the schema defined in this Schema tab is not used for validation or content completion.

Schema Type

Select from the combo box the value **XML Schema**.

Schema URI

Enter the value of the schema location (for example, `${framework}/schema/sdf.xsd`). Use the `${frameworks}` editor variable (on page 299) in the schema URI path instead of a full path to be valid for multiple Oxygen XML Editor installations.

Important: The `${frameworks}` variable is expanded at the time of validation into the absolute location of the directory containing the framework (on page 2967).

Step 5: Create a Custom CSS

If you read the Framework Customization Overview (on page 2133) then you already have some basic knowledge about creating simple styles. The example document contains elements from various namespaces, so you need to use CSS Level 3 extensions (supported by the Author mode layout engine) to associate specific properties with that element.

Defining the General Layout

Now the basic layout of the rendered documents is created.

Elements that are stacked one on top of the other are: `book`, `article`, `section`, `title`, `figure`, `table`, `image`. These elements are marked as having **block** style for display. Elements that are placed one after the other in a flowing sequence are: `b`, `i`. These will have **inline** display.

```css
/* Vertical flow */
book,
section,
para,
title,
image,
ref {
  display:block;
}

/* Horizontal flow */
b,i {
```
Important:
Having block display children in an inline display parent results in Oxygen XML Editor changing the style of the parent to block display.

Styling an Element

The title of any section must be bold and smaller than the title of the parent section. To create this effect, a sequence of CSS rules must be created. The * operator matches any element, it can be used to match titles having progressive depths in the document.

```css
title{
  font-size: 2.4em;
  font-weight: bold;
}
* * title{
  font-size: 2.0em;
}
* * * title{
  font-size: 1.6em;
}
* * * * title{
  font-size: 1.2em;
}
```

It is useful to have before the title a constant text, indicating that it refers to a section. This text can include also the current section number. The :before and :after pseudo-elements will be used, plus the CSS counters.

First declare a counter named sect for each book or article. The counter is set to zero at the beginning of each such element:

```css
book,
article{
  counter-reset: sect;
}
```

The sect counter is incremented with each section, that is a direct child of a book or an article element.

```css
book > section,
article > section{
  counter-increment: sect;
}```
The "static" text that will prefix the section title is composed of the constant "Section ", followed by the decimal value of the `sect` counter and a dot.

```css
book > section > title:before, 
article > section > title:before{ 
content: "Section " counter(sect) ". " ;
}
```

To make the documents easy to read, you add a margin to the sections. In this way the higher nesting level, the larger the left side indent. The margin is expressed relatively to the parent bounds:

```css
section{ 
margin-left:1em; 
margin-top:1em;
}
```

Figure 574. A sample of nested sections and their titles.

In the above screenshot you can see a sample XML document rendered by the CSS stylesheet. The selection "avoids" the text that is generated by the CSS "content" property. This happens because the CSS generated text is not present in the XML document and is just a visual aid.

### Styling Inline Elements

The "bold" style is obtained by using the `font-weight` CSS property with the value `bold`, while the "italic" style is specified by the `font-style` property:

```css
b { 
font-weight:bold;
}
```
Styling Images

The CSS 2.1 does not specify how an element can be rendered as an image. To overpass this limitation, Oxygen XML Editor supports a CSS Level 3 extension allowing to load image data from a URL. The URL of the image must be specified by one of the element attributes and it is resolved through the catalogs specified in Oxygen XML Editor.

The `image` element has the required `@href` attribute of type `xs:anyURI`. The `@href` attribute contains an image location so the rendered content is obtained by using the function:

```
attr(href, url)
```

The first argument is the name of the attribute pointing to the image file. The second argument of the `attr` function specifies the type of the content. If the type has the `url` value, then Oxygen XML Editor identifies the content as being an image. If the type is missing, then the content will be the text representing the attribute value.

Oxygen XML Editor handles both absolute and relative specified URLs. If the image has an `absolute` URL location (for example: "http://www.oasis-open.org/images/standards/oasis_standard.jpg") then it is loaded directly from this location. If the image URL is `relative` specified to the XML document (for example: "images/my_screenshot.jpg") then the location is obtained by adding this value to the location of the edited XML document.

An image can also be referenced by the name of a DTD entity that specifies the location of the image file. For example, if the document declares an entity `graphic` that points to a JPEG image file:

```
<!ENTITY graphic SYSTEM "depo/keyboard_shortcut.jpg" NDATA JPEG>
```

and the image is referenced in the XML document by specifying the name of the entity as the value of an attribute:

```
<mediaobject>
  <imageobject>
    <imagedata entityref="graphic" scale="50"/>
  </imageobject>
</mediaobject>
```

The CSS should use the functions `url`, `attr` and `unparsed-entity-uri` for displaying the image in the Author mode:
To take into account the value of the `@width` attribute of the `imagedata` and use it for resizing the image, the CSS can define the following rule:

```css
imagedata[width]{
    width: attr(width, length);
}
```

Figure 575. Samples of images in Author

---

**Step 6: Associate the Custom CSS to the Framework**

Once you have customized your framework through CSS styling rules, you then need to associate the custom CSS file (on page 119).

**Step 7: Testing the Framework Customization**

To test the new framework (on page 2967) customization, create an XML instance that conforms with the association rules that you specified in your framework customization. You will not specify an XML Schema location directly in the document, using an `xsi:schemaLocation` attribute. Instead, Oxygen XML Editor will detect its associated document type and use the specified schema.

```xml
<book xmlns="http://www.oxygenxml.com/sample/documentation"
      xmlns:abs="http://www.oxygenxml.com/sample/documentation/abstracts">

  <title>My Technical Book</title>
  <section>
    <title>XML</title>
  </section>
</book>
```
In this section of the book I will explain different XML applications.

When trying to validate the document there should be no errors. Now modify the title to title2. Validate again. This time there should be an error.

Invalid content was found starting with element 'title2'. One of '{http://www.oxygenxml.com/sample/documentation}:title' is expected.

Undo the tag name change, go to Author mode, and Oxygen XML Editor should load the CSS from the document type association (on page 2966) and create a layout similar to this:

Figure 576. Example: Testing a Framework Customization

CSS Support in Author Mode

The visual Author editing mode can be customized by creating CSS files to define styles for the XML elements and other components. The Author editing mode supports most CSS 2.1 selectors, numerous CSS 2.1 properties, and some CSS 3 selectors. Oxygen XML Editor also supports stylesheets coded with the LESS dynamic stylesheet language. Also, Oxygen XML Editor has added some custom functions and properties that extend the W3C CSS specification and are useful for a wide range of use-cases for developers who customize Author mode through custom frameworks (on page 1987).

Associating a CSS with an XML Document

Associating a Stylesheet with an XML Document

The rendering of an XML document in the Author mode is driven by a CSS stylesheet that conforms to the version 2.1 of the CSS specification from the W3C consortium. Some CSS 3 features, such as namespaces and custom extensions, of the CSS specification are also supported. Oxygen XML Editor also supports stylesheets coded with the LESS dynamic stylesheet language.
There are several methods for associating a stylesheet (CSS or LESS) with an XML document:

- Insert the `xml-stylesheet` processing instruction with the `@type` attribute at the beginning of the XML document. The easiest way to do this is by using the Associate XSLT/CSS Stylesheet action that is available on the toolbar or in the Document > XML Document menu.

  CSS example:

  ```xml
  <?xml-stylesheet type="text/css" href="test.css"?>
  ```

  LESS example:

  ```xml
  <?xml-stylesheet type="text/css" href="test.less"?>
  ```

- Add a new CSS or LESS file to a framework (on page 2967) (document type). To do so, open the Preferences dialog box (Options > Preferences) (on page 98) and go to Document Type Association. Edit the appropriate framework, open the Author tab, then the CSS subtab. Click the New button to add a new CSS or LESS file.

  **Note:**
  The built-in frameworks are read-only, so you need to Extend (on page 112) or Duplicate (on page 112) them to configure them as custom frameworks.

If a document has no CSS association or the referenced stylesheet files cannot be loaded, a default one is used. A warning message is also displayed at the beginning of the document, presenting the reason why the CSS cannot be loaded.

**Figure 577. Document with no CSS association default rendering**

For information about associating a CSS to a framework (document type), see Configuring and Managing Multiple CSS Styles for a Framework (on page 1998).
Handling CSS Imports

When a CSS document contains imports to other CSS documents, the references are also passed through the XML Catalog (on page 2972) URI mappings to determine an indirect CSS referenced location.

**Example: CSS Import**

For example, if you can have a CSS import, such as:

```html
@import "http://host/path/to/location/custom.css";
```

and then add your own XML Catalog (on page 2972) file that maps the location to a custom CSS in the XML Catalog preferences page (on page 205):

```xml
<uri name="http://host/path/to/location/custom.css" uri="path/to/custom.css"/>
```

**Adding a Custom Default CSS for Every XML Document**

To add a custom CSS that is applied to every XML document, add a mapping in your XML Catalog (on page 2972) file that looks like this:

```xml
<uri name="http://www.oxygenxml.com/extensions/author/css/userCustom.css" uri="path/to/custom.css"/>
```

This extra mapped CSS location will be parsed every time the application processes the CSS stylesheets used to render the opened XML document in the visual Author editing mode. This allows your custom CSS to be used without the need to modify all other CSS stylesheets contributed in the document type configuration.

**Editor Variables in CSS Imports**

You can use various editor variables (on page 292) in CSS imports. When editing an XML document with an associated CSS in Author mode, the editor variables will be expanded and resolved.

**Example: Editor Variable in a CSS Import**

For example, the following editor variable:

```html
@import "${framework(DITA)}/custom.css";
```

is resolved in the DITA framework (on page 2967) folder where the custom.css is placed. In the Document Type Association preferences page (on page 111), you can see a list of document type. The name for your particular document type needs to be passed as a parameter to the framework() function.

**Note:**

If you use editor variables like ${cfdu} (Current File Directory URL), it will be expanded to the URL of the current CSS document that contains the imports rather than the XML document that references the CSS.
Displaying Processing Instructions from Other XML Editors

By default, external processing instructions are hidden (for example, processing instructions used to store metadata in other XML editors). If you want them to be displayed (for example, to edit them), they must be associated with the current document using a CSS (on page 2149) like this:

```css
@namespace oxy "http://www.oxygenxml.com/extensions/author";
oxy|processing-instruction[Pub],
oxys|processing-instruction[PubTbl],
oxoy|processing-instruction[xm-replace_text],
oxoy|processing-instruction[xm-deletion_mark],
oxoy|processing-instruction[xm-insertion_mark_start],
oxoy|processing-instruction[xm-insertion_mark_end]
{
    display:block !important;
}
```

Specifying Media Types in the CSS

The CSS stylesheets can specify how a document is presented on different types of media (on the screen, paper, etc.) You can specify that some of the selectors from your CSS should be taken into account only in the Oxygen XML Editor Author mode and ignored in other media types. This can be accomplished by using the `oxygen` media type.

**Example: oxygen Media Type**

```css
b{
    font-weight:bold;
    display:inline;
}

@media oxygen{
    b{
        text-decoration:underline;
    }
}
```

This example results in the text being bold if the document is opened in a web browser that does not recognize `@media oxygen`, while the text is bold and underlined when opened in Oxygen XML Editor Author mode.

You can also use the `oxygen` media type to specify CSS selectors to be applied in certain operating systems or platforms by using the `os` and `platform` properties. For example, you can specify one set of style rules for displaying Oxygen XML Editor in Windows, and another set of style rules for macOS. The supported properties are as follows:
• **os** - The possible values are: `win`, `linux`, or `mac`.

• **platform** - The possible values are: `standalone`, `eclipse`, or `webapp`.

**Example: os and platform Properties**

```css
@media oxygen AND (os:"win") AND (platform:"standalone") {
  p{
    content:"PPP";
  }
}
```

**Related Information:**

[@media Rule (on page 2153)](#)

**CSS At-Rules**

Oxygen XML Editor supports some of the standard at-rules specified by CSS Level 2.1 and 3. The `@media` rule also include support for some style rules that are specific to Oxygen XML Editor.

**@font-face At-Rule**

Oxygen XML Editor allows you to use custom fonts in the **Author** mode by specifying them in the CSS using the `@font-face` media type. Only the `src` and `font-family` CSS properties can be used for this media type.

**Example: @font-face Rule**

```css
@font-face{
  font-family:"Baroque Script";
  /*The location of the loaded TTF font must be relative to the CSS*/
  src:url("BaroqueScript.ttf");
}
```

**@media Rule**

The `@media` rule allows you to set different style rules for multiple types of media in the same stylesheet. For example, you can set the font size to be different on the screen than on paper. Oxygen XML Editor supports several media types, allowing you to set the style rules for presenting a document on various media (on screen, paper, etc.)

**Supported Media Types**

• **screen** - The styles marked with this media type are used only for rendering a document on screen.

• **print** - The styles marked with this media type are used only for printing a document.

• **all** - The styles marked with this media type are used for rendering a document in all supported types of media.
• **oxygen** - The styles marked with this media type are used only for rendering a document in the Oxygen XML Editor Author mode. For more information, see Specifying Media Types in the CSS (on page 2152).

• **oxygen-dark-theme** - The styles marked with this media type are used only for rendering a document in the Oxygen XML Editor Author mode when a dark theme is used (for example, Graphite).

• **oxygen-high-contrast-black** - The styles marked with this media type are used only for rendering a document in the Oxygen XML Editor Author mode on a Windows High Contrast Theme with a black background.

• **oxygen-high-contrast-white** - The styles marked with this media type are used only for rendering a document in the Oxygen XML Editor Author mode on a Windows High Contrast Theme with a white background.

**Example: @media Rule**

```css
@media oxygen{
  b{
    text-decoration:underline;
  }
}
@media oxygen-high-contrast-white{
  b{
    font-weight:bold;
  }
}
```

**Supported Properties**

Oxygen XML Editor also supports a few properties to set specific style rules that depend upon the size of the visible area in Author mode. These supported properties are as follows:

• **min-width** - The styles selected in this property are applied if the visible area in Author mode is equal to or greater than the specified value.

• **max-width** - The styles selected in this property are applied if the visible area in Author mode is less than or equal to the specified value.

**Example: min-width and max-width Properties**

```css
@media (min-width:500px) {
  p{
    content:'XXX';
  }
}
@media (max-width:700px) {
  p:after{
    content:'yyy';
  }
}
```
Standard W3C CSS Supported Features

Oxygen XML Editor supports most of the CSS Level 3 selectors and most of the CSS Level 2.1 properties.

Supported CSS Selectors

**Tip:**
CSS rules that match attributes are always more specific than element selectors. For more information, see https://drafts.csswg.org/selectors-3/#specificity.

The following table lists the CSS selectors that are supported in Oxygen XML Editor:

<table>
<thead>
<tr>
<th>Expression</th>
<th>Name</th>
<th>CSS Level</th>
<th>Description / Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>Universal selector</td>
<td>CSS Level 2</td>
<td>Matches any element</td>
</tr>
<tr>
<td>$E$</td>
<td>Type selector</td>
<td>CSS Level 2</td>
<td>Matches any $E$ element (i.e. an element with the local name $E$)</td>
</tr>
<tr>
<td>$E F$</td>
<td>Descendant selector</td>
<td>CSS Level 2</td>
<td>Matches any $F$ element that is a descendant of an $E$ element.</td>
</tr>
<tr>
<td>$E &gt; F$</td>
<td>Child selectors</td>
<td>CSS Level 2</td>
<td>Matches any $F$ element that is a child of an element $E$.</td>
</tr>
<tr>
<td>$E$[lang(c)$</td>
<td>Language pseudo-class</td>
<td>CSS Level 2</td>
<td>Matches element of type $E$ if it is in (human) language $c$ (the document language specifies how language is determined).</td>
</tr>
<tr>
<td>$E + F$</td>
<td>Adjacent selector</td>
<td>CSS Level 2</td>
<td>Matches any $F$ element immediately preceded by a sibling element $E$.</td>
</tr>
<tr>
<td>$E \sim F$</td>
<td>General sibling selector</td>
<td>CSS Level 3</td>
<td>Matches any $F$ element preceded by a sibling element $E$.</td>
</tr>
<tr>
<td>$E$[foo$</td>
<td>Attribute selector</td>
<td>CSS Level 2</td>
<td>Matches any $E$ element with the &quot;foo&quot; attribute set (whatever the value).</td>
</tr>
<tr>
<td>Expression</td>
<td>Name</td>
<td>CSS Level</td>
<td>Description / Example</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>E[foo=&quot;warning&quot;]</td>
<td>Attribute selector with value</td>
<td>CSS Level 2</td>
<td>Matches any  element whose  &quot;foo&quot; attribute value is exactly equal to &quot;warning&quot;.</td>
</tr>
<tr>
<td>E[foo~=&quot;warning&quot;]</td>
<td>Attribute selector containing value</td>
<td>CSS Level 2</td>
<td>Matches any  element whose  &quot;foo&quot; attribute value is a list of space-separated values, one of which is exactly equal to &quot;warning&quot;.</td>
</tr>
<tr>
<td>E[lang=&quot;en&quot;]</td>
<td>Attribute selector containing hyphen separated values</td>
<td>CSS Level 2</td>
<td>Matches any  element whose  &quot;lang&quot; attribute has a hyphen-separated list of values beginning (from the left) with &quot;en&quot;.</td>
</tr>
<tr>
<td>E:before and E:after</td>
<td>Pseudo-elements</td>
<td>CSS Level 2</td>
<td>The  &quot;:before&quot; and &quot;:after&quot; pseudo-elements can be used to insert generated content before or after an element's content.</td>
</tr>
<tr>
<td>E:first-child</td>
<td>The first-child pseudo-class</td>
<td>CSS Level 2</td>
<td>Matches element  when  is the first child of its parent.</td>
</tr>
<tr>
<td>E:not(s)</td>
<td>Negation pseudo-class</td>
<td>CSS Level 2</td>
<td>An  element that does not match simple selector  s.</td>
</tr>
<tr>
<td>E:has</td>
<td>Relational pseudo-class</td>
<td>CSS Level 4</td>
<td>The  &quot;:has()&quot; relational pseudo-class is a functional pseudo-class that takes a relative selector as an argument. For more information, see :has Relational Pseudo-Class (on page 2161).</td>
</tr>
<tr>
<td>E:hover</td>
<td>The hover pseudo-class</td>
<td>CSS Level 2</td>
<td>The  &quot;:hover&quot; pseudo-class applies while the user designates an element with a pointing device, but does not necessarily activate it. When moving the pointing device over an element, all the parent elements up to the root are taken into account.</td>
</tr>
<tr>
<td>E:focus</td>
<td>The focus pseudo-class</td>
<td>CSS Level 2</td>
<td>The  &quot;:focus&quot; pseudo-class applies while an element has the focus (accepts keyboard input).</td>
</tr>
<tr>
<td>Expression</td>
<td>Name</td>
<td>CSS Level</td>
<td>Description / Example</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------------------------</td>
<td>-----------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>E:focus-within</td>
<td>The generalized input focus</td>
<td>CSS Level 4</td>
<td>The :focus-within pseudo-class applies to elements that will have the :focus pseudo-class applied. Additionally, the ancestors of an element that matches :focus-within also match.</td>
</tr>
<tr>
<td>E:marker</td>
<td>The marker pseudo-class</td>
<td>CSS Level 4</td>
<td>The ::marker pseudo-element represents the automatically generated marker box of a list item.</td>
</tr>
<tr>
<td>E#myid</td>
<td>The ID selector</td>
<td>CSS Level 2</td>
<td>Matches any E element with ID equal to &quot;myid&quot;.</td>
</tr>
<tr>
<td>E[att^=&quot;val&quot;]</td>
<td>Substring matching attribute</td>
<td>CSS Level 3</td>
<td>An E element whose att attribute value begins exactly with the string val.</td>
</tr>
<tr>
<td>E[att$=&quot;val&quot;]</td>
<td>Substring matching attribute</td>
<td>CSS Level 3</td>
